# Medicine

## HIGHLIGHTS

- Contains everything an undergraduate student of medicine would want to read before examination.
- Colorful clinical images and case scenarios included.
- Reader-friendly pattern. Easy-to-memorize format, interspersed with relevant, and commonly asked exam-questions in a question-answer format and covers all the questions appeared in university examinations till January 2018.
- Management practices have been updated till March 2018.
- Contains comprehensive information in compact boxes and figures, making it a ready reckoner before the examination.
- Recent advances, newer drugs and upcoming sections of geriatrics, immunology, clinical pharmacology have been included.
- Key points are highlighted. Richly illustrated in multicolor, including management algorithms, color coded as in etiology, management, etc.
- Exclusive coverage of high yielding points which is important for answering MCQs.
- Appendices provide reference values of common laboratory investigations, commonly used formulae and neurology examination format.

# Foreword to the Second Edition

**KASTURBA MEDICAL COLLEGE**

**MANGALURU**

*A constituent institution of MAHE, Manipal*

Internal medicine is expanding and evolving rapidly and there is a need for comprehensive yet simple textbook. Indian medical students have to be very competitive and up-to-date to excel in their fields. While a number of textbooks from foreign authors are available for the Indian students, they might not serve the purpose of preparing the students for the Indian examinations. A few Indian authors have accepted this challenge and have published textbooks oriented towards Indian medical examinations. Dr Archith Bloor realized this need many years ago and took up the challenge of publishing a textbook in internal medicine which was received well by the student community. Huge success of the first edition has prompted him to come out with the second edition of the book.

Dr Archith Bloor is an exceptionally gifted clinician and teacher. He has taken keen interest in medical education from his early days in the medical college and with more than a decade of experience in this field, he has been

able to understand the needs of the students with regard to the medical examinations. He has received the Best Teacher Award at Kasturba Medical College, Mangaluru for many years.

The second edition of this compilation has seen qualitative improvements over the previous edition. While the contents of the book are comprehensive, presentation is simple. Clinical images, tables, boxes, algorithms and diagrams are simple and enhance the learning. This book will definitely be an essential learning tool for students of internal medicine.

**Chakrapani M** MD

# Foreword to the First Edition

**KASTURBA MEDICAL COLLEGE**  
MANGALURU  
*A constituent institution of MAHE, Manipal*

I am very proud to write a foreword to this book *Exam Preparatory Manual for Undergraduates—Medicine* written by Dr Archith Bloor, one of the outstanding students, trained in the Department of Medicine of our college of which I am faculty as Professor of Medicine. Coming from a rural background from outskirts of Mangaluru, Dr Bloor after getting a merit seat in Kasturba Medical College, Mangaluru for MBBS in 1998, completed his final MBBS with credit in the year 2003. He joined as a postgraduate student in the year 2005 and was the best outgoing PG student in the May 2008 examinations, a performance for which he was conferred gold medal. Soon after joining our department as a faculty, he had been committed teacher as proven by the Good Teacher Awards in the years 2013 and 2015 and Dr Patrick Pinto Memorial Best Teacher Award in 2014. The importance of these awards lies in that the selection is done by students which shows the efficacy of teaching. Not contented with this alone and trying to do better for the cause of students, I am pleased to know from him that he is writing a textbook on *Exam Preparatory Manual for Undergraduates—Medicine* which is meant for training the students for internal medicine especially to face the final MBBS examination. Having taken part in several scientific meetings, continuing medical educations (CMEs) and conferences in internal medicine, here as a speaker and panelist give him credentials to write the book. I hope that this book will be different from other books. It will be student-centric rather than author-centric.

**M Venkatraya Prabhu** MD

# Preface to the Second Edition

We have been extremely grateful for the positive response rendered towards the book, *Exam Preparatory Manual for Undergraduates—Medicine* and were thus, excited to undertake the challenge of developing a new edition. Surfing beyond plainly updating the literature, this second edition gifted us with the opportunity to further explore topics we ourselves have wrestled with as a student, teacher and teacher educator and also build an understanding of how we approach students and their texts.

In the year and a half following the release of the first edition of this book, we have received numerous feedbacks via e-mails and letters from readers who have given wonderful suggestions on how we could further upgrade the material. We had also built up a large file of ideas based on our own experiences in reading, writing and editing during this time. With the aid of all this information, we have completely revised the book.

In this second edition, the following changes and additions have been incorporated:

- Updated the literature, substantially reordered and updated the material according to the current guidelines in all chapters.
- Included clinical images for all commonly encountered medical conditions.
- Added X-rays, MRIs, CT scans and ECG images of common conditions with explanations.
- Treatment algorithms have been revised and updated.
- Topics regarding clinical trials and research methodology have been added.
- A full chapter on ‘common emergencies in medicine’ is included as a ready reckoner.

- With an eye to the book's potential use as an aid for entrance preparation, high yield points are highlighted in each section
- The bibliography has been updated. Many new editions of books are referenced and updated references have been added.

We must hereby acknowledge those who have helped us with this new edition. We are especially grateful for the ongoing encouragement from our university, Manipal Academy of Higher Education (MAHE) and Yenepoya Medical College (Deemed to be University), Mangaluru, Karnataka, India. We would like to express our gratitude to Dr Ramdas M Pai (Chancellor), Dr HS Ballal (Pro-Chancellor), Dr H Vinod Bhat (Vice-Chancellor), Dr V Surendra Shetty and Dr Poornima Baliga (Pro Vice-Chancellor) of MAHE, for their continued support.

We profusely thank Dr Chakrapani M, for his support and for writing the foreword for this edition.

We would also like to extend our warm thanks to our esteemed colleagues/friends Dr Sheetal Raj, Dr Saritha Aadhi, Dr Sachin Vemula, Dr Kaushiki Kirty, Dr B Thinakar Mani, Dr Sibithooran Karmegan, Dr Vishnu B Chandran, Dr Narendran Krishnamoorthy, Dr Pradeep Krishna Chowdary, Dr Madhurya Mallavarapu, Dr Deepti Ajjangadi, Dr Ashwini Kamath, Dr Holla Subraya Krishna, and Dr Thomas Kuncheria, for their contributions with the clinical images and proofreading.

We humbly place on record our heartfelt gratitude to our students Dr Mishaal Talish, Dr Sidharth Herur, Dr Raghu RV, Dr Sriraksha R Nayak, Dr M Harsha Sagar, Dr Nikhil Kenny Thomas, Dr Vivek K Koushik, Dr Navyashree HC, Dr Padakanti Anudeep Rao, Dr Laveena MariamJohn, Dr Ashwini MV, Dr Alister Joseph Thomas, and Dr Mohamed Faizan Thouseef, for their help in proofreading and correction.

We would further like to thank all our teachers, department colleagues, our current and former students and students from various colleges all over India, for their valuable suggestions and input.

Finally, we would like to acknowledge with gratitude, the support of our all family members, for their support and love, which has made us successful in our endeavors.

Students who have read the book before should find the revised edition more lucid and palatable, while those who have waited for scouts to carve the path will find the road paved and tested. Your suggestions are happily

solicited for any improvements, if necessary.

**Archith Bloor**  
**Ramadas Nayak**

# Preface to the First Edition

The glory of medicine is that it keeps moving forward, that there is always more to learn.

We look for medicine to be an orderly field of knowledge and procedure but it is not. It is an imperfect science, an enterprise of constantly changing knowledge, uncertain information, fallible individuals, and at the same time lives on the line. The gap between what we know and what we aim for persists. And this book is an attempt in bridging the gap.

This book is a first of its kind with an amalgamation of clinical pathology and clinical medicine, resulting in an integrated comprehensive manual.

Every attempt has been made by us to present information in a simplified text augmented with the use of colored illustrations, flowcharts, algorithms which help the reader to understand the concepts, recollect and make use of and thus acquire knowledge in the examinations as well as in clinical practice.

It is designed for use as a companion book for exam preparation for undergraduates. The main characteristics of this book are:

- Reader-friendly pattern
- Color coded as in etiology, management, etc.
- Includes management algorithms
- Key points are highlighted
- Question-answer format
- Covers all the questions appeared in university examinations till April 2016
- Extensively covers all theory and most clinical scenarios
- Management practices have been updated till September 2016
- Recent advances, newer drugs and upcoming sections of Geriatrics,

Immunology, Clinical Pharmacology have been included

- Exclusive coverage of high yielding points which are important for answering MCQs.

This book consists of 23 chapters and is organized into systemwise chapters which are further divided into subsections. Each chapter starts with basic introduction and proceeds to individual disease discussions. The etiology of the diseases have been separately included. Also, important management sections are in separate colored tables, so that selective reading can be done. Important clinical examination-oriented questions have also been included under each section. Diagnostic procedures have been discussed separately. Radiological investigations and their abnormalities have been emphasized especially X-ray findings of specific diseases. Basic reading of ECGs have been covered with the common abnormalities encountered. Clear ECG images have been included for better understanding. Also, many tables comparing clinical situations/abnormalities will aid in better understanding and also help in answering a lot of questions in the clinics as well as viva voce. All common clinical cases (long, semi-long, and short) that you would encounter in your practical examination have been covered extensively to give the readers an edge over.

After many years of teaching undergraduates, we found that undergraduate students find it difficult to understand, remember and answer the questions during examinations in a satisfying way. There are many textbooks, but students face difficulty to refresh their knowledge during examinations. This encouraged us to write a book to fill the niche, to provide basic information to them in a nutshell. Most students are fundamentally 'visually-oriented'. As the saying goes 'a picture is worth a thousand words', it encouraged us to provide many illustrations.

We recommend this book to all students for understanding the basic knowledge and refresh their knowledge during examinations. One of the aims of the students after getting undergraduate degree is to fetch a good ranking in the postgraduate entrance examination. Most graduates cannot answer multiple choice questions in entrance examination by just reading the usual textbooks in medicine. Our book lays specific importance on this aspect and answers to most commonly asked MCQs. This book provides sufficient information which would help postgraduates and practicing clinicians in the knowledge and management of cases.

**Archith Bloor**  
**Ramadas Nayak**

# Acknowledgments

‘Writing this book has been an exercise in sustained knowledge gain, and for those who have played the larger role in our endeavor with constant encouragement and support; Well, you know who you are; Just a thanks would not suffice’.

After almost 6 years of working on it, we could not possibly come up with a full list of all the people who had helped, but we will try our best.

Dr Archith Bloor, thanks his family members namely his mother, Mrs Kumuda; sisters, Ms Arati, Ms Archana and Ms Aparna, his father and others. Dr Ramadas Nayak thanks Mrs Rekha Nayak and Dr Rakshatha Nayak who have patiently accepted his long preoccupation with this work.

We wish to express our gratitude to Dr Ramdas M Pai, Chancellor, Manipal University, Karnataka, India, for giving us an opportunity to be a part of this prestigious institution for nearly 20 years, to pursue our dreams and to grow to be the physician and teacher that we are today.

We are indebted to Dr HS Ballal (Pro-Chancellor), Dr H Vinod Bhat (Vice-Chancellor) and Dr V Surendra Shetty (Pro Vice-Chancellor) of Manipal University, Karnataka, India, for their support.

We are grateful to our beloved Dean, Dr M Venkatraya Prabhu, Kasturba Medical College, Mangaluru, Karnataka, India, for his constant support and encouragement and also for writing the foreword for the first edition.

We would like to express our gratitude to all colleagues in the Department of Medicine, Kasturba Medical College, Mangaluru, for their constant help at every juncture of our career. We would specially like to thank and acknowledge Dr Chakrapani M and Dr Damodar Shenoy, for mentoring Dr Archith to what he is today.

Dr Archith Bloor remains deeply indebted for his humble achievements, his passion for teaching and for instilling in him the tenacity to learn and

achieve his goals to Dr Nagalakshamma, Professor of Botany; Dr Ranjan Shetty and Dr Jayaraj Sindhur, his seniors, who are to him embodiments of the word 'Teacher'. He humbly lays down his gratitude to them for inspiring him.

We would like to express our gratitude to our students (both undergraduate and postgraduate), friends and colleagues who helped us at different stages of preparing the manuscript; to all those who provided the support, talked things over, read, offered comments and assisted in the editing, proofreading and designing of this book. Our heartfelt thanks to Dr Hasmukh Jain, Dr Raghavendra BS, Dr Sheetal Raj, Dr Athulya Roopak, Dr Kaushiki Kirty, Dr Vishnu B Chandran, Dr Joseph Samuel, Dr Jimmy Joseph, Dr Kolla Gautham, Dr Anudeep Reddy, and Dr M Harsha Sagar, for their timely and continued support.

A word of thanks would hardly suffice for our pillars of strength and our support system Dr Suresh Shetty B, Dr Jagadish Rao PP, Dr Abul Fazil, Dr Abhishek Gupta, Dr Veena Jasmine Pinto, Dr Akshata Nayak, Dr Nishita Shetty, Dr Sandip Ganguly, Dr Ruchi Romya Das, Dr Mamta Gupta, Dr Sahil Popli, Dr Pradeep Krishna Chowdary, Dr Yogesh Rasal, Dr Sravan Thumati, Dr Amrutraj, Dr Satish AV, Dr Sachin Vemula, Dr Neil Dominic Fernandes, Dr Mishaal Talish, and Dr Apurva Mittal.

Also, we convey our sincere thanks to Shri Jitendar P Vij (Group Chairman), Mr Ankit Vij (Managing Director), Ms Ritu Sharma (Director–Content Strategy), and Ms Chetna Malhotra Vohra (Associate Director–Content Strategy) of M/s Jaypee Brothers Medical Publishers (P) Ltd, New Delhi, India, for publishing the book in the same format as wanted, well in time.

We thank Ms Sunita Katla (Executive Assistant to Group Chairman and Publishing Manager), Ms Samina Khan (Executive Assistant to Director–Content Strategy), Mr Rajesh Sharma (Production Coordinator), Ms Seema Dogra (Cover Designer), Mr Laxmidhar Padhiary (Proofreader), Mr Rajesh Ghurkundi (Graphic Designer), and Mr Raj Kumar (DTP Operator) of M/s Jaypee Brothers Medical Publishers (P) Ltd, New Delhi, India.

We thank especially Mr Venugopal V (Associate Director—South) and Mr Vasudev H (Mangaluru) of Jaypee Brothers Medical Publishers (P) Ltd, Bengaluru Branch, Karnataka, for taking this book to every corner of Karnataka.

This book has been written for our students who have inspired us to take up this project; it is their questions that made us read and learn and compile this book. This is a book for you and I do not think we can finish without thanking you.

Lastly, we thank God Almighty, for making us what we are, guiding us through our life, and helping us in bringing this book to you all.

There are many more people we could thank, but constraints of space compel us to stop here.

# Contents

## **1. NUTRITION AND ENVIRONMENTAL MEDICINE**

Vitamin A

Vitamin B Complex

Vitamin C

Vitamin D

Trace Elements

Fluorosis

Enteral and Parenteral Nutrition Support

Protein-Energy Malnutrition

Obesity

Environmental Diseases

Radiation Exposure

# CHAPTER

# 1

## VITAMIN A

**Q. Write a short essay/note on clinical features, diagnosis, and treatment of vitamin A deficiency.**

Vitamin A is the name given to a group of fat-soluble vitamin and includes retinoids and carotenoids.

- **Retinoids/Retinol (vitamin A alcohol): Retinoid** is the generic term used for vitamin A in its various forms. It includes both natural and synthetic chemicals that are structurally related to vitamin A. Its oxidized metabolites, namely retinaldehyde and retinoic acid (vitamin A acid) are biologically active compounds. It is the chemical name of vitamin A. It is the transport form and, as retinol ester is also the storage form.
- **Carotenoids:** The most common carotenoid in the food having provitamin A activity is  $\beta$ -Carotene. Major portions of carotenoids are absorbed as such and are stored in liver and fat.

**Sources of vitamin A:** These include:

- **Animal-derived foods:** Preformed retinol is found only in foods of animal origin. Food sources include liver, fish, milk, eggs, butter, and cheese.
- **Yellow and green leafy vegetables:** Dark green and deeply colored fruits and vegetables are the vegetable sources of provitamins A carotenoids. Moderate cooking of vegetables increases the release of carotenoid, thereby improves absorption in the gut.
- Fatty meal facilitates the absorption of carotenoids.

**Functions of vitamin A:** Vitamin A has several metabolic roles. The main functions of vitamin A in humans are as follows:

- **Maintenance of normal vision:** Vitamin A is essential for **dark**

**adaptation** and its deficiency causes nyctalopia.

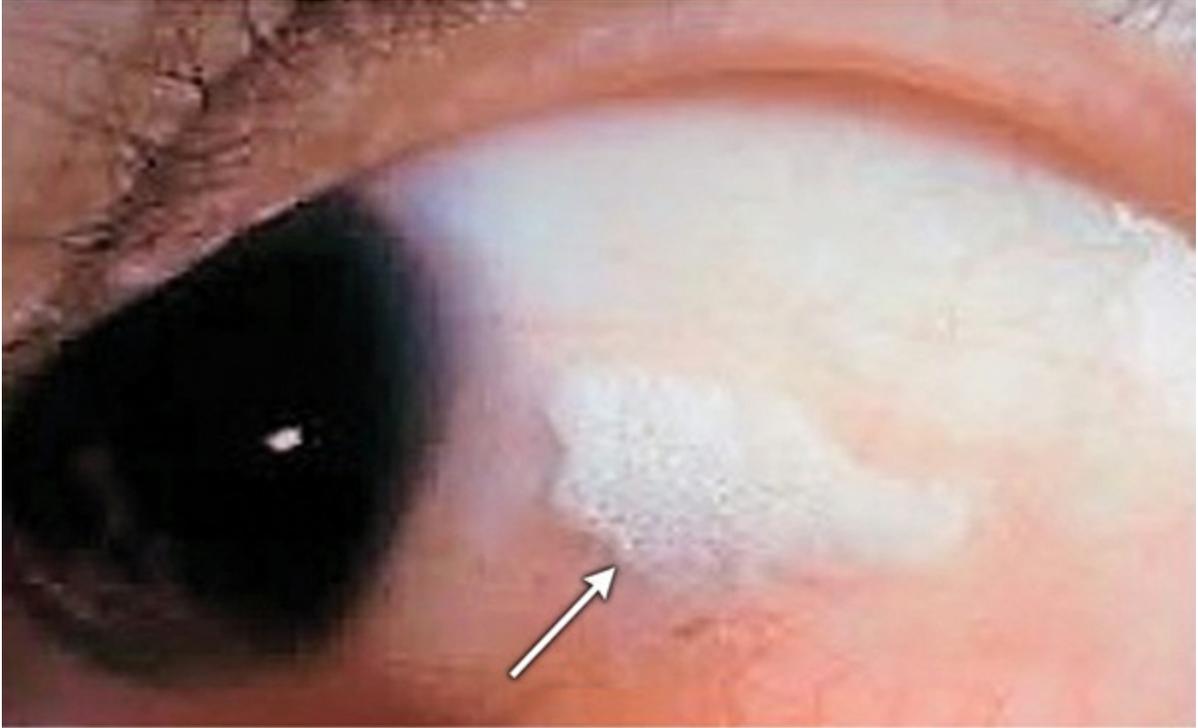

- **Host resistance to infections:** Vitamin A deficiency causes keratinization of mucous membranes and thereby increases the risk of infections. Retinol binding protein (RBP) is a **negative ‘acute phase protein’**.
- **Immune function:** Vitamin A has the ability to stimulate the immune system. Retinoids are required for normal growth, fetal development, fertility, hematopoiesis and immune function.
- **Control of cell growth and differentiation:** Vitamin A is needed for the maintenance of the surface linings of the eyes, growth and repair of epithelial cells, and integrity of the epithelial cells of the respiratory, urinary, and intestinal tracts. In vitamin A deficiency, mucus-secreting cells are replaced by keratin-producing cells and this process is known as squamous metaplasia.
- **Regulation of lipid metabolism:** Fatty acid metabolism, including fatty acid oxidation in fat tissue and muscle, adipogenesis, and lipoprotein metabolism require vitamin A.
- **Antioxidant:** Retinoids,  $\beta$ -carotene, and some related carotenoids act as photoprotective and act as antioxidants.
- **Other functions:** Vitamin A is involved in growth of bone, reproduction, embryonic development and the regulation of adult genes.
- **Tretinoin**, i.e. all-trans retinoic acid (ATRA) is also used to treat acute promyelocytic leukemia (APL), **isotretinoin**, is used to treat psoriasis and 13-cis-retinoic acid is used in the treatment of acne.

## Vitamin A Deficiency (Table 1.1)

### *Clinical Features/Manifestations*

*Effects in the eye:*

- **Bitot’s spots (Fig. 1.1):** In young children with vitamin A deficiency, areas of abnormal squamous cell proliferation and keratinization of the conjunctiva known as Bitot’s spots can be seen.
- **Blindness due to retinal injury:** Vitamin A has an important role in phototransduction. Vitamin A deficiency leads to a absence of visual pigments. This reduces the absorption of various wavelengths of light and results in blindness.

**Fig. 1.1:** Bitot's spot.

**Fig. 1.2:** Xerosis of skin in vitamin A deficiency.

- **Poor adaptation to darkness (nyctalopia):** Night blindness is an early symptom of vitamin A deficiency.

- **Xerophthalmia (dry eye):** It is caused due to keratinization of the conjunctiva.
- **Keratomalacia:** In advanced disease; the cornea becomes hazy and erosions can develop, finally leading to its destruction (keratomalacia).

*Increased susceptibility to infections:*

Vitamin A deficiency can produce keratinization of the mucous membranes of respiratory tracts and urinary tract. This increases the susceptibility to infections (e.g. respiratory infections) and xerosis of skin (Fig. 1.2).

**Other features:** Fatigue, anemia, diarrhea, decreased growth rate, decreased bone development and infertility.

**Table 1.1: Causes of vitamin A deficiency.**

<i>Primary causes</i>	<i>Secondary causes</i>
• Prolonged dietary deprivation	• Sprue
• Vegetarians	• Cystic fibrosis
• Refugees	• Pancreatic insufficiency
• Chronic alcoholics	• Duodenal bypass
• Toddlers	• Chronic diarrhea
• Preschool children	• Bile duct obstruction
	• Giardiasis, and cirrhosis

**Laboratory Investigations**

- **Serum retinol level:** Normal range is 28–86 µg/dL (1–3 µmol/L). The level decreases in vitamin A deficiency.
- **Albumin levels** are indirect measures of vitamin A levels.
- **Complete blood count (CBC)** with differential count to be done, if there is a possibility of anemia, infection, or sepsis.

**Diagnosis**

- It is mainly on the basis of the **clinical features**. Response to replacement therapy is the best way for the diagnosis.
- Serum retinol levels less than 20 µg/dL suggest deficiency, or the ratio of retinol: Retinol binding protein (RBP) <0.8 suggests deficiency.

### Treatment

- Xerophthalmia (irrespective of stage) should be treated with 60 mg of vitamin A in oily solution, usually contained in a soft-gel capsule. 3 doses: day 0, day 1 and day 14.
- If child is suffering from measles give two capsules of 60 mg for two consecutive days.

**Prophylactic vitamin A** at a dose of 60 mg every 6 months is to be given to all high-risk individuals. Patients with malabsorption syndrome need vitamin A supplements.

### Prevention

Prophylactic supplements of vitamin A palmitate in oil

- *Children between 1 and 5 years of age:* 60,000 retinol activity equivalent (RAE) (200,000 IU) per oral every 6 month
- *Infants <6 months:* It can be given a one-time dose of 15,000 RAE (50,000 IU).
- *6–12 months of age:* It can be given a one-time dose of 30,000 RAE (100,000 IU).

### Vitamin A Toxicity

**Q.** Write short essay/note on hypervitaminosis A and its signs.

- **Types of toxicity:** Vitamin A toxicity can be **acute** (usually due to accidental ingestion by children) or **chronic**. Both types of toxicity cause headache and increased intracranial pressure (**pseudotumor cerebri**).
  - **Acute** toxicity also produces **nausea and vomiting**. Single doses of 300 mg in adults or 100 mg in children can be harmful.
  - **Chronic** toxicity also causes **changes in skin, hair (loss), and nails**; liver and bone damage; double vision, ataxia, hyperlipidemia and vomiting.
  - **Retinol is teratogenic** and incidence of birth defects in infants is high with vitamin A intakes of >3 mg a day during pregnancy.
- **Diagnosis is usually clinical.** Unless birth defects are present, adjusting the dose almost always leads to complete recovery.

Recommended dietary allowances (RDAs)/adequate intake of fat soluble vitamins for individuals (Table 1.2).

**Table 1.2: Recommended dietary allowances (RDAs)/adequate intake of fat-soluble vitamins for different age group.**

Age group	Vitamin A(RAE*)	Vitamin D ( $\mu\text{g}/\text{d}$ )	Vitamin E ( $\mu\text{g}/\text{d}$ )	Vitamin K ( $\mu\text{g}/\text{d}$ )
Infants	400–500	5	4–5	2–2.5
Children (1–13 yr)	300–600		6–11	30–60
>14 yr				
• Males	900	5–15	15	75–120
• Females	600–700		11–15	
Pregnancy	750–770	5	15	75–90
Lactation	1200–1300		19	

\*1 RAE (retinol activity equivalents) = 1  $\mu\text{g}$  retinol, 12  $\mu\text{g}$   $\beta$ -carotene; 1  $\mu\text{g}$  calciferol = 40 IU vitamin D.

**Carotenemia** is common among infants and toddlers who eat large amounts of carrots and green leafy vegetables. It can be confused with jaundice, but discoloration of skin spontaneously resolves once the intake of carotenoid rich food is reduced.

## VITAMIN B COMPLEX

### Thiamine (B<sub>1</sub>)

**Functions:** Thiamine is an important **water-soluble** vitamin.

- Involved in **carbohydrate, fat, amino acid, glucose, and alcohol metabolism.**
- Vitamin B<sub>1</sub> is **essential** for the **coenzyme**, thiamine pyrophosphate (TPP). It is required for the following reactions:
  - Decarboxylation of pyruvate (glycolytic pathway) to acetyl CoA (Krebs cycle)
  - Transketolase in the hexose monophosphate (HMP/pentose) shunt pathway
  - Decarboxylation of  $\alpha$ -ketoglutarate to succinate (Krebs cycle).
- Has an additional role in neuronal conduction.

**Sources:** These vitamins can be produced by plants and some microorganisms. However, animals cannot synthesize them.

- Source of thiamine for humans is diet, though small amounts may be synthesized by intestinal bacteria.
- **Dietary sources:** Good dietary sources of thiamine are **whole wheat flour, unpolished rice, cereals, grains, beans, nuts and yeast**. There is little or no thiamine in milled rice and grains. Thus, thiamine deficiency is more common in individuals who consume mainly a rice-based diet.
- It is also present in **liver, meat and eggs**.

**Requirement:** Up to 30 mg of thiamine can be stored in body tissues. Required daily allowance (RDA) is 1–1.5 mg/day. Requirement increases with increased carbohydrate intake, pregnancy and lactation, smoking, alcoholism, prolonged antibiotic intake, serious or prolonged illness.

Causes of thiamine deficiency are listed in Box 1.1 and clinical syndromes of thiamine deficiency are mentioned in Box 1.2.

**Box 1.1:** Causes of thiamine deficiency.

#### **Lack of thiamine intake**

- Food items like milled rice, raw freshwater fish, raw shellfish, and ferns that have a high level of *thiaminase*.
- Food high in *antithiamine factor*, such as tea, coffee, and betel nuts
- Alcoholic state
- Starvation state

#### **Increased consumption states**

- Diets high in carbohydrate or saturated fat intake
- Pregnancy and lactation
- Hyperthyroidism
- Fever—severe infection
- Increased physical exercise

#### **Increased depletion**

- Diarrhea
- Peritoneal dialysis, hemodialysis, diuretic therapies
- Hyperemesis gravidarum

#### **Decreased absorption**

- Chronic intestinal disease
- Alcoholism
- Malnutrition
- Gastric bypass surgery
- Malabsorption syndrome—celiac and tropical sprue

## ***Consequences of Thiamine Deficiency***

Consequence of thiamine deficiency is impaired glucose oxidation.

- Cells **cannot metabolize glucose** aerobically to generate energy as ATP. **Neuronal cells** are **most susceptible**, because they depend almost exclusively on glucose for energy requirements.
- Causes an **accumulation of pyruvic and lactic acids**. This in turn produces **vasodilatation** and **increased cardiac output**.

## Beriberi (Box 1.2)

**Q.** Write short essay/note on clinical features of beriberi/vitamin B<sub>1</sub> (thiamine) deficiency.

**Box 1.2:** Clinical syndromes of thiamine deficiency.

1. Wet beriberi—high cardiac output failure
2. Dry beriberi—peripheral neuropathy
3. Wernicke's encephalopathy
4. Korsakoff's psychosis
5. Leigh syndrome (progressive subacute necrotizing encephalomyopathy)

1. **Wet (cardiovascular) beriberi:** Wet beriberi is the term used for the **cardiovascular involvement** of thiamine deficiency.
  - First effects are **vasodilatation, tachycardia**, a wide pulse pressure, sweating, warm skin, and lactic acidosis.
  - Later, **congestive heart failure** develops, causing orthopnea and pulmonary and peripheral edema. Marked cardiomegaly is present.  
**Infantile beriberi** occurs in infants (usually by age 3 to 4 weeks) who are breastfed by thiamine-deficient mothers. Heart failure can suddenly develop and present with edema, aphonia, tachycardia, tachypnea and absent deep tendon reflexes. If prompt treatment is not given, death occurs quickly.  
**Shoshin beriberi:** A more rapid form of wet beriberi is termed acute fulminant cardiovascular beriberi.
2. **Dry beriberi:** Dry beriberi usually manifests insidiously with **symmetrical peripheral neuropathy**.
  - *Early symptoms:* There is bilateral and roughly symmetrical heaviness and stiffness of the legs.
  - *Later symptoms:* These include weakness, numbness, and pins and

needles (occurring in a stocking-glove distribution).

- *Distribution of neuropathy:* They affect predominantly the lower limbs. They begin with paresthesias in the toes, burning in the feet (severe at night), muscle cramps in the calves, pains in the legs, and plantar dysesthesias.
- *Physical signs:* Calf muscle tenderness, difficulty rising from a squatting position, and decreased vibratory sensation in the toes. The ankle jerk reflexes are lost.
- Deficiency may also cause degeneration of thalamus, mammillary bodies, and cerebellum.

#### **Biochemical tests:**

- Measurement of thiamine, pyruvate and lactate levels in blood or urine.
- Erythrocyte thiamine transketolase activity.

### **Q. Write short essay/note on management/treatment of beriberi/vitamin B<sub>1</sub> (thiamine) deficiency.**

#### **Management**

- Complete bed rest.
- Thiamine 100 mg IM/IV for the first 7 days, followed by 10 mg/day orally for several months. Severe cases may need 400–600 mg/day. Parenteral thiamine produces marked diuresis (in wet beriberi), resulting in dramatic improvement in the symptoms.

### **Q. Write short essay/note on Wernicke's encephalopathy.**

3. **Wernicke's encephalopathy:** It is an acute neuropsychiatric condition. Initially, it is reversible biochemical brain lesion caused by depletion of vitamin B<sub>1</sub> (thiamine). Its causes are listed in Box 1.1.

#### **Clinical features:**

- Wernicke's encephalopathy (WE) is a **triad of global confusion, ophthalmoplegia, and ataxia**, along with confusion. Impairment in the synthesis of one of the important enzymes of the pentose phosphate pathway (erythrocyte transketolase) may explain such a predisposition.
- **Encephalopathy:** It is characterized by confusion, severe disorientation, indifference, and inattentiveness. There is also impaired memory and learning. If untreated patients will progress through stupor

and coma to death.

- **Oculomotor dysfunction:** Nystagmus, lateral rectus palsy, and lesions of the oculomotor, abducens, and vestibular nuclei resulting in conjugate gaze palsy.
- **Gait ataxia:** Ataxia mainly involves stance and gait. It is probably due to a combination of polyneuropathy, cerebellar involvement, and vestibular dysfunction.

**Diagnosis:** For confirmation of the diagnosis measure the circulating thiamine concentration or transketolase activity in red cells using fresh heparinized blood.

#### Management

- Wernicke's disease is a medical emergency and requires immediate administration of thiamine.
- **Dosage:** 500 mg of thiamine intravenously, infused over 30 minutes, three times daily for two consecutive days and 250 mg intravenously or intramuscularly once daily for an additional five days, in combination with other B vitamins.
- Magnesium is often needed because it is a cofactor required for normal functioning of thiamine-dependent enzymes.
- Wernicke encephalopathy may be precipitated by administration of intravenous glucose solutions to individuals with thiamine deficiency. In susceptible individuals glucose administration should be preceded or accompanied by thiamine 100 mg IV.

#### 4. Korsakoff's psychosis/syndrome

##### **Q. Write short note on Korsakoff's psychosis/syndrome.**

- Korsakoff's psychosis is caused by deficiency of thiamine with involvement of central nervous system.
- **Memory disturbances:** It is predominantly associated with defect in retentive memory (severe defect in storing new information and learning). Thus, there are **disturbances of short-term memory**. There is marked deficits in anterograde and retrograde memory, apathy, an intact sensorium and relative preservation of long-term memory and other cognitive skills.
- **Confabulation:** It is a memory disturbance, characterized by the production of fabricated, distorted or misinterpreted memories about oneself or the world, without the conscious intention to deceive. Attention and social behavior are relatively maintained. Affected individuals can perform conversation that may seem normal to an unsuspecting spectator.

- The syndrome is common in chronic alcoholics. It may also be seen with thiamine deficiency due to gastric disorders (e.g. carcinoma, chronic gastritis, or persistent vomiting).

**Treatment:** Parenteral thiamine (100 mg IM daily for 7 days).

## Vitamin B<sub>2</sub> (Riboflavin)

Features of riboflavin deficiency include cheilitis, stomatitis, glossitis, normochromic anemia, and seborrheic dermatitis.

## Pellagra

**Q. Write short essay/note on clinical features and management of niacin deficiency (pellagra).**

**Vitamin B<sub>3</sub> niacin (nicotinamide) deficiency** causes a metabolic encephalopathy called **pellagra**. It is found mostly in populations in which corn is the major source of energy in parts of China, Africa, and India. Pellagra means raw skin.

### *Causes*

- **Inadequate intake:** Maize or jowar (sorghum) diet, malnutrition, chronic alcoholism (who eat little), anorexia nervosa.
- Generalized **malabsorption** (rare).
- **Drug-induced:** Prolonged isoniazid therapy, pyrazinamide, 6-mercaptopurine, 5-fluouracil, azathioprine, ethionamide, carbamazepine, phenytoin, and phenobarbitone.
- **Other disorders:**
  - **Hartnup's disease:** It is a rare genetic disorder, in which there is reduced absorption of basic amino acids including tryptophan by the gut.
  - **Carcinoid syndrome** and pheochromocytoma: In these conditions, tryptophan metabolism is diverted away from the formation of nicotinamide to form amines producing pellagra-like symptoms.

### *Clinical Features*

Pellagra has been easily remembered a disease of four **Ds** namely: (1) **dermatitis**; (2) **diarrhea**; (3) **dementia (depression)**; and (4) **death**. However, these features are not always observed and the mental changes are not a true dementia.

#### 1. **Skin manifestations:**

- **Casal's necklace or collar rash:** Characteristic skin rash develops that is hyperpigmented and scaling that develops in skin areas exposed to

sunlight. This rash forms a ring around the neck and is termed Casal's necklace (Fig. 1.3).

- **Dermatitis:** Lesions of the skin may progress to vesiculation, cracking (ulceration), exudation and secondary infection. Symmetrical chronic thickening, dryness and pigmentation may be seen on the dorsal surfaces of the hands.

## 2. **GI tract:**

- **Diarrhea:** It may be in part due to proctitis and in part due to malabsorption. It is often a feature accompanied by anorexia, nausea, glossitis and dysphagia indicating noninfective inflammation of the entire gastrointestinal tract.
- Other features include raw, painful, bright red tongue (glossitis), angular stomatitis, vaginitis, esophagitis, vertigo, and burning dysesthesias.

**Fig. 1.3:** Casal's necklace and dermatitis.

- ## 3. **Dementia:** This occurs in chronic severe deficiency and may also develop

hallucinations and acute psychosis. Milder deficiency may present with depression, apathy and sometimes thought disorders. Other neurologic symptoms include insomnia, anxiety, disorientation, tremor, delusions, dementia, and encephalopathy.

## **Diagnosis**

- Diagnosis in endemic region depends on the clinical features. Other vitamin deficiencies can also produce similar changes (e.g. angular stomatitis).
- **Dramatic improvement:** The response is usually rapid in the skin (within 24 hours), diarrhea and a striking improvement occurs in the patient's mental state **with nicotinamide** treatment.

### **Management/Treatment**

- **Nicotinamide:** 100 mg 3 times daily orally (approximately 300 mg daily) with a maintenance dose of 50 mg daily.
- High-protein diet with adequate nutrients and treatment of malnutrition.
- Supplementation of other vitamin B complex with iron and folic acid is also given, as other deficiencies are often likely to be present.
- In moderate-to-high doses (1–3 g a day) niacin is a well-established antihyperlipidemic agent.

**Vitamin B<sub>12</sub> and Folic acid discussed on pages 562-70.**

## **Vitamin C**

**Q. Write short essay/note on vitamin C and clinical features of scurvy.**

Vitamin C (ascorbic acid) is a water-soluble vitamin.

**Functions:** These include:

- **Formation of collagen** from procollagen. It is essential for wound healing and facilitates recovery from burns. It is needed for hydroxylation of proline to hydroxyproline (in procollagen) and lysine to hydroxylysine (in mature collagen).
- **Antioxidant properties:** Ascorbic acid is the most active powerful reducing agent controlling the redox potential within cells.
- It is involved in intracellular electron transfer and supports immune function.
- Promotes **absorption of nonheme iron**.
- It is needed for the formation of carnitine, hormones, and amino acids.

- Formation of intercellular cement substances in connective tissues, bones, and dentin, when defective, resulting in weakened capillaries with subsequent hemorrhage and defects in bone and related structures.

**Causes of vitamin C deficiency:** These include:

- Infants fed only on boiled cow's milk during the first year of life are at risk.
- Individuals, who do not eat vegetables such as elderly, people who live alone (singly) and chronic alcoholics.
- Pregnant and lactating women and those with thyrotoxicosis require more vitamin C because of increased utilization.
- Individuals at risk of deficiency:
  - Anorexia nervosa or anorexia from other diseases such as AIDS or cancer
  - Type 1 diabetes require increased vitamin C
  - Patients undergoing peritoneal dialysis and hemodialysis
  - Diseases of small intestine such as Crohn's, Whipple, and celiac disease.

## Deficiency of Vitamin C-Scurvy

Scurvy is caused by deficiency of vitamin C.

**Types of scurvy:** Adult scurvy and infantile scurvy.

**Clinical features of adult scurvy:** Early symptoms may be nonspecific, with malaise, weakness, lethargy and muscle pain (myalgias may be due to reduced production of carnitine).

- **Bone disease:** More common in growing children and manifests after 1–3 months. It is characterized by deranged formation of osteoid matrix and *bone pain*. **Fractures, dislocations**, and tenderness of bones are common in children.
- **Hemorrhages:** Hemorrhaging is a **hallmark** feature of scurvy and can occur in any organ. Hair follicles are one of the common sites of cutaneous bleeding. Marked tendency to bleed into the skin (easy **bruising, petechiae, ecchymosis, perifollicular hemorrhages**), bleeding into muscles, joints and underneath peritoneum. Bruising and hemorrhage may be spontaneous. Most commonly on the legs and buttocks where hydrostatic pressure is the greatest.

- **Delayed/poor wound healing** and breakdown of old scars.
- **Anemia:** It may cause high-output heart failure.
- **Gums:** Inflamed spongy gums (gum swelling) friability, bleeding and infection with loosening of teeth; mucosal petechiae are common.
- **Skin changes:** Roughness, keratosis of hair follicles with ‘corkscrew’ hair, perifollicular hemorrhages.
- **Nails:** Splinter hemorrhages.
- **Other features:** Emotional changes, shortness of breath.

*Clinical features of infantile scurvy (Barlow’s disease):*

- Subperiosteal hemorrhage into shafts of long bones.
- **Scorbutic rosary** denotes enlargement of costochondral junctions, which are tender. May be associated with pectus excavatum.
- Retrobulbar, subarachnoid and intracerebral hemorrhages.
- Painful limbs giving rise to ‘**pseudoparalysis**’.

### ***Laboratory Investigations and Diagnosis***

- Diagnosis is usually made **clinically** in a patient who has skin or gingival signs and is at risk of vitamin C deficiency.
- **Vitamin C level** of <11 µmol/L (0.2 mg/100 mL).
- **Anemia:** It may be normochromic, normocytic (due to bleeding), megaloblastic (due to reduced erythropoiesis) and microcytic hypochromic anemia (due to impaired iron absorption and impaired heme synthesis).
- **Capillary fragility** test can be checked by inflating a blood pressure cuff and looking for petechiae on the forearm.
- **Bleeding time, clotting time and Prothrombin time:** To rule out other bleeding disorders.
- **Imaging Studies:** The findings include: (1) loss of trabeculae results in a ground-glass appearance; (2) thinning of cortex; (3) a line of calcified, irregular cartilage (**white line of Frankel**) may be visible at the metaphysis; and (4) the epiphysis may be compressed and circular calcification surrounding epiphyseal center of ossification (**Wimberger ring sign**) (Fig. 1.4).

**Fig. 1.4:** X-ray of scurvy showing Frenkel line and Wimburger ring sign.

#### **Management/Treatment**

- **Ascorbic acid at 100 mg 3–5 times a day** until total of 4 g is reached, and then reduce the dose to

100 mg daily.

- **Encourage consumption of foods with high vitamin C.**
  - Citrus fruits, especially grapefruits and lemons. Vegetables, including broccoli, green peppers, tomatoes, potatoes, and cabbage.
  - The recommended dose for adults is 120 mg daily, although a dose of 60 mg daily is all that is required to prevent scurvy.
  - Diets high in vitamin C may lower the incidence of certain cancers, particularly esophageal and gastric cancers.

## VITAMIN D

### **Q. Write short note on vitamin D.**

Vitamin D is a fat-soluble secosteroids responsible for enhancing intestinal absorption of calcium, iron, magnesium, phosphate and zinc.

Physiology (Fig. 1.5)

- Vitamin D<sub>3</sub> (Cholecalciferol)
  - Produced in skin with direct sunlight, cod liver oil
  - Preferred form of supplementation
- Vitamin D<sub>2</sub> (Ergocalciferol)
- Less effective as precursor to 1, 25(OH)<sub>2</sub>-vitamin D
- Hepatic conversion of vitamin D<sub>3</sub> to 25-OH-vitamin D (calcidiol)
- Conversion of 25-OH-vitamin D to 1, 25(OH)<sub>2</sub>-vitamin D (calcitriol)

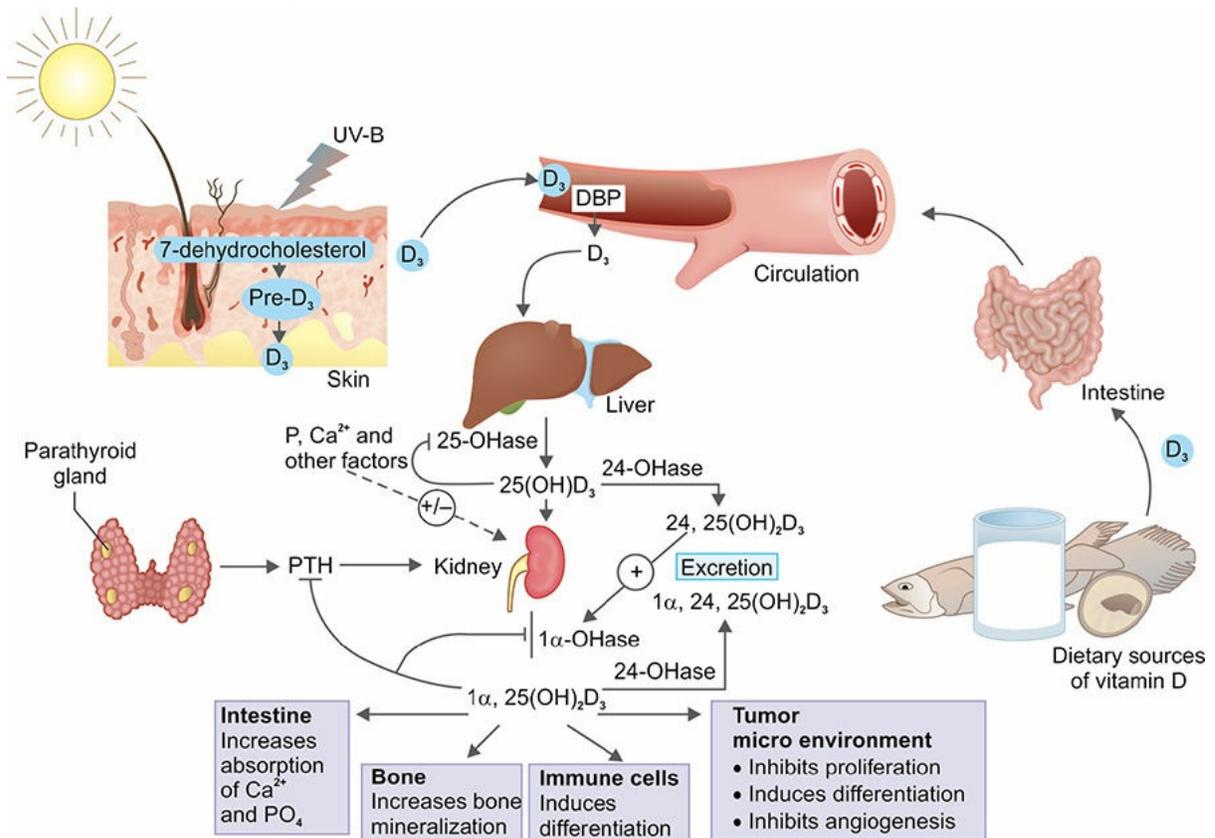

**Functions:** Vitamin D exists in two activated sterol forms (Box 1.3). Its functions include:

**Box 1.3:** Two forms of vitamin D.

- Vitamin D<sub>3</sub> (Cholecalciferol)
  - Produced in skin with direct sunlight, present in cod liver oil
  - Preferred form of supplementation
- Vitamin D<sub>2</sub> (Ergocalciferol)
  - Less effective as precursor to 1, 25(OH)<sub>2</sub>-vitamin D.

1. **Regulation of plasma levels of calcium and phosphorus:** The main functions of 1, 25-dihydroxyvitamin D on calcium and phosphorus homeostasis are:

- **Stimulates intestinal absorption of calcium:** 1, 25-dihydroxyvitamin D stimulates intestinal absorption of calcium in the duodenum through the interaction of 1, 25-dihydroxyvitamin D with nuclear vitamin D receptor.
- **Stimulates calcium reabsorption in the kidney:** 1, 25-dihydroxyvitamin D increases calcium influx in distal tubules of the kidney.
- **Interaction with PTH in the regulation of blood calcium.**
- **Mineralization of bone:** Vitamin D plays a role in the mineralization of osteoid matrix and epiphyseal cartilage in both flat and long bones. Vitamin D stimulates osteoblasts to produce the calcium-binding protein osteocalcin, which is involved in the deposition of calcium during development of bone.

**Fig. 1.5:** Physiology of vitamin D.

2. **Antiproliferative effects:** The vitamin D receptor (VDR) is expressed in the parathyroid gland, and 1, 25(OH)<sub>2</sub> D has an antiproliferative effect on parathyroid cells and it suppresses the transcription of the parathyroid

hormone gene.

3. **Immunomodulatory:** Vitamin D is involved in the innate and adaptive immune system.

## Vitamin D Deficiency

**Q. Write briefly on clinical features, investigations, treatment and prevention of rickets.**

Causes of vitamin D deficiency are listed in Box 1.4.

**Box 1.4:** Causes of vitamin D deficiency.

- Impaired cutaneous production due to limited exposure to sunlight.
- *Dietary absence:* Diets deficient in calcium and vitamin D.
- Malabsorption.

Diseases caused due to vitamin D deficiency are:

- **In children:** Deficiency of vitamin D in a growing child before the epiphyses has fused results in failure of growing bone to mineralize.
  - **Rickets:** Bone *softening* disease, deformity of *long bones* occurs.
- **In adults:**
  - **Osteomalacia:** Bone-thinning disorder, proximal muscle weakness and bone fragility.
  - **Osteoporosis:** Decrease of bone mineralization and increased bone fragility.

## Rickets in Children (Fig. 1.6)

In children, before the closure of epiphyses, vitamin D deficiency causes retardation of growth associated with an expansion of the growth plate known as **rickets**.

### ***Gross Skeletal Changes in Rickets***

It depends on the severity and duration of the vitamin D deficiency and also the stresses to which individual bones are subjected.

*During the nonambulatory stage of infancy*

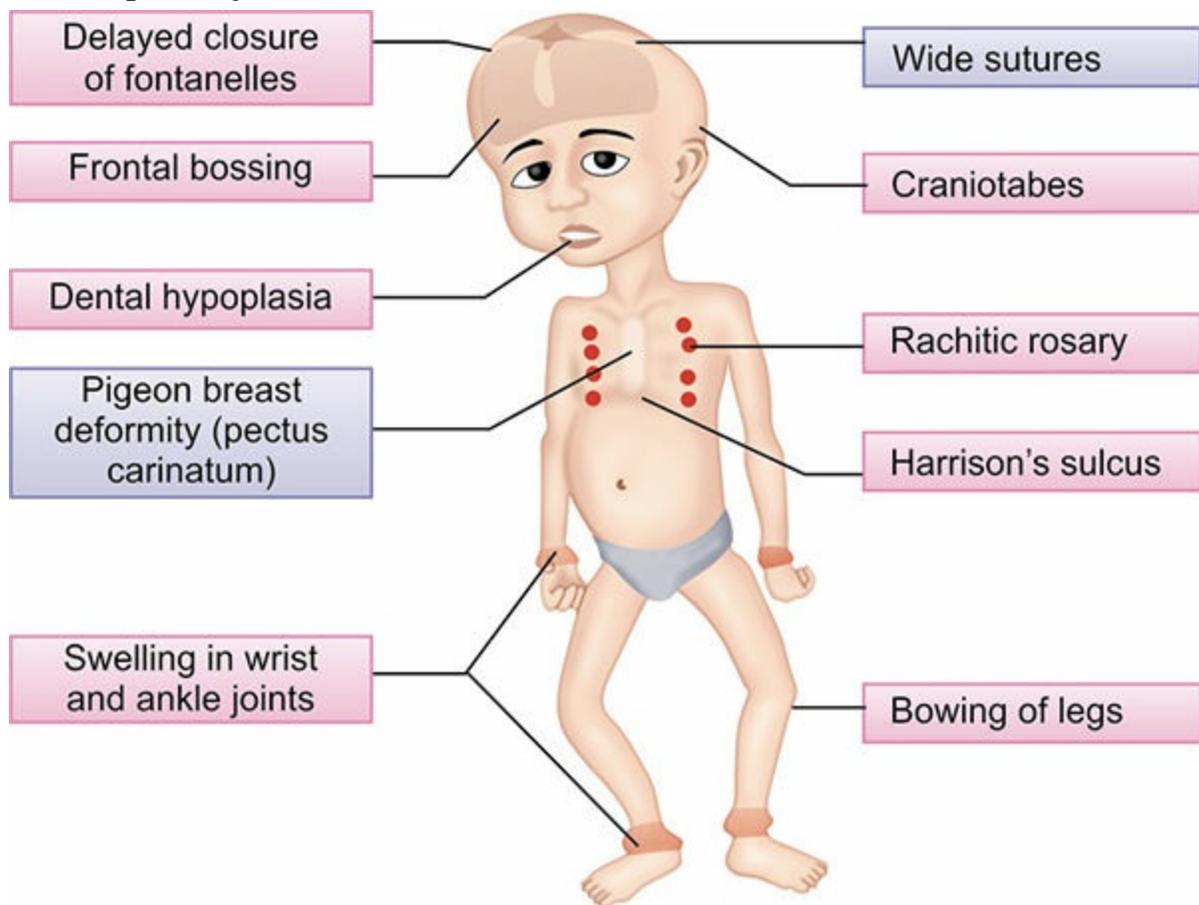

#### 1. **Head:**

- **Craniotabes:** The skull appears square and box-like there is delayed closure of anterior fontanelle, frontal and parietal bossing.

- **Frontal bossing:** Excess of osteoid produces frontal bossing and a squared appearance to the head.
- Delayed eruption of primary teeth, enamel defects and caries teeth.

## 2. Chest:

- **Rachitic rosary:** Overgrowth of cartilage or osteoid tissue at the costochondral junction causes deformation of the chest producing the 'rachitic rosary'.
- **Pigeon breast/chest deformity:** The weakened metaphyseal areas of the ribs are subject to the pull of the respiratory muscles and thus bend inward. This creates anterior protrusion of the sternum producing **pigeon breast deformity** (pectus carinatum).
- **Harrison's sulcus/groove:** It is due to the muscular pull of the diaphragmatic attachments to the lower ribs.
- Respiratory infections and atelectasis.

**Fig. 1.6:** Features of rickets.

### *During the ambulatory stage*

- This occurs when an ambulating child develops rickets. It is characterized by deformities affecting the spine, pelvis, and tibia. Scoliosis, kyphosis and lumbar lordosis are characteristic.
- **Bowing of the legs:** Due to affection of tibia, knock knees, anterior curving of legs.

### ***Extraskkeletal Manifestations***

- **Seizures and tetany:** Secondary to hypocalcemia in vitamin D deficiency rickets.
- **Hypotonia and delayed motor development:** In rickets developing during infancy.
- Protuberant abdomen, bone pain, waddling gait and fatigue.
- **Asymptomatic:** Detected on radiological evaluation.

### ***Investigations***

- **Wrist radiograph:** Findings include: (1) lower ends of the shaft of radius and ulna become splayed, (2) epiphyseal surfaces—fuzzy and ill-defined, and (3) unossified zone between shaft and radial epiphysis—widened ('saucer' deformity). Figure 1.7 shows X-ray with splaying (expansion) of epiphyses and bow legs.
- **Blood:**
  - **Serum calcium:** Low
  - **Serum phosphate:** Low (due to associated secondary hyperparathyroidism).
  - **Serum alkaline phosphatase:** Increased due to increased osteoblast activity.
  - **Plasma 25-hydroxyvitamin D<sub>3</sub> level:** Low in most of the cases.

**Fig. 1.7:** X- ray of rickets showing splaying of epiphyses and bow legs.

Comparison of conditions involving bone metabolism is presented in Table 1.3.

<b>Table 1.3:</b> Comparison of conditions involving bone metabolism.						
<i>Condition</i>	<i>Calcium</i>	<i>Phosphorous</i>	<i>Vitamin D</i>	<i>Alkaline phosphatase</i>	<i>Parathormone</i>	<i>Bone</i>
Rickets/osteomalacia	Decreased	Decreased	Low	Elevated	Elevated	Softening, Loosers zones
Osteopenia	Normal	Normal	Normal	Normal/ decreased	Normal	Decrease bone mass
Osteoporosis	Normal	Normal	Normal/ decreased	Normal/ mild elevation	Normal	Degeneration of bone matrix
Hyperparathyroidism	Increased	Decreased	Normal	Elevated	Elevated	Browns tumor. Lytic lesions
Paget's disease	Normal	Normal	Normal	Variable	Variable	Osteolytic/sclerotic lesion

#### **Treatment of rickets**

- Treat the underlying cause.
- Supplementation diet with calcium and vitamin D.
- For nutritional deficiency of vitamin D: Ergocalciferol, 1,50,000–6,00,000 IU orally or intramuscularly as a single dose. Or give Ergocalciferol in a dose of 2000 IU every day.

**Prevention:** (i) Adequate consumption of vitamin D (1000-5000 IU/day); (ii)

Adequate exposure to sunlight (from 30 minutes to 2 hours/week for infants).

## Osteomalacia

**Q. Discuss the causes, clinical features, investigations and treatment in case of osteomalacia.**

- Vitamin D deficiency in **adults** is accompanied by hypocalcemia and hypophosphatemia which result in **impaired mineralization of bone matrix** proteins, a condition known as osteomalacia. Thus, osteomalacia is a disorder of mineralization of the organic matrix of the skeleton in adults when the epiphyseal growth plates have closed. In contrast, in rickets, the growing skeleton is involved.

Causes of osteomalacia are listed in Box 1.5.

**Box 1.5:** Causes of osteomalacia.

**Nutritional abnormalities:** Dietary deficiency of vitamin D, parenteral nutrition

**Malabsorption:** Tropical sprue, Celiac disease, hepatobiliary diseases, pancreatic insufficiency

**Disorders of vitamin D metabolism:** Vitamin D dependency type I and type II, anticonvulsants, chronic renal failure

**Acidosis:** Distal renal tubular acidosis (type I)

**Phosphate depletion:** Use of non-absorbable antacids, tumor-associated osteomalacia

**Others:** Multiple myeloma, nephrotic syndrome, lead poisoning, inadequate sun exposure

### *Clinical Features*

- Bone pains, muscle weakness, fractures of bones with minor trauma.
- Pain in the hip may cause antalgic gait.
- Weakness of proximal muscle results in waddling gait and may resemble primary muscle disease.
- Collapse of vertebrae causes local pain and deformity.
- Softening of skeleton may produce deformities such as kyphosis, coxa vara, pigeon chest and triradiate pelvis with a narrow pubic arch.

### *Laboratory investigations*

*Blood (same as for rickets as described on page 9).*

**Urinary excretion of calcium:** Reduced.

### *Radiological findings*

- **Bone density:** Reduced (osteopenia).

- **Epiphyseal growth plate:** Increased in thickness, cupped and hazy at the metaphyseal border.
- **Cortical thinning:** Due to secondary hyperparathyroidism.
- **Other features:** Presence of nontraumatic fractures, radiolucent bands called pseudofractures (**Looser's zones**) (**Fig. 1.8**).
- **Bone scan** may be normal or show discrete foci of increased radionuclide uptake.
- **Bone mineral density** as assessed by dual-energy X-ray absorptiometry (DEXA) is reduced at spine, hip and forearm, with the maximum deficits at the cortical-rich bone in the forearms.

**Fig. 1.8:** X-ray shows looser zones (arrow) and osteopenia.

#### **Treatment of osteomalacia**

- **Treat the underlying cause** wherever possible.
- **Dietary deficiency:** It is corrected by 1000–4000 IU of vitamin D<sub>2</sub> (ergocalciferol) or vitamin D<sub>3</sub> (cholecalciferol) for 3 months. This is followed by lower doses as maintenance. Vitamin D should be taken with fatty diet for maximum absorption.
- **Osteomalacia due to malabsorption:** Give 50,000–100,000 IU of vitamin D + calcium supplementation. Small doses of calcitriol (0.5–1.0 µg daily) also effective.
- **Chronic renal failure:** Calcitriol with weekly monitoring of calcium level.

## Vitamin D in health and disease (Table 1.4)

**Table 1.4: Role of vitamin D in health and disease.**

Parathyroid hormone	<ul style="list-style-type: none"> <li>• Hypovitaminosis D causes secondary hyperparathyroidism which increases the risk of MI, HTN and stroke</li> </ul>
Malignancy	<ul style="list-style-type: none"> <li>• Transcription of oncogenes involved with cell differentiation and proliferation is controlled: For example, c-myc, c-fos, c-sis</li> <li>• There is an inverse relationship between sun exposure and cancer mortality. 10 ng/mL rise in vitamin D level is associated with             <ul style="list-style-type: none"> <li>– 17% reduction in cancer incidence, 29% reduction in all cancer mortality and 45% reduction in GI cancer mortality</li> </ul> </li> </ul>
Nervous system function	<ul style="list-style-type: none"> <li>• Vitamin D modulates neurotransmitter and neurological function</li> <li>• Has anticonvulsant and antidepressant effect. 50% of multiple sclerosis patients are vitamin D deficient</li> <li>• Seizures are common with vitamin D deficiency</li> </ul>
Anti-inflammatory function	<ul style="list-style-type: none"> <li>• Suppresses and may prevent autoimmune diseases</li> <li>• Seems to reduce severity and frequency of childhood pneumonia</li> </ul>
Calcium homeostasis	<ul style="list-style-type: none"> <li>• Calcium absorption increases as 25(OH) D blood levels increase</li> </ul>
Cardiovascular function	<ul style="list-style-type: none"> <li>• Risk of myocardial infarction doubles in patients with vitamin D deficiency</li> <li>• Heart failure patients have much lower vitamin D levels. HTN patients given UV light treatments 3 times/week for 6 weeks have shown mild decreases in BP</li> </ul>
Diabetes type 1	<ul style="list-style-type: none"> <li>• Infants and children who were supplemented with had decreased incidence of DM type 1 by 80%</li> </ul>
Diabetes type 2	<ul style="list-style-type: none"> <li>• Low vitamin D levels associated with insulin resistance and <math>\beta</math>-cell dysfunction</li> <li>• Postprandial glucose and insulin sensitivity: Better in healthy adults with highest vitamin D levels</li> <li>• Highest vitamin D levels associated with 60% improvement in insulin sensitivity</li> </ul>
Respiratory system	<ul style="list-style-type: none"> <li>• Vitamin D supplementation provides significant protective effect against influenza</li> <li>• It is also associated with decrease in FEV1 and an increased incidence of rhinobronchial atopy</li> </ul>
Osteoarthritis (OA)	<ul style="list-style-type: none"> <li>• Vitamin D deficiency hastens the progression of OA hip and knee</li> </ul>
Mood disorders	<ul style="list-style-type: none"> <li>• Vitamin D supplementation improves general mood and hastens recovery in seasonal affective mood disorders</li> </ul>
Polycystic ovary syndrome	<ul style="list-style-type: none"> <li>• Deficiency exists in 60% of cases with normalization of menses and/or fertility within 3 months of supplementation</li> </ul>

Pain	<ul style="list-style-type: none"> <li>• Persistent, nonspecific musculoskeletal pain in 93% of patients had vitamin D deficiency</li> <li>• Low back pain patients (53%) have vitamin D deficiency</li> </ul>
Autoimmune disease	Vitamin D insufficiency in: <ul style="list-style-type: none"> <li>• Half of the patients with fibromyalgia + SLE, Graves' disease, ankylosing spondylitis and rheumatoid arthritis</li> </ul>
Falls in the elderly	<ul style="list-style-type: none"> <li>• Vitamin D deficiency reported to affect predominantly the weight-bearing antigravity muscles of the lower limb, which are necessary for postural balance and walking</li> <li>• Improvement in lower extremity muscle strength and balance with vitamin D supplementation thought to explain the reduced number of fall-related fractures</li> </ul>

## Hypervitaminosis D

**Q. Write short answer on hypervitaminosis D.**

### *Clinical Features*

Hypervitaminosis D causes hypercalcemia, which manifest as: (1) nausea and vomiting; (2) excessive thirst and polyuria; (3) severe itching; (4) joint and muscle pains; (5) disorientation and coma; and (6) metastatic calcifications.

**Treatment of hypervitaminosis:** Hydration and treatment of hypercalcemia.

## TRACE ELEMENTS

- The term 'trace' is used for concentrations of elements not exceeding 250 µg/g of extracellular matrix. Trace elements are naturally occurring, homogeneous, inorganic substances required in humans in amounts less than 100 mg/day.
- Classification of trace elements is presented in Box 1.6.
- There are about 15 trace elements of which only 10 are essential nutrients in humans. These include: Iron, zinc, copper, chromium, selenium, iodine, fluorine, manganese, molybdenum and cobalt.

**Box 1.6:** Classification of trace elements.

- Essential trace elements
  - Iodine, zinc, selenium, copper, molybdenum, chromium, cobalt, iron
- Trace elements that are probably essential
  - Manganese, nickel, silicon, boron, vanadium

- Potentially toxic elements with possible essential functions in low doses
  - Fluoride, lead, cadmium, mercury, arsenic, lithium, tin, aluminum

## Iron

**Q. Write short note on daily requirement of iron and important dietary sources of iron.**

- Most essential trace element.
- **Deficiency state:**
  - Asymptomatic
  - Anemia (refer pages 557-62), weakness, headache, irritability, and varying degrees of fatigue and exercise intolerance.

### *Acute Iron Poisoning*

- Develops when iron level exceed 60 mg/kg elemental iron
- **Clinical features:** Vomiting, abdominal pain, bloody diarrhea, shock, dehydration, cyanosis, acidosis, and coma. Can cause hepatotoxicity and bowel obstruction.

#### **Treatment**

- Gastric lavage with sodium bicarbonate solution
- Desferrioxamine 15 mg/kg/hour IV, increased to maximum dose of 35 mg/kg/hour
- Correction of acidosis and shock. Extracorporeal removal with exchange transfusion or continuous venovenous hemofiltration.

## FLUOROSIS

**Q. Write short note on fluorosis and its radiological signs.**

- **Fluorine:** Fluorine's ionic form is known as fluoride. It is component of bone mineral and alters its physical characteristics. Fluoride helps to prevent dental caries, because it increases the resistance of the enamel to acid attack. Requirement in adults is between 1.5 and 4 mg/day and 96% of fluorides in the body found in bone and teeth.
- **Deficiency:** Intake of <0.1 mg/day in infants and <0.5 mg/day in children predisposes to an increased incidence of dental caries.
- **Toxicity:** Results in **fluorosis**. This develops when fluoride content in the water is high (>3 to 5 ppm).

- **Acute** ingestion of >30 mg/kg body weight usually manifests with gastrointestinal symptoms such as diarrhea, vomiting leading to renal failure and may cause death.
- **Dental fluorosis:** It is characterized by mottling of teeth where the enamel loses its luster, teeth appear chalky white with transverse yellow bands. It becomes rough, pigmented, pitted and brittle (fluorite teeth).
- **Skeletal fluorosis:** Its features are:
  - ◆ **Sclerosis of bones** (especially of spine, pelvis and limbs).
  - ◆ **Calcification** of ligaments, *interosseous membrane* (Fig. 1.9) and tendinous insertions.
  - ◆ **Osteoporosis with brittle bones.**
  - ◆ **Severe pain and stiffness** in joints, stiffness in neck and backbone, bow legs. Other features are weakness, anemia and weight loss.

**Fig. 1.9:** X-ray of fluorosis showing calcification of interosseous membrane.

## Angular Stomatitis

**Q. Write short note on angular stomatitis.**

- **Angular stomatitis** refers to cracking of the epithelium at the edge of the lips. It presents with erythema, maceration, scaling, and fissuring at the corners of the mouth. Most commonly bilateral and very painful.
- **Causes of angular stomatitis (Box 1.7).**

**Box 1.7:** Causes of angular stomatitis.

- Iron deficiency anemia
- Secondary infection of *Candida albicans*, *Staphylococcus*
- *Vitamin deficiency:*
  - Riboflavin (B<sub>2</sub>) deficiency
  - Pyridoxine (B<sub>6</sub>) deficiency
  - Niacin deficiency (pellagra)
- Herpes labialis at the angle of mouth
- Angular stomatitis is associated with cheilosis in niacin deficiency and pellagra

## ENTERAL AND PARENTERAL NUTRITION SUPPORT

Some form of nutritional support is needed for patients who cannot eat, should not eat, will not eat or cannot eat enough.

### Indications for Nutritional Support

- Severely malnourished patients on admission to hospital
- Moderately malnourished patients who are not expected to eat for more than 3–5 days (because of their physical illness).
- Normally nourished patients not expected to eat for more than 5 days or to eat less than half their intake for more than 8–10 days.

### Types of Nutritional Support

- Enteral nutrition should be used, if the gastrointestinal tract is functioning normally.
- Parenteral nutrition.

### *Enteral Nutrition (EN)*

- **Pre-requisite:** Must have functioning GI tract. Patients who are not able to swallow may need artificial nutritional support (e.g. after acute stroke)

or throat surgery, or long-term neurological disorders such as motor neuron disease and multiple sclerosis).

- Whenever possible, the enteral route should be used.

*Advantages and disadvantages of enteral nutrition (Table 1.5)*

**Table 1.5: Advantages and disadvantages of enteral nutrition.**

<i>Advantages</i>	<i>Disadvantages</i>
<ul style="list-style-type: none"> <li>• Intake easily/accurately monitored</li> <li>• Provides nutrition when oral intake is not possible or adequate</li> <li>• Less cost than parenteral nutrition</li> <li>• Readily available</li> <li>• Reduces risks associated with disease state</li> <li>• Preserves gut integrity and immunologic function</li> <li>• Decreases likelihood of bacterial translocation</li> <li>• Increased compliance with intake</li> <li>• Decreases the risk of multiorgan failure in intensive care patients</li> </ul>	<ul style="list-style-type: none"> <li>• <i>Mechanical complications:</i> <ul style="list-style-type: none"> <li>– Tube migration</li> <li>– Increased risk of bacterial contamination</li> <li>– Tube obstruction</li> <li>– Pneumothorax</li> </ul> </li> <li>• Costs more than oral diets</li> <li>• Less palatable</li> <li>• <i>Labor:</i> (1) Intensive assessment; (2) Administration; (3) Tube patency; and (4) Site care; monitoring</li> </ul>

*Methods of enteral nutrition (Table 1.6)*

**Table 1.6: Methods of enteral nutrition.**

<i>Tube feeding less than 4 weeks</i>	<i>Tube feeding more than 4 weeks</i>
<ul style="list-style-type: none"> <li>• Nasogastric</li> <li>• Nasoduodenal</li> <li>• Nasojejunal</li> <li>• Orogastric</li> </ul>	<ul style="list-style-type: none"> <li>• Enterostomy</li> <li>• Gastrostomy</li> <li>• Jejunostomy</li> </ul>

Complications of enteral feeding: (1) **Access problems** (e.g. tube obstruction); (2) **Administration problems** (e.g. aspiration pneumonia); (3) **Gastrointestinal complications** (e.g. diarrhea); (4) **Metabolic complications** (e.g. overhydration).

*Rate and method of delivery\**

- *Bolus:* 300 to 400 mL rapid delivery via syringe several times daily
- *Intermittent:* 300 to 400 mL, over 20 to 30 minutes, several times/day via gravity drip or syringe

- *Cyclic*: via pump usually at night
- *Continuous*: via gravity drip or infusion pump.

\*Determined by medical status, feeding route and volume, and nutritional goals.

## ***Parenteral Nutrition***

**Q. Write short essay/note on total parenteral nutrition.**

- *Central access*: **Total parenteral nutrition (TPN)** both long- and short-term placement.
- **Peripheral parenteral nutrition (PPN).**

Venous sites through which the superior vena cava may be accessed are subclavian vein, internal or external jugular vein, axillary vein, brachial vein, basilic vein and cephalic vein.

*Advantages and disadvantages of parenteral nutrition (Table 1.7)*

**Table 1.7: Advantages and disadvantages of parenteral nutrition.**

<b><i>Advantages</i></b>	<b><i>Disadvantages</i></b>
<ul style="list-style-type: none"> <li>• Provides nutrients when less than 2 to 3 feet of small intestine remains</li> <li>• Allows nutrition support when GI intolerance prevents oral or enteral support</li> </ul>	<ul style="list-style-type: none"> <li>• Economic impact</li> <li>• Time-consuming</li> <li>• Inconvenient</li> <li>• Activities and work must be planned around feedings</li> </ul>

*Indications for total parenteral nutrition (Box 1.8)*

**Box 1.8:** Indications for total parenteral nutrition.

- GI non-functioning
- Nil per oral (NPO) > 5 days
- GI fistula
- Acute pancreatitis
- Short bowel syndrome
- Malnutrition with >10–15% weight loss
- Nutritional needs not met; patient refuses food

*Complications of parenteral nutrition (Table 1.8)*

## Refeeding Syndrome

**Definition:** Refeeding syndrome is a syndrome consisting of metabolic disturbances that occur as a result of reinstatement of nutrition to patients who are starved or severely malnourished.

**Time of occurrence:** Usually occurs **within 4 days** of restarting nutritional support.

**Table 1.8: Complications of parenteral nutrition.**

<i>Duration</i>	<i>Mechanical</i>	<i>Metabolic/GI</i>	<i>Infectious</i>
First 48 hours	<ul style="list-style-type: none"> <li>• Malposition</li> <li>• Hemothorax/pneumothorax</li> <li>• Air embolism</li> <li>• Blood loss</li> <li>• Puncture of subclavian/carotid artery</li> </ul>	<ul style="list-style-type: none"> <li>• Fluid overload</li> <li>• Hypoglycemia, hypophosphatemia, Hypokalemia, hypomagnesemia</li> <li>• Refeeding syndrome</li> </ul>	
First 2 weeks	<ul style="list-style-type: none"> <li>• Catheter displacement</li> <li>• Thrombosis, air embolism</li> <li>• Occlusion</li> </ul>	<ul style="list-style-type: none"> <li>• Hypoglycemic coma</li> <li>• Acid-base and electrolyte imbalance</li> </ul>	<ul style="list-style-type: none"> <li>• Catheter-induced sepsis</li> <li>• Exit site infection</li> </ul>
3 months onwards	<ul style="list-style-type: none"> <li>• Tear of catheter</li> <li>• Catheter thrombosis</li> <li>• Air embolism</li> <li>• Blood loss</li> </ul>	<ul style="list-style-type: none"> <li>• Deficiency of essential fatty acids, vitamins or trace element</li> <li>• Metabolic bone disease</li> <li>• Liver disease</li> </ul>	<ul style="list-style-type: none"> <li>• Tunnel infection, catheter-induced sepsis</li> <li>• Exit site infection</li> </ul>

### *Mechanism*

- When nutritional support is given to a starved or severely malnourished patient, there is a rapid change from a catabolic to an anabolic state.
- Administration of carbohydrates stimulates **release of insulin**. This causes cellular uptake of phosphate, potassium and magnesium and may lead to significant falls in their levels in the serum. This results in electrolyte imbalance and can produce serious consequences (e.g. cardiac arrhythmias).

### *Clinical Features*

- Initial features may be nonspecific.
- **Later:** Rhabdomyolysis, leucocyte dysfunction, respiratory and cardiac failure, hypotension, arrhythmias, seizures, coma and sudden death.

#### Treatment of Refeeding Syndrome

- Start nutrition at 5–10 kcal/kg/day and increase levels gradually. Provide thiamine, multivitamins and trace elements. In thiamin-deficient patients, Wernicke's encephalopathy can be precipitated by refeeding with carbohydrates. This is prevented by providing thiamin before starting nutritional support.
- Restore the circulatory volume. Monitor fluid balance and clinical status.
- Replace PO<sub>4</sub> K and Mg.

## PROTEIN-ENERGY MALNUTRITION

**Protein-energy malnutrition (PEM) or protein-calorie malnutrition** include marasmus, kwashiorkor and intermediate states of marasmus-kwashiorkor.

### Marasmus

**Q. Write short note on marasmus.**

- *Marasmus* is the childhood form of starvation. It develops **due to inadequate intake of protein and calories**.
- It is characterized by **emaciation** with apparent muscle wasting and loss of body fat. There is **no edema**. The hair is thin and dry. The marasmic child does not appear as apathetic or anorexic as with kwashiorkor. Diarrhea is frequent and there may be signs of infection.

### Kwashiorkor

- Kwashiorkor develops due to an **inadequate protein intake with reasonable caloric** (energy) intake.
- *Kwashiorkor* occurs in a young child displaced from breastfeeding by a new baby. It may be precipitated by infections (e.g. measles, malaria and diarrheal illnesses). Child appears apathetic and lethargic with severe anorexia.
- **Edema:** In kwashiorkor, marked protein deprivation causes hypoalbuminemia leading to **generalized or dependent edema**.
- **Skin lesions:** Children with kwashiorkor have characteristic *skin lesions*.

This consists of alternating zones of hyperpigmentation, and hypopigmentation, producing **‘flaky paint’ appearance**.

- **Hair changes:** The hair is dry and sparse. There may be loss of color or alternating bands of pale and darker hair (Flag sign).
- **Other features:** The other features that differentiate kwashiorkor from marasmus are:
  - Abdomen is distended due to hepatomegaly (presence of enlarged, fatty liver) and/or ascites.
  - Development of apathy, listlessness, and loss of appetite.
  - Likely presence of vitamin deficiencies.
  - Defects in immunity and secondary infections.

#### Treatment of PEM

- Provision of protein and energy supplements. Control of infection.

## OBESITY

**Q. Describe the risk factors, clinical features, complications and management of obesity.**

**Definition:** Obesity is defined as an accumulation of **excess body fat (adipose tissue)** that is of sufficient magnitude to impair health. Latin word ‘obesus’ meaning stout, fat, plump.

### Classification of Overweight and Obesity by Body Mass Index (Table 1.9)

**Table 1.9: Nutritional status based on the WHO and “Asian criteria” values.**

<i>Nutritional status</i>	<i>WHO criteria BMI cut-off</i>	<i>“Asian criteria” BMI cut-off</i>
Underweight	<18.5	<18.5
Normal	18.5–24.9	18.5–22.9
Overweight	25–29.9	23–24.9
Pre-Obese	–	25–29.9
Obese	>30	>30

Obese type-1 (obese)	30–40	30–40
Obese type-2 (morbid obese)	40.1–50	40.1–50
Obese type 3 (super obese)	>5	>50

## ***Types of Obesity According to Body Fat Distribution***

The distribution of the stored fat is important in obesity and accordingly obesity is divided into:

- **Central ('abdominal', 'visceral', 'android' or 'apple-shaped') obesity:** This type of obesity shows increased accumulation of fat in the trunk and in the abdominal cavity/intra-abdominal (in the mesentery and around viscera). It is associated with a greater risk for several diseases (e.g. type 2 diabetes, the metabolic syndrome and cardiovascular disease) than generalized obesity.
- **Generalized ('gynoid' or 'pear-shaped') obesity:** This type is characterized by excess accumulation of fat diffusely in the subcutaneous tissue.

## **Etiology**

### **Q. Write short essay/note on causes of obesity.**

Accumulation of fat in obesity can be considered by the result of caloric imbalance between the energy consumption (intake of calories) in the diet and energy expenditure through exercise and bodily functions. However, the pathogenesis of obesity is complex and incompletely known.

#### **1. Genetic aspects of human obesity:**

- Obesity is a **polygenic disorder**, with small contributions from a number of different genes.
- Single-gene (**monogenic forms**) disorders are rare and produce severe childhood obesity. These include mutations in the leptin gene and leptin receptor gene, mutations of *POMC* (Proopiomelanocortin), *Mc4R* (melanocortin-4 receptor) genes.
- A few **genetic conditions in which obesity** is a feature including the Prader–Willi and Laurence–Moon–Biedl syndromes.

#### **2. Environmental contributors to human obesity:**

- **Food:** Many environmental factors can influence food intake. Increased consumption of energy-dense foods, larger food portion size,

and increased variety of food, increased availability, reduced cost and increased caloric beverages (soft drinks, juices) promote obesity.

- **Physical activity:** It can be divided into three categories: (1) exercise (fitness and sports-related activities);(2) work-related physical activity; and (3) non-exercise, non-employment (spontaneous) activity. Increased sedentary behavior, reduced activities of daily living and decreased physical activity promote obesity.
3. **Reversible causes of obesity and weight gain:** Minority of patients presenting with obesity have specific cause which can be identified and treated (Table 1.10). Compared to idiopathic obesity, these patients have short history of marked weight gain.

## Pathogenesis (Fig. 1.10)

### 1. Peripheral Afferent System

Peripheral afferent system can be further subdivided into peripheral appetite suppressing signals and peripheral appetite stimulant signals.

#### *Peripheral appetite suppressing signals*

- **Leptin (Greek term leptos, meaning ‘thin’):** Leptin is a **hormone secreted by fat cells** and it stimulates POMC/CART pathway (Fig. 1.11) and inhibits NPY/AgRP pathway and **appetite is suppressed** (anorexigenic). Increased leptin **stimulates physical activity, heat production** (thermogenesis), and **energy expenditure**.
- **Adiponectin:** It is a hormone (**fat-burning molecule**) and the ‘guardian angel against obesity,’ and is produced mainly by fat cells (adipocytes). Its levels are lower in obese.
- **Resistin:** Primarily produced by macrophages and not fat cells. It **causes insulin resistance**.

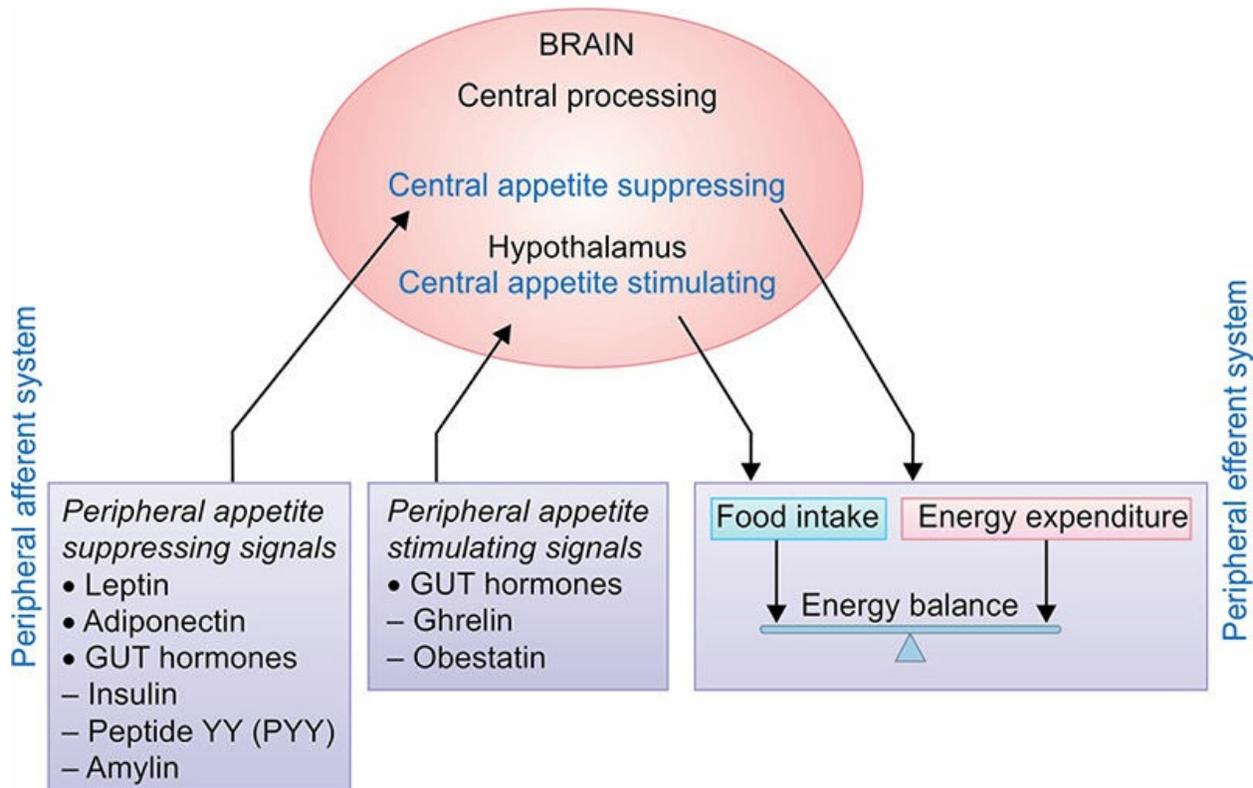

**Table 1.10:** Potentially reversible causes of obesity and weight gain.

<b>Endocrine factors</b>			
• Hypothyroidism			• Stein–Leventhal syndrome
• Cushing’s syndrome			• Hypothalamic damage (e.g. due to trauma, tumor)
• Insulinoma			
<b>Drug induced</b>			
• <i>Psychiatric medications:</i>	<i>and</i>	<i>neurologic Atypical</i>	• <i>Antidiabetes agents:</i> insulin (most forms), sulfonylureas, thiazolidinediones

antipsychotics (e.g. olanzapine)  
pizotifen, sodium valproate,  
flunarizine

- *Steroid hormones*: Progestational steroids, corticosteroids, hormonal contraceptives

- *Antihypertensive agents*:  $\alpha$ -adrenergic and  $\beta$ -adrenergic receptor blockers

**Fig. 1.10:** Regulation of energy balance. Peripheral afferent system (appetite suppressing and stimulating signals) influences the activity of the hypothalamus, which is the central regulator of appetite and satiety. Signals from hypothalamus in turn act on peripheral efferent system (food intake and energy expenditure).

- **Gut hormones:** These include PYY, pancreatic polypeptide, insulin, and amylin.
  - **Insulin:** It is **secreted by cells of the pancreas** and act centrally to **activate the appetite suppressing pathway**.
  - **Peptide YY (PYY):** It is **secreted by the endocrine cells (L cells)** in the ileum and colon. It **reduces appetite**. Other peripheral **appetite suppressing** signals include glucagon-like peptide 1 (**GLP1**) and oxyntomodulin.
  - **Amylin:** It is a peptide secreted with insulin from pancreatic  $\beta$ -cells.

### Peripheral appetite-stimulating signals

- **Gut hormones:**

- **Ghrelin:** It is produced by the **oxyntic cells of the fundus of the stomach** and in the **arcuate nucleus of the hypothalamus**. Ghrelin **increases food intake** (orexigenic effect) and **stimulates appetite** by activating the central appetite stimulating NPY/AgRP pathway.
- **Obestatin:** It is a peptide produced by the **same gene that encodes ghrelin**. It counteracts the **increase in food intake induced by ghrelin**.

- **Retinol-binding protein 4 (RBP4):** Secreted by fat cells. Its actions counteract with those of insulin. Raised levels of RBP4 found in type 2 diabetes mellitus.

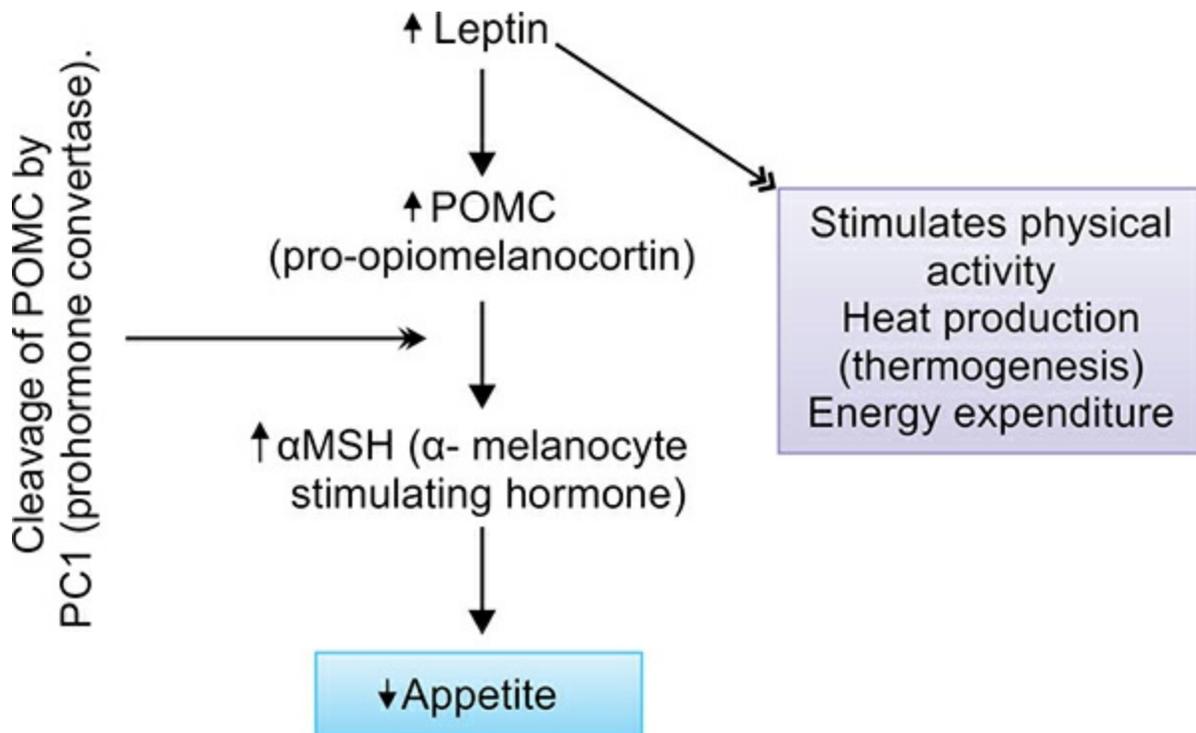

Fig. 1.11: Actions of leptin.

## 2. Central Processing (Table 1.11)

The arcuate nucleus of the hypothalamus processes and integrates neurohumoral peripheral afferent signals and generates efferent signals. It consists of:

**Table 1.11: Examples of central nervous system regulators of energy**

balance.	
<b>Central anabolic (increased intake) regulators</b>	<b>Central catabolic (decreased intake) regulators</b>
Neuropeptide Y	$\alpha$ -Melanocyte-stimulating hormone
Agouti-related protein	Corticotropin-releasing hormone
Melanin-concentrating hormone	Thyrotropin-releasing hormone
Hypocretins and orexins	Cocaine- and amphetamine-regulated transcript (CART)

*Central appetite-suppressing (anorexigenic pathway or leptin melanocortin pathway)*

- In this pathway, **POMC (pro-opiomelanocortin)/CART (cocaine and amphetamine-regulated transcripts) neurons enhance energy expenditure** and weight loss through the production of the anorexigenic (suppresses appetite) neuropeptides mainly  $\alpha$ MSH ( $\alpha$ -melanocyte stimulating hormone) by cleavage of POMC by PC1 (prohormone convertase).

*Central appetite-stimulating (orexigenic) pathway: It consists of:*

- NPY (neuropeptide Y)/AgRP (agouti-related peptide) containing neurons promote food intake (orexigenic effect) and weight gain, through the activation of Y1/5 receptors in secondary neurons.
- Secondary neurons in turn release factors such as melanin-concentrating hormone (MCH) and orexin, which stimulate appetite. This pathway also decreases energy expenditure.

### **3. Peripheral Efferent System**

It is organized into two pathways namely anabolic and catabolic that control food intake and energy expenditure, respectively.

*Energy intake (Food intake)*

- **Food:** The increase in obesity can be related to the type of food consumed (i.e. food-containing sugar and fat) and also psychological factors.
- **Control of appetite:** Signals may affect different aspects of eating behavior. For example:
  - **Ghrelin** (peptide produced by the stomach) **increases hunger but does not affect satiation or satiety.**

- **Cholecystokinin causes satiation**, but has **no effect on satiety**.
- **Leptin act on multiple pathways**, its deficiency causes increased hunger and reduced satiation and satiety.
- Following a meal, substances such as cholecystokinin (CCK), bombesin, and glucagon like peptide-1 (GLP1) are released from the small intestine, and glucagon and insulin from the pancreas. These hormones are involved in the control of satiety. The control of appetite is extremely complex. Many transmitters in the central nervous system affect appetite:
  - **Appetite inhibitors:** Dopamine, serotonin,  $\gamma$ -aminobutyric acid
  - **Appetite stimulators:** Opioids

### *Energy expenditure*

It can be divided into resting (or basal) metabolic rate, the thermic effect of food, and physical activity energy expenditure.

- **Resting basal metabolic rate (BMR):** BMR is the energy expenditure and accounts for about 70% of daily energy expenditure, whereas active physical activity contributes to 5–10% of energy expenditure.
- **Thermic effect of food (thermogenesis):** About 10% of ingested energy is spent in the process of digestion, absorption, and metabolism of nutrients irrespective of physical activity. This is called as dietary induced thermogenesis which is lower in obese individuals.
- **Physical activity:** Obese individuals tend to spend more energy during physical activity as they have a larger mass to move.

## **Pathologic Consequences of Obesity (Complications of Obesity)**

**Q.** Write short essay/note on complications of obesity.

**Morbidity and mortality:** Obesity is associated with an increase in mortality and morbidity. Obese individuals are at risk of early death, mainly from diabetes, coronary heart disease and cerebrovascular disease.

### ***Metabolic Complications of Obesity***

Central obesity or upper body fat distribution is associated with increased concentration of FFA (free-fatty acid), which can produce several metabolic complications of obesity.

*Insulin resistance and type 2 diabetes mellitus*

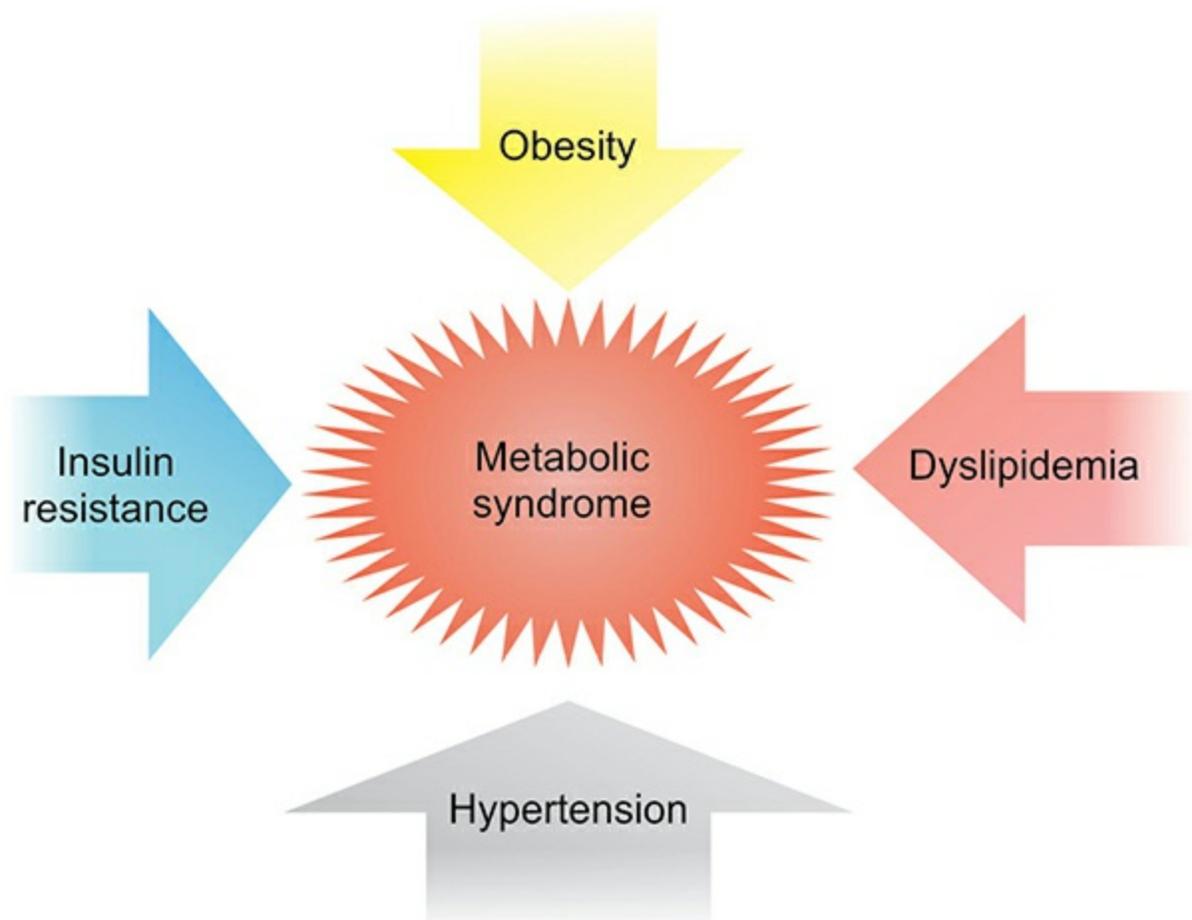

- **Insulin resistance is the decrease/failure of response of target (peripheral) tissues to insulin action.** Insulin resistance can develop in obesity and may produce type 2 diabetes mellitus. **Central/upper body/visceral obesity** are found in more than 80% of patients with **type 2 diabetes**.
- **Causes of insulin resistance in obesity:**
  - **Obese individuals** have **excess circulating free fatty acids (FFAs)** and there is an **inverse correlation between fasting plasma FFAs and insulin sensitivity**. Central obesity is associated with **insulin resistance**. **Excess intracellular FFAs increases gluconeogenesis**.
  - **Adipokines: Adipose tissue** acts as a functional endocrine organ and **secretes variety of proteins** into the systemic circulation, which are **termed adipokines** (or adipose cytokines). **In obesity, adiponectin (one of the adipokines) levels are reduced**, which contributes to insulin resistance.
- **Consequences of insulin resistance (Box 1.9).**

**Box 1.9:** Consequences of insulin resistance.

- *Muscle:* Hyperglycemia and diabetes mellitus
- *Kidneys:* Salt retention and hypertension
- *Ovaries:* Increase testosterone and polycystic ovary syndrome (PCOS)
- *Heart:* Increase plasminogen activator inhibitor (PAI 1) and acute coronary syndrome
- *Cancers:* Colon, prostate, breast
- *Sympathetic system:* Increased cytokines and blood pressure.

### *Dyslipidemia*

- Upper body obesity and type 2 diabetes mellitus are associated with an atherogenic lipid profile. Dyslipidemia includes **increased triglycerides, increased low-density lipoprotein (LDL) cholesterol with very low density lipoprotein (VLDL) cholesterol**, decreased **high-density lipoprotein (HDL) cholesterol**, and decreased levels of the vascular protective adipokine adiponectin.
- Dyslipidemia increases the risk of cardiovascular diseases (**atherosclerosis, cardiomyopathy**) in the metabolic syndrome (Fig. 1.12).

**Fig. 1.12:** Obesity and metabolic syndrome.

### ***Endocrine Manifestations of Obesity***

Reproductive disorders associated with obesity are listed in Table 1.12.

**Table 1.12:** Endocrine manifestations of obesity.

<b><i>Men</i></b>	<b><i>Women</i></b>
<ul style="list-style-type: none"> <li>• Plasma testosterone and SHBG are reduced</li> </ul>	<ul style="list-style-type: none"> <li>• Increased androgen</li> </ul>
<ul style="list-style-type: none"> <li>• Increase estrogen</li> </ul>	<ul style="list-style-type: none"> <li>• Decrease SHBG</li> </ul>
<ul style="list-style-type: none"> <li>• Gynecomastia seen</li> </ul>	<ul style="list-style-type: none"> <li>• PCOS</li> </ul>
<ul style="list-style-type: none"> <li>• Secondary sexual characters preserved</li> </ul>	<ul style="list-style-type: none"> <li>• Not only fertility but their chances of IVF success reduces</li> </ul>

(SHBG: Sex hormone-binding globulin; PCOS: Polycystic ovary syndrome)

### ***Mechanical Complications of Obesity***

**Q. Write short essay/note on mechanical complications of obesity.**

- **Osteoarthritis:** Extremity degenerative joint disease (osteoarthritis) and also gout.
- **Venous stasis/varicose veins.**
- **Acanthosis nigricans:** Reflects the severity of underlying insulin resistance.
- **Increased friability of skin:** It may be seen especially in skinfolds, thereby increasing the risk of fungal and yeast infections.
- **Urinary incontinence.**

### ***Pulmonary Disease***

- These include reduced chest wall compliance, increased work of breathing, increased minute ventilation (due to increased metabolic rate), and decreased functional residual capacity and expiratory reserve volume.
- **Obstructive sleep apnea:** Sleep apnea is common in patients with severe obesity. Sleep apnea can be obstructive (most common), central, or mixed and is often associated with an increased risk of hypertension, right heart failure and sudden death. Obesity hypo ventilation syndrome is also known as **Pickwickian syndrome**.
- **Obesity and asthma:** Reduced TLC (total lung capacity), reduced RV (residual volume) and FRC (functional residual capacity).

### ***Obesity and Cancer (Table 1.13)***

Obesity is the biggest preventable cause of cancer after smoking. Accounts for 14% of cancer deaths in men and 20% in women.

**Table 1.13: Obesity and related cancers.**

<b><i>Males</i></b>	<b><i>Females</i></b>
Esophagus	Gallbladder
Colon	Bile ducts
Rectum	Breasts
Pancreas	Endometrium
Liver	Cervix
Prostrate	Ovaries

## ***Gastrointestinal Disorders***

Following are more prevalent in obese patients:

- **Gastroesophageal reflux disease**
- **Gallstones:** Obesity is associated with increased secretion of cholesterol in the bile, supersaturation of bile, and a higher incidence of gallstones, especially cholesterol gallstones.
- **Fatty liver (steatosis) and nonalcoholic steatohepatitis (NAFLD):** NAFLD can progress to hepatic cirrhosis and rarely to hepatocellular carcinoma.

## ***Obesity and Retinal Disease***

- Overweight diabetics are twice more likely to develop retinopathy than non-obese.
- Waist to hip ratio was only second to glycemic control in its importance in preventing retinopathy in studies.

Conditions and complications associated with obesity are summarized in Table 1.14.

## **Clinical Assessment, Investigations and Diagnosis**

**Aims of assessing of obesity** is to:

1. **Evaluate and severity of obesity:** Severity of obesity can be quantified using the BMI (refer Table 1.9).
2. **Exclude an underlying cause**
3. **Identify complications**
4. **Prepare a management plan**

Appearance of a patient with morbid obesity is shown in Figure 1.13.

**Fig. 1.13:** Appearance of a patient with morbid obesity.

**Q. Write short essay/note on diseases for which obesity is a risk factor.**

**Table 1.14:** Conditions and complications associated with obesity.

<i>Risk factors/system involved</i>	<i>Outcomes</i>
<b>Metabolic syndrome</b>	
• Type 2 diabetes	Coronary heart disease, Ischemic heart disease
• Hypertension	Stroke
• Hyperlipidemia	Diabetes complications
<b>Cardiovascular</b>	Heart failure
<b>Gastrointestinal</b>	Gastroesophageal reflux disease, hiatus hernia
<b>Hepatobiliary</b>	Liver fat accumulation, nonalcoholic steatohepatitis, cirrhosis, gallstones
<b>Pulmonary disease</b>	Exertional dyspnea, breathlessness
<b>Restricted ventilation</b>	Obstructive sleep apnea
	Obesity hypoventilation syndrome (Pickwickian syndrome)
<b>Mechanical effects of weight</b>	Urinary incontinence, osteoarthritis of knees and hips, varicose veins, back strain
<b>Endocrine manifestations</b> (Increased peripheral steroid interconversion in adipose tissue)	Menstrual abnormalities Hormone-dependent cancers (breast, uterus) Polycystic ovarian syndrome (infertility, hirsutism)

## Increased morbidity and mortality

<b>Psychological problems</b>	Lack self-confidence, depression, more physical and sexual abuse, lack of attention, low education, and low self-esteem
<b>Others</b>	Accident proneness, socioeconomic disadvantage (lower income, less likely to be promoted), postoperative problems, increased cancer risk (e.g. colorectal cancer), skin infections (groin and submammary candidiasis; hidradenitis)

## Q. Write short essay/note on management of obesity.

### Management

**Goal:** (1) Initially to reduce weight by about 10% from baseline, (2) Reduce weight of about 0.5 to 1 kg/week for 6 months.

#### 1. Life Style Modification

##### Diet (Table 1.15)

- Low calorie diet, low in saturated fats, low density foods, normal protein intake and increased fibers in diet.
- 1000 Kcal deficit produces 1 kg weight loss per week. No matter what the calorie intake is the constituents remain in same proportion (i.e. carbohydrates 55%, fat 30% and protein 15%).

**Total fasting: Not recommended.** There is diuresis, natriuresis and all deficiencies.

- *Refeeding syndrome:* Severe and potentially fatal electrolyte, fluid and metabolic abnormalities when feeding is resumed.

**Physical activity:** Regular physical activity enables to maintain loss of weight. Has to be done under supervision. Moderate exercise to be done for 30 to 45 minutes and 3 to 5 days/week.

**Behavioral modification:** (1) Useful as adjunct to diet and physical exercise, (2) Patient often needs motivation to lose weight.

#### 2. Drug therapy (Pharmacotherapy)

Lifestyle modification should be considered before starting drug therapy.

##### Centrally acting drugs

###### • Sibutramine

- **Mechanism of action:** Centrally acting, mono amine reuptake inhibitor (primarily serotonin and norepinephrine). By sympathetic stimulation, it prevents decrease in BMR. It reduces appetite.
- **Dose:** 10–15 mg once daily.
- **Side effects:** Hypertension, tachycardia, sweating, dizziness and headache.
- **Contraindications:** Coronary artery disease, cardiac arrhythmias, uncontrolled hypertension.

###### • Rimonabant

- **Mechanism of action:** Endocannabinoid (CB1) receptor blocker. It has both central and peripheral actions and reduces weight and weight-related metabolic factors.
- **FDA approval:** BANNED
- **Side effects:** Depression, anxiety, suicidal tendencies.

##### Peripherally acting drugs

- **Orlistat**

- **Mechanism of action:** Nonsystemic reversible inhibitor of gastric and pancreatic lipases by forming a covalent bond with serine residue. It acts on stomach and intestine.
- **Dose:** 120 mg BD or TID with meals.
- **FDA approval:** For adults and adolescents as well as children.
- **Side effects:** Flatulence, defecation increases, oily evacuation, rectal leakage, steatorrhea.

- **Olestra**

Olestra is synthesized using a sucrose molecule, which can support from 6–8 fatty acid chains arranged radially like an octopus. Too large to move through the intestinal wall and be absorbed. Same taste and mouth feel as fat. Approval as a food additive up to 35% replacement of fats in home cooking and 75% in commercial uses.

- **Others:**

- **Phentermine:** Amphetamine like drug, act centrally to reduce appetite. It has low addictive potential, modest efficacy and CVS side effects.
- **Metformin:** Decreases appetite and thereby reduces weight. Since most DM II patients are obese, this is a good choice in DM II.
- **Tesofensine (TE)** is a norepinephrine, dopamine, and serotonin reuptake inhibitor. Primarily used as an appetite suppressant.
- **Betahistine:** Stimulates the histamine-1 receptor and reduce the craving not only for food in general but for fatty foods in particular. Not approved by FDA.
- **Amylin (pramlintide):** Part of the endocrine pancreas and contributes to glycemic control. Functions as a synergistic partner to insulin.
- **Liraglutide**, a GLP-1 agonist (1.8 or 3 mg daily), is an option for overweight or obese patients.
- **Lorcaserin**, serotonin agonist approved by FDA
- **Combination therapy:**
  - ◆ **Phentermine-topiramate**
  - ◆ **Bupropion-naltrexone**

3. **Bariatric surgical techniques:** Divided into three groups

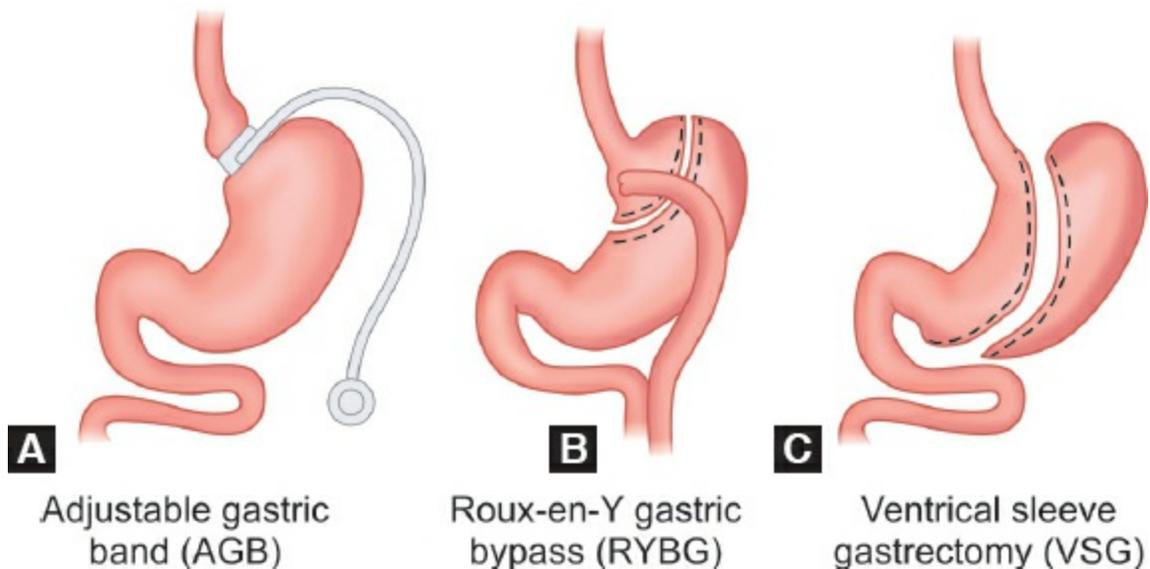

- a. **Malabsorptive procedures:** Induce decreased absorption of nutrients by shortening the functional length of the small intestine (e.g. biliopancreatic diversion and Roux-en-Y gastric bypass). These procedures cause deficiency of nutrients, malnutrition and in some cases, anastomotic leaks and the dumping syndrome (e.g. with the duodenal switch).
- b. **Restrictive procedures:** Reduce the storage capacity of the stomach and as a result early satiety arises, leading to a decreased caloric intake (e.g. adjustable gastric banding, vertical banded gastroplasty and sleeve gastroplasty).
- c. **Restrictive plus malabsorptive procedures** (e.g. duodenal switch, Roux-en-Y gastric bypass, intragastric balloon).

**Liposuction:** It is the removal of large amounts of fat by suction (liposuction). It does not deal with the underlying cause and weight regain frequently occurs. There is no reduction in cardiovascular risk factors with the procedure.

Various surgical options for the treatment of obesity is shown in Figures 1.14A to C.

**Table 1.15: Types of diet in the treatment of obesity.**

<i>Fixed energy diet</i>	<i>Low calorie diet</i>	<i>Very low calorie diet (VLCD)</i>
<ul style="list-style-type: none"> <li>• 1200 to 1800 kcal</li> </ul>	<ul style="list-style-type: none"> <li>• 800–1000 kcal</li> </ul>	<ul style="list-style-type: none"> <li>• 400–600 kcal</li> </ul>
<ul style="list-style-type: none"> <li>• Intake is limited by controlling portion sizes, menu choice and composition</li> </ul>	<ul style="list-style-type: none"> <li>• Applicable to most of the patients</li> </ul>	<ul style="list-style-type: none"> <li>• Even below one's basal metabolic rate</li> </ul>
<ul style="list-style-type: none"> <li>• Minimal self-monitoring</li> </ul>	<ul style="list-style-type: none"> <li>• Fewer restrictions than VLCD</li> </ul>	<ul style="list-style-type: none"> <li>• Used for period of 1–2 months under medical supervision</li> </ul>
<ul style="list-style-type: none"> <li>• Lack of compliance to this rigid pattern</li> </ul>	<ul style="list-style-type: none"> <li>• Supplementation of vitamins and minerals</li> </ul>	<ul style="list-style-type: none"> <li>• 45–70% protein, 30–50% carbohydrates and 2 g fat</li> </ul>
	<ul style="list-style-type: none"> <li>• Reduction of 6–7 kg observed over a year</li> </ul>	<ul style="list-style-type: none"> <li>• Supplementation of vitamins, minerals and trace elements</li> </ul>
		<ul style="list-style-type: none"> <li>• Greater weight loss compared to restrictive diets</li> </ul>

**Figs. 1.14A to C:** Various surgical options for the treatment of obesity.

## ENVIRONMENTAL DISEASES

### Radiation Exposure

#### *Types of Radiation*

- **Ionizing radiation:** Used in X-rays, computed tomography (CT), radionucleotide scans and radiotherapy. Radiations interact with atoms,

and release energy and results in ionization which can cause molecular damage.

- **Penetrating radiation:** It includes uncharged neutrons or high-energy electromagnetic radiations such as X-rays and gamma ( $\gamma$ ) rays. It affects the skin and deeper tissues.
- **Nonpenetrating radiation:** It includes charged subatomic alpha ( $\alpha$ ) and beta ( $\beta$ ) particles.
- **Non-ionizing radiations:** Ultraviolet (UV) rays of sunlight visible light, laser, infrared and microwave. It affects only skin. Nonionizing UV is used for therapy in skin diseases and laser therapy for diabetic retinopathy.

### *Effects of Radiation Exposure*

**Q. Write short essay/note on effects of radiation exposure.**

**Excessive exposure to ionizing radiation:** It may occur accidentally in industries, nuclear power plants and hospitals. It may be also due to deliberate nuclear explosions designed to eliminate populations and rarely by poisoning, e.g. with **polonium**.

#### **Radiation sickness**

**Q. Write short note on radiation sickness.**

- **Mild acute radiation sickness:** It is characterized by nausea, vomiting and malaise following doses of about 1 Gy. Lymphopenia develops within several days, followed 2–3 weeks later by a reduction in all WBCs and platelets.
- **Acute radiation sickness:** It involves several systems and the extent of damage depends on the dose of radiation. Commonly involved systems are hematopoietic, gastrointestinal, central nervous system and skin.

Effects on the individual are classified as either deterministic or stochastic.

#### **Deterministic (threshold) effects**

- **Nature of tissue:** Tissues with actively dividing cells (labile cells), such as bone marrow and gastrointestinal mucosa, are more sensitive to ionizing radiation.
- **Hemopoietic system:** Lymphocyte depletion is the most sensitive indicator of bone marrow injury. After exposure to a fatal dose, aplasia of

the bone marrow is a most common cause of death.

- **Gastrointestinal mucosal toxicity:** May cause death due to severe diarrhea, vomiting, dehydration and sepsis.
- **Gonads:** Highly radiosensitive and may cause temporary or permanent sterility.
- **Eye:** Cataracts.
- **Skin:** Radiation dermatitis (radiation burns) characterized by skin erythema, purpura, blistering and secondary infection may occur. Complete loss of body hair develops after an exposure  $>5$  Gy.
- **Lung:** Acute inflammatory reactions and pulmonary fibrosis.
- **Central nervous system syndrome:** Exposures of  $>30$  Gy causes nausea, vomiting, disorientation and coma. Death due to cerebral edema can follow within 36 hours. It may also cause **permanent neurological deficit**.
- **Bone necrosis and lymphatic fibrosis** occur following regional irradiation, particularly for breast cancer.
- **Thyroid gland** due to its capacity to concentrate iodine is responsible for its susceptibility to damage even after exposure to relatively low doses of radioactivity.

### *Stochastic effects*

Stochastic (chance) effect is directly proportional to the dose of radiation.

- **Carcinogenesis:** It represents a stochastic effect. With acute exposures, leukemias (e.g. acute myeloid leukemia) may develop after a latent period of 2–5 years and solid tumors (e.g. skin, thyroid and salivary glands) after a latent period of about 10–20 years. Thereafter the incidence of cancer increases with time. Cancer risk depends on the amount of radiation received, the time to accumulate the total dose and the interval following exposure.
- **Teratogenic effects.**

### **Management of Radiation Exposure**

- **Large-dose exposures:** Maintain adequate hydration, control of sepsis and the management of marrow aplasia. Associated injuries such as thermal burns require treatment.
- **Internal exposure to radioisotopes:** Treated with chelating agents (such as Prussian blue used to chelate  $^{137}$ -cesium after ingestion). White cell colony stimulation and hematopoietic stem cell transplantation may be required for marrow aplasia.

- A cumulative risk of cancer following repeated imaging procedures has been well known and reduction of X-ray exposures should be made, whenever possible.

## High Altitude

### *Illnesses at High Altitude*

#### **Q. Write short essay/notes on mountain sickness.**

For normal individuals, ascent to altitudes up to 2,500 m or travel in a pressurized aircraft cabin is harmless. Above 2,500 m high-altitude illnesses may develop in healthy individuals, and above 3,500 m symptoms commonly develop. Sudden ascent to altitudes above 6,000 m (e.g. by aviators, balloonists and astronauts), may cause decompression sickness. The clinical features of decompression sickness is similar to in divers and even cause loss of consciousness. However, most high-altitude illness develops in travellers and mountaineers.

#### *Acute mountain sickness*

Acute mountain sickness (AMS) is a syndrome characterized by headache, fatigue, anorexia, nausea and vomiting, difficulty sleeping or dizziness. Ataxia and peripheral edema may be present.

- **Etiology:** Not fully understood. Probably hypoxemia increases cerebral blood flow and intracranial pressure.
- **Symptoms:** Develop within 6–12 hours of an ascent and vary in severity from trivial to completely incapacitating.

#### **Treatment**

- **Mild cases** require **rest and simple analgesics**. Symptoms usually resolve after 1–3 days at a stable altitude, but may recur with further ascent. Occasionally, it may then progress to cerebral edema.
- **If the symptoms persist**, it indicates the need to descend but may respond to **acetazolamide** (carbonic anhydrase inhibitor) that produces a metabolic acidosis and stimulates ventilation. Acetazolamide is used as a prophylaxis, if a rapid ascent is planned.

#### *Chronic mountain sickness (Monge's disease)*

- It occurs on long exposure to high altitude.
- **Symptoms: Headache**, poor concentration and signs of **polycythemia**.
- **Physical examination:** Cyanosis and clubbing of fingers.

#### *High-altitude cerebral edema*

- High-altitude cerebral edema (HACE) is a rare, life-threatening condition and usually preceded by AMS.
- **Symptoms:** Ataxia and altered consciousness. In addition to features of AMS, the patient also develops confusion, disorientation, visual disturbance, lethargy and can lead to loss of consciousness.
- **Signs:** Papilledema and retinal hemorrhages are common. Focal neurological signs may be detected.

#### Treatment

- Improve oxygenation.
- Descent is needed, and if descent is not possible, oxygen therapy in a portable pressurized bag is useful.
- Dexamethasone: 8 mg immediately and 4 mg 4 times daily.

### *High-altitude pulmonary edema*

#### **Q. Write short essay/notes on high-altitude pulmonary edema.**

- High-altitude pulmonary edema (HAPE) is a life-threatening condition.
- **Time of occurrence:** It usually occurs in the first 4 days after ascent above 2500 m. Unlike HACE, HAPE may develop *de novo* without the preceding signs of AMS.
- **Symptoms:**
  - Initially, **dry cough, exertional dyspnea** and **extreme fatigue**. Later, the cough becomes wet and may be with **blood-stained sputum**.
  - **Tachycardia** and **tachypnea** develop at rest. **Crackles** may be heard in both lung fields. It may lead to severe hypoxemia, pulmonary hypertension.
- **Investigations:**
  - **Radiologically** show **diffuse alveolar edema**.
  - Decreased arterial oxygen saturation.

#### Treatment

**Reversal of hypoxia** with **immediate descent** and **oxygen administration**. **Nifedipine** (20 mg 4 times daily) is given to reduce pulmonary arterial pressure. If there is delay in descent, oxygen therapy in a portable pressurized bag should be given.

### *High-altitude retinal hemorrhage*

It may be found in about 30% of trekkers at 5,000 m and is usually

asymptomatic and resolve spontaneously. Visual defects can develop when the hemorrhage involves the macula. There is no specific treatment.

### *Venous thrombosis*

Can develop at altitudes over 6000 m. Risk factors are dehydration, inactivity, cold and use of oral contraceptive pill at high altitude.

### *Refractory cough*

Cough is common at high altitude and usually benign. Causes include breathing of dry, cold air and increased mouth breathing. It may be similar to cough that occurs in early HAPE.

## HEATSTROKE

**Q. Write short essay/note on heat-related illnesses and causes of hyperthermia.**

### Hyperthermia

- *Definition:* Hyperthermia is defined as an elevation of the core body temperature above the normal diurnal range of 36 to 37.5 °C due to failure of thermoregulation.
- A temperature above 40 °C (or 104 °F) is generally considered as severe hyperthermia.

Heat-related illnesses are listed in Box 1.10.

### Box 1.10: Heat-related illnesses.

- Heat cramps
- Heat edema
- Heat exhaustion
- Exertional heat injury
- Heatstroke

### Heatstroke

**Q. Write short essay/note on heatstroke.**

### *Types of Heatstroke*

1. **Classic/Non exertional**

- ‘Summer Heat Waves.’
  - No sweat in 84–100% of patients.
  - More insidious onset.
  - Usually affects elderly and debilitated patients with chronic underlying disease.
  - Rhabdomyolysis and acute renal failure (ARF) rare.
2. **Exertional:**
- Young, healthy, labourers, athletes, military recruits who over exert themselves in high ambient (temperatures or in a hot environment) to which they are not acclimatized.
  - Rhabdomyolysis and acute renal failure (ARF) common.
  - Usually have predisposing factor.

**Q. Write short essay/note on causes of hyperthermia.**

***Predisposing Factors***

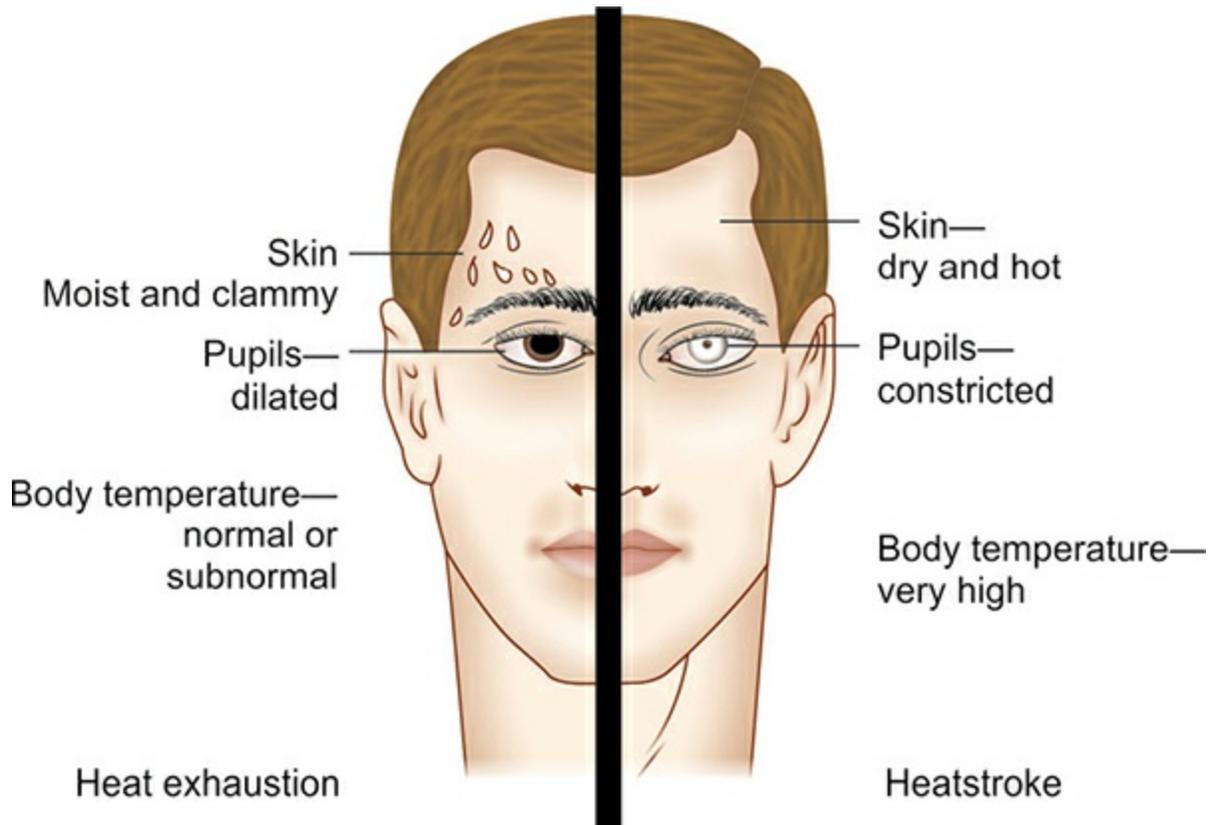

1. **Increased heat production:** Hyperthyroidism, exercise, sepsis.
2. **Impaired heat loss** (impaired sweating)
  - **Drugs:** Anticholinergics, anti-Parkinsonian drugs, antihistamines, butyrophenones, phenothiazines, tricyclics.
  - **Abnormal sweat glands:** Examples: (1) sweat gland injury following acute heatstroke, barbiturate poisoning;(2) cystic fibrosis; and (3) healed thermal burn.
  - **Salt and water depletion:** diuretic induced.
  - Hypokalemia
3. **Impaired voluntary mechanisms:** Coma, physical disability, mental illness
4. **Impaired delivery of blood to peripheral circulation:** Cardiovascular disease, hypokalemia (decreased muscle blood flow), dehydration.
5. **Others:** Elderly, high ambient temperature and humidity, poor ventilation, lack of acclimatization, obesity, fatigue, diabetes mellitus, malnutrition and alcoholism.

***Clinical Features***

- It may develop without any warning prodrome prior to development of nonexertional heatstroke (classic heatstroke).
- As thermoregulatory mechanisms fail **body temperature rises rapidly** and patient can **deteriorate rapidly** from apparent baseline health to coma or mentally dull state.
- **Three cardinal signs are:**
  1. **CNS dysfunction**

2. **Hyperpyrexia** (core temperature  $>40\text{ }^{\circ}\text{C}$ )
3. **Hot dry skin.** Pink or ashen depending on circulatory state. However may be clammy and sweat.

Clinical features of heat exhaustion and heatstroke are depicted in Figure 1.15.

**Fig. 1.15:** Clinical features of heat exhaustion and heatstroke.

### *Central nervous system*

- **Direct thermal toxicity** causes cell death, cerebral edema and local hemorrhage. Irritability or irrational behavior may precede the development of either form of heatstroke.
  - **Confusion, aggressive behavior, delirium, convulsions** and pupillary abnormalities may progress rapidly to coma.
  - $\pm$  decorticate posturing, fecal incontinence, flaccidity or hemiplegia (however, focal signs are unusual).
- **Cerebellar signs**, including **ataxia and dysarthria**
  - **Hypothalamic damage** may exacerbate heatstroke by further impairing sweating and heat loss.

- Lumbar puncture may show increased protein, xanthochromia and slight increase in lymphocytes.

### *Cardiovascular system*

- **Tachycardia, dysrhythmias**
- Hypotension or normotensive with wide pulse pressure.
- Hyperdynamic-hemodynamic profile.
- **Myocardial pump failure.** Myocardial damage and frank infarction frequent even in patients with normal coronaries due to the effect of heat on myocytes and coronary hypoperfusion secondary to hypovolemia.

### *Respiratory system*

- **Extreme tachypnea** with respiratory rate up to 60/minute.
- Crackles and cyanosis-signs of **pulmonary edema**
- Direct thermal injury to pulmonary vascular endothelium may lead to cor pulmonale or **acute respiratory distress syndrome (ARDS)**.

### *Metabolic*

- Dehydration leading to raised urea and creatinine, and hemoconcentration.
- Sweating results in **low levels of Na, Mg, K**, during early phase of the illness. Hypokalemia decreases sweat secretion and therefore exacerbates the condition.
- **Rhabdomyolysis** resulting in hyperkalemia, hypocalcemia and renal failure.
- **Metabolic acidosis and respiratory alkalosis common.**

### *Splanchnic*

- Ischemic intestinal ulceration common. May lead to hemorrhage.
- Hepatic damage common. In 5–10%, hepatic necrosis may be severe enough to cause death.

### *Renal*

- As a direct result of heat potentiated by dehydration and **rhabdomyolysis**.
- **Acute renal failure** 5–6 times more common in patients with exertional heatstroke in whom it occurs in 30–35%.

### *Hematological*

- **Anemia and bleeding:** Result from direct inactivation of platelets and

clotting factors by heat, liver failure, and platelet aggregation due to heat.

- **DIC:** Due to activation of clotting cascade by damaged vascular endothelium. Latter may be damaged as a direct result of heat.

## ***Investigations (Box 1.11)***

### **Box 1.11:** Investigations in heatstroke.

- Temperature recording
- Electrolytes, urea, creatinine, calcium
- Liver function tests
- Creatine phosphokinase (CPK)
- Arterial blood gas (ABG)
- ECG monitoring
- Urine output
- Full blood count (FBC), clotting, fibrinogen, FDP, D-dimer: Anemia frequent, platelets low/normal, lymphocytosis
- Test urine for myoglobin

### **Management**

- The most important causes of severe hyperthermia [greater than 40 °C (104 °F)] due to a failure of thermoregulation are heatstroke, neuroleptic malignant syndrome, and malignant hyperthermia. [Other differentials refer (Box 1.12)].
- The context in which symptoms develop usually suggests the etiology [e.g. exertional heatstroke following exercise in high ambient temperature and humidity; malignant hyperthermia after anesthetic agents; neuroleptic malignant syndrome (NMS) among patients treated with antipsychotic medications].

### **Box 1.12:** Differential diagnosis of heatstroke.

- Acute CNS infection, intracranial bleed. (serotonin, cocaine, amphetamine, antihistamine)
- Cerebral malaria
- Severe sepsis
- Thyroid storm
- Drug toxicity

### **First Aid for Heatstroke or Sunstroke**

- Remove victim to cooler location, out of the sun.
- Loosen or remove clothing, and if possible immerse the victim in very cool water.
- If immersion cannot be done, cool victim with water, or wrap in wet sheets and fan to facilitate quick evaporation.
- Use cold compresses mainly in the region of the head and neck, armpits and groin.
- Seek medical attention immediately—continue first aid to lower temp. Until medical help takes over.
- Not to administer any medication to lower fever because it is not useful and may be in fact cause

more harm.

- Do Not use an alcohol rub.
- Do Not give anything by mouth including water until the condition has been stabilized.

### In Hospital Care

Usually treat the heatstroke in a critical care unit. Various cooling methods are listed in Table 1.16.

**Table 1.16:** Various cooling methods that can be carried out in heatstroke.

• Evaporative	• Cooling blankets
• Immersion	• Gastric lavage
• Strategic ice packs	• Peritoneal lavage
• Ice cold IV fluids	• Cardiac bypass
• Ice packing	• Endovascular cooling catheters

### Supportive

- **IV volume replacement.**
- If inotrope required dobutamine probably drug of choice.
- **Urgent treatment of hyperkalemia.**
- **Do not treat hypocalcemia per se;** only give calcium, if ECG changes of severe hyperkalemia occur as calcium may exacerbate rhabdomyolysis.
- Small dose of mannitol may benefit patients with rhabdomyolysis, intravenous lorazepam for shivering.

### Avoid following medications

- ASA: Uncouples oxidative phosphorylation and increases temperature.
- Paracetamol: Increases hepatic dysfunction and may create toxicity.
- Dantrolene is not effective, but good for malignant hyperthermia.

## Hypothermia (HT)

- **Definition:** Hypothermia is defined as a core temperature below 35 °C (95 °F).
  - **Mild hypothermia:** Core temperature 32–35°C (90–95 °F).
  - **Moderate hypothermia:** Core temperature 28–32°C (82–90 °F).
  - **Severe hypothermia:** Core temperature below 28°C (82 °F).
- Primary hypothermia happens because of overwhelming cold exposure. Heat production in itself is normal.
- **Secondary hypothermia:** Hypothyroidism, Addison's disease, malnutrition, burns, hypothalamic abnormalities, sepsis, thiamine deficiency, alcohol intoxication, hypoglycemia, etc.

## Clinical Symptoms (Table 1.17)

**Table 1.17:** Clinical symptoms of hypothermia (HT).

<i>Mild (HT I)</i>	<i>Moderate (HT II)</i>	<i>Severe (HT III)</i>	<i>Severe (HT IV)</i>
<ul style="list-style-type: none"> <li>• Normal mental status with shivering. Estimated core temperature 32–35°C (90–95°F).               <ul style="list-style-type: none"> <li>– Increased metabolic rate</li> <li>– Maximum shivering thermogenesis,” cold diuresis.”</li> <li>– Amnesia/dysarthria/ataxia</li> <li>– Loss of coordination</li> <li>– Tachycardic, tachypneic</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Altered mental status without shivering. Estimated core temperature 28–32°C (82–90°F).               <ul style="list-style-type: none"> <li>– Stupor</li> <li>– No shivering</li> <li>– Bradycardic/atrial fibrillation</li> <li>– Decreased BP and RR</li> <li>– Pupils dilated (&lt;30°C)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Unconscious. Estimated core temperature 24–28°C (75–82°F)</li> </ul>	<ul style="list-style-type: none"> <li>• Apparent dead Core temperature 13.7–24°C (57–75°F) (resuscitation may be possible)               <ul style="list-style-type: none"> <li>– Coma</li> <li>– No corneal or oculocephal reflexes</li> <li>– Decreased ECG</li> <li>– Ventricular fibrillation (Maximum heart rate 122°C)</li> <li>– Apnea</li> <li>– Asystole</li> <li>– Areflexia/fix pupils</li> <li>– Flat EEG (1)</li> </ul> </li> </ul>

### Investigations

These include: Blood glucose, renal function tests, electrolytes including calcium, CPK, TSH, ABG, complete hemogram, X-ray chest and ECG.

#### *Electrocardiographic changes*

- Hypothermia causes characteristic ECG changes because of slowed impulse conduction through potassium channels. This results in prolongation of all the ECG intervals, including RR, PR, QRS, and QT.
- Elevation of the J point (only if the ST segment is unaltered), producing a characteristic **J or Osborn wave (Fig. 1.16)**. The height of the Osborn wave is roughly proportional to the degree of hypothermia.

**Fig. 1.16:** ECG of Osborn wave.

### Management

- **Evaluation and support of the airway, breathing, and circulation.**
- **Prevention of further heat loss.**
- **Initiation of rewarming** appropriate to the degree of hypothermia. Various rewarming methods are:
  - Passive rewarming:
    - ◆ **Endogenous heat production:** Shivering, metabolic rate, TSH, sympathetic activity.
    - ◆ Involves decreasing heat loss.
      - ◇ Remove from cold environment.
      - ◇ Remove wet clothes.
      - ◇ Provide blanket.
  - Active external rewarming and active internal (core) rewarming (Table 1.18)
- **Treatment of complications:** Careful attention to potential complications, including hypotension during active rewarming, arrhythmia, hyperkalemia, hypoglycemia, rhabdomyolysis, bladder atony, and bleeding diathesis.

**Table 1.18:** Methods of active external rewarming and active internal (core) rewarming.

<i>Active external rewarming</i>	<i>Active internal (core) rewarming</i>
<ul style="list-style-type: none"> <li>• Heat to body surfaces</li> <li>• Heating blankets (fluid-filled)</li> <li>• Air blankets</li> <li>• Radiant warmers</li> </ul>	<ul style="list-style-type: none"> <li>• Warm IV fluids</li> <li>• Warm, humid oxygen</li> <li>• Peritoneal lavage</li> <li>• Gastric/esophageal lavage</li> </ul>

- Immersion in hot bath
- Water bottles/heating pads
- Less effective than internal rewarming, if vasoconstricted. Concern about after drop.
- Rewarming rates: 1– 2.5°C/hour
- Bladder/rectal lavage
- Pleural/mediastinal lavage
- Microwaves (diathermy)
- Extracorporeal circulatory rewarming

## DROWNING (SUBMERSION INJURIES)

**Q. Write short essay on near drowning in fresh water.**

**Drowning:** Asphyxiation caused by submersion in a liquid that causes interruption of the body's oxygen absorption.

**Near-drowning:** Term formerly used to describe victim's survival at least 24 hours after submersion.

Salt versus fresh water is no longer emphasized as degree of pulmonary insult is determined by quantity aspirated.

- **Wet drowning:** Aspiration of water into airways and lungs (85%)
  - 1 to 3 cc of aspirated water will lead to destruction of surfactant, alveolar instability, noncardiogenic pulmonary edema, and impaired gas exchange.
- **Dry drowning:** Severe parasympathetically mediated laryngospasm (15%)

Both types result in common pathway of hypoxia which leads to acidosis, cardiac arrest, and brain death.

### Pathophysiology of Drowning

#### **Risk Factors for Drowning (Box 1.13)**

Three peaks in incidence: (1) Toddlers, (2) Adolescents and (3) Elderly.

Various stages of drowning are shown in Flowchart 1.1.

**Box 1.13:** Risk factors for drowning.

- Drug and alcohol intoxication
- Cardiac arrest
- Hypoglycemia
- Seizure
- Suicidal or homicidal behavior
- Child abuse

## Signs and Symptoms

About 70% develops signs within 7 hours.

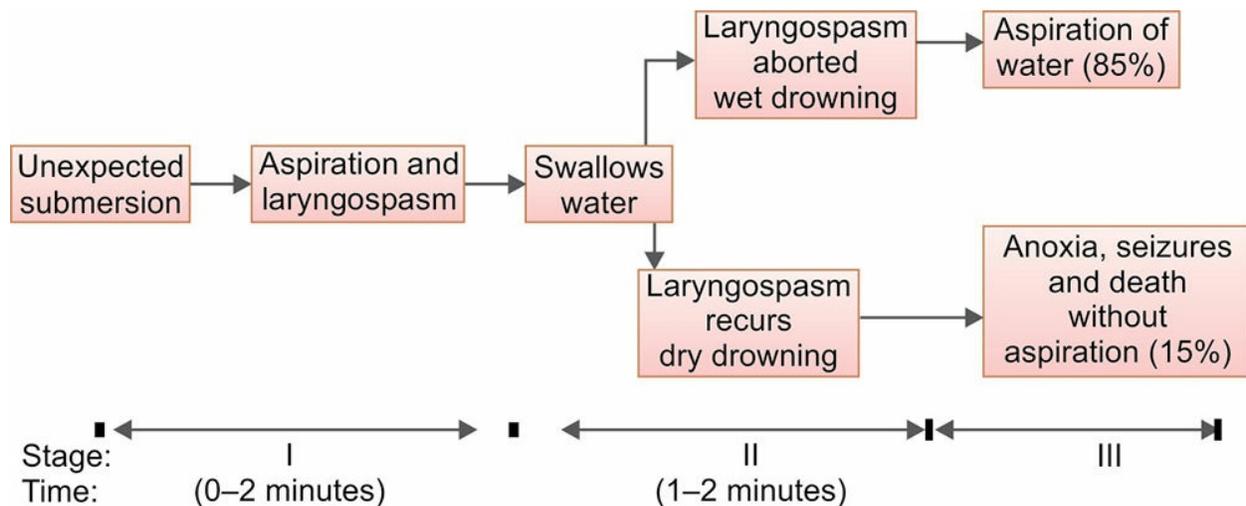

- Alertness → agitation → coma.
- Cyanosis, coughing and pink frothy sputum (pulmonary edema).
- Tachypnea, tachycardia.
- Low-grade fever.
- Rales, rhonchi and less often wheezes.
- Signs of associated trauma to the head and neck should be sought.
- End organ effects.

**Pulmonary:** Fluid aspiration results in varying degrees of hypoxemia, noncardiogenic pulmonary edema-acute respiratory distress syndrome (ARDS).

**Neurologic:** Hypoxemia and ischemia cause neuronal damage, which can produce cerebral edema and elevations in intracranial pressure which can progress into hypoxic ischemic encephalopathy.

**Cardiovascular:** Arrhythmias secondary to hypothermia and hypoxemia like sinus tachycardia, sinus bradycardia, and atrial fibrillation.

**Flowchart 1.1:** Various stages of drowning.

**Acid-base and electrolytes:** A metabolic and/or respiratory acidosis is often observed. Rarely drowning in concentrated seawater can produce life-threatening hypernatremia, hypermagnesemia, and hypercalcemia due to absorption of swallowed seawater.

## ***Renal***

Renal failure due to acute tubular necrosis resulting from hypoxemia, shock, hemoglobinuria, or myoglobinuria is rare.

Poor prognostic signs of drowning are listed in Box 1.14.

### **Box 1.14:** Poor prognostic signs in drowning.

- Duration of submersion > 5 minutes (most critical factor).
- Time to effective basic life support > 10 minutes.
- Resuscitation duration > 25 minutes.
- Glasgow coma scale < 5 (i.e. comatose).
- Persistent apnea and requirement of cardiopulmonary resuscitation in the emergency department.
- Arterial blood pH < 7.1 upon presentation.

### **Management**

- Includes prehospital care, emergency department (ED) care, and inpatient care.
- **Ventilation is the most important** initial treatment of submersion injury.
- **Standard CPR protocol needs to be followed.**
- Identify spine injuries and other major organ injuries and manage accordingly.
- *Supportive care:* Renal failure, shock, infections, etc.

# Endocrinology

# CHAPTER 2

## DISORDERS OF PITUITARY AND HYPOTHALAMUS

### Pituitary Hormones and Their Principal Actions (Table 2.1)

**Q.** Write short essay/note on:

- Pituitary hormones and their principal actions.
- List the hormones of anterior pituitary.

**Table 2.1:** Pituitary hormones and their principal actions.

<i>Hormone</i>	<i>Actions</i>
Anterior pituitary hormones	
• Thyroid stimulating hormone (TSH)	Synthesis and secretion of thyroxine (T <sub>4</sub> ) and triiodothyronine (T <sub>3</sub> )
• Growth hormone (GH)	Growth induction
• Follicle stimulating hormone (FSH) and luteinizing hormone (LH)	Sex steroid production, follicle growth, germ cell maturation <i>Males:</i> <ul style="list-style-type: none"><li>• FSH and LH: Spermatogenesis</li><li>• FSH: Stimulates sertoli cells to secrete androgen binding protein (ABP), transferrin, plasminogen activator and inhibin</li><li>• LH: Stimulates Leydig cells to produce testosterone</li></ul> <i>Females:</i> <ul style="list-style-type: none"><li>• FSH and LH are necessary for the development of corpus luteum during the luteal phase of menstrual cycle.</li><li>• FSH promotes growth and development of ovarian follicles during the follicular phase of menstrual cycle</li></ul>

	<ul style="list-style-type: none"> <li>• LH (LH surge) induces ovulation</li> </ul>
<ul style="list-style-type: none"> <li>• Prolactin (PRL)</li> </ul>	Controls milk production by breasts
<ul style="list-style-type: none"> <li>• Adrenocorticotrophic hormone (ACTH)</li> </ul>	Controls cortisol release from adrenal cortex and skin pigmentation
Posterior pituitary hormones	
<ul style="list-style-type: none"> <li>• Arginine vasopressin (AVP)</li> </ul>	Promotes reabsorption of water by renal tubules
<ul style="list-style-type: none"> <li>• Oxytocin</li> </ul>	Promotes uterine contraction and expression of milk from the breasts

## Hypopituitarism

**Q. Write short essay/note on hyposecretion of anterior pituitary/hypopituitarism/panhypopituitarism.**

### *Definition*

- Hypopituitarism is defined as **combined deficiency (partial or complete) of any of the anterior pituitary hormones.**
- Panhypopituitarism is defined as **deficiency of all anterior pituitary hormones.**

It may be due to selective or multiple deficiencies of pituitary hormones or hypothalamic disease releasing hormones.

### *Etiology*

See Box 2.1.

**Box 2.1:** Various causes of hypopituitarism.

A helpful mnemonic is the phrase ‘nine Is’: **Invasive, Infarction, Infiltrative, Injury, Immunologic, Iatrogenic, Infectious, Idiopathic, and Isolated.**

- Isolated hormone deficiencies
- Invasive tumors: Pituitary adenomas, hypothalamic tumors
- Injury: Surgery, irradiation, stalk section
- Infarction: Sheehan’s syndrome (post-partum pituitary necrosis), diabetic antepartum necrosis, carotid aneurysm
- Inflammatory diseases: Granulomatous disease, autoimmune (lymphocytic) hypophysitis
- Infiltrative diseases: Hemochromatosis, amyloidosis
- Injury: Head trauma
- Immunologic: Lymphocytic hypophysitis
- Infections: Tuberculosis, syphilis, fungal infection.
- Idiopathic
- Developmental defects (Kallmann syndrome)

---

## ***Clinical Features (Table 2.2)***

The presentation is highly variable and depends on the underlying cause/lesion. Symptoms and signs depend on the degree of hypothalamic and/or pituitary deficiencies. Mild deficiencies may be asymptomatic.

- **Hypopituitarism secondary to pituitary tumors:** Symptoms are **due to mass effects** (e.g. headache, visual impairment, electrolyte alterations and disorders of the autonomic nervous system produced by hypothalamic involvement). As the lesions progress (e.g. non-functioning pituitary tumors) there is a sequential loss of hormone secretion.
- Prolactin (PRL) deficiency is rare, except for complete destruction of pituitary or genetic syndromes.
- The order of diminished trophic hormone reserve function by pituitary compression usually follows the order **GH > FSH > LH > TSH > ACTH**.
- Longstanding panhypopituitarism produces a classic picture of **pallor with hairlessness ('alabaster skin')**.

## ***Laboratory Investigations***

1. **Demonstration of low levels of trophic pituitary hormones:** Biochemical diagnosis of pituitary insufficiency is made by demonstration of low levels of trophic pituitary hormones in the setting of low levels of target hormones.
  - **Low free thyroxine (T<sub>4</sub>) with low or inappropriately normal TSH** level suggests **secondary hypothyroidism**.
  - **Low early morning cortisol** with low or inappropriately normal ACTH.
  - **Low testosterone level without elevation of gonadotrophins (LH and FSH)** suggests **hypogonadotropic hypogonadism**.
  - **Low IGF-1 (insulin-like growth factor-1)** level indicates **GH deficiency**.
2. **Provocation tests:** These may be necessary to assess pituitary reserve.
  - **GH reserve:** GH response to insulin-induced hypoglycemia, l-dopa, arginine, growth hormone-releasing hormone (GHRH), or growth hormone-releasing peptides (GHRPs). Insulin-induced hypoglycemia (also known as **insulin tolerance test**) is the **gold standard test**.

- **TRH reserve:** Prolactin level fails to rise after TRH.
  - **Pituitary ACTH reserve:** Corticotropin-releasing hormone (CRH) administration induces ACTH release, and administration of synthetic ACTH (cosyntropin) causes adrenal cortisol release. It is an indirect indicator of pituitary ACTH reserve
  - **ACTH reserve:** It is assessed by measuring ACTH and cortisol levels during insulin-induced hypoglycemia.
  - **TSH reserve:** TSH response to TRH.
3. **Surgical biopsy of tumor:** Usually done as part of a therapeutic operation of tumors. Histological examination of pituitary tumors will help in identifying the type of tumor namely chromophobe (usually non-functioning), acidophil (typically prolactin- or growth hormone secreting) or basophil (typically ACTH-secreting). Immunohistochemistry useful in confirming their secretory capacity.

**Table 2.2: Clinical features due to deficiencies of various pituitary hormones.**

<b>Deficiency</b>	<b>Features</b>
GH deficiency ( <i>GH often the earliest to be lost</i> )	Decreased growth in children but may be clinically occult in adult patients. GH deficiency is associated with a decreased sense of well-being, lethargy, muscle weakness and increased fat mass
LH and FSH deficiency	Hypogonadism may precede the clinical appearance of a hypothalamic-pituitary lesion. Leads to loss of libido and impotence in males, and oligomenorrhea or amenorrhea in females. In both sexes, infertility and osteoporosis occur, axillary and pubic hair becomes sparse, and the skin becomes fine and wrinkled. In males, there may be gynecomastia and decreased frequency of shaving.
ACTH deficiency	Weakness, nausea, vomiting, anorexia, weight loss, fever, and hypotension may occur. Normal plasma electrolytes (relative preservation of mineralocorticoid production). In contrast to the hyperpigmentation that occurs during states of ACTH excess (Addison's disease, Nelson's syndrome), depigmentation and diminished tanning may develop due to ACTH insufficiency
TSH deficiency	Secondary hypothyroidism is usually less severe than primary hypothyroidism, and goiter is absent. Cold intolerance, dry skin, mental dullness, bradycardia, constipation, weight gain, hoarseness,

	and anemia are seen.
PRL deficiency	Failure of lactation (postpartum)

**Management:** It is by replacement of deficient hormones (Box 2.2).

**Box 2.2:** Replacement therapy for adult hypopituitarism.

### **Adrenocorticotrophic hormone**

Hydrocortisone 15-25 mg daily in divided doses. Mineralocorticoid replacement not needed.

### **Follicle-stimulating hormone/Luteinizing hormone**

*Female Patients (any one)*

- Conjugated estrogen 0.65 mg/day
- Micronized estradiol 1 mg/day
- Ethinyl estradiol 0.02–0.05 mg/day
- Estradiol skin patch 4–8 mg twice weekly
- Estradiol plus testosterone

*Male Patients (any one)*

- Testosterone enanthate 200 mg IM every 2–3 weeks
- Testosterone skin patch 2.5–5.0 mg/day; can increase dose up to 7.5 mg/day
- Testosterone gel 3–6 g daily

### **Growth hormone**

- Adults: Somatotropin 0.2–1.0 mg SC (subcutaneously) daily
- Children: Somatotropin 0.02–0.05 mg/kg/day

### **Thyroid-stimulating hormone**

L (levo)-Thyroxine 0.05–0.2 mg daily according to T<sub>4</sub> levels

### **Vasopressin**

- Intranasal desmopressin-rhinal tube 5–20 µg twice daily
- Oral DDAVP (Desmopressin) 300–600 µg daily, usually in divided doses

## **Sheehan's Syndrome**

**Q. Write short note on Sheehan's syndrome.**

Sheehan's syndrome is a potentially life-threatening complication due to **infarction of pituitary gland following postpartum hemorrhage.**

### ***Mechanism***

During pregnancy, the pituitary gland is enlarged and is more vulnerable to ischemia. Post-partum hemorrhage and consequent systemic hypotension can cause pituitary infarction.

## ***Clinical Features***

- Earliest symptom is **failure to lactate**.
- **Failure to regain menstruation after delivery**
- **Other symptoms of hypopituitarism:** They appear over months or years. Few patients may present acutely (hypotension, hyponatremia, hypothyroidism).
- Coma and death can occur in severe cases.

## ***Diagnosis***

Refer laboratory findings of hypopituitarism (refer page 30).

**MRI:** In early stages, may show hypertrophied pituitary. Later stages, atrophic pituitary and empty sella.

**Treatment of Sheehan's syndrome:** Control of hemorrhage and volume replacement. Administration of deficient hormones.

## **Empty Sella Syndrome**

### **Q. Write short note on empty sella syndrome.**

- Often an incidental MRI finding (Fig. 2.1).
- In this condition, herniation of arachnoid diverticulum through an incomplete diaphragm sellae results in symmetrically ballooned sella, which gets filled up with CSF.
- Usually have normal pituitary function, implying that the surrounding rim of pituitary tissue is fully functional.
- An empty sella can be a primary congenital weakness of the diaphragm or secondary subsequent to infarction of a pituitary adenoma or to surgical or radiation-induced damage to the sellar diaphragm.
- Hypopituitarism may develop insidiously.
- Common in obese, multiparous women with chronic headache.
- Rarely, functional pituitary adenomas may arise within the rim of pituitary tissue, and these are not always visible on MRI.

**Fig. 2.1:** MRI image of empty sella.

## Kallmann Syndrome

### **Q.** Write short note on Kallmann syndrome.

- It is due to defective hypothalamic gonadotropin-releasing hormone synthesis.
- Olfactory bulb agenesis or hypoplasia is associated with **anosmia or hyposmia**.
- Conditions associated with this are color blindness, optic atrophy, cleft palate, renal abnormalities, cryptorchidism, and neurologic abnormalities like synkinesis or mirror movements.
- The deficiency **prevents progression through puberty** due to low LH and FSH levels and sex steroids.
- Male patients: Delayed puberty and hypogonadism, including micropenis. Replacement by human chorionic gonadotropin (hCG) or testosterone for a long term is needed.
- Female patients: It manifests as **primary amenorrhea** and failure of secondary sexual development. Long-term treatment with estrogen and progestin is warranted.

## Growth Hormone Therapy (Table 2.3)

**Q.** Lists the indications and side effects of growth hormone therapy.

**Route of administration of GH:** Subcutaneously after 8.00 pm, 3 to 7 times a week (0.15 to 0.3 mg/kg/week).

- Effect is dose-dependent and the response is better if started earlier. Average increment in height = 10 cm/year.
- Better response in classic growth hormone deficiency (GHD).

**Table 2.3:** Indications and side effects of growth hormone therapy.

<i>Indications</i>	<i>Side effects</i>
GH (growth hormone) deficiency	Edema
Intrauterine growth retardation (IUGR)	Arthralgia
Non-GH deficient short stature FSS (familial short stature), CGD (constitutional growth delay)	Myalgia, muscle stiffness
Chronic renal failure	Paresthesias
Burns	Carpal tunnel syndrome
Steroid therapy	Hypertension
Osteoporosis	Melanocytic nevi
HIV-associated cachexia	Hypothyroidism
Sports abuse	

## Pituitary Apoplexy

**Q.** Write short note on pituitary apoplexy.

Pituitary apoplexy is a rare life-threatening endocrine emergency resulting from sudden hemorrhage into the pituitary gland or sudden infarction of the gland.

### *Clinical Features*

- Sudden severe headache, double vision, sudden severe visual loss.
- Cardiovascular collapse, change in consciousness, neck stiffness, and sometimes hypoglycemia. Sometimes acute life-threatening hypopituitarism.
- GnRH deficiency is most common. Acute adrenal insufficiency is

common due to loss of ACTH. TSH deficiency occurs in half of the patients.

- The condition can evolve over 1 to 2 days.
- **CT/MRI findings:** Pituitary imaging without contrast (CT or MRI) usually reveals signs of intra-pituitary or intra-adenoma hemorrhage, stalk deviation and compression of normal pituitary tissue and, in severe cases, signs of parasellar subarachnoid hemorrhage.

#### Management of pituitary apoplexy

- **Initial management:** Conservative with careful monitoring of fluid and electrolyte balance along with immediate replacement of deficient hormones, in particular corticosteroids. Close monitoring of vision. High dose corticosteroids and supportive treatment needed.
- **Surgical decompression:** If there is a rapid deterioration in visual acuity and fields, surgical decompression of the optic chiasm may be required.

## Pituitary Tumors

**Q. Write short essay/note on clinical manifestation, investigations and management of pituitary tumors.**

Pituitary tumors are the most common cause of pituitary disease, and most of them are benign pituitary adenomas.

### *Classification*

- Pituitary tumors are classified depending on the tumor size into **microadenomas** (<1 cm in diameter) and **macroadenomas** (exceed 1 cm in diameter).
- Pituitary adenomas may be **functional** (i.e. associated with hormone excess and clinical manifestations thereof) or **nonfunctional** (i.e. without clinical symptoms of hormone excess). Nonfunctional tumors detected incidentally during MRI/CT examination or at autopsy are called as pituitary **incidentalomas**.

Various tumors of pituitary are listed in Table 2.4.

Other tumors of pituitary are listed in Box 2.3.

**Box 2.3:** Other tumors of pituitary.

- Craniopharyngioma
- Metastatic tumors
- As a component of multiple endocrine neoplasia type I (MEN-I), which includes parathyroid, pancreatic and pituitary (usually prolactinoma) tumors

**Table 2.4: Pituitary tumors, hormone produced and their associated disorder.**

<i>Pituitary adenomas</i>	<i>Hormone produced</i>	<i>Associated disorder</i>
Lactotroph adenoma (prolactinoma)	Prolactin	Hypogonadism, galactorrhea and amenorrhea (in females)
Somatotroph adenoma	Growth hormone	Acromegaly (adults) and gigantism (children)
Corticotroph adenoma	Adrenocorticotrophic hormone (ACTH) and other POMC-derived peptides	Cushing's disease
Gonadotroph adenoma	Follicle-stimulating hormone (FSH) and luteinizing hormone (LH)	Mass effects, hypopituitarism
Thyrotroph adenoma	Thyroid-stimulating hormone (TSH)	Hyperthyroidism
Mammomatotroph adenoma	Prolactin, GH	Combined features of GH and prolactin excess
Nonfunctioning/null cell adenoma	None	Mass effects, hypopituitarism

### ***Clinical Features***

The signs and symptoms may be due to mass effects and endocrine abnormalities.

1. **Mass effects:** Mass effects of the enlarging tumor can produce specific signs and symptoms due to hypofunction by pressure on surrounding normal pituitary tissue (see hypopituitarism). The mass effect is due to involvement of neighboring structures
  - **Due to stretching of the diaphragm sellae or by invasion of bone:** It causes **headache** and is common (especially in patients with macroadenomas) but non-specific.
  - **Due to pressure effects on optic chiasma, nerve or tract:** **Visual field abnormalities** which include loss of acuity and optic atrophy (superior temporal quadrantanopsia or temporal hemianopsia).
  - **Due to lateral extension into cavernous sinus** with subsequent compression of cranial nerve which produces **palsies** of these cranial (**III, IV and VI**) nerves. This results in diplopia and strabismus and

facial numbness.

- **Due to mass effects on hypothalamus:** Obesity, disturbances of sleep, thirst, appetite, temperature regulation and diabetes insipidus (DI).
- **Others:** Anosmia (frontal lobe involvement), vomiting, papilledema (raised intracranial tension).
- **Occasionally,** pituitary tumors infarct or bleeding into produces ‘**pituitary apoplexy**’ (refer page 32).

## 2. **Clinical features due to secretion of hormones** (Table 2.4).

### **Investigations**

- **Plain radiograph of the pituitary fossa (skull):** It may show one or more of the following findings: Enlargement of sella tursica, calcification of suprasellar region, erosion of clinoid process and double floor of the sella.
- **CT scan with contrast enhancement:** More sensitive to detect bony erosions and presence of calcification.
- **Magnetic resonance imaging (MRI) of the pituitary:** MRI before and after gadolinium is superior to CT scanning and shows pituitary mass. Small lesions within the pituitary fossa (small pituitary microadenomas) are very common. Such small lesions are sometimes detected during MRI scanning of the head for other reasons and are called ‘pituitary incidentalomas’.
- **Visual field plotting** by automated computer perimetry or Goldmann perimetry.
- **Functional assessment of the pituitary gland:** By hormonal assays and include PRL, IGF-1 (insulin-like growth factor-1), 24-hours urinary cortisol, FSH, LH and thyroid function tests.

### **Treatment of pituitary tumors**

#### 1. **Surgery**

- Surgery (except for prolactinomas) is the **primary mode of treatment** for pituitary tumors that warrant intervention.
- Surgery via the **trans-sphenoidal** adenectomy or hypophysectomy is the treatment of choice. Very large tumors are removed via the open **transcranial** (usually transfrontal) route. It is usually performed by an endoscopic or endonasal approach.

#### 2. **Medical therapy**

- **Somatostatin analogues and/or dopamine agonists:** Octreotide is administered post-resection. Drug therapy with dopamine agonists such as bromocriptine and cabergoline are effectively used in the management of prolactinomas. They induce a rapid fall in PRL levels

and can decrease the size of tumor and possibly avoid surgery.

### 3. Radiation therapy

- It is usually **used as adjunctive therapy after surgery** or when surgery is impracticable or incomplete or in **combination with medical therapy**. Radiotherapy suppresses the tumor growth and reduces its secretory capacity.

Radiotherapy includes **external radiotherapy, or implantation of Yttrium** in the pituitary fossa, or gamma knife or a modified linear accelerator.

- **Gamma knife** (stereotactic radiosurgery) involves precise delivery of large single high-energy dose directly to the tumor under stereotactic surgery and is particularly useful for residual tumor in the cavernous sinus.

## Acromegaly

**Q. Write short essay/note on acromegaly and its major clinical signs.**

**Growth hormone (GH)** is required for proper growth and development. It directly affects metabolism of fat and indirectly effects bone growth.

- Excess secretion of GH prior to closure of epiphyseal growth plates in long bone before onset of puberty causes **pituitary gigantism**.
- Excess secretion **after puberty** causes **acromegaly**.
- Males and females are equally affected.

### *Etiology of Acromegaly*

**Excess of growth hormone (GH excess)** after puberty may be due to:

- **Pituitary tumor (somatotrope pituitary adenoma)** is the **most common cause**. Acromegaly is caused by growth hormone (GH) secretion usually from a macroadenoma of pituitary gland. Few adenomas secrete both GH as well as prolactin.
- **Other tumors:** In a few patients, acromegaly is caused by tumors of the **pancreas, lungs, and adrenal glands** (either because they produce GH themselves or, more frequently they produce GHRH, the hormone that stimulates the pituitary to make GH).

### *Clinical Features (Table 2.5 and Figs. 2.2A to C)*

Clinical features are due to increased GH (growth hormone) and IGF-1 (insulin-like growth factor-1).

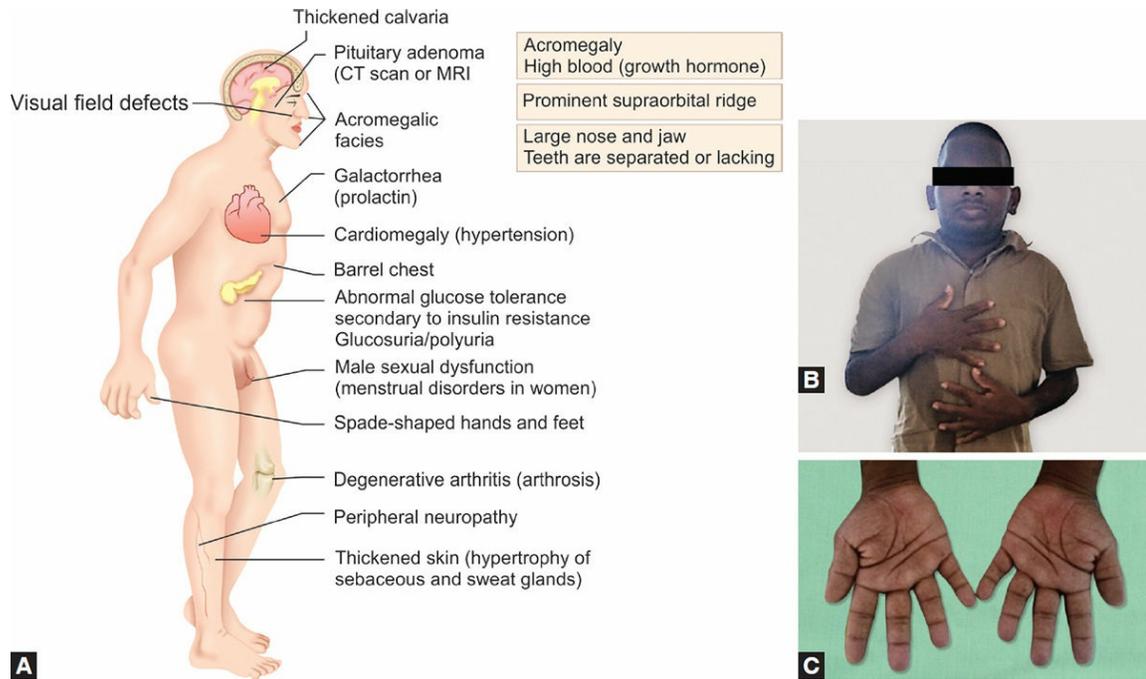

### *Investigations*

#### 1. **Biochemical investigations**

- **GH levels:** Acromegaly can be confirmed by assessment of GH secretion. Basal fasting GH levels [normal, 1–5 ng/mL (46–232 pmol/L)] are >10 ng/mL (465 pmol/L) in more than 90% of patients and range from 5 ng/mL (232 pmol/L) to >500 ng/mL (23,000 pmol/L), with a mean of approximately 50 ng/mL (2300 pmol/L).

**Table 2.5: Various systems involved in acromegaly and presenting features.**

<i>System/tissue involved</i>	<i>Features</i>
Local tumor effects	Pituitary enlargement, visual-field defects, cranial nerve palsy, headache
Somatic systems	Acral enlargement including thickness of soft tissue of hands and feet
Musculoskeletal system and neurological	Gigantism, prognathism, jaw malocclusion, widely spaced teeth, arthralgias and arthritis, carpal tunnel syndrome, acroparesthesia, proximal myopathy, hypertrophy of frontal bones, osteoporosis
Skin and integumental	Skin tags, acanthosis nigricans, increased sweat and sebum resulting in moist and oily skin, enlargement of lips, nose and tongue, increased heel pad thickness
Gastrointestinal system	Macroglossia, colonic polyps, visceromegaly, pancreatic cancer
Cardiovascular system	Left ventricular hypertrophy, asymmetric septal hypertrophy, cardiomyopathy, hypertension, congestive heart failure, coronary artery disease
Pulmonary system	Sleep disturbances, sleep apnea (central and obstructive), narcolepsy
Visceromegaly	Tongue, thyroid gland, salivary glands, liver, spleen, kidney, prostate
Reproduction	Menstrual abnormalities, galactorrhea, decreased libido, impotence, low levels of sex hormone-binding globulin, gynecomastia
Multiple endocrine neoplasia type 1	Hyperparathyroidism, pancreatic islet cell tumors
Carbohydrate metabolism	Impaired glucose tolerance, insulin resistance and hyperinsulinemia, diabetes mellitus
Lipid	Hypertriglyceridemia
Mineral	Hypercalciuria, increased levels of 25-hydroxyvitamin D3, urinary hydroxyproline levels increased
Electrolyte	Low renin levels, increased aldosterone levels
Thyroid	Low thyroxine binding globulin levels, goiter

**Figs. 2.2A to C:** Clinical features of acromegaly. (A) Summary of various clinical features (diagrammatic); (B) Acromegalic facies and thick and spade-shaped hands (C).

- **Glucose tolerance test:** GH levels are measured **during an oral glucose tolerance test (OGTT)**. Normally, plasma GH suppresses to below 0.5  $\mu\text{g/L}$  (approximately 2 mU/L). In acromegaly, there is failure to suppress GH below 0.3  $\mu\text{g/L}$  and is diagnostic of acromegaly. Some patients may show a paradoxical rise and about 25% of patients with acromegaly have a positive diabetic glucose tolerance test.
  - **IGF-1 (insulin-like growth factor-1) levels:** It is **the single best test** useful in diagnosis. IGF1 is almost always elevated in acromegaly. A normal IGF1 together with random growth hormone  $< 1 \mu\text{g/L}$  will exclude acromegaly if the diagnosis is clinically unlikely.
  - Serum IGFBP-3 concentrations are elevated in patients with acromegaly.
  - **Postprandial plasma glucose may be elevated**, and serum insulin is increased in 70% of patients.
  - **Prolactin:** Shows mild to moderate elevation in about 30% of patients due to cosecretion of prolactin from the tumor.
  - **Others:** Elevated serum phosphorus.
2. **Radiological investigations (Figs. 2.3A to C)**

### *X-ray*

- **Plain films of skull:** Shows sellar enlargement in 90% of cases. Other findings may be thickening of the calvarium, enlargement of the frontal and maxillary sinuses, and enlargement of the jaw.
- **Radiographs of the hand:** Shows increased soft tissue bulk, 'arrowhead' tufting of the distal phalanges, increased width of intra-articular cartilages, and cystic changes of the carpal bones.
- **Radiographs of the feet:** Shows similar changes to that of hand, and there is **increased thickness of the heel pad** (Normal heel pad thickness <22 mm). X-ray of spine: Scoliosis, calcification of spinal ligaments.

**MRI scan of pituitary:** If the biochemical tests are abnormal, MRI will almost always reveal and localize the pituitary adenoma. If the MRI is normal, abdominal and chest imaging should be performed to look for an ectopic source of hormone secretion.

3. **Pituitary function:** Partial or complete anterior hypopituitarism is common.
4. **Visual field examination:** Defects are common (e.g. bitemporal hemianopia).

### **Treatment of acromegaly**

- Untreated acromegaly is associated with markedly reduced survival. Most deaths are due to **heart failure, coronary artery disease and hypertension** related causes. Patients with acromegaly have an increase in neoplasia (i.e. carcinoma colon).
  - Treatment is indicated in all except the elderly or those with minimal abnormalities.
  - **Aim of therapy:** To achieve a mean growth hormone level below 2.5 µg/L or a normal IGF1.
1. **Surgery:** Trans-sphenoidal surgical removal of pituitary adenoma is the first line therapy.

**Figs. 2.3A to C:** X-ray findings in acromegaly. (A) Lateral x-ray skull showing sellar enlargement, thickening of the calvarium, enlargement of the frontal and maxillary sinuses, and enlargement of the jaw; (B) X-ray ankle shows increased thickness of the heel pad in acromegaly; (C) X-ray of hand showing increased soft tissue bulk, 'arrowhead' tufting of the

distal phalanges.

2. **Medical therapy: Indication for primary treatment with drugs:** Patients

- without risk of visual impairment from the tumor
- who are not fit candidates for surgery and those who decline surgery
- with tumors that is unlikely to be controlled by surgery
- with persistence of acromegaly after surgery
- who require the preservation of intact pituitary function (especially fertility).

**Drugs used:** There are three receptor targets for the treatment of acromegaly.

a. **Somatostatin receptor ligands (SRL)**

- About 90% growth-hormone secreting adenomas express somatostatin receptor subtypes (SSTR) namely SSTR2 and SSTR5.
- **Mode of action:** Somatostatin analogues (**Octreotide, Pasireotide or Lanreotide**) are more effective than dopamine agonists and act on pituitary somatostatin receptors to produce inhibition of GH and IGF-I.
- **Limitations:** Costly, transient diarrhea, nausea, abdominal discomfort due inhibition of motor activity, gallstones, and hair loss < 10%.

b. **GH receptor antagonist**

- **Pegvisomant** is a GH receptor antagonist, blocks peripheral IGF-1 action in almost all patients, and is indicated in patients who are inadequately controlled with other modalities or in patients experiencing clinically significant drug side effects.
- **Limitations:** Daily injection, costly, acts on peripheral tissues and neither affects pituitary tumor nor secretion of GH, GH raises 76% due to loss of negative feedback by lower IGF1 levels, LFTs to be monitored as increased AST.

c. **Dopamine receptor agonists:** Act on D<sub>2</sub> receptors. **Bromocriptine or cabergoline** are dopamine receptor agonists and are useful in those with mildly elevated IGF-1.

3. **Radiotherapy**

- **Indications:** It is usually employed as second line treatment 1) if acromegaly persists after surgery, 2) in patients who are not fit candidates for surgical therapy, and 3) in whom medical therapy fails.
- External radiotherapy or implantation of Yttrium into the gland.
- Stereotactic radiosurgery (gamma knife, cyber knife).

4. **Others:** Treatment of associated conditions such as diabetes, hypertension and hyperlipidemia.

## Prolactinoma

**Q. Write short essay/note on:**

- **Prolactinoma and hyperprolactinemia.**
- **Causes, clinical features, investigations and treatment of hyperprolactinemia.**
- **Prolactinoma** is a pituitary tumor that produces prolactin and is the most common functional pituitary tumor. Most of these tumors are

microadenomas.

- Elevated level of plasma prolactin is known as **hyperprolactinemia**.

## ***Causes of Hyperprolactinemia (Box 2.4)***

### ***Clinical Features***

Hyperprolactinemia stimulates milk production in the breast and inhibits GnRH and gonadotropin secretion. It usually presents with:

- **Hypogonadism, decreased libido, infertility and galactorrhea** (spontaneous or expressible) in both sexes.
- **In females: Amenorrhea, oligomenorrhea, and osteoporosis**
- **In males: Hypogonadotropic hypogonadism leading to loss of libido, impotence,** gynecomastia and rarely galactorrhea.
- A sufficiently large macroadenoma usually produces visual field defects and headache.

**Box 2.4:** Causes of hyperprolactinemia.

#### **Physiological**

Pregnancy, 'stress', nursing, nipple stimulation

#### **Pathological**

- A. Drug-induced: Estrogens, opiates, dopamine-receptor antagonists (phenothiazines, butyrophenones, metoclopramide), dopamine-depleting agents (reserpine, methyl dopa)
- B. Disease states
  1. Pituitary adenomas (lactotroph, somatotroph-lactotroph, stalk compression by chromophobe tumors)
  2. Hypothalamic and stalk disease (craniopharyngiomas, irradiation, granulomas, stalk section/compression)
  3. Primary hypothyroidism
  4. Miscellaneous (cirrhosis, chronic renal failure, seizures)

## ***Investigations***

The investigation of prolactinomas is the same as for other pituitary tumors discussed above (pages 30-1).

- **Normal range for serum prolactin is approximately 5 to 20 mg/L. Serum PRL** over 150 µg/L in a nonpregnant woman is generally due to pituitary adenoma; a level of over 300 µg/L is almost diagnostic of tumor (even in a nursing mother).
- **Visual fields** should be checked.

- **Primary hypothyroidism** must be excluded.
- **Anterior pituitary function** should be assessed if there is evidence of hypopituitarism or radiological evidence of a pituitary tumor.
- **MRI or contrast-enhanced CT scan of the pituitary:** It is needed if there are any clinical features suggestive of a pituitary tumor. It is desirable when prolactin is significantly elevated (above 1000 mU/L). It can easily delineate macroprolactinoma (tumors above 10 mm diameter), but microprolactinoma (smaller ones) may be more difficult to delineate.

#### Treatment

Hyperprolactinemia is usually treated to prevent the long-term effects of estrogen deficiency or testosterone deficiency in the male.

- **Medical treatment by dopamine agonists: Bromocriptine** (2.5 mg thrice daily) or **cabergoline** (0.25 mg–0.5 mg twice a week). They reduce the secretion of prolactin as well as size of pituitary tumor.
- **Trans-sphenoidal removal:** It is indicated if dopamine agonists fails or in the presence of a large, invasive tumor.
- **External radiotherapy:** Rarely necessary.
- **Asymptomatic patients** who do not require restoration of pregnancy give estrogens to prevent bone loss and should be regularly monitored.

## Diabetes Insipidus (DI)

**Q. Write short note on diabetes insipidus (DI) and its diagnosis.**

Diabetes insipidus (DI) is an uncommon disorder resulting from **deficiency of vasopressin/antidiuretic hormone (ADH) or its action**. It is characterized by the persistent passage of excessive **amounts of dilute urine** and thirst.

### *Types of Diabetes Insipidus (DI)*

- **Primary deficiency** (neurogenic, pituitary, hypothalamic, cranial or central DI): It is due to agenesis or destruction of neurohypophysis.
- **Secondary deficiency:** It is due to inhibition of ADH secretion (primary polydipsia).
- **Deficient action of ADH** (nephrogenic DI)
- Transient **diabetes insipidus of pregnancy** produced by accelerated metabolism of vasopressin (Gestogenic DI).

**Box 2.5:** Causes of diabetes insipidus (DI).

#### Central DI

1. **Idiopathic** (30%)
2. **Neoplastic or infiltrative lesions of hypothalamus** (pituitary tumors with suprasellar extension, metastases, leukemia, histiocytosis-X, sarcoidosis, germinomas, pinealomas)
3. **Pituitary or hypothalamic surgery**
4. **Severe head injury**, usually associated with skull fracture
5. **Ruptured cerebral aneurysms**
6. **Infections** (e.g. encephalitis, TB, etc.)
7. **Autoimmune**: Associated with thyroiditis
8. **Familial**: Two types AD and X-linked inheritance

**Wolfram syndrome** (also known as **DIDMOAD** syndrome) characterized by DI, DM, optic atrophy and deafness, septo-optic dysplasia

#### ***Nephrogenic DI***

1. **Primary/congenital or familial**: X-linked recessive vasopressin receptor mutation.
2. **Acquired**: Chronic pyelonephritis, hypokalemia, hypercalcemia, sickle cell disease, protein deprivation drug-induced (lithium, demeclocycline, amphotericin B, aminoglycosides, cisplatin, rifampicin, colchicine), amyloidosis, other renal diseases (chronic renal failure, obstructive uropathy, polycystic disease), Sjögren's syndrome

## ***Causes of Diabetes Insipidus (Box 2.5)***

### ***Clinical Features***

- **Polyuria and polydipsia**: Urinary frequency (polyuria) 4 to 18 L/day, nocturia and compensatory excessive thirst (polydipsia) are the most marked symptoms.
- Other features: Change in mentation, insomnia, weight loss.
- Skin, mucous membranes cool.
- If left untreated changes in LOC (loss of consciousness), tachycardia, tachypnea, hypotension (shock-like symptoms), but unlike hypovolemic shock, urine output is increased.
- Can lead to **hypernatremia**, restlessness, agitation, diminished deep tendon reflexes, seizures.

### ***Complications***

- Hypernatremia, dehydration and its neurological sequelae
- Growth retardation
- Hydronephrosis (due to excessive urine output).

### ***Investigation and Diagnosis***

- **Careful history, examination** and document presence of **polyuria**

(usually 4 to 15 L/24h).

- **Measurement of osmolality of plasma and urine:** It establishes the diagnosis.
  - Normally, plasma osmolality is  $<290$  mOsm/kg and urine osmolality is 300–450 mOsm/kg.
  - In patients with DI and excess urine free water, there is high or high normal plasma osmolality ( $>295$  mOsm/kg) and low urine osmolality (50–150 mOsm/kg).
  - In primary polydipsia plasma osmolality tends to be low and may be lower than urinary osmolality.
- **Urine:**
  - **High 24 hours urine volumes.** If the volume is  $<2$  L, there is no need for further investigation.
  - **Clear and of low specific gravity** of urine.
  - **Low urine osmolality** and usually less than that of plasma osmolality.
- **Serum sodium is high or high normal** (hypernatremia) and indicates loss of water.
- **MRI of pituitary and hypothalamus.**

**Q. Write short note on water deprivation test.**

- **Water deprivation test (Fig. 2.4):** Indication
  - Diagnosis or exclusion of diabetes insipidus.
  - To differentiate diabetes insipidus from primary polydipsia.
  - **Procedure**
    - ◆ Should be done in the morning under observation with 8 hours fasting. No fluids (water deprivation) from 07:30 hours.
    - ◆ Measure plasma and urine osmolality, urine volume and weight hourly for up to 8 hours.
    - ◆ Abandon fluid deprivation if weight loss is  $>3\%$ .
    - ◆ If plasma osmolality  $>300$  mOsm/kg and/or urine osmolality  $<600$  mOsm/kg, ADH (vasopressin) is given in the dose of  $2 \mu\text{g}$  IM at end of test. Allow free intake of fluids but measure urine osmolality for 2–4 hours.
  - **Interpretation**
    - ◆ **Normal response:** Withholding fluid in normal individuals, the plasma osmolality remains within normal range (275–295 mOsm/kg) while urine osmolality rises above 600 mOsm/kg (800–1200 mOsm/kg).

- ◇ Urine osmolality is greater than plasma osmolality after restriction of water.
- ◇ Urine osmolality increase minimally (<10%) after exogenous ADH.

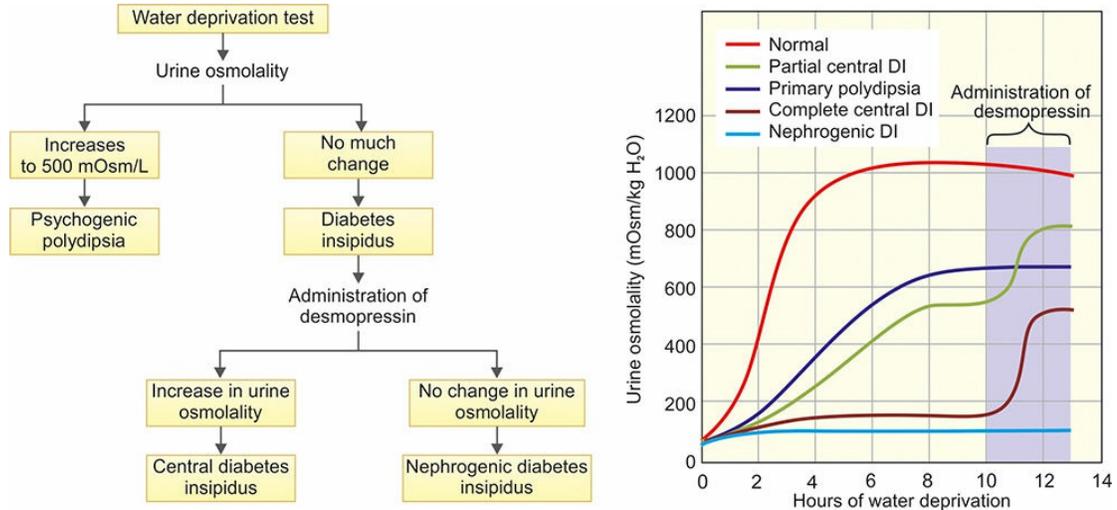

Fig. 2.4: Water deprivation test and its interpretation.

- **Primary polydipsia**
  - ◇ Patients with primary polydipsia start with low normal plasma osmolality (280 mOsm/kg).
  - ◇ Urine/plasma osmolality ratio rises to >2 after dehydration (water deprivation).
- **Central diabetes insipidus**
  - ◇ After water restriction in patients with DI, the plasma osmolality rises above normal (>300 mOsm/kg) without rise in urine osmolality (<600 mOsm/kg) or specific gravity of urine. (Normally urine osmolality rises to 1000–1200 mOsm/kg after water restriction). Urine osmolality remain less than plasma osmolality and urine/plasma osmolality ratio remains <1.5.
  - ◇ After ADH is given, urine osmolality increase 100% in complete CDI and over 50% in partial CDI.
- **Nephrogenic diabetes insipidus**
  - ◇ Urine osmolality remain less than plasma osmolality.
  - ◇ After ADH, urine osmolality increase by <50%.
- Alternative to water deprivation test is by infusing hypertonic (5%) saline and measure ADH secretion in response to increasing plasma osmolality.

## Treatment

### Goals of treatment

- **Balance fluid intake with output:** In acute cases, rapidly replace fluid and in chronic cases with slow replacement to prevent cerebral edema.
- Daily weights, accurate in/out, urine specific gravity and osmolality.

### Drugs

- **Desmopressin (DDAVP):** An initial dose of 10 µg of the intranasal form is given at bedtime. This dose is titrated up in 5 µg increments as needed depending on the response of the nocturia. The typical daily maintenance dose is 10–20 µg once or twice daily.
- **Chlorpropamide:** Increases the renal responsiveness to vasopressin. Hypoglycemia may develop.
- **Carbamazepine:** Is an alternate drug which enhances ADH release and raises the sensitivity of the collecting duct to it.
- **Clofibrate:** Is a lipid lowering agent which stimulates residual ADH production in the hypothalamus, therefore increasing ADH release from the posterior pituitary.
- **Thiazide diuretics:** (e.g. bendrofluazide) are the only effective drugs for nephrogenic DI.
- **NSAIDs:** Also act independent of ADH. Work by inhibiting renal prostaglandin synthesis and decreasing the glomerular filtration rate.

### Treatment of nephrogenic DI

- Provision of adequate fluids, calorie and low sodium diet.
- Correct the underlying cause.
- Drugs: Diuretics, high dose of DDAVP and other drugs (indomethacin, chlorpropamide, clofibrate and carbamazepine).

### Box 2.6: Indications for thyroid function tests.

- Screening for thyroid dysfunction
- Surveillance: Women with postpartum thyroiditis, post- neck irradiation
- Monitoring: Treatment of hyperthyroidism and hypothyroidism

## THYROID DISORDERS

### Thyroid Function Tests (TFTs)

**Q.** Write short essay/note on various thyroid function tests.

Indications for thyroid function tests are listed in Box 2.6.

### Various Thyroid Function Tests (Fig. 2.5)

**Basic thyroid evaluation**

<b>Free thyroxine or FT4</b>	High	Primary hyperthyroid	NTI or patient on eltroxin	Secondary hyperthyroid
	Normal	Sub-clinical hyperthyroid	Euthyroid	Sub-clinical hypothyroid
	Low	Secondary hypothyroid	Non-thyroid illness (NTI)	Primary hypothyroid
		Low	Normal	High
		<b>Thyroid stimulating hormone (TSH)</b>		

**Fig. 2.5:** Basic thyroid evaluation

**Q. Write short essay/note on thyroid stimulating hormone.**

**1. Serum thyroid stimulating hormone/thyrotropin (TSH)**

It is measured by immunoradiometric assays (TSH IRMAS). Normal range for serum TSH is approximately 0.4 to 5.0 mU/L.

*Interpretation*

- **Thyroid diseases:** As a single test of thyroid function TSH is the most sensitive index of thyroid function.
  - TSH levels can help in **differentiating hyperthyroidism, hypothyroidism and euthyroidism** (normal thyroid gland function) in most cases.
  - Raised/elevated levels indicate primary hypothyroidism. Low/suppressed levels indicate primary thyrotoxicosis.
- **Nonthyroid diseases:** Other conditions affecting TSH levels include:
  - TSH-secreting tumors of pituitary
  - Severe nonthyroidal illness (e.g. sick euthyroid syndrome)
  - Low TSH may be observed in first trimester of pregnancy and with high doses of corticosteroids
  - Secondary hypothyroidism due to hypothalamic-pituitary disease may produce low, normal or normal-high levels of TSH that are

inappropriate for the very low free  $T_4$  level.

2. **Thyrotropin releasing hormone (TRH) stimulation test:** It may be used in the investigation of hypothalamic pituitary dysfunction.
  - Serum TSH is measured before and after the intravenous administration of TRH.
  - **Use:** To differentiate secondary or tertiary hypothyroidism.
    - Secondary hypothyroidism (pituitary disease): TRH administration does not produce increase in TSH.
    - Tertiary hypothyroidism (hypothalamic disease): TRH administration produces delayed increase in TSH.
    - In primary hypothyroidism, TRH administration produces a prompt increase in TSH.
3. **Serum free  $T_3$  (Triiodothyronine  $fT_3$ ) and free  $T_4$  (Free thyroxine/ $fT_4$ )**
  - Advantage of this test compared to the measurement of total  $T_3$  and  $T_4$  is that these are not influenced by changes in the thyroid hormone binding globulins (TBG), prealbumin and albumin. Its level reflects secretory activity
  - **Primary thyrotoxicosis:**  $fT_3$  and  $fT_4$  levels are elevated.
  - **$T_3$ -thyrotoxicosis:**  $fT_4$  levels are normal and  $fT_3$  levels are elevated.
  - **On  $T_4$  therapy:**  $fT_4$  levels are elevated and  $fT_3$  levels are normal.
4. **Total serum thyroxine ( $tT_4$ )**
  - Its levels are altered by factors that affect the concentration of TBG. Normal ranges is 4.6–11.2  $\mu\text{g/dL}$ .
  - **Increased:** In hyperthyroidism, during pregnancy, estrogen therapy, Tamoxifen use and as a congenital anomaly.
  - **Decreased:** In hypothyroidism, nephritic syndrome, androgen therapy, liver failure, or drugs (e.g. salicylates, sulfonyleureas and phenytoin).
5. **Total serum triiodothyronine ( $tT_3$ ):** Its levels are subject to the same limitations as for  $tT_4$  in relation to TBG. Normal range: 75–195  $\text{ng/dL}$ .
5.  **$T_3$  resin uptake, free  $T_4$  index (FTI), effective  $T_4$  ratio**

Nowadays, above three tests (4, 5 and 6) are not used.

7. **Reverse T3 (rT3):** Reverse T3 (rT3) is mainly a degraded product of T4 in peripheral tissues. Thyroid gland also secretes but in insignificant amount.

**Significance:** Raised in patients with high TBG. Normal in hypothyroid patients treated with thyroxine.

3. **Thyroglobulin (Tg):** It is secreted by follicular cells of thyroid and is involved in iodination and synthesis of thyroid hormones.

- **Use:** To predict the outcome of therapy for hyperthyroidism.
  - **Increased:** Well-differentiated thyroid carcinoma, hyperthyroidism
  - **Decreased:** Total thyroidectomy or destruction of thyroid by radiation.

3). **Uptake of radioactive iodine (RAIU) or technetium**

- The iodine uptake activity of thyroid can be measured by administering orally a low/trace dose of radioactive iodine  $^{131}\text{I}$  or  $^{121}\text{I}$  and the radioactivity over the thyroid is measured after 4 hours, using a counter over the neck. The amount of radioactivity that is taken up by the thyroid gland is known as radioactive iodine uptake (RAIU). Alternatively, thyroid uptake is measured by giving technetium-99m ( $^{99\text{m}}\text{Tc}$ ) intravenously.
- Uses of radioactive iodine uptake (RAIU) are listed in Box 2.7.

**Box 2.7:** Uses of radioactive iodine uptake (RAIU).

- Evaluation of hyperthyroidism
- Differentiate Graves from toxic goiter
- Function of a thyroid nodule as hot or cold

- **Interpretation:** Normal uptake ranges from 10% to 35% in 24 hours.
  - **Uptake increased: Overactive** thyroid gland synthesizing excess  $\text{T}_3$  shows increased uptake of iodine. A very high RAIU is seen in hyperthyroidism (e.g. Graves' disease, toxic multinodular goiter and adenoma and early thyroiditis). Iodine/enzyme deficiency may show increased uptake even in the absence of thyrotoxicosis.
  - **Uptake decreased:** Low RAIU is seen in hypothyroidism, late thyroiditis. Excess iodine may show diminished uptake even in the presence or thyrotoxicosis. Acute autoimmune thyroiditis may manifest as low iodine uptake thyrotoxicosis.

- **Use:** To determine the functional activity and morphology of the thyroid gland.
    - **Very useful in determining the activity of a solitary thyroid nodule.** Functional nodule appears as a ‘hot’ nodule, and a nonfunctional appears as a ‘cold’ nodule.
    - **Useful in follow-up of patients with treated thyroid cancer.**
    - **Detection of ectopic thyroid tissue:** Confirmation a mass on the tongue as lingual thyroid, in the midline of the neck as thyroglossal duct, or in the mediastinum as substernal goiter.
  - **Contraindication:** RAIU is contraindicated in children and during pregnancy/lactation.
- 3). **Ultrasound of thyroid gland:** Look for nodularity, vascularity, lymph nodes and for guided FNAC.
1. **Thyroid autoantibody tests:** The different types of thyroid autoantibodies responsible for the autoimmune thyroid disorders are:
- **Antimicrosomal antibody**
  - **Antithyroid peroxidase (TPO) antibody (TPOAb):** They are involved in the tissue destructive process associated with hypothyroidism in Hashimoto and atrophic thyroiditis.
  - **Antithyroglobulin (Tg) antibody**
  - **TSH receptor (TR) antibody (TRAb):** These antibodies were previously known as thyroid stimulating immunoglobulin (TSI) or long-acting thyroid stimulators (LATS). Laboratory assessment of antithyroid peroxidase antibodies is replacing the antimicrosomal and antithyroglobulin antibodies.
2. **Tests to determine etiology of thyroid disease**
- **Calcitonin:** It is secreted by parafollicular C-cells and is increased in medullary carcinoma of thyroid.
  - **Fine-needle aspiration cytology/excision biopsy:** It is helpful in diagnosis thyroid diseases.

## Thyrotoxicosis

**Q. Discuss the etiology, clinical features, investigations (laboratory diagnosis), complications and management of hyperthyroidism/thyrotoxicosis.**

**Q. Discuss the etiopathogenesis, clinical features, investigations, diagnosis and management/treatment modalities of Grave's disease.**

### **Definition**

**Thyrotoxicosis** is a state of circulating thyroid hormone excess (with hypermetabolic state) caused by exposure to **excessive levels of thyroid hormone** (free T<sub>3</sub> and T<sub>4</sub>). This increase in circulating hormone may be either from destruction of thyroid gland or from ectopic source.

**Hyperthyroidism** (thyroid overactivity): It is the **clinical consequence due to the excessive circulating thyroid hormone due to excessive thyroid function/hyperfunction** and is the **most common cause of thyrotoxicosis**. Its causes are listed in Table 2.6.

**Table 2.6: Causes of hyperthyroidism.**

#### **Primary hyperthyroidism**

- Graves disease
- Toxic multinodular goiter
- Toxic adenoma (Plummer's disease)
- Iodine excess (Jod Basedow)
- Activating mutation of TSH receptor

#### **Thyrotoxicosis without hyperthyroidism**

- Subacute thyroiditis, Hashitoxicosis
- Amiodarone induced
- Radiation induced
- Thyrotoxicosis factitia
- Struma ovarii
- Infarction of thyroid gland

#### **Secondary hyperthyroidism**

- TSH secreting pituitary adenoma
- Human chorionic gonadotropin-mediated hyperthyroidism (hyperemesis gravidarum, trophoblastic disease)
- Gestational thyrotoxicosis

### **Etiology (Table 2.6) and Pathogenesis of Hyperthyroidism**

**Q. Write short essay/notes on causes of hyperthyroidism.**

Few of the causes of hyperthyroidism/thyrotoxicosis are discussed below.

## 1. Graves' disease

- Graves' disease is the most common form of thyrotoxicosis. It is characterized by one or more of the following features: **(1) thyrotoxicosis, (2) goiter, (3) ophthalmopathy (exophthalmos), and (4) dermatopathy (pretibial myxedema).**
- **Age and gender**
  - It may occur at any age, with a peak incidence between **20–40 years** of age.
  - Females are affected five times more commonly than males.
- **Autoantibodies:** It is an autoimmune disorder with auto antibodies.
  - **TSI or TSH-receptor antibodies (TRAb):** IgG type of antibodies directed against the TSH receptors on the follicular cell of thyroid. They stimulate thyroid hormone production and enlargement of thyroid.
  - **Thyroid-stimulating immunoglobulin (TSI):** It is the driving force for thyrotoxicosis.
- **Ophthalmopathy and dermatopathy:** Observed in Graves' disease is due to immunologically mediated activation of fibroblasts in the extraocular muscles and skin. This along with accumulation of **glycosaminoglycans** and trapping of water causes edema initially. Later fibroblasts cause fibrosis.
- Genetic factors may be significant in a minority of cases (e.g. HLA-DR3 associated).
- **Hyperthyroidism may be triggered by viral or bacterial infections.** *E.coli* and *Yersenia enterocolitica* possess cell membrane TSH receptors. The antibodies produced against these microorganisms can cross-react with the TSH receptors (molecular mimicry).

## 2. Treatment-induced hyperthyroidism. Drugs include iodine, amiodarone, interferon-alpha, and rarely, lithium.

- a. **Iodine induced hyperthyroidism:** It develops following excess intake of iodine in diet or exposure to radiographic contrast media or iodine medication.
  - Usually develops in patients with autonomously functioning thyroid gland (e.g. nodular goiter/Graves' disease). It can also occur in endemic goiter and with iodine (**Jod-Basedow phenomenon**). It is characterized by suppressed serum TSH level with normal levels of circulating thyroid hormone.
  - Paradoxically, excess iodine uptake by the thyroid may inhibit the synthesis thyroid hormone (**Wolff-Chaikoff effect**). Thus, iodide toxicity can lead to iodine goiter, hypothyroidism or myxedema.
- b. **Amiodarone-induced hyperthyroidism (AIT):** Amiodarone is an antiarrhythmic drug and 200 mg dose has 75 mg iodine. It can also induce hyperthyroidism which can be:
  - **Type I AIT:** It develops in patients with preexisting Graves' disease or multinodular goiter. The hyperthyroidism is probably triggered by the high iodine content of amiodarone. Jod-Basedow

effect (refer above) occurs in patients with underlying thyroid disease.

- **Type II AIT:** It is not associated with previous thyroid disease. It is due to a direct cytotoxicity of the drug on thyroid follicular cells leading to a destructive thyroiditis with release of  $T_3$  and  $T_4$ . It produce transient thyrotoxicosis and may later progress to hypothyroid phase.

### 3. Thyrotoxicosis factitia

- It is primarily a psychiatric disorder due to excessive intake of thyroxine causing thyrotoxicosis.
- Patients are clinically thyrotoxic without eye signs of Graves.
- High doses of thyroxine lead to TSH suppression and causes shrinkage of the thyroid.
- Stop thyroxine and give symptom relief drugs.

### 4. Toxic multinodular goiter

- Constitutes 14% of thyrotoxicosis cases.
- Commonly occurs in elderly women (>50).
- Goiter will be nodular.
- $T_3$  (greater),  $T_4$  raised and TSH undetectable.

### 5. Toxic solitary adenoma/nodule (Plummer's disease)

- Constitutes <5% of all thyrotoxicosis (hyperthyroidism) cases and the solitary nodule is follicular adenoma.
- Usually occur in female >40 years of age.

## *Clinical Features of Thyrotoxicosis (Table 2.7)*

**Q. Write short essay/notes on clinical features/signs/manifestations of thyrotoxicosis/hyperthyroidism.**

**Q. Write short note on cardiac complications of hyperthyroidism.**

**Table 2.7: Clinical features of thyrotoxicosis.**

<i>Organ/System involved</i>	<i>Symptoms</i>
Thyroid	Diffuse or nodular enlargement, warmth and bruit (due to increased vascularity)

Gastrointestinal system	<b>Weight loss, increased appetite</b> , vomiting, increased frequency of stool, diarrhea and steatorrhea
Cardiovascular system	Exertional dyspnea, palpitations, angina, <b>sinus tachycardia, atrial fibrillation</b> , wide pulse pressure, cardiac failure, cardiomyopathy, 'scratchy' midsystolic murmur (Means-Lerman scratch)
Nervous system	Nervousness, <b>irritability</b> , psychosis, emotional lability, fine <b>tremors</b> . Inability to concentrate, hyperreflexia, proximal myopathy, bulbar myopathy, ill-sustained clonus
Skin and integumentary system	Soft, warm and moist. Increased sweating, pruritus, palmar erythema, spider naevi, onycholysis, pretibial myxedema (Graves') pigmentation, alopecia, clubbing ( <b>thyroid acropachy</b> )
Reproductive system	Menstrual disturbances (amenorrhea or oligomenorrhea), repeated abortions, infertility, loss of libido, impotence
General	<b>Heat intolerance</b> , fatigue, gynecomastia, apathy, thirst
Eyes	Lid lag, exophthalmos, proptosis, extraocular diplopia, exposure keratitis, lagophthalmos (classically seen in Graves' disease)

*Note:* Bold words indicate symptoms of greater discriminant value.

- **Elderly** patients present with anorexia, apathy, fatigue, weight loss and dominant cardiovascular and myopathic features (**apathetic hyperthyroidism**).
- **Younger** patients present predominantly with neurological manifestations.
- **Children** present with excessive height or excessive growth rate, or with behavioral problems (e.g. hyperactivity), and weight gain rather than loss.

### ***Thyroid Ophthalmopathy (eye signs) (Box 2.8 and Figs. 2.6A to D)***

- The ophthalmopathy causes **abnormal protrusion of the eyeball (exophthalmos)**. Sympathetic overactivity may produce a characteristic **wide, staring gaze and lid lag**.
- It is observed in about 50% of the patients when first seen. It may precede Graves' disease by many years or may develop even after successful treatment of Graves' disease.

*Pathogenesis of Ophthalmopathy: Not Clear.*

- Ophthalmopathy is characterized by **increase in the volume of the retro-orbital connective tissues** and **extraocular muscles** with a **rise in retrobulbar** pressure. This produces exophthalmos and compression of optic nerve (congestive ophthalmopathy).

- Ocular myopathy may also be found. The infiltrative process most common in the **inferior rectus** muscle and it fails to relax normally. This produces upward gaze limitation and is the most common physical finding in patients with ophthalmopathy. Involvement of the medial rectus produces impairment of in lateral gaze.

**Symptoms:** Excessive lacrimation, redness, grittiness, diminution of visual acuity and diplopia.

**Signs:** **Exophthalmos, lid lag, lid retraction**, corneal ulcers, chemosis, ophthalmoplegia, visual field defects and papilledema.

### Treatment of thyroid ophthalmopathy

**Most patients do not require any treatment.** Symptomatic measures include:

- By sleeping upright: Some patients may gain relief.
- Taping of eyelids: To ensure closure at night
- Medical:
  - **Methylcellulose or hypromellose eye drops** to aid lubrication for grittiness and use of tinted glasses to reduce lacrimation.
  - **Papilledema, loss of visual acuity and visual field defect need emergency treatment** and are treated by systemic **prednisolone** (30–120 mg daily). If there is no response, **orbital decompression** should be performed.
- **Surgical:** Lateral tarsorrhaphy for corneal ulcers. Persistent diplopia is corrected by corrective eye muscle surgery.

**Figs. 2.6A to D:** (A and B) Exophthalmos (front and side view); (C) Infiltration of extraocular muscles in hyperthyroidism; (D) Eye signs and enlarged nodular goiter (arrow).

**Box 2.8:** Eye signs of thyrotoxicosis.

- Dalrymple sign: Rim of sclera is seen all around the cornea, on looking straight forward.
- Rosenbach's sign: Fine tremor of the upper eyelids on slight closure of the eye.
- Joffroy's sign: Lack of wrinkling of the forehead when a patient looks upward.
- Möbius sign: Lack of convergence on looking to near object.
- Von Graefe's sign (lid lag sign): Lagging of the upper eyelid on looking downward without moving the head.
- Stellwag's sign: Staring look with infrequent blinking.
- Vigouroux sign: Eyelid fullness
- Grove sign: Resistance to pulling down the retracted upper lid)
- Ballet sign: Restriction of one or more extraocular muscles)
- Kocher sign: Staring look (upper sclera visible)
- Naffziger's sign: Standing behind, patient's neck is extended and examiner looks from behind along the superior orbital margin of the patient. Eyeball is seen beyond the superior orbital margin in exophthalmos.

**Fig. 2.7:** Non-pitting pedal edema-myxedema

### ***Pretibial Myxedema (Infiltrative Dermopathy)***

**Q. Write short essay/notes on pretibial myxedema.**

- It is present in a minority of patients.
- This is most common in (Fig. 2.7) the skin overlying the **shins** (anterior aspect of leg extending on to the dorsum of the foot). Rarely, affects face and arms.

- It presents as **scaly thickening and induration** (raised pinkish or purplish plaques) of the dermis due to deposition of glycosaminoglycans and infiltration by lymphocytes. The skin may have a peau d'orange appearance with coarse hair.

### Treatment of Pretibial Myxedema

*Local injections of triamcinolone or application of betamethasone ointment.*

Box 2.9 lists the other disorders associated with Graves' disease.

**Box 2.9:** Other disorders associated with Graves' disease.

- Autoimmune disorders
  - Endocrine: Addison's disease, type 1 DM, Hashimoto's thyroiditis, primary gonadal failure, hypophysitis.
  - Non-endocrine: Celiac disease, pernicious anemia, myasthenia gravis, immune thrombocytopenic purpura, rheumatoid arthritis, vitiligo, alopecia areata.
- Others: Hypokalemic periodic paralysis and mitral valve prolapse

### Subclinical Thyrotoxicosis

- **Presentation:** Atrial fibrillation in individuals above 60 years of age and bone loss in postmenopausal women.
- **Lab findings:** Serum levels of free T<sub>4</sub> and triiodothyronine are within normal. Serum TSH levels is subnormal (<0.1 mU/L).

### Investigations of Graves' Disease

- **TSH levels: Very low or undetectable.** This is performed as the primary test, and normal level excludes thyrotoxicosis.
- **Serum T<sub>3</sub> and T<sub>4</sub> levels:** Raised in most cases. T<sub>3</sub> thyrotoxicosis is associated with raised T<sub>3</sub> levels and normal T<sub>4</sub> level.
- **Absence of TSH response** following intravenous **TRH**.
- **<sup>131</sup>I uptake by the thyroid gland:** It may be increased, but not necessary to perform in most of the patients.
- **TSH receptor antibody (TRAb):** Present in most cases.
- Few patients may show minor LFT abnormalities, mild hypercalcemia and glycosuria.

**Q. Write short essay/notes on drugs used in thyrotoxicosis.**

**Q. Write short essay/notes on adverse effects of antithyroid drugs.**

### Management of hyperthyroidism of Graves' disease

Three methods of treatment of hyperthyroidism of Graves' disease are: (1) antithyroid drugs (ATD)

with initial supplementation by  $\beta$ -blocker, (2) surgical treatment and (3) radioactive iodine

## 1. Antithyroid drugs (ATD)

**Indications:** Primary therapy in **pregnancy**, in **children** and **adolescents** and **severe Graves' disease with eye changes**. The drugs include:

- a. **Thionamides:** e.g. **propylthiouracil, carbimazole, methimazole.**
  - **Mechanism of action:** Inhibit the function of **thyroid peroxidase (TPO) enzyme** and prevent binding of iodine to tyrosine. (prevents iodination and organification). Propylthiouracil (100–600 mg/day) inhibit peripheral conversion  $T_4$  to  $T_3$  and is preferred in pregnant women and severe thyrotoxicosis.
  - **Carbimazole:** It has additional immunosuppressive action.
    - **Dose:** **5–15 mg thrice daily for 3–4 weeks** followed by 10 mg thrice daily for 4–8 weeks. Maintenance dose: 5–20 mg daily.
    - **Total duration of treatment:** 18–24 months.
    - **Adverse effects:** Rashes, urticaria, fever, arthralgia, blood dyscrasias (**agranulocytosis**), hepatotoxicity, aplasia cutis in neonates.
- b. **Potassium perchlorate:** It reduces uptake of iodine. It is more toxic and produces red cell aplasia. It is used only as temporary measure in iodine-induced thyrotoxicosis or when other therapy is not acceptable.
- c. **Potassium iodide:**
  - Mechanism of action: Decreases synthesis of  $T_3$  and  $T_4$  and inhibit hormone release. It makes thyroid gland firm and less vascular and it is the fastest acting thyroid inhibitor.
  - **Indication:** Only in (i) **preparation for thyroidectomy** and (ii) **thyrotoxic crisis**.
- d. **Beta adrenergic blockers**
  - Non-selective and used for **immediate relief and control symptoms** due to sympathetic overactivity such as anxiety, palpitation, increased bowel activity, lid retraction, finger tremors.
  - **Drug of choice and dosage:** Propranolol in the dose of 20 to 40 mg 6 hourly.
- e. Lithium (rarely used)
  - **Advantages of antithyroid drugs:**
    - No surgical risk, scar, or chances of injury to parathyroid or recurrent laryngeal nerve.
    - Hypothyroidism, if induced, is reversible.
    - Can be used even in children and young adults.
  - **Disadvantages:**
    - Prolonged (often lifelong) treatment is needed and relapse rate is high.
    - Not practicable in uncooperative patient.

## 2. Surgical treatment

- **Subtotal thyroidectomy** is the **treatment of choice**.

Surgical treatment is reserved for multinodular goiter (MNG) with following features.

- Severe hyperthyroidism in children.
- Pregnant women who cannot tolerate antithyroid drugs.
- Large goiters with severe ophthalmopathy or with pressure symptoms.
- Patients who require quick normalization of thyroid function
- **Preparation for thyroidectomy:** It includes pretreatment with propranolol, carbimazole and

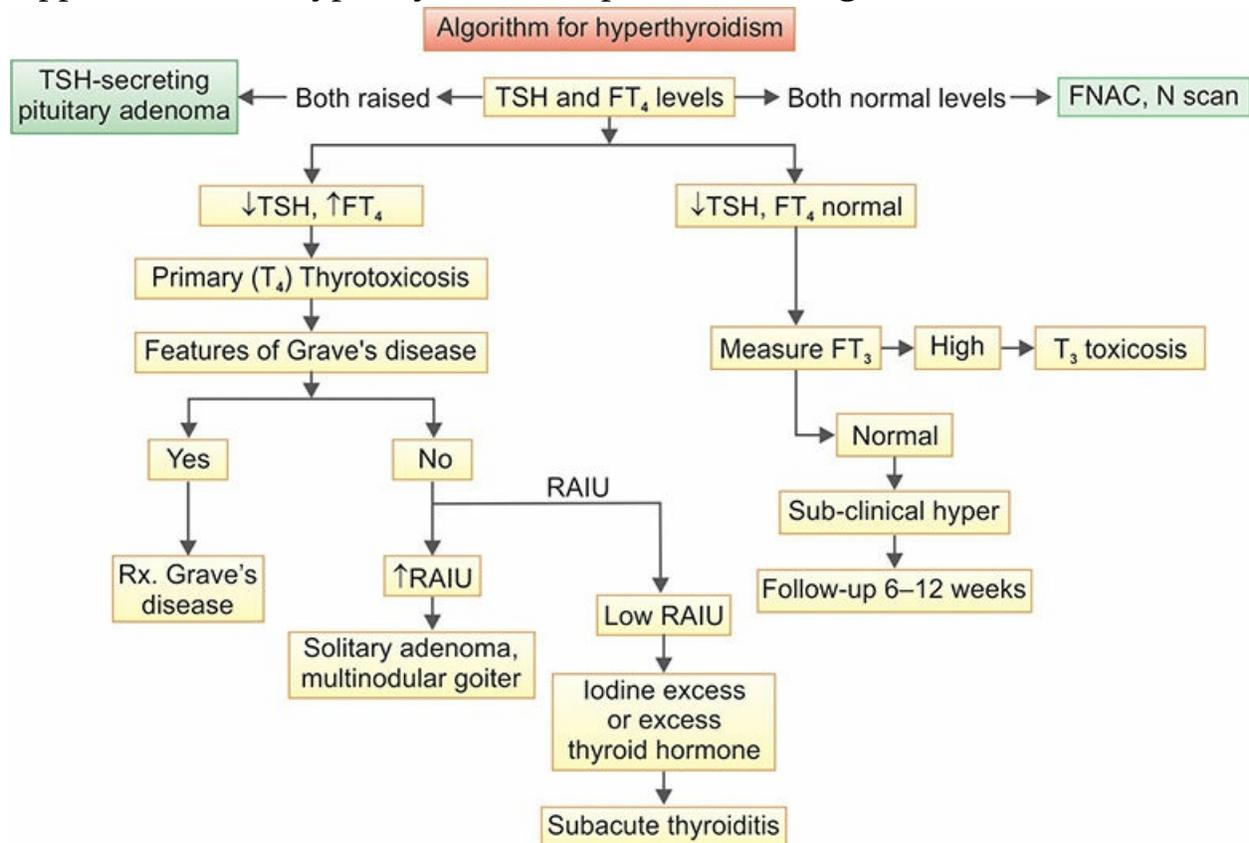

potassium iodide (to decrease vascularity and make the gland more firm) 60 mg twice daily for 2 weeks before surgery.

- **Postoperative complications:** Hypothyroidism, hypoparathyroidism and damage to recurrent laryngeal nerve.

### 3. Radioactive iodine (RAI)

- $^{131}\text{I}$  concentrated in thyroid, emits gamma-ray radiation from within the follicles and destroy thyroid cells. Taken orally as sodium salt of  $^{131}\text{I}$  dissolved in water or as pills. Patients must be euthyroid before treatment.
- **Dose:** 185–555 MBq
- **Indications:** (i) Patients **above 40 years of age**, (ii) young patients with a short life-span due to some other reason, and (iii) young individuals who are sterilized.
- **Complication: Hypothyroidism**, infertility, secondary cancers.
  - **Contraindications:**
    - Never given for children and pregnant/lactating women
    - Not recommended with patients of severe ophthalmopathy
    - Not advisable in chronic smokers.

Approach for the hyperthyroidism is presented in Figure 2.8.

**Fig. 2.8:** Approach to diagnosis in hyperthyroidism.

[FT<sub>4</sub>: free T<sub>4</sub> (tetrahydrothyronine); FT<sub>3</sub>: free T<sub>3</sub> (triiodothyronine); TSH: thyroid-stimulating hormone; RAIU: radioactive iodine uptake]

## ***Hyperthyroid Crisis/Thyrotoxic Crisis/Thyroid Storm***

**Q. Write short essay/note on hyperthyroid crisis/thyrotoxic crisis/thyroid storm/thyroid crisis.**

It is a rare **life-threatening** medical emergency that develops as **complication of thyrotoxicosis** which is associated with a mortality of 10%.

### *Causes of hyperthyroid crisis*

Various precipitating factors are:

- **Severe infections** in a patient with previously undetected or inadequately treated hyperthyroidism/thyrotoxicosis.
- **Following surgery:** May develop **following subtotal thyroidectomy** in an ill-prepared patient or some other surgery in an undetected hyperthyroidism/thyrotoxicosis.
- **Following radiotherapy:** May occur within a few days of  $^{131}\text{I}$  therapy in an inadequately prepared patient. This is because of a transient rise in serum thyroid hormone levels caused due to acute damage by irradiation.
- **Other precipitating factors:** Cerebrovascular accidents, diabetic ketoacidosis, acute coronary syndrome, use of Iodine contrast agent, sudden withdrawal of antithyroid medications, stress, major trauma.

### *Clinical features*

- The clinical manifestations are due to marked hypermetabolism and excessive adrenergic response.
- Hyperpyrexia from 104°F to 106°F is common and is associated with flushing and sweating.
- **Marked tachycardia**, often with atrial fibrillation and high pulse pressure; occasionally heart failure occurs. A fatal outcome is associated with heart failure and shock.
- **Central nervous system symptoms** include marked **agitation, restlessness, delirium**, and coma.
- **Gastrointestinal symptoms** include nausea, vomiting, diarrhea, and jaundice.

### **Treatment of hyperthyroid crisis**

- Patients should be **rehydrated** and given **antibiotics** if there is infection.
- **Control hyperthermia:** By external cooling. **DO NOT** administer salicylates, as it converts  $\text{T}_4$  to

T<sub>3</sub>.

- **Propranolol:** Either orally (80 mg 4 times daily) or intravenously (1–5 mg 4 times daily). It also blocks peripheral conversion of T<sub>4</sub> to T<sub>3</sub>.
- **Propylthiouracil** 800–1200 mg orally every 4 hours **or carbimazole** (inhibit the synthesis of new thyroid hormone) 15–30 mg stat followed by 15 mg TID. In an unconscious or uncooperative patient, carbimazole can be administered rectally with good effect.
- **Lugol's iodine:** 10 drops TID about one hour after propylthiouracil or carbimazole.
- **Sodium iopodate:** 500 mg/day orally will restore serum T<sub>3</sub> levels to normal within 48–72 hours. This is a radiographic contrast medium which inhibits the release of thyroid hormones and also reduces the conversion of T<sub>4</sub> to T<sub>3</sub>. Hence, more effective than potassium iodide or Lugol's solution.
- **Benzodiazepines:** For agitation.
- **Corticosteroids:** **IV hydrocortisone** 100–200 mg every 6 hours suppresses many of the manifestations of hyperthyroidism.
- **Bile acid sequestrants**, cholestyramine 4 g orally four times daily decreases thyroid hormone levels by interfering with enterohepatic circulation and recycling of thyroid hormone.
- **Digoxin:** To control cardiac failure and atrial fibrillation (AF). Lithium and plasmapheresis have been tried.

### Box 2.10: Etiology of hypothyroidism.

#### Primary:

1. Hashimoto's thyroiditis
2. Radioactive iodine therapy for Graves' disease
3. Subtotal thyroidectomy for Graves' disease, nodular goiter, or thyroid cancer
4. Excessive iodide intake (radiocontrast dyes)
5. Subacute thyroiditis (usually transient). Postpartum thyroiditis
6. Iodide deficiency
7. Drugs: Lithium, interferon-alfa, amiodarone
8. Dyshormonogenesis—Pendred syndrome

**Secondary:** Hypopituitarism due to pituitary adenoma, pituitary ablative therapy, or pituitary destruction

**Tertiary:** Hypothalamic dysfunction (rare)

Rarely peripheral resistance to the action of thyroid hormone

## Hypothyroidism

**Q. Describe the etiology, clinical features, diagnosis and management of primary hypothyroidism/spontaneous atrophic hypothyroidism?**

- Hypothyroidism is a **clinical syndrome resulting from a deficiency of thyroid hormones**. It results in a generalized slowing down of metabolic processes.

- **Infants and children:** Hypothyroidism results in marked **slowing of growth and development**, with serious permanent consequences, including mental retardation, when it occurs in infancy (**cretinism**).
- **Adults:** Hypothyroidism causes a **generalized decrease in metabolism**, with slowed heart rate, diminished oxygen consumption, and deposition of glycosaminoglycans in intracellular spaces, particularly in skin and muscle, producing in extreme cases the clinical picture of **myxedema**.

### *Classification and Etiology (Box 2.10)*

**Q. Write short essay/note on causes of hypothyroidism and treatment.**

- **Primary hypothyroidism:** Due intrinsic disorder of the thyroid gland.
- **Secondary hypothyroidism** is rare and is caused due to failure of TSH production due to disease of anterior pituitary or hypothalamus.

#### *Hashimoto's thyroiditis (Spontaneous atrophic hypothyroidism)*

- **Most common cause** of primary hypothyroidism.
- Organ-specific **autoimmune disorder** of thyroid characterized by lymphoid infiltration of thyroid leading to fibrosis and atrophy.
- Patients have **TRAb** that block the effects of endogenous TSH.
- It may be observed in **some patients of Graves' disease** treated with antithyroid drugs 10–20 years earlier.
- Patients have **high-risk of developing other autoimmune disorders** such as type 1 diabetes mellitus, pernicious anemia and Addison's disease.

#### *Postpartum thyroiditis*

- It is usually transient, self-limiting condition that follows pregnancy.
- It may produce hyperthyroidism, hypothyroidism or the two sequentially.

#### *Excessive iodide*

- Inhibits iodide organification and synthesis of  $T_4$  and  $T_3$  (**Wolf-Chaikoff effect**). Most patients quickly recover from this effect. However, patients with abnormal thyroid gland can develop hypothyroid if iodine is given for more than a few days.
- Risk factor for iodine-induced hypothyroidism is patients with chronic autoimmune thyroiditis, partial thyroidectomy, previous history of radioiodine therapy and subacute thyroiditis.

## Clinical Features (Table 2.8)

**Table 2.8: Clinical features of hypothyroidism.**

<i>Organ/System involved</i>	<i>Symptoms</i>
General	Lethargy, somnolence, <b>weight gain</b> , <b>goiter</b> , cold intolerance, hoarse voice, pallor
Thyroid	Enlargement of the gland
Gastrointestinal	Reduced appetite, constipation, ileus, ascites, macroglossia
Cardiorespiratory	Angina, <b>bradycardia</b> , hypertension (diastolic), cardiac failure, <b>pericardial effusion</b> , pleural effusion, dyslipidemia, hyperhomocysteinemia
Neuromuscular	Aches and pains, muscle stiffness, delayed relaxation of tendon reflexes ( <b>Woltman's sign</b> )*, carpal tunnel syndrome, <b>depression</b> , psychosis, cerebellar <b>ataxia</b> , deafness, myotonia, proximal myopathy, pseudohypertrophy of muscles, Hashimoto encephalopathy
Skin	<b>Myxedema</b> (non-pitting edema of the skin of hands, feet and eyelids), dry flaky skin and hair, alopecia, vitiligo, purplish lips and malar flush, carotenemia, erythema abigne, xanthelasmas, madarosis (thinning of lateral 1/3 of eyebrows)
Reproductive	<b>Menorrhagia</b> , infertility, galactorrhea (hyper-prolactinemia), impotence
Hematological	Macrocytosis, anemia
Renal	Impaired GFR, renal dysfunction
Miscellaneous	<b>OSA</b> , <b>hyponatremia</b> , weight gain.

*Note:* Bold words indicate symptoms of greater discriminant value.\* Woltman's sign (hung up ankle jerk) is due to decreased myosin ATPase activity and decreased rate of reaccumulation of calcium in the sarcoplasmic reticulum

### **Q. Write short essay/note on clinical features of hypothyroidism.**

- Depends on the duration and severity of the hypothyroidism.
- **Consequence of prolonged hypothyroidism:**
  - **Infiltration of many body tissues** by the mucopolysaccharides, hyaluronic acid and chondroitin sulfate.
  - **Infiltration of the dermis** produces nonpitting edema (myxedema). The term myxedema refers to the **accumulation of mucopolysaccharides in the subcutaneous tissues**. It is most marked in the skin of the hands, feet and eyelids.
  - **Myxedema facies:** It is a peculiar facial appearance characterized by

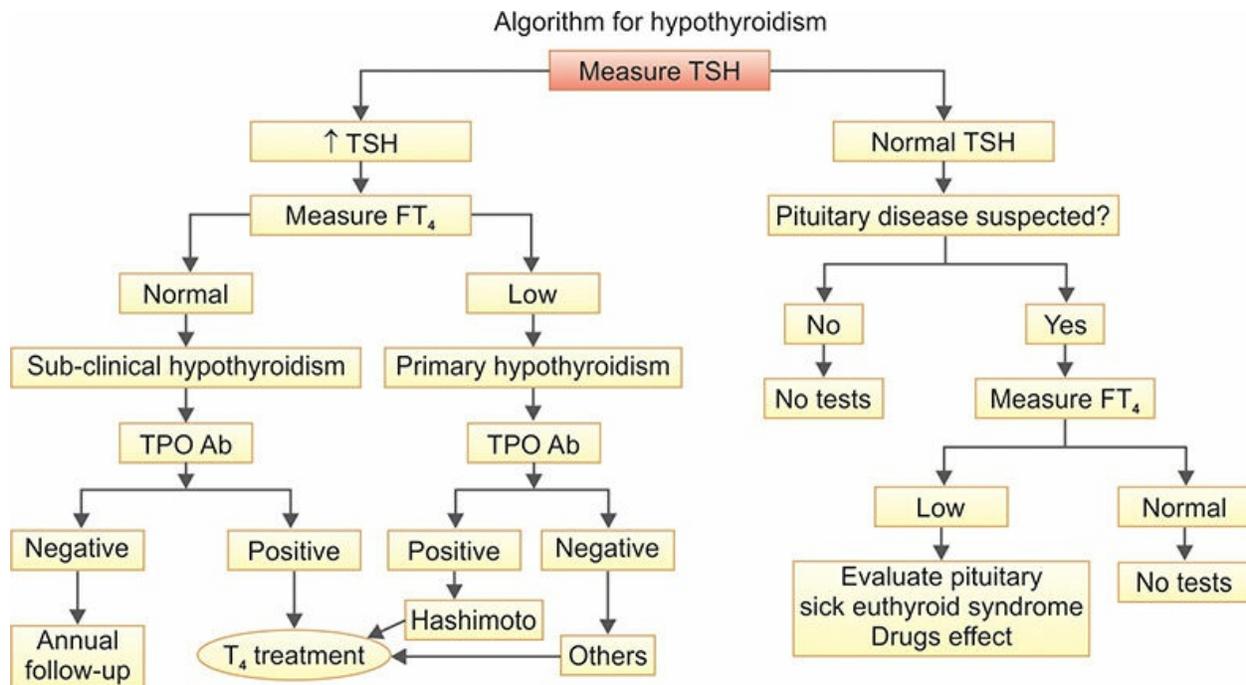

striking **periorbital puffiness** (due to myxedema), scanty eyebrows, **facial pallor** (due to vasoconstriction and anemia), or a **lemon-yellow tint to the skin** (due to **carotenemia** produced by reduced conversion of carotene to vitamin A), purplish lips and malar flush.

- **Most cases** of hypothyroidism are **not clinically obvious** and should be kept in mind when individuals complain of non-specific symptoms such as tiredness, weight gain, depression or carpal tunnel syndrome. Many cases are diagnosed on biochemical screening.

### ***Investigations of Primary Hypothyroidism (Fig. 2.9)***

Majority of hypothyroidism results from an intrinsic disorder of the thyroid gland (primary hypothyroidism).

- **Serum TSH:** It is the investigation of choice. **High TSH level confirms primary hypothyroidism.**
- **Serum T<sub>4</sub> levels:** **Low level** confirms the hypothyroid state.
- **Thyroid and other organ-specific antibodies** may be found.
- **Other abnormalities:**
  - **Increased serum aspartate transferase** from muscle and/or liver
  - Increased serum lactate dehydrogenase (LDH) and **creatine kinase (CK):** With associated myopathy
  - **Hypercholesterolemia and hypertriglyceridemia**
  - **Hyponatremia:** Due to an increase in ADH and impaired free water clearance.
  - **Anemia:** Usually normochromic and normocytic
  - **Electrocardiogram (ECG):** Demonstrates sinus bradycardia, low voltage QRS complexes and ST segment and T wave abnormalities.
  - **Chest radiograph:** May reveal enlarged cardiac shadow.

**Fig. 2.9:** Algorithm for hypothyroidism.

[T4: free T4 (tetrahydrothyronine); TPOAb: thyroid peroxidase antibodies; TSH: thyroid-stimulating hormone]

**Q. Write short essay/note on treatment of hypothyroidism (drug, dose and duration of therapy).**

**Treatment of Hypothyroidism**

- Hypothyroidism is treated with T<sub>4</sub>.

Replacement therapy with **levothyroxine sodium** (thyroxine, i.e. T) is given for life, once daily dosage (1.6–1.8 µg/kg/day).

**Starting dose:** It depends upon the severity of the deficiency and on the age and fitness of the patient.

- **For healthy patients**
  - <50 years at 1.0 µg/kg/day
  - >50 years should be <50 µg/day. Dose increase by 25 µg, if needed, at 6–8 weeks intervals.
- **For patients with heart disease:** 12.5–25 µg/day and increase by 12.5–25 µg/day, if needed, at 6–8 weeks intervals. Few patients with ischemic heart disease may develop angina or worsen with therapy. They require β-blockers, vasodilators or CABG or angioplasty.

**Dosage adjustments**

- Should be taken on an empty stomach with water, ideally an hour before breakfast.
- **Age:** In elderly start with half dose.
- **Severity and duration of hypothyroidism:** Increase the dose in severe cases
- **Weight:** 0.5 µg/kg/day increase up to 3.0 µg/kg/day
- **Malabsorption:** Requires increase dose
- **Concomitant drug therapy:** Thyroxine only to be taken on empty stomach

- **Pregnancy:** 25–50% increase in dose, safe in lactating mother
- **Presence of cardiac disease:** Start low dose or alternate day treatment.

#### **Monitoring**

- **Goal:** It is to **normalize TSH level** regardless of cause of hypothyroidism and to **restore T<sub>4</sub> within the normal range**.
- **Adequacy of replacement:** Assessed clinically and by **thyroid function tests** after 6 weeks on a steady dose.
- Complete suppression of TSH should be avoided because it may cause atrial fibrillation and osteoporosis.
- Lifelong therapy is needed.

## Myxedema Coma

**Q. Write short essay on clinical features and management of myxedema coma and myxedema madness.**

Myxedema coma is a very rare, life-threatening medical emergency that develops as a complication of hypothyroidism usually in an elderly patient.

It develops in patients with long-standing, severe untreated hypothyroidism (or may not have been diagnosed) in whom adaptive mechanisms fail to maintain homeostasis.

- **Precipitating factors:** Infections, drugs (amiodarone,  $\beta$ -blockers, diuretics, anesthetic agents, barbiturates, lithium, narcotics, phenothiazines), cardiac failure, hypoxia, hyponatremia and hypercapnia.
- **Warning signs:** Presence of cool pale skin (due to **hypothermia**—body temperature may be as low as 25°C) and absence of mild diastolic hypertension.
- **Laboratory findings**
  - Serum **free T<sub>4</sub> is low**, **serum TSH** is usually **high** but sometimes only slightly elevated.
  - **Serum creatine phosphokinase** mostly markedly raised.

### Myxedema Madness

- Patient presents with **hypothermia** and neuropsychiatric manifestations.
- **Neuropsychiatric manifestations:** Include
  - **Myxedema madness:** Depression is common in hypothyroidism. Rarely, elderly patient with severe hypothyroidism may become frankly demented or psychotic, sometimes with striking delusions and

hallucinations. It may develop shortly after starting T<sub>4</sub> replacement.

- **Myxedema coma:** Depressed level of consciousness, convulsions and coma.
- Patient may develop severe cardiac failure, pericardial effusions, hypoventilation, and metabolic abnormalities such as hypoglycemia and hyponatremia.
- **Lab findings:**
  - Hypoglycemia and hyponatremia, increased CO<sub>2</sub>, decreased WBC count and Hct, increased CPK.
  - Reduced ECG voltage, blood gases often reveal respiratory acidosis, hypoxia and hypercapnia.

#### Management of myxedema coma (Table 2.9)

Treatment must be started before biochemical confirmation of the diagnosis.

**Table 2.9: Management of myxedema coma.**

<i>Abnormality</i>	<i>Treatment</i>
Hypothyroidism	Large initial intravenous dose of 300–500 µgT <sub>4</sub> ; if no response within 48 hours, add T <sub>3</sub>
Hypocortisolemia	Intravenous hydrocortisone 200–400 mg daily
Hypoventilation	Intubation and mechanical ventilation
Hypothermia	Gentle warming of patient with blankets, no active rewarming
Hyponatremia	Mild fluid restriction, 3% saline
Hypotension	Cautious volume expansion with crystalloid or whole blood
Hypoglycemia	Glucose administration
Precipitating event	Identification and elimination by specific treatment (liberal use of antibiotics)
Other measures	Monitor cardiac output and pressures Whenever needed, cautious use of intravenous fluids, high-flow oxygen or assisted ventilation

### Sick Euthyroid Syndrome/Nonthyroid Illness State (NTIS)

**Q. Write short note on sick euthyroid syndrome.**

- **Nonthyroidal illness influences thyroid hormone production and action at multiple levels, including H-P-T axis, thyroid hormone transport, and metabolism.**

- Changes in thyroid function in the setting of systemic illness, surgery, or fasting not caused by primary thyroid or pituitary dysfunction are referred to as the nonthyroidal illness syndrome (also called ‘sick euthyroid syndrome’). Also called ‘low-T<sub>3</sub> syndrome’, due to the most common abnormality, a decreased level of serum total triiodothyronine (T<sub>3</sub>).
- Measurement of serum thyroxine (T<sub>4</sub>) concentration can be normal, low or elevated.
- Serum TSH (thyrotropin), is usually normal but can be influenced by nonthyroidal illness.
- Conditions associated with euthyroid sick syndrome include malnutrition, HIV, anorexia nervosa, trauma, myocardial infarction, chronic renal failure, diabetic ketoacidosis, cirrhosis and sepsis.
  - Treatment with thyroxine is not recommended.

## Subclinical Thyroid Diseases

**Q.** Write short note/essay on subclinical thyroid diseases.

**Q.** Write short note on subclinical hypothyroidism.

**Box 2.11:** Common causes of subclinical hypothyroidism.

- Iatrogenic
- Hashimoto’s thyroiditis
- Postpartum thyroiditis
- Medications: Amiodarone, lithium, interferon, sorafenib
  - Partial thyroidectomy
  - Head and neck radiation

## *Subclinical Hypothyroidism*

- Subclinical hypothyroidism is defined as an increased serum TSH in the presence of a normal serum F T<sub>4</sub> and T<sub>3</sub> concentration. Prevalent in women and elderly persons.
- Common causes of subclinical hypothyroidism (Box 2.11)

## Clinical consequences

- Progression to overt hypothyroidism → 2–5% yearly

- Risk of CV disease: Diastolic dysfunction, diastolic hypertension, increase in LDL-C, increased hsCRP, alteration in coagulation parameters, endothelial dysfunction
- Infertility
- Neuropsychiatric manifestations.

#### **Indication for treatment with levothyroxine**

- Patients who are pregnant or planning for pregnancy
- Patients with serum TSH > 10.0 mU/L
- Symptoms or signs of hypothyroidism
- Age <70 years
- TSH >7.0 mU/L with antibodies positive
- Goiter
- High vascular risk including ischemic heart disease, diabetes, dyslipidemia.

#### **Box 2.12:** Causes of subclinical hyperthyroidism.

- Iatrogenic
- Autonomous nodules (solitary and in MNG)
- Graves' disease
- Thyroiditis
- Graves' disease in remission
- High hCG

### ***Subclinical Hyperthyroidism***

**Q. Write short note on subclinical hyperthyroidism.**

#### **Etiology of subclinical hyperthyroidism (Box 2.12)**

Natural course: 40–60% normalize. About 4% progresses to overt hyperthyroidism.

#### **Effects of subclinical hyperthyroidism**

- Functional cardiac effects of subclinical hyperthyroidism (Box 2.13).
- Noncardiac effects
  - **Osteoporosis, decreased BMD, increased risk of fractures**
  - **Muscle weakness, dementia**

There is no evidence to treat subclinical hyperthyroidism with antithyroid drugs.

#### **Box 2.13:** Functional cardiac effects of subclinical hyperthyroidism.

- Resting tachycardia
- Atrial fibrillation
- LV hypertrophy
- Increase LV mass index
- Increase cardiac workload
- Diastolic dysfunction (impaired relaxation)
- Increased systolic function at rest
- Impaired systolic response to exercise

## Thyroiditis

**Q. Write short note on causes of thyroiditis.**

It is a heterogeneous group of inflammatory disorders involving the thyroid gland. Etiologies range from autoimmune to infectious origins.

The clinical course may be acute, subacute, or chronic.

### *Causes of Thyroiditis (Table 2.10)*

#### Subacute Thyroiditis (De Quervain's Thyroiditis)

**Q. Write short note on subacute thyroiditis (de Quervain's thyroiditis/granulomatous thyroiditis).**

- A spontaneously remitting, painful, subacute inflammatory disease of the thyroid characterized by transient inflammation of the thyroid gland.
- Most prevalent in the temperate zone.
- **Gender and age:** Affects more frequently women between the third and sixth decades of life.

### *Clinical Features*

- **Prodromal viral symptoms:** Often preceded by a viral infection (e.g. Coxsackie, mumps, adenovirus) of upper respiratory tract. Prodromal symptoms include fever, malaise and pain in the neck with tachycardia and local thyroid tenderness.

**Table 2.10: Causes of thyroiditis.**

Type	Causes
Acute	• Bacterial infections: <i>Staphylococcus</i> , <i>Streptococcus</i> ,

	<p><i>Enterobacter</i></p> <ul style="list-style-type: none"> <li>• Fungal infections: <i>Aspergillus</i>, <i>Candida</i>, <i>Histoplasma</i></li> <li>• Radiation: After <math>^{131}\text{I}</math> treatment</li> <li>• Drugs: Amiodarone (may also be subacute or chronic)</li> </ul>
Subacute	<ul style="list-style-type: none"> <li>• Viral or granulomatous (de Quervain's) thyroiditis</li> <li>• Silent thyroiditis (includes post-partum thyroiditis)</li> <li>• Mycobacterial infection</li> <li>• Drug induced: Interferon, amiodarone</li> </ul>
Chronic	<ul style="list-style-type: none"> <li>• Autoimmune: Hashimoto's thyroiditis, Riedel's thyroiditis</li> <li>• Parasitic thyroiditis: Echinococcosis, strongyloidiasis, cysticercosis</li> <li>• Traumatic: Palpation thyroiditis</li> </ul>

- **Anterior neck pain** in the region of thyroid occurs abruptly and may be sometimes unilateral.
  - It **may radiate to the ear, mandible or occiput**. Pain may shift to the contralateral lobe (creeping thyroiditis).
  - Pain may be **aggravated by moving the head, swallowing, or coughing**.
- **Functional impairment: Initially** there is **hyperthyroidism** and **later** followed by a period of **hypothyroidism**. Finally **full recovery occurs in 4–6 months**. In about 5% of cases hypothyroidism may persist.
- **Signs: Enlarged and tender thyroid gland.**

### **Laboratory Findings**

- **Erythrocyte sedimentation rate (ESR):** Elevated (>55 mm/h)
- **Leukocyte counts:** Normal or slightly elevated
- **Serum IL-6 and Tg concentrations:** Increased during the thyrotoxic phase.
- **Thyroid radionuclide uptake** is reduced or absent.
- **Thyroid antibodies** are **transiently detectable** at low titers in a minority of patients.

### **Treatment**

- Mild cases: Salicylates or non-steroidal anti-inflammatory drugs relieve pain and tenderness
- Severe cases: Corticosteroids (prednisone 40–60 mg/day) have a more dramatic and rapid effect.
- Symptoms of thyrotoxicosis should be managed with  $\beta$ -adrenergic blocking agents (propranolol 20–40 mg, 3–4 times daily)

- In patients with hypothyroidism L-T<sub>4</sub> replacement is needed

## Hashimoto's Thyroiditis

### **Q. Write short essay/note on Hashimoto's (autoimmune) thyroiditis.**

- Hashimoto's thyroiditis is an **autoimmune** condition characterized by destructive lymphoid infiltration of the thyroid and high titers of circulating:
  - a. **Antithyroid peroxidase (TPO) antibody (TPOAb)** in 95% patients.
  - b. **Antithyroglobulin (Tg) antibody** in 60–80% patients.
- **Age and gender:** Most often diagnosed between 50 to 60 years of age, 5 to 7 times more frequent in women than in men.
- **Association with other autoimmune diseases:** Often associated with ulcerative colitis or type 1 diabetes mellitus.

**Pathology: Lymphocytic infiltration** (lymphoid follicles with germinal centre), fibrosis, follicular cell hyperplasia and presence of **oxyphil cells** (Askanazy cells/Hürthle cells).

### **Clinical Features**

- **Most patients are asymptomatic.** Some may have a feeling of tightness or fullness in the neck. Neck pain and tenderness are rare.
- **Hypothyroidism: Commonest cause of goitrous hypothyroidism.** About 25% present with hypothyroidism and remaining are at a higher risk of developing in future years. Hashitoxicosis is seen in the acute phase.
- Chronic autoimmune thyroiditis is a **component of type 2 autoimmune polyglandular syndrome**
- **Physical examination:** Diffuse enlargement of thyroid with firm or rubbery consistency.

### **Investigations**

#### **Q. Investigations and treatment of Hashimoto's thyroiditis.**

- **Thyroid function tests:** Show features of **hypothyroidism**
- **Antithyroid peroxidase (TPO) antibody (TPOAb)** in 95% patients
- **Antithyroglobulin (Tg) antibody** in 60–80% patients

- **Antinuclear factor (ANF)** may be found in patients below the age of 20 years
- **Ultrasound of thyroid:** Reduced echogenicity
- **Fine-needle aspiration cytology (FNAC) of thyroid.**

**Complication:** An increased risk for **thyroid lymphoma** (rare).

#### Treatment of Hashimoto's thyroiditis

- Levothyroxine/thyroxine (150–200 µg/day) is indicated for the treatment of hypothyroidism and it may produce shrinkage of goiter. The dose of thyroxine should be sufficient enough to suppress serum TSH to low but detectable levels.

## Riedel's Thyroiditis (Sclerosing Thyroiditis/Ligneous Thyroiditis/Invasive Fibrous Thyroiditis)

- Rare, chronic inflammatory disorder of unknown etiology.
- Characterized by dense fibrosis of the thyroid gland and adjacent tissues, and extracervical areas (fibrous mediastinitis, retroperitoneal fibrosis, retro-orbital fibrosis, sclerosing cholangitis, and pancreatitis).

### *Clinical Features*

- Occurs mainly in middle-age or elderly women.
- Usually present with a long history of a painless, progressively increasing anterior neck mass. Most patients are euthyroid.
- **Pressure symptoms:** Dysphagia, cough, hoarseness, stridor, attacks of suffocation) may be present.
- **Physical examination:** A **stony-hard or woody thyroid** mass which varies in size from small to very large. It may involve one or both lobes and is **fixed to surrounding structures**.

### *Investigations*

- **Thyroid antibodies:** May be found in about 45% of patients.
- **Serum calcium:** May be low due to parathyroid invasion.
- **Differential diagnosis:** From thyroid carcinoma or lymphoma of the thyroid requires open biopsy, since FNAB may be difficult to interpret.

#### Treatment of Riedel's thyroiditis

- **Surgical treatment** is necessary to relieve pressure on the trachea and to establish diagnosis.
- Corticosteroids are of little or no value.

## Goiter

Goiter is the enlargement of thyroid gland.

### **Classification (Table 2.11)**

**Table 2.11: Classification of goiter.**

#### **Diffuse**

- Simple (nontoxic): Physiological (puberty, pregnancy), iodine deficiency (endemic goiter)
- Toxic goiter: Graves' disease
- Autoimmune/inflammatory: Hashimoto's thyroiditis, de Quervain's thyroiditis, Riedel's thyroiditis
- Dyshormonogenesis goitrogens (e.g. sulfonyleureas)

#### **Nodular**

- Multinodular goiter, toxic multinodular goiter (Plummer's disease)
- Solitary nodular fibrotic (Riedel's thyroiditis)
- Cysts
- Tumors:
  - Benign: Adenomas
  - Malignant: Carcinoma, lymphomas
- Miscellaneous: Sarcoidosis, tuberculosis

## Simple (Nontoxic) Goiter

Diffuse nontoxic (simple) goiter is characterized by the **diffuse enlargement of the thyroid gland without any nodularity**. This includes:

- Simple hyperplastic goiter (colloid goiter)
- **Cause:** Physiological in pregnancy, puberty and iodine deficiency.
- **Appearance:** Large, smooth firm, non-tender goiter
- **Effect:** Euthyroid and pressure effect.

### **Risk Factors for Malignancy in Goiter (Box 2.14)**

#### **Diffuse Nontoxic (Simple) Goiter**

**Q. Write short essay/note on clinical features, investigations and treatment of goiter/multinodular goiter.**

Diffuse nontoxic (simple) goiter is characterized by the diffuse enlargement of the thyroid gland without any nodularity.

## Etiology

Types: (A) endemic, and (B) sporadic.

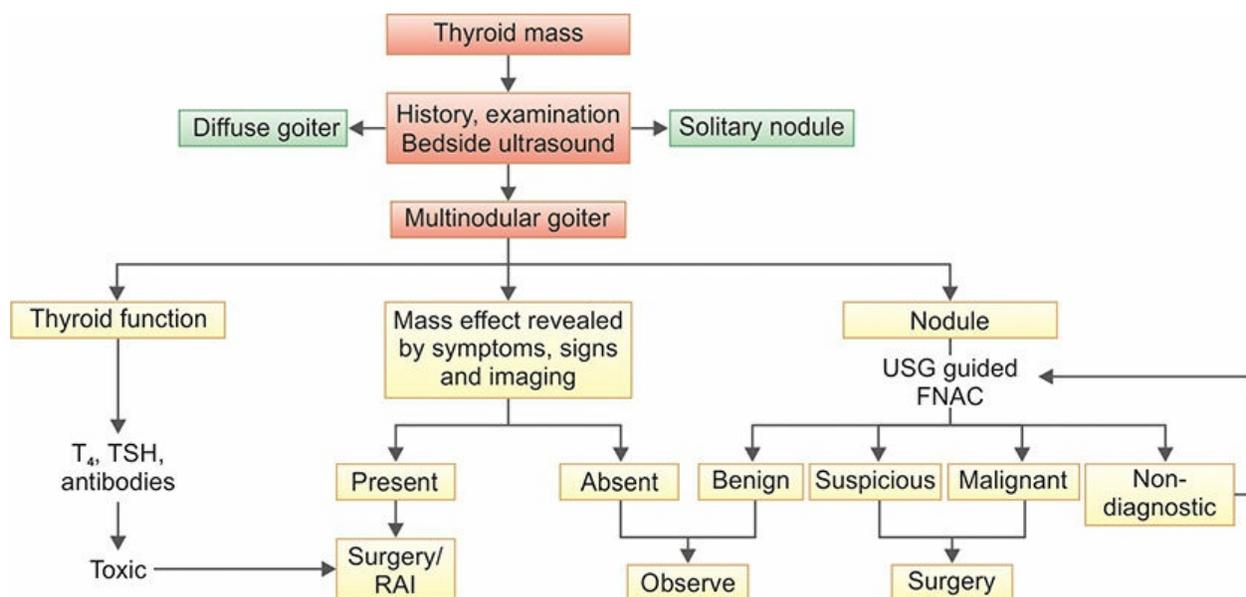

### A. Endemic goiter

This term is used when goiters are present in more than 10% of the population in a given region. The causes are:

- **Deficiency of iodine:** This may be due to low iodine in the soil, water, and food. Consequences of iodine deficiency: Decreased synthesis of thyroid hormone and causes compensatory increase in TSH. This leads to follicular cell hypertrophy and hyperplasia and goitrous enlargement.
- **Goitrogens:** These are substances ingestion of which interferes with thyroid hormone synthesis. Goitrogenic substances include vegetables which belong to Brassicaceae (Cruciferae) family such as cabbage, cauliflower, Brussels sprouts, and turnips; and Cassava root which contains a thiocyanate that inhibits iodide transport within the thyroid. Consumption of this may worsen the concurrent iodine deficiency.

### Box 2.14: Risk factors for malignancy.

- Solitary thyroid nodules in patients > 60 or < 30 years of age
- Irradiation of the neck or face during infancy or teenage years
- Symptoms of pain or pressure (especially a change in voice)
- Male sex
- Large nodules (>3 or 4 cm)
- Growth of nodule

**Fig. 2.10:** Algorithm for approach to goiter and its treatment modality.  
(RAI: radioactive iodine therapy)

### *B. Sporadic goiter*

- Less frequent than endemic goiter
- Age: Puberty or in young adult life
- Sex: Female preponderance.
- Causes: In most cases of sporadic goiter the cause is not known.

### **Clinical Features**

- **Endemic goiter:** Diffuse enlargement of the thyroid with euthyroid state in the initial stage. This is called as simple goiter. But, later they may develop hypothyroidism. In children and adults endemic goiter may be present with features of hypothyroidism and mental retardation.
- **Cretinism:** Iodine deficiency may produce severe hormone-induced physiological damage to fetus and newborn and cause cretinism. This is characterized by stunting, deaf-mutism, malformed limbs, spastic motor disorders, goiter, and mental impairment.

### **Investigations (Fig. 2.10)**

- Serum inorganic iodide: Reduced
- Urinary iodide excretion: Low < 50 µg/day.
- Serum T<sub>4</sub>: Normal
- Serum T<sub>3</sub>: May be normal or raised due to increased conversion of T<sub>4</sub> to T<sub>3</sub>
- TSH: May be normal or mildly raised.

#### **Treatment**

- Early stages: Replacement with iodine
- Later may need suppressive therapy with T<sub>4</sub>.

## **PARATHYROID DISORDERS**

### **Calcium Homeostasis (Fig. 2.11)**

**Q. Write short note on calcium homeostasis and its importance.**

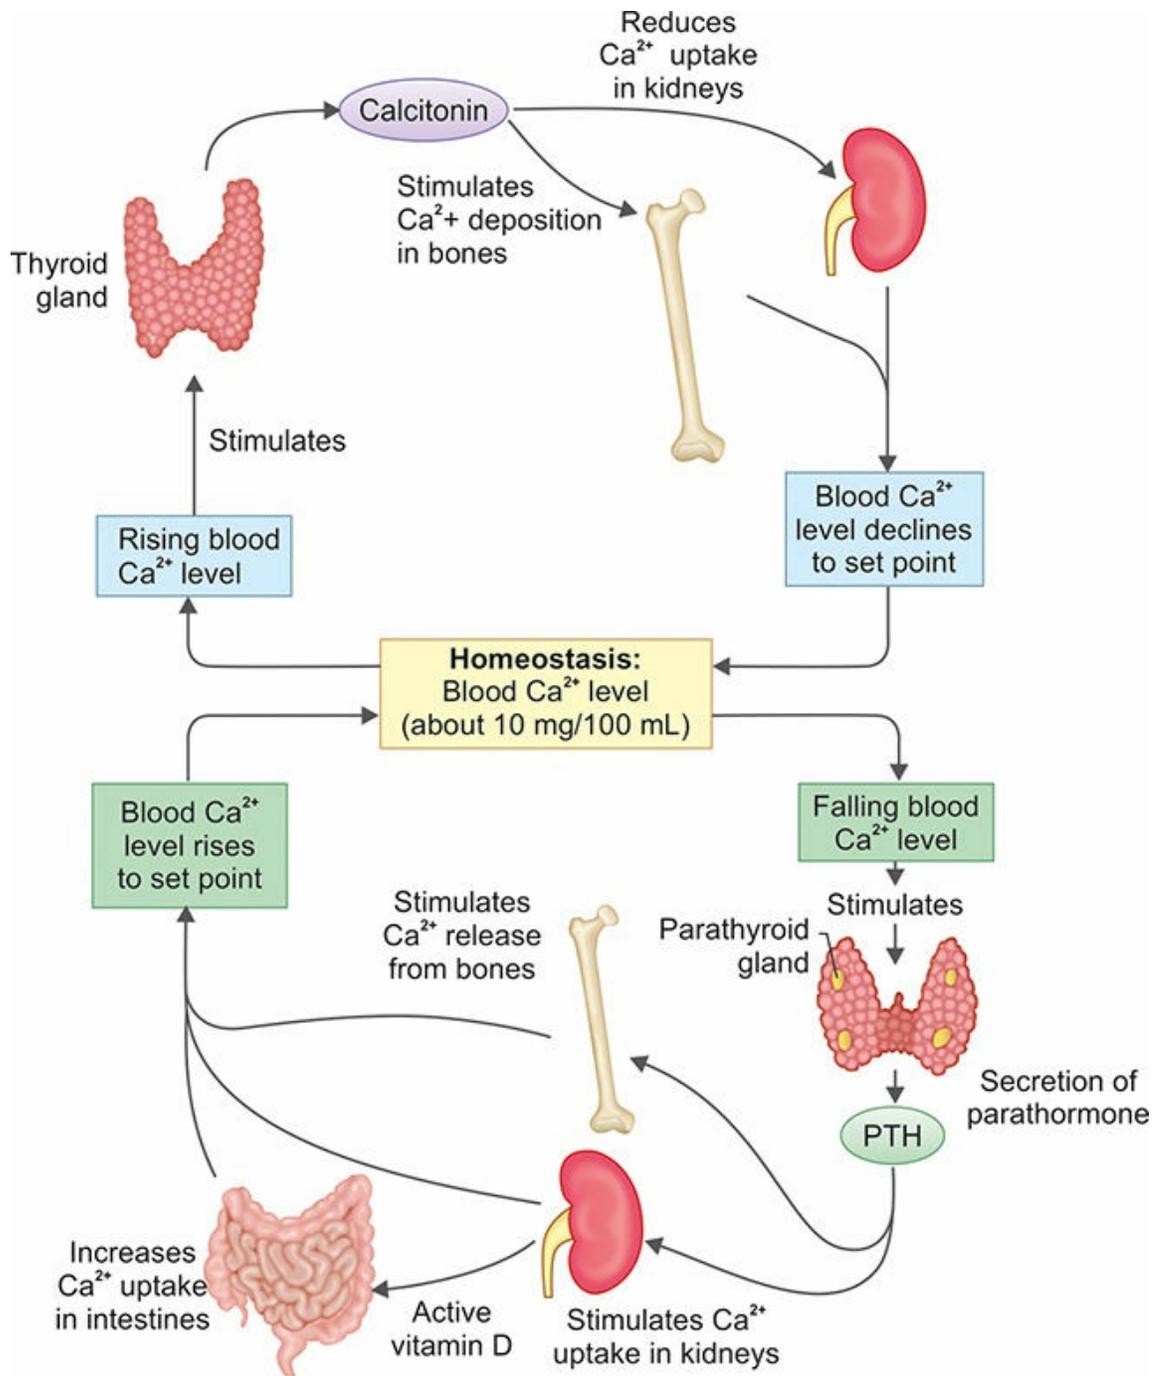

## ***Distribution of Calcium***

- Calcium weight is 400 mg/kg in infant and 950 mg/kg in adult.
- About 99% of total body calcium in the bone.
- Remaining 1% in intracellular fluid (ICF), extracellular fluid (ECF), and cell membranes. It can be divided in three components: (1) 50% ionized, (2) 40% bound to protein, and (3) 10% complex with anions (citrate, phosphate).

## ***Importance of Ionized Calcium***

Ionized calcium ( $\text{Ca}^{++}$ ) is physiologically important because:

1. One of the major intracellular messengers.
  - Precise levels are necessary for muscle contraction (cardiac, skeletal).

**Fig. 2.11:** Calcium metabolism.

- Responsible for exocytosis of secretory granules in neuronal synapses.
- Serves as second messenger in many cells.

2. Necessary for blood clotting.

**Blood Ca<sup>++</sup> level:** 8.5–10.2 mg/dL. Usually 10 mg/100 mL (so 500 mg total in plasma = 0.5 g).

## ***Regulation of Calcium Levels***

It occurs in three different organs namely

1. **Small intestine:** Ingestion of  $\text{Ca}^{++}$  in food, taken up across the gut.
2. **Kidney:**  $\text{Ca}^{++}$  is filtered through the nephron, and can be excreted in the urine.
3. **Bone:** Major storage site for  $\text{Ca}^{++}$ .

### *Calcium cycling in bone tissue*

Two processes that go on continuously and include bone formation and bone resorption.

- Calcium phosphate crystals are called '**hydroxyapatite**'. The surfaces of crystals can exchange  $\text{Ca}^{++}$  and phosphate ions with extracellular fluid.
- **Osteoblasts:** Synthesize a collagen matrix that holds calcium phosphate in crystallized form. Once surrounded by bone, osteoblast becomes osteocyte.
- **Osteoclasts:** They break down bone (removes  $\text{Ca}^{++}$  from bone). Change local pH, causing  $\text{Ca}^{++}$  and phosphate to dissolve from crystals into extracellular fluids.

## ***Hormonal Regulators***

1. **Calcitonin (CT):** Secreted from the C-cells in the thyroid gland.

### **Actions:**

- Lowers  $\text{Ca}^{++}$  in blood.
- Promotes deposition of  $\text{Ca}^{++}$  into bone. It actually inhibits bone resorption by osteoclasts.

**Control of secretion:** Increased plasma  $\text{Ca}^{++}$  stimulates C-cells to synthesize and release CT.

2. **Parathormone (PTH):** Secreted from cells of the parathyroid glands (chief cells).

### **Actions:**

- Increases  $\text{Ca}^{++}$  in the blood
- Increases  $\text{Ca}^{++}$  resorption from the bone
  - Stimulates the osteoclasts

- Increases the number of osteoclasts
  - Increases  $\text{Ca}^{++}$  resorption from the pre-urine filtrate in the nephron.
3. **Vitamin D (1, 25 vitamin  $\text{D}_3$ )**
- Actions:** Vitamin D increases
- a. Calcium absorption from intestine.
  - b.  $\text{PO}_4$  absorption from intestine.
  - c. Renal reabsorption of Ca and  $\text{PO}_4$ .
  - d. Bone resorption from old bone and mineralize new bone (net resorption).
- Overall effect:** Increase serum Ca and  $\text{PO}_4$ .

## Hyperparathyroidism

**Q. Write short essay on clinical features, investigations and management of primary hyperparathyroidism.**

### *Classification and Causes of Hyperparathyroidism (Table 2.12)*

**Q. Write short essay on classification of hyperparathyroidism.**

**Table 2.12: Classification and causes.**

Type	Serum calcium	Serum PTH	Causes
<b>Primary:</b> Autonomous secretion of PTH by parathyroid	Raised	Raised	Single adenoma (90%), multiple adenomata, nodular hyperplasia and carcinoma of parathyroid
<b>Secondary:</b> Parathyroid hyperplasia with increased PTH secretion in an attempt to compensate for prolonged hypocalcemia.	Low	Raised	Chronic renal failure, malabsorption, osteomalacia and rickets.
<b>Tertiary:</b> Adenoma formation and autonomous PTH secretion. Occurring in cases of secondary hyperparathyroidism	Raised	Raised	Chronic secondary hyperparathyroidism Post renal transplantation.

## ***Clinical Features of Hyperparathyroidism***

- **Classical symptoms of primary hyperparathyroidism** are described by the adage ‘moans, bones, stones, abdominal groans’. However, nowadays only few patients present in this way.
  - **Moans:** Psychiatric manifestations—lethargy, fatigue, depression, memory loss, psychoses, neuroses, paranoia, confusion, stupor, coma
  - **Bones:** Arthritis, osteomalacia, osteitis
  - **Stones:** Renal stones, uremia, polydipsia, polyuria
  - **Groans:** Constipation, nausea, vomiting, peptic ulcers, indigestion, pancreatitis
- Disorder is most often (more than 70%) diagnosed by incidental finding of hypercalcemia on biochemical testing.
- **Nonspecific symptoms.** About 50% of patients are asymptomatic while others have nonspecific symptoms. These include: Anorexia, nausea, vomiting, constipation, weakness, fatigue, lassitude, tiredness, generalized aches, weight loss, pain, drowsiness, poor concentration, memory loss and depression.
- **Manifestations of hyperparathyroidism:** Involve primarily the kidneys and the skeletal system.
  1. **Renal manifestations:** Due either to deposition of calcium in the renal parenchyma or to recurrent nephrolithiasis.
    - **Recurrent renal calculi** (usually composed of either calcium oxalate or calcium phosphate).
    - **Nephrocalcinosis:** Deposition of calcium salts in the renal parenchyma.
    - Polyuria and polydipsia.
    - Loss of renal function with uremia, hypokalemia, hyperuricemia, hyperchloremic acidosis and dilute urine.
  2. **Skeletal manifestations**
    - Bone pain, osteopenia, osteoporosis, fractures and deformity due to osteitis fibrosa cystica (10–25% of patients)
    - Localized bone swelling/brown tumor (e.g. mandible).
  3. **Other manifestations**

- Hypertension is a common feature.
  - Calcification of cornea (observed by slit-lamp examination), arterial walls and soft tissues of hand.
  - Peptic ulcers
  - Myopathy
4. A family history of hypercalcemia or primary hyperparathyroidism secondary to a parathyroid adenoma raises the possibility of multiple endocrine neoplasia (MEN) syndrome. Features of multiple endocrine neoplasia syndromes are presented in Box 2.15.

**Box 2.15:** Features of multiple endocrine neoplasia syndromes.

**MEN 1 (Wermer's syndrome)**

- Parathyroid hyperplasia (very common)
- Pancreatic tumors (benign or malignant)
  - Gastrinoma
  - Insulinoma

Glucagonoma, VIPoma (both rare)

- Pituitary tumor
  - Growth hormone-secreting
  - Prolactin-secreting
  - ACTH-secreting
- Other tumors: Lipomas, carcinoids, adrenal and thyroid adenomas

**MEN 2A (Sipple syndrome)**

- Medullary carcinoma of the thyroid
- Pheochromocytoma (benign or malignant)
- Parathyroid hyperplasia

**MEN 2B**

- Medullary carcinoma of the thyroid
- Pheochromocytoma
- Mucosal neuromas, ganglioneuromas
- Marfanoid habitus
- Hyperparathyroidism (very rare)

**Treatment**

- Treatment of hypercalcemia (discussed below)
- **Treatment of primary parathyroidism:**
  - Adenoma: Surgical removal
  - Hyperplasia: Removal of all four parathyroid glands and transplantation of some of the excised tissue to the forearm.
- **Treatment of secondary disease**

- Calcium supplements
- Vitamin D
- **Treatment of tertiary disease**
- Phosphate binders
  - Amphojel, Basaljel
  - Tums

## *Investigations*

**Biochemical investigations:** Estimation of several fasting serum calcium and phosphate samples should be done.

- **Hallmark of primary hyperparathyroidism:**
  - **Hypercalcemia and hypophosphatemia with detectable or elevated intact PTH levels** during hypercalcemia. When this combination is present in an asymptomatic patient then further investigation is usually unnecessary.
- Established hypercalcemia in more than one serum measurement accompanied by elevated immunoreactive PTH is characteristic (iPTH).
- **Correction of serum calcium concentrations:** It should be corrected to the prevailing serum albumin concentration. Calcium level is corrected for low albumin levels by adding 0.8 mg/dL to the total serum calcium level for every 1.0 g/dL by which the serum albumin concentration is lower than 4 g/dL.
- May be associated with mild hyperchloremic acidosis.
- Renal function tests.

### *Urine investigations*

- **Hypercalciuria** (>300 mg/24 hours): Observed in ~30% of patients.
- **Increased markers of bone resorption:** These include urinary pyridinoline, deoxypyridinoline and N-telopeptide of collagen.

### *EKG findings*

- Shortened QT interval.
- Rarely cardiac arrhythmias.

### *Radiological abnormalities*

- Most sensitive and specific radiologic finding of **osteitis fibrosa cystica** is **subperiosteal resorption of cortical bone**, best seen in high-resolution

films of the phalanges.

- A similar process in the **skull** leads to a **salt-and-pepper appearance**.
- Bone cysts or **brown tumors** may be evident as osteolytic lesions.
- The other important skeletal consequence of hyperparathyroidism is **osteoporosis**. Unlike other osteoporotic disorders, hyperparathyroidism often results in the preferential loss of cortical bone.
- Dental films may disclose loss of the lamina dura of the teeth, but this is a nonspecific finding also seen in periodontal disease.
- **Nephrocalcinosis**: Appear as scattered opacities within the renal outline.
- **Soft tissue calcification**: For example, calcification of arterial wall.

**Dual-energy X-ray absorptiometry (DEXA) and CT scan**: Reveal reduced bone density.

**Investigations for localization of the tumor**: Parathyroid imaging is generally indicated only for patients who have undergone previous parathyroid surgery. Investigations to localize the tumor include:

- High-resolution ultrasonography, CT scanning and subtraction imaging and scintigraphy with technetium 99 sestamibi.
- Selective neck vein catheterization with PTH estimation.

## Hypercalcemia

**Treatment** of hyperparathyroidism is presented in Box 2.16.

### **Q. Write short essay/note on hypercalcemia.**

- Normal serum calcium level is 8–10 mg/dL (2.0–2.5 mmol/L) and normal ionized calcium levels are 4–5.6 mg/dL (1–1.4 mmol/L).
- Raised calcium level is known as hypercalcemia. Hypercalcemia is considered as mild if the total serum calcium level is between 10.5 and 12 mg/dL (2.6–3 mmol/L) and severe when the level is above 14 mg/dL.
- Hypercalcemia is one of the most common biochemical abnormalities. It is often detected incidentally during routine biochemical investigation in asymptomatic patients. However, it can present with chronic symptoms and occasionally as an acute emergency.

**Box 2.16**: Treatment of hyperparathyroidism.

---

#### **PRIMARY HYPERPARATHYROIDISM**

##### **Medical Management**

1. Treatment of hypercalcemia (discussed below)
2. Bisphosphonates—alendronate
3. Calcimimetics—Cinacalcet (activate the calcium-sensing receptor in the parathyroid gland, thereby inhibiting PTH secretion)
4. Estrogen- progesterone, raloxifene, denosumab

#### **Indications for Surgery: Parathyroidectomy**

1. Symptomatic patients (nephrolithiasis, symptomatic hypercalcemia)
2. Asymptomatic patients with
  - Serum calcium concentration of 1.0 mg/dL or more above the upper limit of normal.
  - Skeletal indications
    - Bone density at the hip, lumbar spine, or distal radius that is > 2.5 standard deviations below peak bone mass (T-score <-2.5).
    - Previous asymptomatic vertebral fractures
  - Renal indications
    - ◆ Estimated glomerular filtration rate (eGFR) <60 mL/min.
    - ◆ Twenty-four-hour urinary calcium >400 mg/day
    - ◆ Nephrolithiasis or nephrocalcinosis by radiograph, ultrasound, or CT.
  - Age <50 years

#### **SECONDARY HYPERPARATHYROIDISM**

- Treatment of chronic kidney disease (CKD)
- Supplement calcium and vitamin D

#### **TERTIARY HYPERPARATHYROIDISM**

No specific treatment

## ***Causes of Hypercalcemia (Table 2.13)***

**Q. Write short essay/note on causes of hypercalcemia.**

**Table 2.13: Causes of hypercalcemia.**

<p><b>Parathyroid hormone related with normal or elevated PTH levels</b></p> <ul style="list-style-type: none"> <li>• Primary hyperparathyroidism (commonest) or tertiary hyperparathyroidism</li> <li>• Lithium therapy—induced hyperparathyroidism</li> <li>• Familial hypercalciuric hypercalcemia</li> </ul>	<p><b>Vitamin D related with low PTH levels</b></p> <ul style="list-style-type: none"> <li>• Vitamin D intoxication: Iatrogenic or self-administered excess</li> <li>• Granulomatous diseases (sarcoidosis, tuberculosis, berylliosis)</li> <li>• Lymphoma</li> <li>• Idiopathic hypercalcemia of infancy</li> </ul>
<p><b>Malignancy related with low PTH levels (second commonest cause)</b></p> <ul style="list-style-type: none"> <li>• Multiple myeloma</li> <li>• PTH related protein secretion: Tumors of lung and kidney</li> <li>• Secondary deposits in bone: Breast carcinoma</li> </ul>	<p><b>High bone turnover</b></p> <ul style="list-style-type: none"> <li>• Long-term immobilization</li> <li>• Hyperthyroidism</li> <li>• Drugs: For example, thiazide diuretics</li> <li>• Paget’s disease with immobilization</li> </ul>

- Production of osteoclastic factors by tumors

#### Associated with renal failure

- Secondary hyperparathyroidism
- Aluminum intoxication

#### Excessive calcium intake

Milk-alkali syndrome

## Clinical Features

(refer clinical features of hyperparathyroidism above pages 55-6).

### Q. Write short essay/note on the management of hypercalcemia.

#### Management

Treatment of acute hypercalcemia

- **Adequate rehydration** is essential, usually at least 4–6 L of 0.9% saline on day 1, and 3–4 L for several days thereafter.
- **Intravenous bisphosphonate** is the treatment of choice for hypercalcemia of malignancy or of undiagnosed cause. Pamidronate is preferred (15–60 mg as an intravenous infusion in 0.9% saline or dextrose over 2–8 hours).
- **Calcitonin** (200 units IV 6-hourly)
- **Prednisolone** (30–60 mg daily) is effective in few instances (e.g. in myeloma, sarcoidosis and vitamin D excess).
- Oral phosphate (sodium cellulose phosphate) 5 g three times daily.

#### General measures

- **Diuretics after correction of volume:** For example, furosemide 40–160 mg/day or ethacrynic acid 50–200 mg/day. Forced diuresis with 4–6 L of intravenous fluid/day and furosemide 2 hourly. Sodium, potassium and magnesium should be supplemented.

Saline decreases concomitant reabsorption of sodium and calcium in both the proximal and distal renal tubules, and enhances urinary excretion of calcium.

- **Mithramycin** 10–25 µg/kg intravenously over 6 hours for 3–8 days.

Special therapies in few selected cases

- Malignancy induced hypercalcemia: Indomethacin 25 mg 6 hourly orally in few cases.
- Hemodialysis with a low-calcium bath.

## Hypoparathyroidism

### Q. Write short note on causes and general management of hypoparathyroidism.

Deficient secretion of PTH which manifests itself biochemically by

- Hypocalcemia
- Hyperphosphatemia
- Diminished or absent circulating iPTH and

- Clinically the symptoms of neuromuscular hyperactivity.

### ***Causes of Hypoparathyroidism***

- **Surgical hypoparathyroidism:** Commonest. It may be due to the removal of the parathyroid glands or due to interruption of blood supply to the parathyroid glands.
- **Idiopathic hypoparathyroidism**
  - Occurs at an **early age** (genetic origin) with autosomal recessive mode of transmission ‘multiple endocrine deficiency –autoimmune-candidiasis (MEDAC) syndrome’
  - ‘Juvenile familial endocrinopathy’—‘Hypoparathyroidism—Addison’s disease—mucocutaneous candidiasis (HAM) syndrome’
  - Circulating antibodies for the parathyroid glands and the adrenals are frequently present.
  - Other associated disease: Pernicious anemia, ovarian failure, autoimmune thyroiditis, diabetes mellitus.
- Infantile hypoparathyroidism.
- Pseudohypoparathyroidism (resistance to PTH).
- **Functional hypoparathyroidism:** In patients who has chronic hypomagnesemia of various causes. Magnesium is necessary for the PTH release from the glands and also for the peripheral action of the PTH.
- **DiGeorge syndrome** is a familial condition where the hypoparathyroidism is associated with intellectual impairment, cataracts and calcified basal ganglia, and occasionally with specific autoimmune disease.

**Dental manifestation:** Abnormal enamel formation with delayed or absent dental eruption and defective dental root formation.

**Malabsorption syndrome:** Presumably secondary to decreased calcium level and may lead to steatorrhea with long standing untreated disease.

**Chronic hypoparathyroidism:** Lethargy, weakness, fatigue, thin and patchy hair, brittle nails, dry and scaly skin, personality changes, cataracts, permanent brain damage.

**Other clinical manifestation:** Posterior lenticular cataract.

**Treatment of hypoparathyroidism**

- **During acute phase: Calcium** is given intravenously as for tetany (refer page 59).
- **Substitution therapy:** 1- $\alpha$ -hydroxycholecalciferol (alfacalcidol) or 1, 25 dihydroxycholecalciferol (calcitriol) at a dose of 0.25–2  $\mu$ g/day.

## Tetany

It is characterized by muscle spasms due to increased excitability of peripheral nerves.

### Causes of Tetany (Table 2.14)

**Q. Write short essay/note on causes of tetany/ hypocalcemia.**

Tetany is caused due to hypocalcemia or alkalosis or hypomagnesemia.

**Table 2.14: Causes of tetany.**

<b>Due to hypocalcemia</b>	
<b>Increased phosphate levels</b> <ul style="list-style-type: none"> <li>• Chronic renal failure (common)</li> <li>• Phosphate therapy</li> </ul>	<b>Vitamin D deficiency</b> <ul style="list-style-type: none"> <li>• Osteomalacia/rickets</li> <li>• Vitamin D resistance</li> </ul>
<b>Hypoparathyroidism</b> <ul style="list-style-type: none"> <li>• Surgical—after neck exploration (thyroidectomy, parathyroidectomy—common)</li> <li>• Congenital deficiency (DiGeorge syndrome)</li> <li>• Idiopathic hypoparathyroidism (rare)</li> <li>• Severe hypomagnesemia</li> </ul>	<b>Others</b> <ul style="list-style-type: none"> <li>• Acute pancreatitis (quite common)</li> <li>• Citrated blood in massive transfusion (not uncommon)</li> <li>• Low plasma albumin, e.g. malnutrition, chronic liver disease</li> <li>• Malabsorption, e.g. celiac disease</li> </ul>
<b>Resistance to PTH</b> Pseudohypoparathyroidism	<b>Drugs</b> <ul style="list-style-type: none"> <li>• Calcitonin</li> <li>• Bisphosphonates</li> </ul>
<b>Due to alkalosis</b>	
<ul style="list-style-type: none"> <li>• Repeated vomiting of gastric juice</li> <li>• Excessive intake of oral alkali</li> </ul>	<ul style="list-style-type: none"> <li>• Hyperventilation, e.g. hysteria</li> <li>• Primary hyperaldosteronism</li> </ul>
<b>Due to hypomagnesemia</b>	

## Clinical Features

**Q. Write short essay/note on clinical features of tetany.**

### Neuromuscular

- **In children:** Characteristic **triad of carpopedal spasm, stridor and**

**convulsions.** Carpal spasm is characterized by flexion of the metacarpophalangeal joints, extension of the interphalangeal joints and opposition of the thumb (main d'accoucheur).

- **In adults: Tingling in the hands, feet** and around the mouth (**circumoral paresthesia**).
- **Latent tetany:** In this signs of overt tetany are lacking. Tests for recognizing latent tetani are:

**Q. Write short note on Chvostek's sign and Trousseau's sign.**

1. **Chvostek's sign:** It is elicited by tapping the skin over the facial nerve in front of the external auditory meatus. It causes an ipsilateral contraction of the facial muscles, but up to 10% of population has a positive test.
2. **Trousseau's sign:** Inflate BP cuff on arm to 20 mm Hg > systolic BP for 3–5 min and watch for carpopedal spasm (flexion at the wrist, flexion at the metatarsophalangeal (MP) joints, extension of the interphalangeal (IP) joints adduction thumbs/fingers).

**Cardiac manifestation:** Prolonged QT interval in the ECG, resistance to digitalis, hypotension, refractory heart failure with cardiomegaly can occur (Fig. 2.12).

**Q. Write short essay/note on management of tetany.**

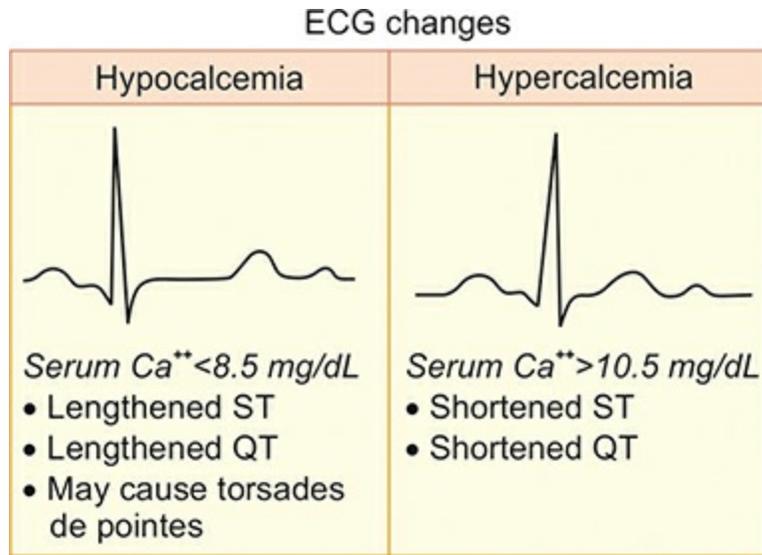

**Treatment**

Control of tetany

- **Calcium gluconate:** Slow intravenous (over 10 min) injection of 20 mL of 10% solution of calcium gluconate is rapidly effective in controlling the tetany.
- **Magnesium:** If tetany is not relieved by above treatment, administration of magnesium may be necessary.

Correction of alkalosis

- If alkalosis is due to persistent vomiting, treat with intravenous isotonic saline and potassium.
- In alkalosis is due to alkali excess, it should be withdrawn. If needed, ammonium chloride 2 g 4 hourly orally will control tetany.
- **Hysterical hyperventilation:** It may be controlled by rebreathing expired air from a suitable bag or inhalation of 5% carbon dioxide in oxygen.

**Fig. 2.12:** ECG changes in hypo/hypercalcemia.

## Pseudohypoparathyroidism (PHP)

- PHP is an inherited disorder of target-organ unresponsiveness to PTH.
- It mimics hormone-deficient forms of hypoparathyroidism, with hypocalcemia and hyperphosphatemia, but the PTH level is elevated.

### *Clinical Features*

**PHP type IB** is a disorder of isolated resistance to PTH, which presents with the biochemical features of hypocalcemia, hyperphosphatemia and secondary hyperparathyroidism.

**PHP type IA** has, in addition to these biochemical features, a characteristic somatic phenotype known as **Albright's hereditary osteodystrophy (AHO)** (**Figs. 2.13A to C**). This consists of short stature, round face, short neck, brachydactyly, shortened metatarsals, subcutaneous ossifications and mental retardation. Because of shortening of the metacarpal bones—most often the fourth and fifth metacarpals—affected digits have a dimple, instead of a knuckle, when a fist is made.

Certain individuals in families with PHP inherit the somatic phenotype of AHO without any disorder of calcium metabolism; this state is called **pseudopseudohypoparathyroidism or PPHP**.

**Figs. 2.13A to C:** Albright's hereditary osteodystrophy (AHO): (A) Brachydactyly; (B) Shortened metatarsals; (C) X-ray of knee region.

## ADRENAL GLAND DISORDERS

### Hormones Secreted by the Adrenal Gland (Table 2.15)

**Q.** Write short note on hormones secreted by the adrenal gland.

**Table 2.15:** Various hormones secreted by adrenal gland.

Site	Category	Hormone produced
Adrenal cortex		
• Zona glomerulosa	Mineralocorticoid	Aldosterone
• Zona fasciculata	Glucocorticoid	Cortisol
• Zona reticularis	Androgens	<ul style="list-style-type: none"> <li>• Dehydroepiandrosterone sulfate</li> <li>• Dehydroepiandrosterone</li> <li>• Androstenedione</li> </ul>
Adrenal medulla	Catecholamines	<ul style="list-style-type: none"> <li>• Adrenaline</li> <li>• Noradrenaline</li> </ul>

### Cushing's Syndrome

**Q.** Write short essay on causes, clinical features, investigations and management of Cushing's syndrome.

**Cushing's syndrome** is the term used to describe the **clinical state of increased free circulating glucocorticoid**.

- It occurs *most often following the therapeutic administration of synthetic steroids* or ACTH.

**Q. Write short essay on Cushing's disease.**

- **Cushing's disease** results from corticosteroid excess due to **pituitary dependent bilateral adrenal hyperplasia**. The pituitary tumors producing Cushing's disease are usually microadenomas (<10 mm in size) which usually do not cause symptoms by local mass effect. It usually develops sporadically but may be a component of multiple endocrine neoplasia type 1.
- All the spontaneous forms of the syndrome are rare.

***Causes of Cushing's Syndrome (Table 2.16)***

**Common causes of ectopic ACTH secretion (Box 2.17)**

A cushingoid appearance can be caused by excess alcohol consumption (pseudo-Cushing's syndrome)—the pathophysiology is poorly understood.

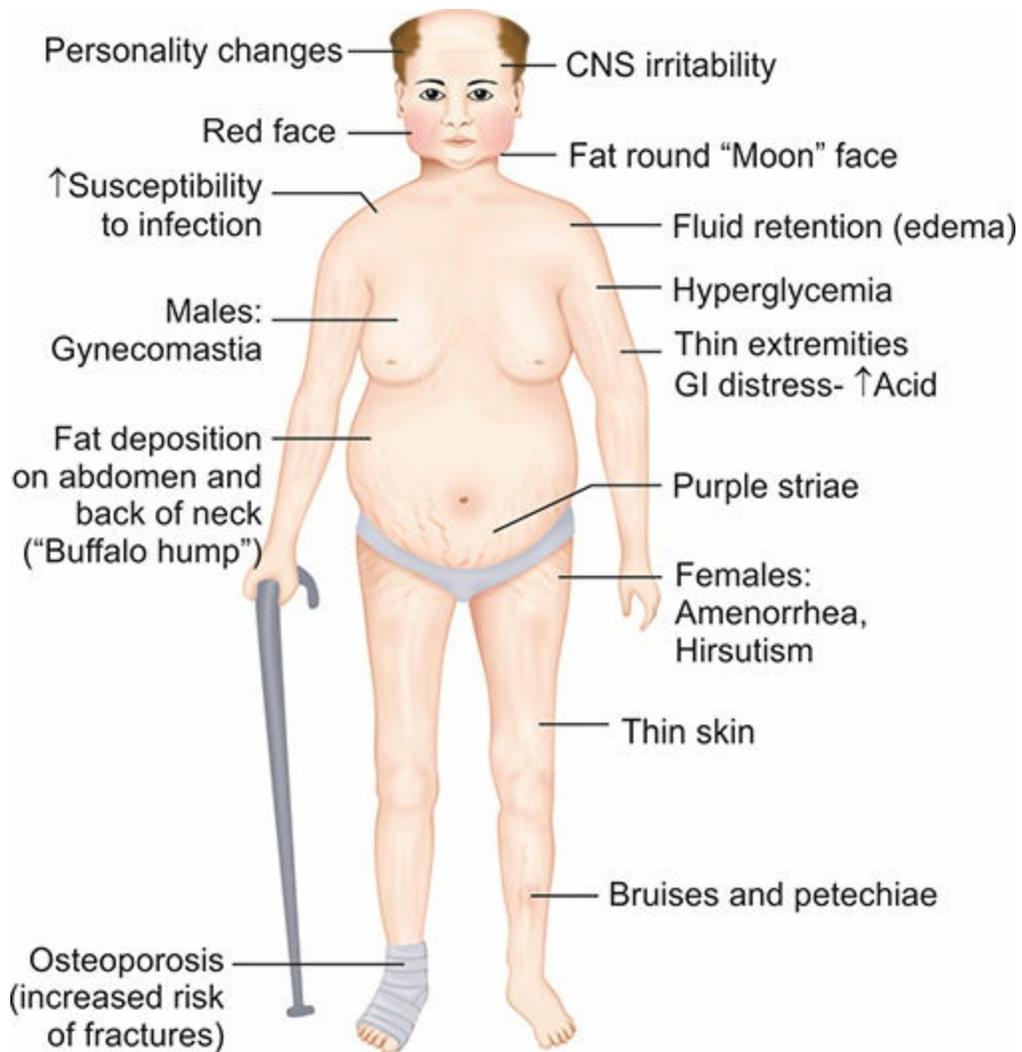

**Box 2.17:** Common causes of ectopic ACTH secretion.

<i>Type of tumor</i>	<i>Percentage</i>
Small cell carcinoma of the lung	50%
Endocrine tumors of foregut origin	35%
• Thymic carcinoid	
• Pancreatic islet cell tumor	
• Medullary carcinoma thyroid	
• Bronchial carcinoid	
Pheochromocytoma	5%
Ovarian tumors	2%

***Clinical Features (Figs. 2.14, 2.15, Table 2.17 and Box 2.18)***

**Q. Write short essay on major signs of Cushing's syndrome.**

- Systemic fungal infections and tinea versicolor may develop in untreated patients.
- Higher risk of coronary artery disease and venous thrombosis.
- The predominant clinical features of Cushing's syndrome are those of glucocorticoid excess.

**Fig. 2.14:** Clinical features of Cushing's syndrome.

**Figs. 2.15A to D:** Features of Cushing's syndrome: (A) Cushing's habitus, obesity and moon facies; (B) Buffalo hump;(C and D) Pigmented striae.

**Table 2.16: Causes of Cushing's syndrome.**

<i>ACTH-dependent causes</i>	<i>ACTH-independent causes 25%</i>
<ul style="list-style-type: none"> <li>• ACTH-secreting pituitary tumor (<b>Cushing's disease</b>)— 65%</li> <li>• Pituitary CRH-secreting neoplasm (ectopic CRP syndrome)</li> <li>• Nonpituitary ACTH-secreting neoplasm (ectopic ACTH syndrome)—10%</li> </ul>	<ul style="list-style-type: none"> <li>• Adrenal adenoma</li> <li>• Adrenal carcinoma</li> <li>• Micronodular adrenal disease</li> <li>• McCune-Albright syndrome</li> <li>• Massive macronodular adrenal disease</li> <li>• Iatrogenic (use of corticosteroids)</li> </ul>

**Table 2.17: Clinical features of Cushing's syndrome (% prevalence).**

--	--	--

<i>Clinical feature</i>	<i>Prevalence</i>	<i>Cause</i>
<b>General</b>		
Weight gain/obesity	90%	Accumulation of fat and retention of fluid
Central obesity ('lemon on match-stick')		Centripetal distribution of fat
Buffalo hump		Fat accumulation at the lower part of neck
Moon face		Rounded plethoric appearance
Hypertension	85%	Increase in plasma volume and sodium retention
<b>Skin</b>		
Hirsutism	70–75%	Increased secretion of adrenal androgen
Plethoric appearance		Thinning of the skin
Purplish striae over abdomen, buttocks and thighs		Thinning of the skin from collagen breakdown
Bruising		Thinning of blood vessels from collagen breakdown
<b>Musculoskeletal</b>		
Back pain	80%	Osteopenia, osteoporosis and vertebral compression fractures
Muscle weakness	65%	Proximal myopathy and <b>hypokalemia</b> . Loss of protein in muscle
<b>Gonadal dysfunction</b>		
Menstrual disorders (oligomenorrhea, amenorrhea), decreased libido and impotence	70–85%	Gonadal dysfunction
<b>Neuropsychiatric</b>		
Emotional lability, depression, euphoria, psychosis, irritability	85%	
<b>Metabolic</b>		
Glucose intolerance	75%	Metabolic abnormalities
Diabetes	20%	
Hyperlipidemia	70%	
Polyuria	30%	
Kidney stones	15%	

- Skin pigmentation occurs only with ACTH-dependent causes.

- Impaired glucose tolerance or frank diabetes is common, especially in the ectopic ACTH syndrome.
- Hypokalemia due to the mineralocorticoid activity of cortisol is common with ectopic ACTH secretion.
- Proximal muscle weakness, sleep apnea, osteoporosis, hypertension are common features of the disease.

*Features of Cushing's syndrome due to ectopic ACTH secretion*

- Impaired glucose tolerance due to gluconeogenesis.
- Hypokalemic alkalosis due to the mineralocorticoid activity of cortisol.
- Skin pigmentation.

### ***Investigations in Cushing's Syndrome (Fig. 2.16)***

**Box 2.18:** Mnemonic for Cushing's syndrome.

- C** Central obesity, **C**ollagen fiber weakness, **C**omedones (acne)
- U** Urinary free cortisol increased along with glucose
- S** Striae, **S**uppressed immunity
- H** **H**ypercortisolism, **H**ypertension, **H**yperglycemia, **H**ypercholesterolemia
- I** **I**atrogenic due to administration of corticosteroids
- N** **N**on-iatrogenic, **N**eoplasms
- G** **G**lucose intolerance, **G**rowth retardation

There are two phases of the investigation:

1. Confirmation of the presence or absence of Cushing's syndrome.
2. Differential diagnosis of its cause (e.g. pituitary, adrenal or ectopic).
  - Most obese, hirsute, hypertensive patients do not have Cushing's syndrome
  - Some cases of mild Cushing's have relatively subtle clinical signs.
  - Confirmation rests on demonstrating inappropriate cortisol secretion, not suppressed by exogenous glucocorticoids
  - Random cortisol measurements are of no value.

## Confirmatory tests to establish the presence of Cushing's syndrome

- **48-hour low-dose dexamethasone test:** Normal individuals suppress plasma cortisol to  $<50$  nmol/L. Patients with Cushing's syndrome fail to show complete suppression of plasma cortisol levels. This test is **highly sensitive** ( $>97\%$ ).

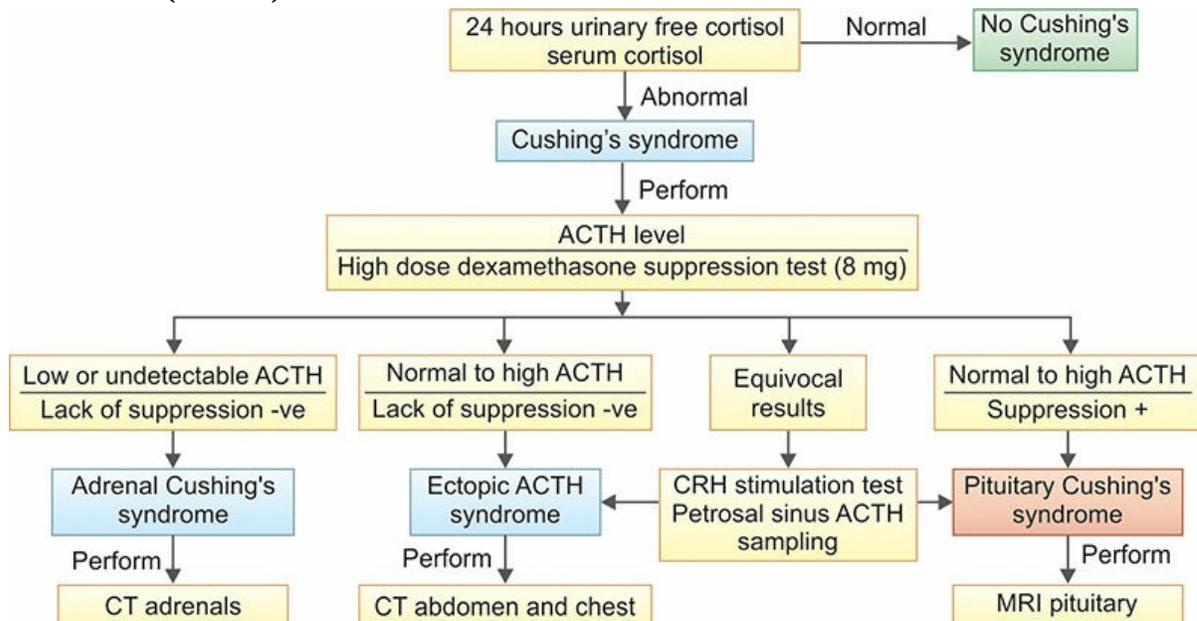

Fig. 2.16: Algorithm of Cushing's syndrome.

- **24-hour urinary free cortisol measurements:** This is simple, but less reliable—repeatedly normal values (corrected for body mass) render the diagnosis most unlikely, but some patients with Cushing's have normal values on some collections (approximately 10%).
- **Plasma cortisol levels:** In normal individuals, measurement of plasma cortisol levels at 8 AM and 12 midnight will show the lowest levels at midnight. This circadian rhythm is lost in Cushing's syndrome and the cortisol levels remain the same throughout the day. A midnight level below  $1.8$   $\mu\text{g/dL}$  is normal, and has a high sensitivity for excluding Cushing's syndrome. However, it has a low specificity.
- **Overnight dexamethasone suppression test**
- **Low dose dexamethasone suppression test**
- **Late-night salivary cortisol:** It may be used as a screening test for Cushing's syndrome. Concentration of cortisol in saliva is highly

correlated with free plasma cortisol, irrespective of salivary flow rates and stable at room temperature for 1 week.

### Tests that establish the cause of Cushing’s syndrome

- **Plasma ACTH level at 8 AM** (Table 2.18)
- **High-dose dexamethasone suppression test** (Table 2.19)
- **Plasma potassium levels**
  - Normal in **pituitary dependent disease** and tumors of adrenal gland.
  - Low (3.5 mmol/L) in **ectopic ACTH syndrome**.
- **ACTH/cortisol response to corticotrophin-releasing factor (CRF)**.
  - Increased in pituitary dependent disease
  - Unchanged in ectopic ACTH syndrome and tumors of adrenal gland
- **Bilateral inferior petrosal sinus sampling for ACTH before and after CRF stimulation.**

### Other investigations

- **Biochemical investigations:** Blood glucose, cholesterol and LDL may be raised.
- **Radiological investigations**
  - **Plain radiograph** of the skull. Radiograph of chest to detect lung cancer.
  - **CT scan** of anterior mediastinum, upper abdomen and pancreas to rule out tumors.
  - **CT/MRI** head and MRI abdomen.

**Table 2.18:** Interpretation of plasma ACTH level at 8 AM.

<i>Level of plasma ACTH</i>	<i>Probable source of ACTH as</i>
Normal levels (10–80 ng/L)	Pituitary
Intermediate values (80–300 ng/L)	Pituitary dependent disease or ectopic ACTH syndrome
Very high levels (>300 ng/L)	Ectopic ACTH syndrome
Low ACTH (<10 ng/L)	Adrenal tumors, macronodular adrenal hyperplasia or exogenous steroid administration

**Table 2.19:** Tests in Cushing’s syndrome.

<i>Test and protocol</i>	<i>Measure</i>	<i>Normal test result or positive suppression</i>	<i>Use and explanation</i>
<b>Dexamethasone (for Cushing's)</b>			
<b>Overnight</b>			
Take 1 mg on going to bed at 23:00 h	Plasma cortisol at 09:00 h next morning	Plasma cortisol <100 nmol/L	Outpatient screening test. Some 'false positives'
<b>'Low-dose'</b>			
0.5 mg 6-hourly Eight doses from 09:00 h on day 0	Plasma cortisol at 09:00 h on days 0 and +2	Plasma cortisol < 50 nmol/L on second sample	For diagnosis of Cushing's syndrome
<b>'High-dose' used in differential diagnosis</b>			
2 mg 6-hourly Eight doses from 09:00 h on day 0	Plasma cortisol at 09:00 h on days 0 and +2	Plasma cortisol on day +2 less than 50% of that on day 0 suggests pituitary-dependent disease	Differential diagnosis of Cushing's syndrome Pituitary-dependent disease suppresses in about 90% of cases

## Management

### 1. Adrenal tumors

#### – Surgical resection

- ◆ **Adrenal adenomas:** Surgical removal. Postoperatively, prednisolone is given as a replacement therapy till the contralateral adrenal, hypothalamus and pituitary recovers.
- ◆ **Adrenal carcinomas:** Surgical resection, irradiation of tumor bed and administration of adrenolytic drug (mitotane).

#### – Medical adrenalectomy: Medications that inhibit steroidogenesis include ketoconazole, metyrapone, mitotane, aminoglutethimide and octeotide

### 2. Cushing's disease

#### – Treatment of choice: Trans-sphenoidal **removal of the tumor.**

#### – Radiotherapy and radiosurgery for recurrent or residual ACTH- secreting tumors. External pituitary irradiation alone is slow acting and useful in only 50–60% of cases.

#### – Medical therapy to reduce ACTH (e.g. bromocriptine): Rarely effective

#### – Bilateral adrenalectomy:

- ◆ Done if the diagnosis is uncertain. Followed by pituitary irradiation with Yttrium-90 implantation to prevent the development of Nelson's syndrome.
- ◆ Prednisolone and fludrocortisones should be given post-operatively for a variable length of time.

### 3. Ectopic ACTH syndrome

#### – Surgical removal of benign tumors (e.g. bronchial carcinoid).

#### – Radiotherapy and chemotherapy: For malignant tumors.

- Recurrent tumors may be treated with metyrapone or aminoglutethimide.

## Box 2.19: Medical therapy of hypercortisolism.

## INDICATIONS

- Management of hypercortisolism when surgery is contraindicated
- Control of hypercortisolism in preparation for surgery or awaiting radiation
- Persistence or recurrence of hypercortisolism after surgery
- Treatment of occult ectopic ACTH syndrome

## MEDICAL THERAPY

### Adrenal Enzyme Inhibitors

#### Oral Drugs

- Ketoconazole: 200–400 mg thrice daily
- Metyrapone: 600–4500 mg/day

#### Intravenous Etomidate

#### Adrenolytic Agents

- Mitotane 0.5–3 g/day

#### Other Agents

#### Drugs that Target Pituitary

- Cabergoline
- Pasireotide (somatostatin analog)

#### Glucocorticoid-Receptor Antagonists (mifepristone)

Medical therapy of hypercortisolism is mentioned in Box 2.19.

## Nelson's Syndrome

### **Q. Write short note on Nelson's syndrome.**

- Nelson's syndrome is **increased pigmentation** (because of high levels of ACTH) associated with an enlarging pituitary tumor post- bilateral adrenalectomy.
- It occurs in about 20% of cases after bilateral adrenalectomy for Cushing's disease.
- The syndrome is rare now that adrenalectomy is an uncommon primary treatment, and its incidence may be reduced by pituitary radiotherapy soon after adrenalectomy.
- *Treatment:* Nelson's adenoma may be treated by pituitary surgery and/or radiotherapy.

## Hyperaldosteronism

### **Q. Write short essay on:**

- **Etiology, clinical features, diagnosis and management of primary hyperaldosteronism.**

- **Conn's syndrome.**

Excessive production of the aldosterone hormone is called hyperaldosteronism.

### ***Classification***

- **Primary hyperaldosteronism:** Develops due to an abnormality in the zona glomerulosa of the adrenal gland.
- **Secondary hyperaldosteronism:** Develops due to the stimulation of aldosterone secretion by angiotensin II following activation of renin-angiotensin system.

### ***Primary Hyperaldosteronism***

#### *Etiology*

- Adrenal adenoma (**Conn's syndrome**)
- Bilateral hyperplasia of zona glomerulosa
- Idiopathic
- ACTH dependent (glucocorticoid-responsive or dexamethasone-suppressible): This is characterized by secretion of aldosterone under ACTH control. Therefore, treatment consists of administration of glucocorticoids to suppress release of ACTH.

**Consequences:** Excess secretion of aldosterone results in **sodium retention, potassium loss and metabolic alkalosis.**

#### *Clinical features*

- **Hypertension:** Most important clinical consequence of hyperaldosteronism
- **Tetany** due to metabolic alkalosis
- **Muscle weakness** due to hypokalemia.
- **Polyuria and polydipsia** due to nephrogenic DI.

### ***Investigations***

#### *Investigation for diagnosis*

- **Hypokalemia:** However, normal serum potassium does not exclude the diagnosis.
- **Urinary potassium loss:** Levels >30 mEq/day during hypokalemia are

inappropriate

- **Plasma aldosterone concentration (PAC):** Elevated ( $>15$  ng/dL) and is not suppressed with 0.9% saline infusion (2 L over 4 hours) or flurocortisone administration.
- **Suppressed plasma renin activity (PRA)** or immunoreactivity.
- **PAC: PRA ratio (*Plasma aldosterone: renin ratio (ARR)*):** Used as the screening test for primary hyperaldosteronism. A level above 20 is abnormal when plasma aldosterone is measured in ng/dL and PRA is measured in ng/mL/min.
- **Confirmatory aldosterone suppression test**
- Others
  - **Oral salt loading test:** Suppression of aldosterone below 8.5 ng/dL rules out primary hyperaldosteronism.
  - Saline infusion test
  - **Oral captopril test:** In primary hyperaldosteronism, this test does not produce any significant decrease in PAC.

#### *Investigation for differential diagnosis*

- **CT/MRI scanning:** To detect adenoma and hyperplasia. Scanning of the adrenal with selenium-75 cholesterol to detect an adenoma.
- **Adrenal vein catheterization:** To detect hypersecretion of aldosterone.
  - Unilateral hypersecretion in adenoma.
  - Bilateral hypersecretion in hyperplasia.
- **Dexamethasone suppression.**
  - Lowers plasma aldosterone transiently in adenoma.
  - Prolonged suppression in glucocorticoid sensitive hyperaldosteronism.
- **Measurement of 18-OH-cortisol levels.**
  - Very high levels observed in adenomas and glucocorticoid-responsive hyperplasia.
  - Slightly raised in idiopathic hyperplasia.

#### **Management of primary hyperaldosteronism**

- **Potassium ( $K^+$ ) supplementation**
- **Definitive treatment:** Adrenalectomy, bilateral if multiple tumors are present.
- **Aldosterone antagonists:** Spironolactone and eplerenone are useful in patients where surgery

cannot be performed. High dose of spironolactone (up to 400 mg/day) may be required. A few patients may develop gynecomastia with spironolactone and the incidence is lower with eplerenone. Amiloride (10–40 mg/day) may also be tried.

### **Box 2.20:** Causes of secondary hyperaldosteronism.

#### **Physiological:**

- Salt depletion from inadequate intake or excessive loss through kidney or gastrointestinal tract
- Pregnancy (due to estrogen-induced increases in plasma renin substrate)

#### **Pathological:**

- Inadequate renal perfusion: Excessive diuretic therapy, nephrotic syndrome, liver failure, congestive cardiac failure, Bartter's syndrome accelerated or malignant phase of hypertension, severe renal artery stenosis
- Renin-secreting renal tumor (very rare)

## ***Secondary Hyperaldosteronism***

### **Q. Write short note on secondary hyperaldosteronism.**

Secondary hyperaldosteronism is secondary to an extra-adrenal cause. The aldosterone release occurs in response to activation of the renin-angiotensin system. It is characterized by *increased levels of plasma renin* that stimulates the zona glomerulosa.

*Causes of secondary hyperaldosteronism (Box 2.20)*

## **Adrenocortical Insufficiency**

### ***Classification and Causes (Box 2.21)***

#### **Q. Write a short essay/note on classification and causes of adrenocortical insufficiency.**

#### **Q. Write short essay/note on etiology and clinical features of Addison's disease.**

Adrenocortical insufficiency, or hypofunction, may be due to primary adrenal disease (primary hypoadrenalism) or decreased stimulation of the adrenals due to a deficiency of ACTH (secondary hypoadrenalism).

## **Addison's Disease**

Addison's disease or chronic adrenocortical insufficiency is an uncommon disorder resulting from progressive destruction of the entire adrenal cortex.

*Clinical features of Addison's disease (Table 2.20 and Figs. 2.17A and B)*

**Q. Write a short essay/note on major clinical signs of Addison's disease.**

- Fatigue and weight loss are the most prominent symptoms.
- Clinical features are produced due to the deficiency of glucocorticoid, mineralocorticoid and androgen as well as excess of ACTH.
- Primary adrenal failure may present
  - Acute with hypotension and acute circulatory failure (Addisonian crisis); or
  - Chronic with vague features of ill health, sometimes including gastrointestinal symptoms, features suggestive of postural hypotension, and salt craving.
- Skin pigmentation is nearly always present in primary adrenal insufficiency (but not in secondary).
- **Cardinal features of Addison's disease:** Hypotension, pigmentation and previous history of acute adrenal crisis following stress, or slow recovery from illness.
- **Other autoimmune diseases associated with Addison's disease:** Hashimoto's thyroiditis, primary atrophic hypothyroidism, pernicious anemia, type 1 diabetes mellitus, primary ovarian failure and hypoparathyroidism.
- **Type II polyglandular autoimmune syndrome** is characterized by the association of two or more of the above endocrinopathies.
- **Type I polyglandular autoimmune syndrome** is the combination of adrenal insufficiency, hypoparathyroidism and chronic mucocutaneous candidiasis.
- **Type II polyglandular autoimmune syndrome/Schmidt syndrome** is the association of Addison's disease and Hashimoto's thyroiditis.

**Box 2.21:** Causes of adrenocortical insufficiency.

**Primary adrenocortical insufficiency (adrenal causes)**

- **Autoimmune adrenal insufficiency**
- **Metastatic malignancy** (Lung, breast, stomach carcinomas) or lymphoma
- Adrenal hemorrhage
  - Waterhouse-Friderichsen syndrome
  - Anticoagulation therapy

- Infectious: **Tuberculosis**, CMV, fungi (histoplasmosis, coccidioidomycosis), HIV
- Adrenal infarction: APLA, SLE
- Adrenoleukodystrophy
- Infiltrative disorders: Amyloidosis, hemochromatosis, sarcoidosis
- Bilateral adrenalectomy
- Congenital adrenal hyperplasia
- Familial glucocorticoid deficiency and hypoplasia
- Drugs: Ketoconazole, metyrapone, aminoglutethimide, trilostane, mitotane, etomidate, rifampin, cyproterone acetate
- Autoimmune polyglandular syndrome 1 and 2
- Kearns-Sayre syndrome

**Secondary adrenocortical insufficiency (inadequate ACTH)**

- Exogenous glucocorticoid therapy
- Hypopituitarism: Selective removal Pituitary
- Pituitary apoplexy
- Granulomatous disease of pituitary (tuberculosis, sarcoidosis, eosinophilic granuloma)
- Secondary tumor deposits in pituitary (breast, bronchus)
- Postpartum pituitary infarction (Sheehan’s syndrome)
- Pituitary irradiation

**Box 2.22:** Three step process in the investigation of adrenocortical insufficiency.

1. Confirm adrenal insufficiency by demonstrating inappropriately low cortisol secretion
2. Determine whether the cortisol deficiency is primary or central AI
3. Determine the cause of the underlying disorder

*Investigations*

**Q. Write a short essay/note on biochemical abnormality in Addison’s disease.**

Box 2.22 lists the 3 step process in the investigation of adrenocortical insufficiency

**Table 2.20:** Clinical features of adrenocortical insufficiency.

<b>Glucocorticoid deficiency</b>	<b>Mineralocorticoid deficiency</b>	<b>Adrenal androgen deficiency</b>	<b>ACTH excess</b>
Fasting hypoglycemia	Hypotension	Decreased axillary hair in females	Pigmentation of exposed areas, pressure areas like elbows, knees and knuckles, palmar creases, mucous
Increased insulin sensitivity	Dizziness	Decreased pubic hair in females	

Muscle weakness	Salt craving	Loss of libido in females	membranes, conjunctive and recently acquired scars, perineum, axillae and areolae of breasts [due to increased production of pro-opiomelanocortin (POMC), that is cleaved into adrenocorticotrophic hormone (ACTH) and melanocyte-stimulating hormone (MSH)]
Morning headache	Weight loss	Asymptomatic-during prepuberty	
Increased production of POMC → increased melanin	Anorexia		
Increased pigmentation: palmar creases, gingival border, axilla	Electrolyte anomalies (hyponatremia, hyperkalemia, metabolic acidosis)		
Fatigue, malaise, weakness, weight loss, anorexia, nausea, vomiting, diarrhea or constipation, postural hypotension			

**Figs. 2.17A and B:** (A) Pigmentation of palms; (B) Oral pigmentation in Addison's disease.

- **08:00 AM cortisol level**
  - Levels less than 3  $\mu\text{g/dL}$  is suggestive of AI
  - Levels  $>11 \mu\text{g/dL}$  exclude AI
  - Random cortisol in ill patient  $\rightarrow 20 \mu\text{g/dL}$  reassuring.
- **Plasma ACTH level**

- Elevated in adrenal insufficiency.
- **ACTH stimulation test:** There is failure of rise in plasma cortisol level following the administration of 250 µg of synthetic ACTH.
  - Low dose (1 µg) test
    - ◆ Baseline and 30 minute cortisol levels
    - ◆ More physiological ACTH level/stimulation
    - ◆ Useful in central AI
    - ◆ Useful for assessing recovery after chronic steroid treatment.
  - High dose (250 µg) test
    - ◆ Baseline, 30 and 60 minute levels
    - ◆ Stronger stimulation than 1 µg test.
- **Other investigations:**
  - PRA is high and plasma aldosterone levels are low or normal.
  - **Radiograph:**
    - ◆ Tuberculous adrenalitis: Chest radiograph may show evidences of pulmonary tuberculosis
    - ◆ Plain radiograph of abdomen, CT scan and MRI scan may show calcification in the adrenal gland.
- **Adrenal autoantibodies:** ACA—adrenal cortex antibody and anti-21-OH-hydroxylase antibody
- Elevated blood urea, hyponatremia and hyperkalemia.
- **Blood sugar: Low levels.**
- **Peripheral blood:** Mild anemia, mild eosinophilia.
- Central AI: Evaluate for secretion of other pituitary hormones.

### Management

- **Primary adrenal insufficiency:**

#### Acute treatment:

- Normal saline for volume resuscitation
- Look for/treat hypoglycemia by 25% dextrose
- Steroids:
  - ◆ Loading dose: 50–100 mg/m<sup>2</sup> hydrocortisone IV/IM
  - ◆ Continue hydrocortisone with 50–100 mg/m<sup>2</sup>/day, divided 6th or 8th hourly
  - ◆ Long-term treatment:
    - ◇ **Daily glucocorticoid replacement (hydrocortisone):10–15 mg/m<sup>2</sup>/day in divided**

doses.

- ◇ Daily mineralocorticoid replacement: Fludrocortisone 0.05–0.2 mg daily

**Table 2.21:** Relative steroid potencies.

<i>Type of steroid</i>	<i>Glucocorticoid (GC)</i>	<i>Mineralocorticoid</i>
Hydrocortisone	1	++
Prednisone/Prednisolone	3 to 5	+
Methylprednisolone	5 to 6	0
Dexamethasone	25 to 50	0
Fludrocortisone	15 to 20	+++++

- **Relative steroid potencies (Table 2.21)**

- **Stress conditions**

- Primary goal is to avoid serious consequences of an adrenal crisis → always wear identification
- Illness:
  - ◆ Minor stress (e.g. sore throat, rhinorrhea, T (temperature) < 38°C) → may not require increase in dose
  - ◆ Moderate stress (e.g. severe URTI) → double the glucocorticoid (GC) replacement dose
  - ◆ Major stress (e.g. T > 38°C and/or vomiting), three to four times the GC replacement dose.
- **Surgery:**
  - ◆ During general anesthesia, +/- surgery, the GC requirements increases greatly
  - ◆ Dose equivalent to 100 to 150 mg hydrocortisone for major surgical procedures in divided doses.
  - ◆ Stress dosing is generally continued until the patient can tolerate oral intake, is afebrile, and is hemodynamically stable
- Tuberculous adrenalitis causing Addison's disease is treated with antituberculous chemotherapy.

## Acute Adrenal Crisis

### **Q. Write short note on acute adrenal crisis.**

Acute adrenal crisis is a state of acute adrenocortical insufficiency and occurs in patients with Addison's disease who are exposed to the stress of infection, trauma, surgery, or dehydration due to salt deprivation, vomiting, or diarrhea.

**Other causes:** Acute adrenal crisis can also develop after

- Bilateral adrenal infarction
- Bilateral adrenal hemorrhage: Adrenal hemorrhage and often death may

occur following meningococemia (Waterhouse-Friderichsen syndrome). It is rare with secondary adrenal insufficiency.

### ***Clinical Features***

- **Major manifestations:**

- Shock, but may present with non-specific symptoms such as weakness, fatigue, lethargy, anorexia, nausea, vomiting, abdominal pain, confusion or coma.
- Abdominal tenderness and fever

- **Crisis in patients with long-standing adrenal insufficiency:** Show features of chronic adrenal insufficiency and may show hyperpigmentation (due to chronic ACTH hypersecretion) weight loss, serum electrolyte abnormalities.

**Lab findings** that suggest the diagnosis of acute adrenal crisis: **hyponatremia, hyperkalemia, lymphocytosis, eosinophilia, and hypoglycemia.**

#### **Management**

- Start therapy as soon as acute adrenal crisis is suspected
- Correction of hypovolemia and sodium depletion with normal saline
- Infuse 5% dextrose solution if there is hypoglycemia. Administer hydrocortisone (100 mg IV bolus) OR dexamethasone (4 mg IV bolus)
- Administer hydrocortisone at the dose of 100 mg 6 hourly. Taper it over 26–48 hours to a maintenance dose once the underlying stress resolves
- Treat the precipitating cause.

### ***Equivalent Doses of Glucocorticoids (Table 2.22)***

- Compared to hydrocortisone, prednisolone has only 25% of mineralocorticoid activity (Table 2.23).
- Both dexamethasone and betamethasone have negligible mineralocorticoid activity.

**Table 2.22: Equivalent doses of glucocorticoids (anti-inflammatory potency).**

Hydrocortisone (cortisol)	20 mg	Methylprednisolone	4 mg
Cortisone acetate	25 mg	Betamethasone	0.75 mg

Prednisolone

5 mg

Dexamethasone

0.75 mg

## Role of Steroid Therapy

### *Common Indication and Contraindications of Steroids (Table 2.23)*

**Q. Write short note on the use and abuse of steroids/the present role of steroid therapy.**

**Table 2.23: Common indication and contraindications of steroids.**

<i>Common indication of steroids</i>	<i>Common contraindications of steroids</i>
<ul style="list-style-type: none"> <li>• Bronchial asthma</li> <li>• Raised intracranial tension</li> <li>• Cerebral edema</li> <li>• Connective tissue diseases (e.g. rheumatoid arthritis, SLE)</li> <li>• Nephrotic syndrome</li> <li>• Adrenal insufficiency</li> <li>• Shock, septicemia</li> <li>• Leukemia, lymphoma, as an adjunct in chemotherapy for malignancies</li> <li>• Carditis</li> <li>• Demyelinating diseases</li> <li>• Tuberculosis of pericardium and tuberculous meningitis</li> </ul>	<ul style="list-style-type: none"> <li>• Active tuberculosis</li> <li>• Peptic ulcer</li> <li>• Bleeding tendencies</li> <li>• Diabetes</li> <li>• Uncontrolled hypertension</li> <li>• Active infection</li> </ul>
• Transplant rejection, GVH (graft versus host disease), bone marrow transplantation	Transplant rejection, GVH (graft versus host disease), bone marrow transplantation
• Psoriasis, inflammatory bowel disease	Psoriasis, inflammatory bowel disease
• Eye conditions: Scleritis, chorioretinitis	Eye conditions: Scleritis, chorioretinitis

*Measures to reduce the side effects of corticosteroids therapy (Table 2.25)*

**Q. Write short note on measures to minimize the side effects of corticosteroid.**

**Table 2.25:** Measures to reduce side effects of corticosteroids therapy.

**By administering**

- |   |   |
|---|---|
| <ul style="list-style-type: none"><li>• Lowest required dose</li><li>• On alternate days rather than daily</li><li>• As a single dose than in divided doses</li><li>• In the morning</li><li>• For the shortest required duration</li><li>• For indications only</li><li>• Only under medical supervision</li></ul> | <ul style="list-style-type: none"><li>• Monitor intake of calories to prevent weight gain</li><li>• Reduce intake of sodium</li><li>• Use H<sub>2</sub> receptor blockers or proton-pump inhibitors</li><li>• Provide high calcium intake and pump inhibitors</li><li>• Use bisphosphonates</li></ul> |
|---|---|

## Waterhouse-Friderichsen Syndrome

**Q. Write short note on Waterhouse-Friderichsen syndrome.**

- It is characterized by **acute hemorrhagic infarction (destruction) of both the adrenal glands** and is usually associated with fulminant **meningococcal septicemia**. It produces cutaneous petechiae, vasomotor collapse and shock.
- Can occur at any age but is more common in children.
- **Abrupt in onset** and profound prostration occurs within a few hours. It produces petichiae, purpuric lesion and hemorrhage into the skin.
- Prompt recognition and appropriate therapy: Intravenous fluids, high dose antibiotics (Penicillin, cephalosporins, sulfonamides), vasopressors, inotropes, plasma transfusion, steroids must be instituted immediately, or death follows within hours to a few days due to cardiac and/or respiratory failure.

## Pheochromocytoma

**Q. Write short essay/note on clinical features, diagnosis and treatment of pheochromocytoma.**

- Pheochromocytoma is a very rare tumor of the sympathetic nervous system composed of chromaffin cells that secretes catecholamines noradrenaline (norepinephrine) adrenaline (epinephrine).
- Important because they are a rare cause of surgically correctable

hypertension.

- **Paraganglioma**

- Pheochromocytomas that develop in extra-adrenal paraganglia are known as paragangliomas.
  - It arises from both sympathetic and parasympathetic paraganglia, located anywhere from the base of the skull to the pelvis.
  - Paragangliomas typically occur in the head and neck but are also found in the thorax, pelvis and bladder.
- Traditionally, the features of pheochromocytomas have been summarized by the ‘rule of 10s’ (Box 2.23).
  - Neurofibromatosis type 1 (Von Recklinghausen’s disease) is associated with an increased incidence of pheochromocytoma.

**Box 2.23:** Rule of 10s for pheochromocytoma.

10% Extra adrenal (closer to 15%)- 10% abdominal  
10% Occur in children  
10% Familial (Now modified as closer to 25%)  
10% Sporadic are bilateral or multiple (more if familial)  
10% Not associated with hypertension  
10% Malignant  
10% Discovered incidentally  
10% Recur (more if adrenal)

***Clinical Features (Box 2.24)***

- **Paroxysmal hypertension:**

- Characterized by episodes of **pallor or flushing, headache sweating, palpitations, and anxiety** (fear of death).
- Paroxysms last 10–60 min duration, daily to monthly
- **Paroxysms are spontaneous or precipitated by:**
  - ◆ Diagnostic procedures, intra-arterial contrast
  - ◆ Drugs (opioids, unopposed beta-blockade, anesthesia induction, histamine, ACTH, glucagon, metoclopramide)
  - ◆ Strenuous exercise, movement that increases intra-abdominal pressure (lifting, straining)
  - ◆ Micturition (bladder paraganglioma)

- **Sustained hypertension is more common than paroxysmal hypertension.**
- **Complications of hypertension:** Stroke, myocardial infarction, cardiomyopathy and left ventricular failure.
- **Gastrointestinal symptoms:** Abdominal pain, vomiting, constipation and weight loss.
- **Hypercalcemia:** Observed in associated MEN2 hyperparathyroidism
- **Mild glucose intolerance**
- Lipolysis and weight-loss

**Box 2.24:** Signs and symptoms of pheochromocytoma.

5 Ps

- |                                |   |
|--------------------------------|---|
| 1. Pressure (Hypertension)—90% | } Classical triad of 3 Ps<br>Lack of these 3 Ps excludes<br>the diagnosis |
| 2. Pain (Headache)—80%         |   |
| 3. Perspiration—70%            |   |
| 4. Palpitation—65%             |   |
| 5. Pallor—42%                  |   |

**Familial pheochromocytoma (Table 2.26)**

**Table 2.26:** Familial pheochromocytoma.

MEN 2a	50% pheochromocytoma (usually bilateral), medullary carcinoma of thyroid, hyperparathyroidism
MEN 2b	50% pheochromocytoma (usually bilateral), medullary carcinoma of thyroid, mucosal neuroma, marfanoid habitus
Von Hippel-Landau	50% pheochromocytoma (usually bilateral), retinoblastoma, cerebellar hemangioma, nephroma, renal/pancreas cysts
NF1 (Von Recklinghausen's)	2% pheochromocytoma (50% if NF-1 and HTN) Café-au-lait spots, neurofibroma, optic glioma
Familial paraganglioma	
Familial pheochromocytoma and islet cell tumor	
Other: Tuberous sclerosis, Sturge-Weber, ataxia-telangiectasia, Carney's Triad (pheochromocytoma, gastric leiomyoma, pulmonary chondroma)	

**Investigations (Table 2.27)**

Plasma metanephrine is the most sensitive test

**Table 2.27:** Laboratory findings in pheochromocytoma.

<i>Investigation</i>	<i>Level</i>	<i>Sensitivity</i>	<i>Specificity</i>
24-hour urine Vanillylmandelic acid (VMA)	Raised	63%	94%
24-hour urine metanephrines and normetanephrines	Raised	76%	94%
24-hour urine free catecholamines	Raised	83%	88%
24-hour urine free catecholamines + metanephrines	Raised	90%	98%
Plasma catecholamines	Raised	85%	80%
Plasma metanephrines	Raised	99%	89%

### *Other investigations*

- **Chromogranin A:** It is a major secretory protein present in the soluble matrix of chromaffin granules and is elevated.
- **Provocative** (glucagon provocative test) and adrenolytic (clonidine, phentolamine test) tests: Rarely necessary.
- **CT scan:** To localize tumor.
- **Scintigraphy:** Useful for localization of tumor and includes
  - MIBG (<sup>123</sup>I-labeled meta-iodobenzylguanidine) scintigraphy.
  - Somatostatin receptor scintigraphy using <sup>111</sup>indium-labeled diethylenetriamine pentaacetic acid octreotide scan.
  - (<sup>18</sup>F) flurodihydroxyphenylalanine (DOPA) PET scan.
- **Plasma noradrenaline:** Selective venous sampling and estimation of plasma noradrenaline level may be useful in localizing the tumor in difficult cases.

### **Management**

- **Excision of the tumor** is the main treatment. Special care has to be taken preoperatively, intraoperatively and postoperatively.

#### ***Preoperative preparation regimens***

- Combined **α + β-blockade** to be given at least 2 weeks preoperatively to control the hypertension. Antihypertensive agents used are: phenoxybenzamine, selective α<sub>1</sub>-blocker (prazosin, terazosin, or doxazosin) and propranolol.
- High sodium diet —patients are encouraged to start a diet high in sodium content (>5000 mg

daily) because of the catecholamine-induced volume contraction and the orthostasis associated with alpha-adrenergic blockade.

- If uncontrolled add
  - Metyrosine
  - Calcium channel blocker (CCB)-Nicardipine
  - Avoid diuretics as already ECF volume contracted
  - Intraoperative blood pressure needs to carefully monitored and controlled.
  - Postoperative hypotension can be avoided by adequate fluid replacement and hypoglycemia (10–15% of patients) due to removal of catecholamine suppression of insulin secretion by glucose infusion.
- Postoperatively patients may become hypertension free
- **If tumor cannot be excised:**
  - Long-term treatment with  $\alpha$ - and  $\beta$ -adrenoreceptors blocking drugs (phenoxybenzamine and propranolol, or labetalol) is advocated.
  - $\beta$ -blockers should never be given alone.
  - Patients can also be subjected to nuclear medicine treatment.

# GONADAL DISORDERS

## Male Hypogonadism

**Q.** Discuss the causes and approach to male hypogonadism.

### *Classification and Causes of Male Hypogonadism (Table 2.28)*

#### Androgen Deficiency Symptoms

- Musculoskeletal
  - Decreased vigour and physical energy
  - Diminished muscle strength
- Sexuality
  - Decreased interest in sex
  - Reduction in frequency of sexual activity
  - Poor erectile function/arousal
  - Loss of nocturnal erections
  - Reduced quality of orgasm
  - Reduced volume of ejaculate
- Mood disorder and cognitive function
  - Irritability and lethargy
  - Decreased sense of well-being, lack of motivation
  - Low mental energy, difficulty with short-term memory
  - Depression
  - Low self-esteem, insomnia, nervousness
- Vasomotor and nervous
  - Hot flushes, sweating

**Table 2.28:** Classification and causes of male hypogonadism.

#### ***HYPOTHALAMIC-PITUITARY DISORDERS***

Panhypopituitarism

LH and FSH deficiency

- a. With normal sense of smell
- b. With hyposmia or anosmia (Kallmann's syndrome)

c. With complex neurologic syndromes

Prader-Willi syndrome < Laurence-Moon, Bardet-Biedl syndromes < Möbius' syndrome < Lowe's syndrome

### **GONADAL ABNORMALITIES**

Klinefelter's syndrome

Other chromosomal defects (XX male, XY/XXY, XX/XXY, XXXY, XYY)

Bilateral anorchia (vanishing testes syndrome)

Cryptorchidism

Noonan's syndrome

Myotonic dystrophy

Adult seminiferous tubule failure < Adult Leydig cell failure

Insert<

Secondary hypogonadism

Hyperprolactinemia

Glucocorticoid treatments

Chronic, systemic illness

Anorexia nervosa

Diabetes mellitus

Obesity

Malignant tumors of testes

Infiltrative diseases—hemochromatosis

Chronic orchitis - TB, leprosy, syphilis.

Pituitary apoplexy

Trauma

Idiopathic

### **DEFECTS IN ANDROGEN ACTION**

Complete androgen insensitivity (testicular feminization)

Incomplete androgen insensitivity

## ***Physical Signs***

- Diminished muscle mass
- Loss of body hair
- Abdominal obesity
- Gynecomastia
- Testes frequently normal, occasionally small

### ***Prepubertal onset: Eunuchoidism***

- Lack of adult male hair distribution

- Sparse axillary, pubic hair
- Lack of temporal hair recession
- High-pitched voice
- Infantile genitalia
  - Small penis, testes and scrotum
- ↑ fat deposition in pectoral, hip, thigh and lower abdomen
- Eunuchoidal proportion
  - Arm span > height > 5 cm
  - Upper/lower segment ratio < 1

## Investigation

- Serum testosterone: 8.00 AM
- Serum FSH, LH
- Semen analysis
- Others: Peripheral leukocyte karyotype, other pituitary hormones, serum prolactin, iron saturation, MRI brain.

## Treatment

### *Treatment of primary hypogonadism*

- Testosterone replacement
- Treatment of the underlying disease

### **Q.** Write short note on testosterone replacement.

#### *Testosterone replacement*

- Intramuscular preparations—**testosterone enanthate** (250–300 mg IM q 3 wk)
- Transdermal patch/gel
- Oral agent—**testosterone undecanoate** (40–80 mg po 2–3 times daily)
- **Undesirable effects:** BPH, prostatic cancer, dyslipidemia, polycythemia, transaminitis

#### *Treatment of secondary hypogonadism*

- GnRH pulsatile infusion
- hCG

## Box 2.25: Causes of male infertility.

- Endocrine
  - Hypothalamic-pituitary disorders
  - Testicular disorders
  - Defects of androgen action
  - Hyperthyroidism
  - Hypothyroidism
  - Adrenal insufficiency

- Congenital adrenal hyperplasia
- Systemic illness
- Defects in spermatogenesis
- Immotile cilia syndrome
- Drug-induced
- Ductal obstruction
  - Congenital
  - Acquired

Seminal vesicle disease

Prostatic disease

Varicocele

Retrograde ejaculation

Antibodies to sperm or seminal plasma

Anatomic defects of the penis

Poor coital technique

Sexual dysfunction

Idiopathic

## Impotence

**Q. What is impotence? Discuss briefly.**

- **Definition:** Male sexual dysfunction is termed impotence.
- **Manifestations:** It includes loss of desire, inability to obtain and maintain erection, premature ejaculation, absence of emission and inability to achieve orgasm.

### *Causes of Male Infertility (Box 2.25)*

#### *Erectile Dysfunction*

Erectile impotence may be due to various causes, but majority are of psychological origin. In each case of erectile impotence, it is necessary to rule out the organic causes (Table 2.29).

#### Gynecomastia

**Q. Write short note on gynecomastia.**

It is clinically defined as the presence of a rubbery or firm mass concentrically extending from the nipples in a male secondary to proliferation of both **stromal and epithelial component of the glands**.

It must be differentiated from pseudogynecomastia (**lipomastia**) seen in

obese individuals, which is characterized by **only fat deposition** without glandular proliferation.

### ***Causes of Gynecomastia (Table 2.30)***

#### ***Clinical Features***

- **Enlargement of breast (refer Fig. 11.12C):** The principal complaint is unilateral or bilateral concentric enlargement of breast glandular tissue.
- **Breast pain:** Present in one-fourth of patients and objective tenderness in about 40%.
- A complaint of nipple discharge can be elicited in 4% of cases.

Patients with gynecomastia may have a slightly increased risk of development of breast carcinoma.

#### **Treatment**

##### **1. Medical treatment**

- The underlying disease should be corrected if possible, and offending drugs should be discontinued.
- Antiestrogens or selective estrogen receptor modulators, such as tamoxifen or raloxifene, have been found useful in relieving pain and reversing gynecomastia in some patients. Aromatase inhibitors have also been tried but are not as beneficial as tamoxifen.

##### **2. Surgical treatment**

Reduction mammoplasty should be considered for cosmetic reasons

##### **3. Radiotherapy**

- Patients with prostatic carcinoma may receive low-dose radiation therapy (900 cGy or less) to the breasts before initiation of estrogen therapy. This may prevent or diminish the gynecomastia that usually results from such therapy
- Radiotherapy should not be given to other patients with gynecomastia

**Table 2.29: Organic causes of erectile dysfunction.**

<b><i>Neurologic</i></b>	<b><i>Urogenital</i></b>	<b><i>Drugs</i></b>
Anterior temporal lobe lesions	Trauma	Antiandrogens
Spinal cord lesions	Castration	Estrogens
Autonomic neuropathy	Priapism	5 alfa-reductase inhibitors
<b>Vascular</b>	Peyronie’s disease	GnRH agonists
Leriche’s syndrome	<b>Systemic illness</b>	Antihypertensives
Pelvic vascular insufficiency	Cardiac insufficiency	Diuretics
Sickle cell disease	Cirrhosis	Psychotropic agents
<b>Endocrine</b>	Uremia	Tranquilizers

Diabetes mellitus	Respiratory insufficiency	Monoamine oxidase inhibitors
Hypogonadism	Lead poisoning	Tricyclic antidepressants
Hyperprolactinemia	<b>Postoperative</b>	Tobacco
Adrenal insufficiency	Aortoiliac or aortofemoral reconstruction	Alcohol
Feminizing tumors	Lumbar sympathectomy	Cocaine
Hypothyroidism	Perineal prostatectomy	
Hyperthyroidism	Retroperitoneal dissection	

**Table 2.30: Causes of gynecomastia.**

<b>Physiologic</b>	<b>Endocrine</b>
Neonatal, pubertal, involutional	Primary hypogonadism with Leydig cell damage, hyperprolactinemia, hyperthyroidism, androgen receptor disorders, excessive aromatase activity
<b>Drug-induced</b>	<b>Systemic diseases</b>
Androgens and anabolic steroids, chorionic gonadotropin, estrogens and estrogen agonists, growth hormone, cyproterone, flutamide, isoniazid, ketoconazole, metronidazole, cimetidine, omeprazole, ranitidine, cancer chemotherapeutic agents (especially alkylating agents), amiodarone, captopril, reserpine, spironolactone, verapamil, psychoactive agents, diazepam, haloperidol, phenothiazines, tricyclic antidepressants, alcohol, amphetamines, heroin, marijuana, highly active antiretroviral therapy (HAART), phenytoin, penicillamine	Hepatic cirrhosis, uremia
	<b>Neoplasms</b>
	Testicular germ cell or Leydig cell tumors hCG-secreting nontrophoblastic neoplasms
	<b>Idiopathic</b>

## Short Stature

### **Q. Write short note on short stature and its differential diagnosis.**

- Short stature is defined as a height that is below the 2.5th percentile OR two or more standard deviations below the mean for age and gender for a given population.
- A growth velocity that is below the 5th percentile for age and gender is called growth deceleration (e.g. <5 cm/year after the age of 5 years).
- Dwarfism is defined as short stature for the age of the patient.
- Most common causes of dwarfism are familial short stature and constitutional delay of growth and puberty.

## Causes of Short Stature (Table 2.31)

**Table 2.31:** Causes of short stature.

<i>Nonendocrine causes</i>	<i>Endocrine disorders</i>
Constitutional short stature Familial short stature Genetic short stature Intrauterine growth retardation and SGA syndromes of short stature <ul style="list-style-type: none"> <li>• Turner’s syndrome and its variants</li> <li>• Noonan’s syndrome (Fig. 2.18A)</li> <li>• Prader–Willi syndrome</li> <li>• Laurence–Moon and Bardet–Biedl syndromes</li> </ul>	GH deficiency and variants <ul style="list-style-type: none"> <li>• Congenital GH deficiency</li> <li>• With midline defects</li> <li>• With other pituitary hormone deficiencies</li> <li>• Isolated GH deficiency</li> <li>• Pituitary agenesis</li> <li>• Acquired GH deficiency</li> <li>• Hypothalamic-pituitary tumors</li> </ul>
Chronic disease Cardiac disorders (left-to-right shunt, congestive heart failure) Pulmonary disorders (cystic fibrosis, asthma) Gastrointestinal disorders: Malabsorption (e.g. celiac disease) Hematologic disorders <ul style="list-style-type: none"> <li>• Sickle cell anemia</li> <li>• Thalassemia</li> </ul> Renal disorders <ul style="list-style-type: none"> <li>• Renal tubular acidosis</li> <li>• Chronic uremia</li> </ul> Immunologic disorders <ul style="list-style-type: none"> <li>• Connective tissue disease</li> <li>• Juvenile rheumatoid arthritis</li> </ul> Chronic infection (TB) Malnutrition <ul style="list-style-type: none"> <li>• Voluntary dieting</li> <li>• Anorexia nervosa</li> <li>• Cancer chemotherapy</li> </ul>	<ul style="list-style-type: none"> <li>• Hypothalamic-pituitary tumors</li> <li>• Histiocytosis X</li> <li>• Central nervous system infections</li> <li>• Head injuries</li> <li>• GH deficiency following cranial irradiation</li> <li>• Central nervous system vascular accidents</li> <li>• Hydrocephalus</li> <li>• Empty sella syndrome</li> <li>• Abnormalities of GH action</li> <li>• GH insensitivity (Laron’s dwarfism)</li> <li>• Pygmies</li> <li>• Psychosocial dwarfism</li> <li>• Hypothyroidism</li> <li>• Glucocorticoid excess (Cushing’s syndrome)</li> <li>• Pseudohypoparathyroidism</li> <li>• Disorders of vitamin D metabolism</li> <li>• Diabetes mellitus, uncontrolled</li> <li>• Diabetes insipidus, untreated</li> </ul>

## Differential Diagnosis of Short Stature (Table 2.32)

**Table 2.32:** Differential diagnosis of short stature.

<i>Cause</i>	<i>Characteristic findings</i>
GH deficiency	Frontal bossing, high-pitched voice, central obesity
Hypothyroidism	Immature facies, dry skin, coarse hair

Cushing's syndrome	Central obesity, striae, hypertension
Gonadal dysgenesis	Webbed neck, multiple pigmented naevi, delayed sexual development, shield chest
Pseudohypoparathyroidism	Moon facies, mental retardation, obesity, short metacarpals
Bone-cartilage dysplasia	Abnormal proportions, macrocephaly
Russell-Silver dwarfism	Small at birth, pointed facies, asymmetry
Other causes	Turner's syndrome, IUGR, premature birth, cyanotic congenital heart diseases, chronic liver disease, chronic pulmonary or kidney disease, undernutrition, uncontrolled type 1 diabetes mellitus, rickets, malabsorption

### ***Causes of Tall Stature (Table 2.33)***

**Table 2.33:** Causes of tall stature.

<b><i>Nonendocrine causes</i></b>	<b><i>Endocrine disorders</i></b>
Constitutional tall stature, genetic tall stature	Pituitary gigantism
Cerebral gigantism, homocystinuria	Sexual precocity
Marfan's syndrome (Fig. 2.18B), Beckwith-Wiedemann syndrome, XYY and XYYY syndromes, Klinefelter's syndrome, syndromes of tall stature	Thyrotoxicosis
	Infants of diabetic mothers

**Figs. 2.18A and B:** (A) Short stature in Noonan syndrome; (B) Tall stature in Marfan syndrome.

# **Diabetes Mellitus**

# CHAPTER 3

## INTRODUCTION

**Q. Write short essay/note on definition and classification of diabetes mellitus (DM).**

### Definition

Diabetes mellitus, the **most common endocrine disease**, is a metabolic syndrome characterized by **hyperglycemia** due to **absolute or relative insulin deficiency/resistance or both**.

- The prevalence of diabetes is increasing sharply in the developing countries because of more sedentary lifestyles. India and China have the largest prevalence of diabetics.

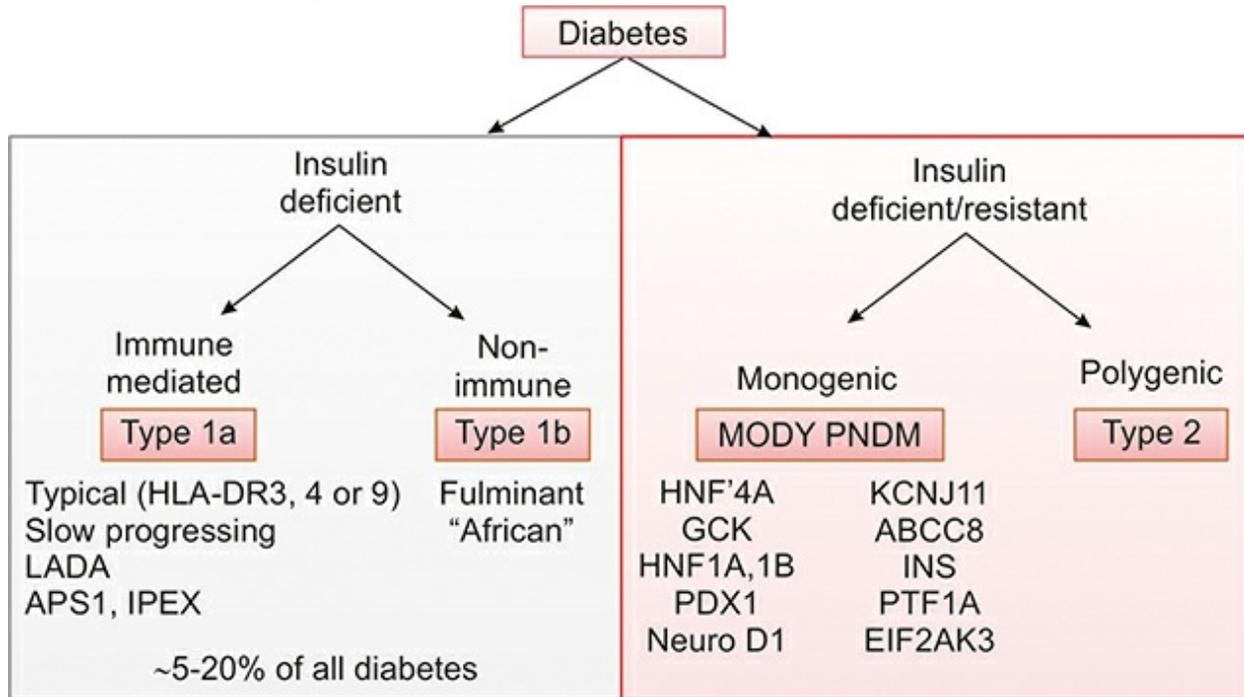

### Classification and Etiology

**Q. Write short essay/note on etiology/causes of diabetes mellitus (DM).**

Diabetes mellitus is classified according to etiopathogenesis that leads to hyperglycemia into different groups (Table 3.1 and Fig. 3.1) but **majority of cases fall into one of two** broad classes namely: **type 1** (not type I) and **type 2** (not type II).

- **Type 1 DM:** In this there is **absolute (complete or near total) deficiency of insulin**. It is subdivided into two subtypes namely **type 1 A** which is due to **autoimmune** destruction of  $\beta$ -cells and **type 1 B** where the cause of  $\beta$ -cell destruction is **unknown**.
- **Type 2 DM:** It constitutes a **heterogeneous group** characterized by variable degrees of **insulin resistance, impaired insulin secretion and increased glucose production**. It also develops due to several genetic and metabolic syndromes.
  - **Risk categories:** Type 2 DM is usually preceded by a period of

abnormal glucose homeostasis classified as **impaired fasting glucose (IFG)** or **impaired glucose tolerance (IGT)**.

**Fig. 3.1:** Types of diabetes mellitus.

(ABCC8: ATP-binding cassette transporter sub-family C member 8; APS1: autoimmune polyendocrinopathy syndrome type 1; EIF2AK3: eukaryotic translation initiation factor 2-alpha kinase 3; GCK: glucokinase; HNF4: hepatocyte nuclear factor 4; IPEX: immune dysregulation, polyendocrinopathy, enteropathy, X-linked; INS: insulin; KCNJ11: potassium inwardly-rectifying channel, subfamily J, member 11; LADA: latent autoimmune diabetes of adults; MODY: maturity onset diabetes of the young; Neuro D1: neurogenic differentiation 1; PDX1: pancreatic and duodenal homeobox 1; PNDM: permanent neonatal diabetes mellitus; PTF1A: pancreas transcription factor 1 subunit alpha)

### Table 3.1: Classification of diabetes mellitus.

- I. **Type 1 diabetes** (destruction of beta cell usually leading to absolute deficiency of insulin)
  - Type 1 A: Immune-mediated
  - Type 1 B: Idiopathic
- II. **Type 2 diabetes** (may range from predominantly insulin resistance with relative insulin deficiency to a predominantly insulin secretory defect with insulin resistance)
- III. **Other specific types of diabetes**
  - A. **Genetic defects of  $\beta$ -cell development or function characterized by mutations in**
    - Hepatocyte nuclear transcription factor (HNF) 4  $\alpha$  (Maturity-onset diabetes of the young 1 -MODY 1)
    - Glucokinase (MODY 2)
    - HNF-1  $\alpha$  (MODY 3)

- B. **Genetic defects in insulin action:** Type A insulin resistance, Ieprechaunism, Rabson-Mendenhall syndrome, lipodystrophy syndromes
- C. **Exocrine pancreatic defects:** Pancreatitis, pancreatectomy, hemochromatosis, pancreatic neoplasm, cystic fibrosis, fibrocalculous pancreatopathy
- D. **Endocrinopathies:** Acromegaly, Cushing syndrome, hyperthyroidism, pheochromocytoma, glucagonoma
- E. **Infections:** Cytomegalovirus, coxsackie B virus, congenital rubella
- F. **Drugs or chemical induced:** Glucocorticoids, pentamidine, nicotinic acid, thyroid hormone, diazoxide,  $\beta$ -adrenergic agonists, thiazides, phenytoin,  $\alpha$ -interferon
- G. **Genetic syndromes sometimes associated with diabetes:** Down syndrome, Klinefelter syndrome, Turner syndrome, Wolfram's syndrome, DIDMOAD (diabetes insipidus, diabetes mellitus, optic atrophy, and deafness), Friedreich's ataxia, Huntington's disease, Laurence-Moon-Biedl syndrome, myotonic dystrophy, porphyria, Prader-Willi syndrome
- H. Uncommon forms of immune-mediated diabetes: 'Stiff-man' syndrome, anti-insulin receptor antibodies

#### IV. Gestational diabetes mellitus (GDM)

#### V. Latent autoimmune diabetes in adults (LADA)

### ***Features of Current Classification of DM***

- The terms insulin dependent diabetes mellitus (IDDM) and non-insulin dependent diabetes mellitus (NIDDM) are no longer used now. Because many patients with type 2 DM eventually need insulin for control of hyperglycemia.
- The age or treatment modality is not a criterion for classification. Type 1 DM most often occurs in younger patients before the age of 30 and an autoimmune destruction of  $\beta$  cell can start at any age. However, about 10% of patients above the age of 30 years have type 1 DM. Type 2 DM usually develops with increasing age. However, it is now being diagnosed more frequently in children and young adults (particularly in obese adolescents).

### ***Metabolic Effects of Lack of Insulin (Table 3.2)***

**Table 3.2: Functions of insulin and metabolic effects of insulin deficiency.**

<b><i>Functions of insulin</i></b>	<b><i>Consequences of insulin deficiency</i></b>
<b>Functions that decreases blood glucose level</b>	<b>Insulin deficiency increases the blood glucose level</b>
<ul style="list-style-type: none"> <li>• Increases activity of glycolytic enzymes</li> </ul>	<ul style="list-style-type: none"> <li>• Decreased activity of glycolytic enzymes</li> </ul>

• Increases glycogen synthesis	• Glycogen breakdown into glucose increases (gluconeogenesis)
• Increases uptake of glucose by skeletal and cardiac muscle	• Decreased glucose transport into skeletal and cardiac muscle
• Decreases activity of gluconeogenic enzymes	• Increased activity of gluconeogenic enzymes (gluconeogenesis)
<b>Lipid metabolism:</b> Increases lipid synthesis	Lipolysis (raised plasma free fatty acids), ketogenesis
<b>Protein metabolism:</b> Enhances tissue uptake of amino acids and accelerates protein synthesis	Decrease in tissue uptake of amino acids and reduced protein synthesis
<b>Other functions</b>	
• Increases transmembrane K <sup>+</sup> transport	• Decrease in movement of K <sup>+</sup> into the cell
• Decreases cyclic AMP level in adipose tissue and liver	• Increased cyclic AMP levels in adipose tissue and liver

## Etiopathogenesis of Type 1 Diabetes Mellitus (T1DM)

**Q. Write short essay/note on pathogenesis of diabetes mellitus.**

- Accounts for ~ **5–10%** of all cases
- **Age:** Most common in **childhood (younger than 20 years of age)**. Since, it can develop at any age; the term ‘juvenile diabetes’ should be avoided.

### *Etiology*

- **Autoimmune disease** characterized by:
  - **Pancreatic β-cell destruction**
  - **Absolute deficiency of insulin.**
- **Idiopathic:** It is a rare form in which there is no evidence for autoimmunity.

### *Pathogenesis of Type 1 Diabetes Mellitus (Fig. 3.2)*

- It is an **autoimmune disease** that involves interplay of both genetic susceptibility and environmental factors.

**Genetic susceptibility:** Incidence of type 1 diabetes is greater in twins of affected individuals than in the general population, and greater in monozygotic than in dizygotic twins.

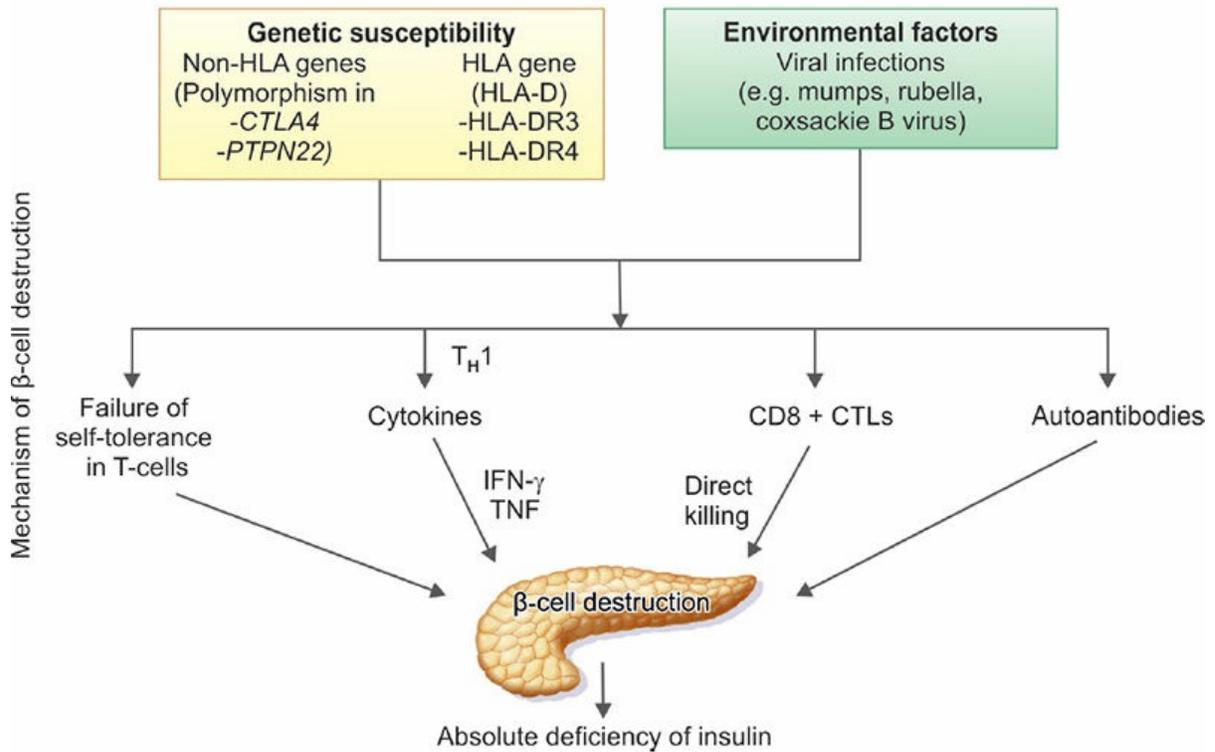

- **HLA genes:** About 95% of patients with type 1 diabetes have either human leukocyte antigen (**HLA-DR3 or HLA-DR4, or both**), compared

with the general population.

**Environmental factors: Viral infections may trigger islet cell destruction** and associations have been found between type 1 diabetes and infection with *mumps, rubella, coxsackie B, or cytomegalovirus*. Environmental event initiates the process in genetically susceptible individuals. Relative deficiency of vitamin D may also be responsible.

**Mechanisms of  $\beta$ -Cell destruction (Fig. 3.2):** The autoimmune damage starts many years before the disease becomes clinically evident. An inflammatory response in the pancreas called '**insulinitis**' develops and there is infiltration of the islets with activated T lymphocytes.

- **Phases in the development of diabetes mellitus:**
  - **Phase with normal glucose tolerance:** In most of the patients, islet cell autoantibodies appear much earlier than overt diabetes. Beta cell mass and insulin secretion progressively decreases however normal levels of blood glucose is maintained.
  - **Phase of impaired glucose intolerance:** Features of diabetes do not become evident even with destruction of 70–80% of beta cells. At this point, residual functional beta cells cannot maintain glucose tolerance and patient develops glucose intolerance.
  - **Phase of frank diabetes:** Stress, infection or puberty may be associated with increased insulin requirements and may trigger the transition from glucose intolerance to frank diabetes.
    - ◆ **Honeymoon phase:** *After the initial clinical presentation of frank type 1 DM, a phase may occur during which time patient is euglycemic with modest doses of insulin or, rarely without insulin for some time. This is referred to as 'honeymoon phase'. This usually lasts for a few months after which the patient develops frank DM again.*
    - ◆ **Hyperglycemia and ketosis** occur after **more than 90% of the  $\beta$  cells have been destroyed** by an autoimmune process.
- **Immunologic markers:** These include autoantibodies against islet cell, insulin, glutamic acid decarboxylase (GAD65), zinc transporter ZnT8 and tyrosine phosphatase IA-2 and IA-2 $\beta$ . One or more of these autoantibodies are detected in 85–90% of individuals when fasting hyperglycemia is initially detected.

**Fig. 3.2:** Pathogenesis of type 1 diabetes mellitus.

- Type 1 DM can be associated with various autoimmune disorders as outlined in Table 3.3.
- **Slow-burning variant of type 1DM:** It is characterized by slower progression to insulin deficiency and develops in later life and is sometimes called **Latent Autoimmune Diabetes in Adults (LADA)**. LADA may be difficult to distinguish from type 2 DM.

**Table 3.3:** Various autoimmune disorders that can be associated with Type 1 DM.

<i>Autoimmune disease</i>	<i>Autoantibody type</i>	<i>Autoantibody percentage</i>	<i>Disease prevalence (%)</i>
Addison's disease	21- Hydroxylase	1.5	0.5
Celiac disease	Transglutaminase	12	6
Pernicious anemia	Parietal cell	21	2.6
Thyroiditis or Graves' disease	Peroxidase or thyroglobulin	25	4

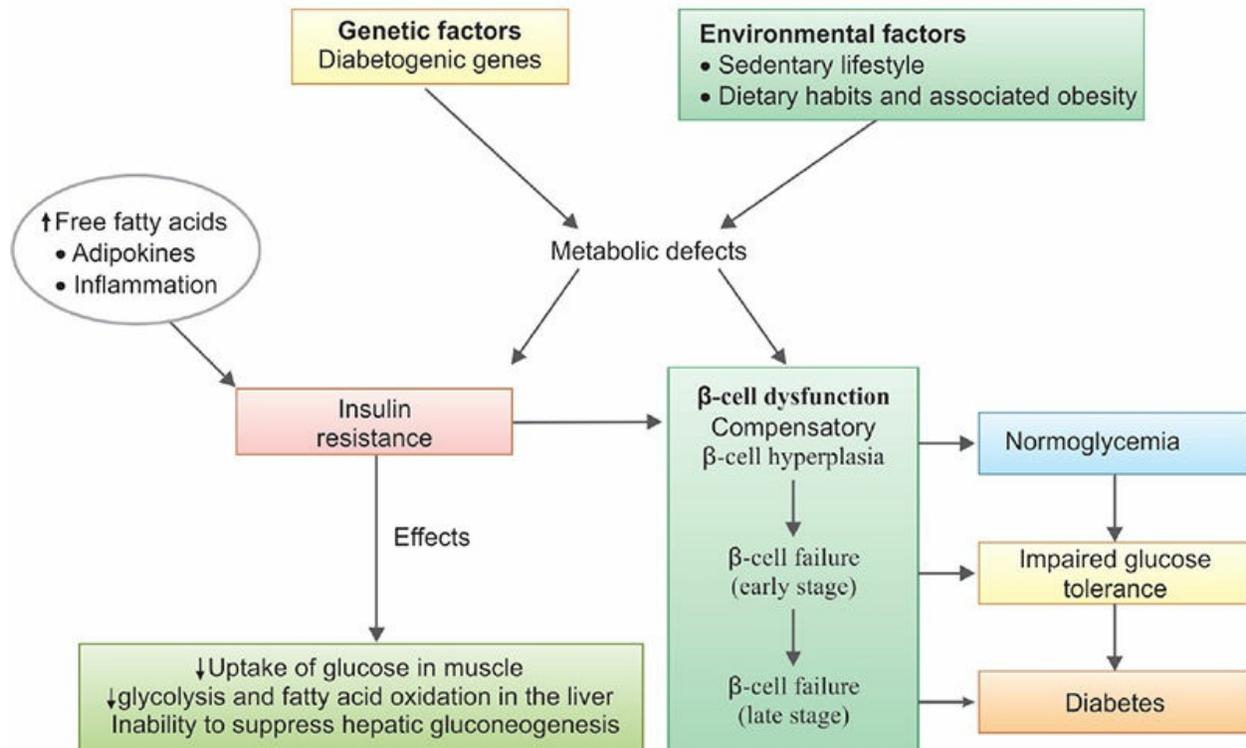

## Pathogenesis of Type 2 Diabetes Mellitus (Fig. 3.3)

Type 2 diabetes is a **multifactorial disease**. The four major factors are increasing **age, obesity, ethnicity and family history**. Type 2 diabetes is associated with central obesity, hypertension, hypertriglyceridemia, and decreased HDL cholesterol (metabolic syndrome).

- **Environmental factors** play a role and includes:
  - **Sedentary lifestyle**
  - **Dietary habits and associated obesity**. Over-eating, obesity and under activity is associated with the development of type 2 DM.
- **Genetic factors**: It is much more significant in type 2 DM than in type 1 DM.
  - Type 2 diabetes has a **concordance rate of 35% to 60% in monozygotic twins compared with 17% to 30% in dizygotic twins**.
  - Lifetime risk for type 2 diabetes in an offspring is more than double **if both parents are affected**.
  - Diabetogenic genes have been found.
- In contrast to type 1 DM, in type 2 DM there is no HLA relationship and there is no evidence of an autoimmune basis. Pancreatic  $\beta$ -cell mass is intact in type 2 DM, in contrast to type 1 DM. The  $\alpha$ -cell mass is increased.

### ***Characteristics of Type 2 DM***

These include: (1) insulin resistance, (2) abnormal/impaired insulin secretion/action, (3) increased hepatic production of glucose, and (4) abnormal fat metabolism.

**Fig. 3.3:** Pathogenesis of type 2 diabetes. Insulin resistance associated with obesity is induced by free fatty acids, adipokines, and chronic inflammation in adipose tissue. Insulin resistance causes  $\beta$  cells of pancreas to undergo compensatory hyperplasia and the resulting hypersecretion of insulin maintains normoglycemia. However, at some point,  $\beta$ -cell compensation is followed by  $\beta$ -cell failure, and diabetes develops.

- **Insulin resistance**

**Q. Write short essay/note on insulin resistance.**

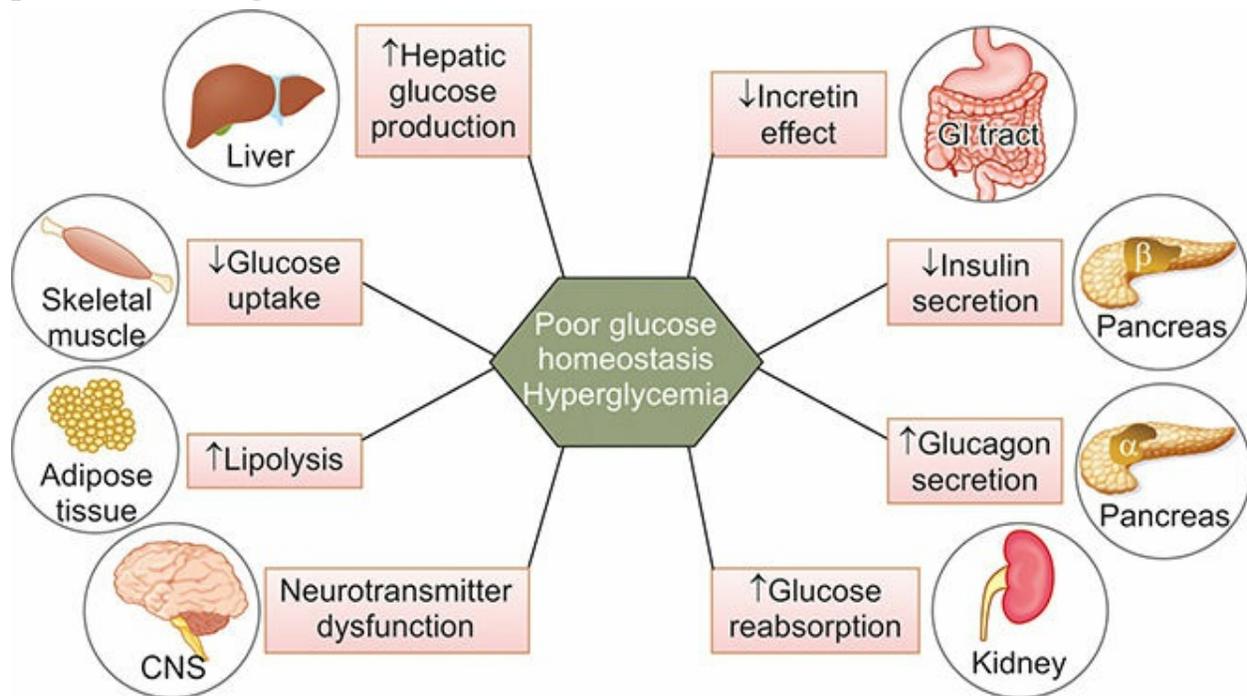

- Insulin resistance is **the decrease/failure of target (peripheral) tissues to insulin action.**
- Main factors in the development of insulin resistance are combination of genetic susceptibility and **obesity**. The obesity accompanying type 2 DM is central obesity and central adipose tissue is more ‘lipolytic’ than peripheral sites. Insulin resistance is induced by free fatty acids, adipokines, and chronic inflammation in adipose tissue.
- **Consequences of insulin resistance:**
  - ◆ **Decreased uptake of glucose in muscle** results in post-prandial hyperglycemia. The defects in the uptake are due to defect in the receptors present in target tissues and usually at the post-receptor level.

- ◆ **Reduced glycolysis and fatty acid oxidation** in the liver.
- ◆ **Inability to suppress hepatic gluconeogenesis**
- **Abnormalities of insulin secretion and action**
  - **β-Cell dysfunction:** Abnormalities (abnormal/impaired) of insulin secretion develops early in the course of type 2 diabetes and is due to β-cell dysfunction. β-cell dysfunction is multifactorial in origin. In type 2 diabetes, β-cell dysfunction manifests as **inadequate insulin secretion by the pancreatic β cells (relative insulin deficiency)** in association with insulin resistance and hyperglycemia.
  - **Compensatory β-cell hyperplasia:** Pancreatic β cells **initially respond** to long-term demands of peripheral insulin resistance **by undergoing compensatory hyperplasia leading to increased insulin secretion (hypersecretion)**. Thus, the hyperinsulinemic state can compensate for peripheral resistance and maintain normal blood glucose for years.
    - ◆ **β-cell failure (early stage):** However, at some point, β cells exhaust their capacity to adapt. β-cell compensation cannot maintain normal blood sugar level. This stage, the patient develops impaired glucose tolerance.
    - ◆ **β-cell failure (late stage):** The early stage of cell failure is followed by decreased insulin secretion, hyperglycemia and frank diabetes develops.
- **Increased hepatic production of glucose:** Relative lack of insulin is associated with increased production of glucose from the liver (due to inadequate suppression of gluconeogenesis) and reduced glucose uptake by peripheral tissues. Increased hepatic glucose output produces fasting hyperglycemia.
- **Abnormal fat metabolism:** Insulin resistance in adipose tissue causes lipolysis and increased production of free fatty acid from adipocytes. This leads to increased synthesis of lipid [very-low-density lipoprotein (VLDL) and triglyceride] in hepatocytes. Deposition of fat in the liver is a common association with central obesity and is increased by insulin resistance and/or deficiency. The deposition of fat/lipid or steatosis in the liver may result in nonalcoholic fatty liver disease (NAFLD). This is also responsible for the dyslipidemia observed in type 2 DM [i.e. **raised triglycerides, decreased high-density lipoprotein (HDL), and raised**

**small dense low-density lipoprotein (LDL)].**

Hyperglycemia (**glucotoxicity**) and elevated free fatty acid levels (**'lipotoxicity'**) and dietary fat may also cause further beta cell loss and deterioration of glucose homeostasis.

Pathophysiology of type 2 diabetes mellitus—the ominous octet is presented in Figure 3.4.

**Fig. 3.4:** Pathophysiology of type 2 diabetes mellitus—**THE OMINOUS OCTET**. Multiple drugs in combination may be needed to improve glucose homeostasis. The treatment should target the underlying pathophysiology.

## CLINICAL FEATURES OF DIABETES MELLITUS

**Q. Write short essay/note on clinical features of diabetes mellitus/type 1 diabetes mellitus/type 2 diabetes mellitus.**

Usually, the clinical features of type 1 and type 2 DM are distinctive.

### Type 1 Diabetes Mellitus

- **Age:** Usually begins before the age of 30 years but can occur at any age.
- Weight is normal to lean (wasted).
- **Classical triad of diabetes:** The onset of symptoms may be abrupt, with

**polyuria, polydipsia, polyphagia** to metabolic derangements. Weight loss may develop over days or weeks.

- In **severe cases patient** may develop **ketoacidosis** during intercurrent illness or following surgery.
- **Insulin requirement:** In the initial 1 or 2 years, the exogenous insulin required may be minimal because of endogenous insulin secretion. But later, its requirement suddenly increases.
- Characteristically, the **plasma insulin is low** and **C peptide levels are low** and unmeasurable. *Glucagon levels are raised and suppressible with insulin.*

## Type 2 Diabetes Mellitus

- **Age:** Usually begins in older **above the age of 40 years** and frequently in **obese individuals**. Due to increase in obesity and sedentary lifestyle, it is now detected also in children and adolescents.
- **Presentation:** The symptoms develop gradually, over a period of months to years. **Polyuria, polydipsia, unexplained weakness or weight loss.**
- In **asymptomatic individuals**, the **diagnosis is made after routine blood** (hyperglycemia) **or urine testing (glycosuria).**
- Patients may complain of symptoms like lack of energy, blurring of vision (due to glucose induced changes in refraction) or pruritus vulvae or balanitis caused by *Candida* infection.
- Many patients may present with one of the chronic complications of diabetes and are found to be diabetic on investigations. These include: Staphylococcal skin infections, retinopathy, polyneuropathy, erectile dysfunction, and arterial disease (myocardial infarction or peripheral gangrene).
- **Ketoacidosis is infrequent** and presentation is usually mild. In the decompensated state, they are susceptible to the syndrome of hyperosmolar hyperglycemic state (hyperosmolar non-ketotic coma).
- **Insulin levels in the plasma are normal to high.** Glucagon levels are raised, but resistant to insulin.

## Latent Autoimmune Diabetes in Adults (LADA)

**Q. Write short essay on latent diabetes.**

- LADA is a form of **autoimmune type 1 diabetes** which is diagnosed in individuals who are older than the usual age of onset of type 1 diabetes. Often, LADA is mistaken for **type 2 diabetes**, based on their age at the time of diagnosis.
- Alternate terms for ‘LADA’ include late-onset autoimmune diabetes of adulthood, ‘slow onset type 1’ diabetes, and ‘type 1.5’.

### ***Features of LADA***

- **Age:** Usually less than or equal to 25 years age.
- **Clinical presentation:** Similar to non-obese type 2 diabetes.
- Initial control achieved with diet alone or diet plus oral antidiabetic drugs (OAD). Insulin dependency occurs within months (rarely can take years). LADA shares an increased frequency of risk for an HLA-DQB1 genotype than patients with type 1 diabetes and for a variant in the transcription factor 7-like 2 (TCF7L2) gene with patients with type 2 diabetes.
- Other features of type 1 DM
  - Low fasting and post glucagon stimulated C peptide levels
  - ICA and GADA positive.
- Importance of diagnosis: High-risk of progression to insulin dependency.
  - Avoid metformin treatment
  - Early introduction of insulin therapy.

### **Maturity Onset Diabetes of the Young (MODY)**

#### **Q. Write short essay on maturity onset diabetes of the young (MODY).**

Maturity onset diabetes of the young (MODY) is a heterogeneous disorder characterized by noninsulin-dependent monogenic form of diabetes diagnosed at a young age (<25 years) with autosomal dominant transmission and lack of autoantibodies accounting for 2–5% of diabetes.

- **Mutations** in several **transcription factors** or in **glucokinase** result in insufficient insulin release from pancreatic  $\beta$ -cells, causing MODY. Almost 11 subtypes of MODY are identified based on the mutated gene.
- MODY **can occur at any age**. About 70% forms of MODY are MODY-3 (hepatic transcription factor-1 gene) and 10% MODY-2 (glucokinase gene).

### Features of Maturity Onset Diabetes of the Young

- **Age:** Young onset of diabetes <25 years of age
- **Strong family history** of early onset diabetes (2–3 generations affected)
- Evidence of **macrovascular complications in earlier generation**
- **Sulfonylurea sensitivity.** Non-insulin dependence (not requiring insulin even after 5 years of diagnosis).
- **Absence of insulin resistance** phenotype: normal blood pressure, triglycerides, HDL.

### Subtypes of MODY (Table 3.4)

MODY can be of 2 distinct groups that are distinguished based on characteristic phenotypic features and patterns on oral glucose tolerance testing.

1. Glucokinase MODY: requires no treatment
2. Transcription factor (i.e. hepatocyte nuclear factor-1 alpha) MODY requires low-dose sulfonylurea therapy and permanent neonatal diabetes mellitus (PNDM) (caused by Kir6.2 mutation) requires high-dose sulfonylurea therapy.

Differences between type 1 DM, type 2 DM and MODY are listed in Table 3.5.

**Table 3.4: Types of maturity onset diabetes of the young (MODY).**

<i>MODY type</i>	<i>Defective chromosome</i>	<i>Mutation in</i>	<i>Phenotypic features</i>
1.	20 q	HNF-4 $\alpha$ (hepatocyte nuclear factor)	Adolescent/early adult: Progressive in insulin secretory defect
2.	7 p	GCK (glucokinase gene)	Since birth: Stable mild fasting hyperglycemia
3.	12 q	HNF-1 $\alpha$	Adolescent/early adult: Progressive insulin secretory defect
4.	13 q	IPF-1 (insulin promoter factor)	Early adult: Very rare, mild diabetes
5.	17 q	HNF-1 $\beta$	Adolescent: Progressive diabetes
6.	2 q	Neuro D1	Early adult: Rare
7.	2 p	KLF-11	Early adult: Pancreatic

			atrophy
8.	9 q	CEL (carboxyl ester lipase)	Early adult: Rare
9.	7 q	Pax-4	Early adult: Rare
10.	11 p	INS	Rare
11.	8 p	BLK	Rare

**Table 3.5: Differences between type 1 DM, type 2 DM and MODY.**

<i>Features</i>	<i>Type 1 DM</i>	<i>Type 2 DM</i>	<i>MODY</i>
Frequency	Common	Increasing	2–5% of type 2 DM
Genetics	Polygenic	Polygenic	Monogenic autosomal dominant
Family history	<15%	>50%	100%
Ethnicity	Different races	Different races	Asians, Polynesians, indigenous Australians
Age of onset	Throughout childhood	Post-puberty	<25 years
Severity of onset	Acute and severe	Mild	Mild/asymptomatic
Ketosis/diabetic ketoacidosis	Common	Uncommon	Rare
Obesity association	–	>90%	+/-
Acanthosis nigricans and metabolic syndrome	Absent	Common	Absent
Autoimmunity	Positive	Negative	Positive
Pathophysiology	$\beta$ Cell destruction	Insulin resistance and relative insulinopenia	$\beta$ -cell dysfunction

**Table 3.6: WHO criteria: Levels of blood glucose in normal, pre-diabetes and diabetes in glucose tolerance test.**

	<i>Euglycemic</i>	<i>Pre-diabetes (impaired glucose tolerance)</i>	<i>Diabetes</i>
Fasting glucose level	<100 mg/dL	>100 mg/dL but less than 126 mg/dL	>126 mg/dL on more than one occasion
2-hour OGTT (75 gm anhydrous glucose in water)	<140 mg/dL	>140 mg/dL but <200 mg/dL	>200 mg/dL

# DIAGNOSIS OF DIABETES MELLITUS

**Q. Write short note/essay on diagnosis of diabetes mellitus.**

- **Classical symptoms:** Diabetes may present with polyuria, polydipsia and polyphagia. There may significant weight loss despite polyphagia.
- **Symptoms due to depressed immune status:** Diabetes is associated with immune dysfunction. It may result in activation of pulmonary tuberculosis, non-healing of wounds, candidial pruritus vulvae or balanitis, recurrent styes and recurrent urinary tract infections.
- **End-organ involvement:** Some patients may present with symptoms of end-organ involvement such as retinopathy, nephropathy or neuropathy.
- **Risk factors of DM:** Some patients may have identifiable risk factors such as obesity, pregnancy and first-degree relatives of known diabetics.

## Normal Glucose Levels

Normally the **blood glucose levels** are maintained in a very narrow range of **70–120 mg/dL**.

Glycemia can be classified into three categories: euglycemia (normal), pre-diabetes (impaired) and diabetes (Table 3.6).

**Pre-diabetes:** It is defined as condition in which there is **impaired glucose tolerance**, but elevated **blood sugar does not reach the criterion accepted for an outright diagnosis of diabetes**. Pre-diabetes may be either ‘impaired fasting glucose’ (IFG), based upon a fasting plasma glucose result, or ‘impaired glucose tolerance’ (IGT), based upon the fasting and 2-hour oral glucose tolerance test results (OGTT). Recently, the term ‘pre-diabetes’ has been changed to ‘**categories of increased risk for diabetes**’. The criteria for diagnosis are:

**Q. Write short note/essay on impaired fasting glucose (IFG).**

- **Impaired fasting glucose (IFG):** Fasting glucose level is **>100 mg/dL but <126 mg/dL** (whole blood glucose  $\geq 88$  mg/dL but  $< 110$  mg/dL). This diagnostic category does not need glucose tolerance test. It is not a distinct clinical entity, but individuals have the future risk of frank diabetes and cardiovascular disease.

**Q. Write short note/essay on impaired glucose tolerance (IGT).**

- **Impaired glucose tolerance (IGT):** GTT values **>140 mg/dL but <200 mg/dL** (whole blood glucose between 125 and 175 mg/dL 2 hours after oral glucose load). Impaired glucose tolerance is not a disease but a risk factor for future diabetes and cardiovascular disease. This is heterogeneous group of people who are obese, have fatty liver and are on medication which can alter glucose tolerance. IGT patients have the same risk of cardiovascular disease as those with frank diabetes, but microvascular complications are rare.
- Additionally, HbA<sub>1c</sub> in the range of **5.7–6.4%** is also included in ‘pre-diabetes’.

**Risks in pre-diabetes:** (1) **Progression to frank diabetes** over time and (2) **cardiovascular disease**.

- IFG and IGT are associated with the **metabolic syndrome**.
- **Medical nutrition therapy** aimed at reducing 5–10% loss of body weight, exercise have been found to prevent or delay the development of diabetes in individuals with IGT. However, no drug therapy is recommended at present. Acarbose and metformin have been tried in Pre-diabetes.

## Diagnostic Criteria for Diabetes Mellitus

**Q. Write short essay/note on oral glucose tolerance test: WHO diagnostic criteria.**

### WHO diagnostic criteria for diabetes mellitus (Box 3.1)

**Box 3.1:** WHO criteria for the diagnosis of diabetes mellitus.

- Fasting plasma glucose >126 mg/dL (7.0 mmol/L)
- Random plasma glucose >200 mg/dL (11.1 mmol/L) with classical signs and symptoms.
- One abnormal laboratory value is diagnostic in symptomatic individuals
  - Two values are needed in asymptomatic individuals
  - The glucose tolerance test is only required for borderline cases and for diagnosis of gestational diabetes.
- HbA<sub>1c</sub> >6.5 (48 mmol/mol)

**Q. Write short note on WHO diagnostic criteria for diabetes mellitus.**

### Criteria for diagnosis of diabetes (American Diabetes Association—Box 3.2)

**Box 3.2:** Criteria for diagnosis of diabetes (American Diabetes Association 2016).

Typical symptoms of DM (polyuria, polydipsia, polyuria, weight loss) + random plasma glucose >**200 mg/dL** (symptoms of diabetes + random whole blood glucose >175 mg/dL)

**OR**

Fasting plasma glucose ≥**126 mg/dL** (fasting whole blood glucose ≥110 mg/dL).

**OR**

2-hour plasma glucose ≥**200 mg/dL** during an oral glucose tolerance test (OGTT) (whole blood ≥ 175 mg/dL during an oral 75 g glucose tolerance test).

**OR**

Glycated hemoglobin (HbA<sub>1c</sub>) ≥**6.5%**

**Q. Write short note/essay on ADA criteria for the diagnosis of diabetes mellitus.**

**Q. Write short note/essay on differential diagnosis of glycosuria.**

### Differential diagnosis of glycosuria (Box 3.3)

**Box 3.3:** Differential diagnosis of glycosuria.

Glycosuria with hyperglycemia

- Endocrine disorders: Diabetes mellitus, acromegaly, Cushing's syndrome, hyperthyroidism, hyperadrenocorticism, functioning  $\alpha$ - or  $\beta$ -cell pancreatic tumors, pheochromocytoma
- Non-endocrine diseases: Increased intracranial tension (brain tumor or hemorrhage), liver disorders, drugs (e.g. corticosteroids, adrenocorticotropic hormones, thiazides), alimentary glycosuria

Glycosuria without hyperglycemia: Renal glycosuria, pregnancy

- Normal renal threshold is blood glucose level of 180 mg/dL and at this level there is no glycosuria. If the blood sugar level exceeds the renal threshold (usually  $>180$ – $200$  mg/dL), the excess glucose will not be reabsorbed into the blood and will be eliminated in the urine as in cases of diabetes mellitus. The presence of detectable amounts of **glucose in urine** is termed **glycosuria**.
- When there is glycosuria, it should be determined whether it is secondary to hyperglycemia (diabetes mellitus) or renal glycosuria or alimentary (lag storage) glycosuria or any other causes (non-diabetic glycosuria).

### Renal glycosuria

**Q. Write short note/essay on renal glycosuria and Marble's criteria for diagnosis of renal glycosuria.**

- **Definition:** Renal glycosuria is the excretion of glucose in the urine at normal blood glucose concentrations in the absence of any signs of generalized proximal renal tubular dysfunction. There is decreased renal threshold below the normal level of 180 mg/dL) for glucose. Renal glycosuria is a benign condition transmitted as an autosomal dominant disorder.

- Diagnosis of renal glycosuria: It is based on the Marble's criteria (Box 3.4).

**Box 3.4:** Marble's criteria for the diagnosis of renal glycosuria.

- Constant glycosuria with little fluctuation related to diet
- Normal OGTT (oral glucose tolerance test)
- Identification of urinary reducing substance as glucose
- Normal storage and utilization of carbohydrates

### Alimentary (lag storage) glycosuria

**Q. Write short note/essay on alimentary (lag storage) glycosuria.**

- Alimentary glycosuria is characterized by a transient abnormal rise in

blood glucose level following moderate amount of a meal (which normally does not cause appearance of glucose in the urine) and appearance of glucose in the urine. It develops because the blood sugar level exceeds the normal renal threshold (180 mg/dL).

- **Conditions associated** with alimentary glycosuria:
  - Glucose tolerance test reveals a peak at 1 hour above renal threshold (which causes glycosuria) but the fasting and post-prandial (i.e. 2 hours after meal) glucose values are normal.
  - Following gastric surgery (e.g. gastrectomy or gastrojejunostomy) with rapid gastric emptying time.
  - Hyperthyroidism
  - Liver diseases
  - Some normal individuals.

## Oral Glucose Tolerance Test (OGTT)

**Q.** Write short essay/note on oral glucose tolerance test (OGTT).

**Indication:** It is not recommended for routine diagnosis of either type 1 or type 2 DM. This is because fasting plasma glucose identifies the abnormal glucose metabolism.

- In patients where the fasting plasma glucose is in the range of impaired fasting glucose (100–125 mg/dL)
- Diagnosis of gestational diabetes mellitus
- Uncertainty about the diagnosis of diabetes

**Preparation of the patient:** Patient should be taking an unrestricted carbohydrate diet for at least 3 days or more prior to the test. Because carbohydrate-restricted diet reduces glucose tolerance. Patient should be with normal physical activity.

- OGTT is performed in the morning after patient has fasted overnight (at least 8 hours).
- The patient should rest for at least half an hour before starting the test, and refrain from smoking, tea/coffee or exercise during the test.

**Test:** A fasting venous sample of blood is drawn to estimate the glucose level.

- Patients is given 75 g of anhydrous glucose dissolved in 250–300 mL of

water orally over 5 minutes. Dose in children is 1.75 g of glucose/kg body weight upto a maximum of 75 g. Time of starting glucose is taken as 0 hour.

- A single venous sample of blood is drawn 2 hours after the glucose administration and glucose level is estimated. (previously, blood samples were collected at 1/2 hour, 1 hour, 1 ½ hour, 2 hours).
- The criteria for impaired glucose tolerance (IGT) are discussed (refer page 83).

## MANAGEMENT OF DIABETES MELLITUS

### **Q. Long essay on:**

- **Treatment and monitoring the control of uncomplicated diabetes mellitus.**
- **Diagnosis and management of type 1 DM/type 2 DM.**
- **Diagnosis and treatment of obese patient with type 2 DM.**

## Diet and Lifestyle Management

### **Q. Write short essay/note on:**

- **Dietary management of diabetes mellitus.**
- **Medical nutrition therapy in diabetes.**

Aims of dietary management (Box 3.5).

**Box 3.5:** Aims of dietary management in diabetes.

- Achieve good glycemic control
- Reduce hyperglycemia and avoid hypoglycemia
- Reduce the risk of diabetic complications
- Weight management:
  - Weight maintenance for type 1 DM and non-obese type 2 DM
  - Weight loss for overweight and obese type 2 DM
- Maintain adequate intake of nutrition
- Avoid atherogenic diets or restrict diet those aggravate complications (e.g. avoid high protein diet in nephropathy)

## ***Medical Nutrition Therapy (MNT)***

MNT should optimally manage the “ABCs” of diabetes control: glycated

hemoglobin (A1C), Blood pressure, and low-density lipoprotein (LDL) Cholesterol.

MNT for diabetes **has to be individualized**, with consideration given to eating habits and lifestyle factors. There must be flexibility in use of ordinary foods for patients and families. The best diet advised is the Mediterranean Diet.

MNT can reduce the Hb A1c levels by 0.6–1.4% if strictly adhered to.

- A **regular pattern of meals** (and snacks) is important to maintain a constant daily intake of carbohydrate, and protects against hypoglycemia. Mild deviations in one or two meals does not matter. It is overall long-term dietary pattern that is important.
- Diet in the management of diabetes **varies with the type of disease**.
  - In **insulin-dependent** patients and those on intensive insulin regimens, since adjustment of insulin can cover wide variations the composition of the **diet is not of critical importance**.
  - In **non-insulin-dependent** patients who are not on exogenous insulin, **rigorous adherence to diet** is needed, as the endogenous insulin reserve is limited. The increased demand produced by excess calories or increased intake of rapidly absorbed carbohydrate cannot be met.
- **Caloric content of the diet:** It is first decision to be taken based on the need to gain, lose, or maintain current weight. **Two basic types of diet** used in the treatment of diabetes are: (i) **low calorie weight reducing diets** and (ii) **weight maintenance diets**. Dietary prescriptions, should be such that there is daily deficit of 500 kcal, provide a realistic diet and produce a weekly weight loss of around 0.5 kg. Calorie recommendations for adults carrying out ‘average’ activity are 36 kcal/kg for men and 34 kcal/kg for women. Recommended diabetic diet should aim at achieving a BMI of 22.
- **Protein requirement:** Minimal protein requirement for good nutrition is about **0.9 g/kg of body weight/day** (acceptable range is 1.0–1.5 g/kg/day) and should constitute **10–15% of the total calorie intake**. Very low protein diets may retard the progression of diabetic nephropathy. Protein content should be limited to 0.8 g/kg/day, or about 10 % of daily calories, once nephropathy develops.
- **Fat:** The calories required through carbohydrate and fat must be determined individually. **Restriction of fat** is necessary **if weight loss is**

**desired**, because of the high energy value of fat compared to protein and carbohydrate. An **average recommendation** of fat for non-obese diabetic patients and those without hyperlipidemias is **30% or less of total calories**, with 10% each as saturated, monounsaturated and polyunsaturated fats. Monounsaturated fats improve plasma lipid profile with reduction in total and LDL cholesterol without lowering HDL cholesterol in type 2 DM patients.

- **Carbohydrate:** After choosing the protein and fat content, the remaining calories are to be derived from carbohydrate. It should **constitute 50–55% of the daily caloric intake**, of which significant amount should be in the form of non-starch polysaccharide, as dietary fiber. Foods with higher fiber content have a lower glycemic index. **Restrict mono and disaccharides** (fructose, sucrose and glucose). The non-nutritive sweeteners saccharin, aspartame, sucramate and acesulfame K are used to reduce energy intake without loss of palatability.
- **Alcohol consumption:** It accounts for extra calories and has tendency to inhibit gluconeogenesis. Thus, it may potentiate the hypoglycemic action of sulfonylureas and insulin. In addition, alcohol predisposes towards the development of lactic acidosis in patients taking metformin. Hence, it should best avoided.

Recommended intake of various nutrients in diabetic patients is presented in Table 3.7.

Pattern of distribution of calories is presented in Table 3.8.

**Table 3.7: Recommended intake of various nutrients in diabetic patients.**

<i>Nutrient</i>	<i>Recommended intake</i>
Carbohydrate	~50–60% of total calories
Protein	15–20% of total calories
Total fat	25–35% of total calories
Saturated fat	<10% of total calories (<7% in dyslipidemia)
Polyunsaturated fat	~10% of total calories
Monounsaturated fat	Up to 20% of total calories
Cholesterol	<300 mg/day (<200 mg/day in dyslipidemia)
Total calories	Adjust based on age, weight and height.

- Sedentary individuals: 30 Kcal/kg/day
- Moderately active individual: 35 Kcal/kg/day
- Heavily active individuals: 40 Kcal/kg/day

**Table 3.8:** Pattern of distribution of calories.

Percentage of total calories	Provision for
20	Breakfast
35	Lunch
15	Late evening feed
30	Dinner

**Table 3.9:** Treatment goals for adults with diabetes.

Index	Goal
Glycemic control HbA <sub>1c</sub>	<7.0%
Preprandial capillary plasma glucose	3.9–7.2 mmol/L (70–130 mg/dL)
Peak postprandial capillary plasma glucose	<10.0 mmol/L (<180 mg/dL)
Blood pressure	<130/80
Lipids	
• Low-density lipoprotein	<2.6 mmol/L (100 mg/dL)
• High-density lipoprotein	>1 mmol/L (40 mg/dL) in men >1.3 mmol/L (50 mg/dL) in women
• Triglycerides	<1.7 mmol/L (150 mg/dL)

## Exercise

**Advantages:** Exercise improves insulin sensitivity, reduces fasting and postprandial glucose, and has metabolic, cardiovascular and psychological benefits in diabetic patients.

- **American Diabetes Association (ADA) recommends:** 30–60 minutes of aerobic activity 3–4 times a week
- Exercise regimens should be individualized. This may be in the form of walking, gardening, swimming or cycling.

Goals of therapy are presented in Table 3.9.

## ORAL HYPOGLYCEMIC (GLUCOSE-

## LOWERING) DRUGS

**Q. Write short essay/note on oral hypoglycemic drugs and their mechanism of actions and indications.**

Agents used for treatment of type 1 and type 2 diabetes are listed in Table 3.10.

Based on their mechanisms of action, oral hypoglycemic drugs are subdivided into agents that increase insulin secretagogues, reduce glucose production, increase insulin sensitivity, enhance GLP-1 action, or promote urinary excretion of glucose.

Various categories of oral hypoglycemic drugs are listed in Table 3.10.

**Table 3.10:** Agents used for treatment of type 1 and type 2 diabetes.

	<i>Mechanism of action</i>	<i>Examples</i>	<i>HbA<sub>1c</sub> reduction (%)</i>	<i>Specific advantages</i>	<i>Specific disadvantages</i>
<b>Oral</b>					
Biguanides	Hepatic glucose production	Metformin	1–2	Weight neutral/mild weight loss do not cause hypoglycemia, inexpensive	Diarrhea, nausea, lactic acidosis, vitamin B <sub>12</sub> deficiency (0.5%).
Insulin secretagogues: Sulfonylureas	Insulin secretion	Glibenclamide (glyburide), glipizide	1–2	Inexpensive	Hypoglycemia, weight gain sulfonamide allergies
Insulin secretagogues: Non-sulfonylureas	Insulin secretion	Repaglinide, nateglinide, nitiglinide	1–2	Short onset of action, lower postprandial glucose	Hypoglycemia
Insulin secretagogues: Dipeptidyl peptidase IV inhibitors	Prolong endogenous GLP-1 action	Saxagliptin, sitagliptin, vildagliptin	0.5–0.8	Do not cause hypoglycemia	Nasopharyngitis Meniscus lesions Headache Contact dermatitis Osteoarthritis Tremor
α-Glucosidase inhibitors	↓ GI glucose absorption	Acarbose, miglitol	0.5–0.8	Reduce postprandial	GI flatulence, liver function

				glycemia	abnormalities Contraindicated in kidney disease, inflammatory bowel disease
Thiazolidinediones <i>Contraindication: CHF, liver disease</i>	↓ Insulin resistance ↑ glucose utilization	Rosiglitazone, pioglitazone	0.5–1.4	Lower insulin requirements	Peripheral edema, CHF, weight gain, fractures, macular edema; rosiglitazone may increase cardiovascular risk
<i>Sodium glucose cotransporter 2 (SGLT2) inhibitors</i>	Help eliminate glucose in the urine	Canagliflozin, dapagliflozin, empagliflozin	0.4 to 1.1	No hypoglycemia, weight loss	Genital and urinary infections
<b>Bile acid sequestrants</b>					
Bile acid sequestrants <i>Contraindications: Elevated plasma triglycerides</i>	Bind bile acids, mechanism of glucose lowering not known	Colesevelam	0.5		Constipation, dyspepsia, abdominal pain, nausea, triglycerides interfere with absorption of other drugs, intestinal obstruction
<b>Parenteral</b>					
Insulin	↑ Glucose utilization, ↓ hepatic glucose production, and other anabolic actions	Refer Table 3.14	Not limited	Known safety profile	Injection, weight gain, hypoglycemia
GLP-1 receptor agonists <i>Contraindications: Renal disease, agents that also slow GI motility</i>	↑ Insulin, ↓ glucagon, slow gastric emptying satiety	Exenatide, liraglutide	0.5–10	Weight loss, do not cause hypoglycemia	Injection, nausea, risk of hypoglycemia with insulin secretagogues, pancreatitis, renal failure
Amylin agonists	Slow gastric	Pramlintide	0.25–0.5	Reduce	Injection,

<i>Contraindication: Agents that also slow GI motility</i>	emptying, ↓ glucagon			postprandial glycemia; weight loss	nausea, risk of hypoglycemia with insulin
<b>Medical nutrition therapy and physical activity</b>	↓ Insulin resistance, ↑ insulin secretion	Low-calorie, low-fat diet, exercise	1–3	Other health benefits	Compliance difficult, long term success low

## Biguanides-Metformin

### **Q. Write short essay/note on metformin.**

- It reduces both fasting level of blood glucose and the degree of postprandial hyperglycemia in patients with type 2 diabetes but has no effect on normal subjects. It is thought to act by inhibiting the hepatic gluconeogenesis.
- It is particularly useful in obese patients or those patients who are not responding optimally to maximal doses of sulfonylureas.
- Hypoglycemia does not occur with therapeutic doses of metformin, which permits its description as a ‘euglycemic’ drug rather than an oral hypoglycemic agent.
- Metformin is not indicated for patients with type 1 diabetes.

**Box 3.6:** Contraindication for metformin.

1. Malabsorption or GI disturbances/GI intolerance
2. Low BMI? less than 21 kg/m<sup>2</sup>, marked weight loss
3. Organ failure: Creatinine: >1.4 mg/dL
  - Liver failure: Acute/chronic
  - Cardiac failure, hypotension/sepsis
4. Active vitamin B<sub>12</sub> deficiency

Contraindication for metformin (Box 3.6).

## Insulin Secretagogues (Table 3.11)—Agents that Affect the ATP-sensitive K<sup>+</sup> Channel

### *Sulfonylureas*

### **Q. Write short essay/note on sulfonylurea and name newer sulfonylureas.**

They specifically bind to a receptor that closes an ATP-sensitive potassium

channel of the pancreatic  $\beta$  cell, thus depolarizing the cell membrane. This results in an influx of extracellular calcium through voltage gated calcium channels, which causes insulin granules to move toward the cell surface, facilitating exocytosis. Thus sulfonylureas have an insulinotropic effect on pancreatic  $\beta$  cells.

The sulfonylureas are most appropriate for use in non-obese mild type 2 diabetes. In obese mild diabetics and others with peripheral insensitivity to levels of circulating insulin, primary emphasis should be on weight reduction. Weight gain is a frequent side effect of sulfonylureas.

**First generation:** Tolbutamide, chlorpropamide.

**Second generation:** Glibenclamide (glyburide), glipizide, gliclazide, glimepiride.

**Third generation:** Glimiperide

- Glibenclamide should be taken about half an hour before meals, since rapid absorption is delayed when the drug is taken with food. Most sulfonylureas act via the 140 kDa part of the receptor while glimiperide acts via 65 kDa part of the receptor, hence has better cardiovascular safety.

**Table 3.11:** Properties of insulin secretagogues.

<i>Class/Genetic Name</i>	<i>Daily dosage in milligrams (mg)</i>	<i>Duration of action in hours</i>
<b>Sulfonylureas</b>		
Glimepiride	1–8	24
Glipizide	5–40	12–18
Glipizide (extended release)	5–20	24
Glyburide/glibenclamide	1.25–20	12–24
Glyburide (micronized)	0.75–12	12–24
<b>Nonsulfonylureas (Meglitinides)</b>		
Repaglinide	0.5–16	2–6
Nateglinde	180–360	2–4
<b>GLP-1 Agonist</b>		
Exenatide	0.01–0.02	4–6
Liraglutide	0.6–1.8	12–24
<b>Dipeptidyl Peptidase-4 Inhibitors</b>		
Saxagliptin	2.5–5	12–16
Sitagliptin	100	12–16

## ***Nonsulfonylureas-Meglitinides***

- **Repaglinide and nateglinide** are not sulfonylureas but interact with the ATP-sensitive potassium channel. Owing to their short half-life, these are given with each meal or immediately before to reduce meal related glucose excursions.
- **Advantages of meglitinides:** Flexibility in mealtime dosing- ‘Ramzan Drug’, no significant increase in bodyweight, can be utilized in mild to moderate renal failure and lesser hypoglycemia.

## **Agents that Enhance GLP-1 Receptor Signaling—Incretin-based Therapy**

- The **incretin effect** is defined as the increased stimulation of insulin secretion caused by oral administration of glucose.
  - Two intestinal peptide hormones (incretin hormones) namely-**glucose-dependent insulintropic peptide (GIP) and glucagon-like peptide1 (GLP1)** have a potentiating effect on secretion of insulin by pancreas. In response to food, GIP is secreted by the K cells in the duodenum and GLP1 by the L cells of the ileum.
  - These hormones act on their receptors present on islet cells of pancreas and stimulate insulin secretion in response to food. This stimulation of insulin secretion by the gut is referred to as the intestinal secretion of insulin or incretin effect.
  - **The insulin secretion is markedly greater in response to an oral than to an intravenous glucose challenge.**
- **Glucagon-like peptide-1 analogues**
  - **Drugs:** Exenatide, lixisenatide, and liraglutide may be used in combination with metformin, a sulfonylurea, or a thiazolidinedione. These analogues need to be given parenterally.
  - **Advantages:** They produce weight loss and risk of hypoglycemia is low.
  - **Side effects:** Include nausea, diarrhea and rarely pancreatitis.
- **Dipeptidyl peptidase 4 (DPP-4) inhibitors, Gliptins**

**Q. Write short note on dipeptidyl peptidase-4 (DPP-4)**

### **inhibitors/vildagliptin.**

- An alternative approach to the use of GLP-1 analogues is to inhibit dipeptidyl peptidase 4 to conserve endogenous GLP-1. DPP-4 enhance the incretin effect.
- The enzyme dipeptidyl peptidase 4 (DPP-4) rapidly inactivates GLP1. Inhibition of this enzyme thus potentiates the effect of endogenous GLP1 secretion.
- **Drugs available: Linagliptin, saxagliptin, alogliptin, sitagliptin and vildagliptin** are oral agents. They are most effective in the early stages of type 2 DM when insulin secretion is relatively preserved. They are recommended for second line use in combination with metformin or a sulfonylurea.
- They have a moderate effect in lowering blood glucose and risk of hypoglycemia is low.
- **Side effects:** Nausea, diarrhea, headache, upper respiratory symptoms, myalgia and rare risk for pancreatitis.
- **Teneligliptin** is a newer, more potent DPP-4 inhibitor which is safe in renal failure.

### **$\alpha$ -Glucosidase Inhibitors**

**Q.** Write short essay/note on  $\alpha$ -glucosidase inhibitors/acarbose.

**Drugs in this group:** acarbose, miglitol and voglibose.

**Mechanism of action:**  $\alpha$ -glucosidase is an enzyme present on the brush border of the small intestine. It is needed for the breakdown of oligosaccharides (carbohydrates) into simple sugars (before carbohydrates can be absorbed) in the intestinal lumen.

- $\alpha$ -glucosidase inhibitors **reduce glucose absorption** by inhibiting the enzyme  $\alpha$ -glucosidase. This results in poor absorption of carbohydrates thereby reduces postprandial hyperglycemia.
- They neither affect glucose utilization nor insulin secretion.

**Indications:** They are useful in the management of patients who develop **significant post-prandial hyperglycemia** but otherwise have relatively well-controlled blood glucose levels.

- **Dosage:** Dose of both acarbose and miglitol is 25 mg which is first started

with a single dose taken just before evening meal. This can be gradually increased to 50 mg with each meal. Dose of voglibose is 0.2–0.3 mg, just before each meal.

- **Major side effects:** These drugs are poorly tolerated and may produce diarrhea, flatulence, and abdominal distension. They are due to increased delivery of unabsorbed oligosaccharides to the large intestine where it undergoes fermentation.
- **Advantages:** They are not as potent as other oral hypoglycemic drugs in lowering the HbA<sub>1c</sub> but they are unique because it reduces the postprandial glucose rise even in patients with type 1 DM. They do not produce hypoglycemia.

## Thiazolidinediones

**Q. Write short essay/note on thiazolidinediones.**

**Drugs in this group:** Thiazolidinediones (more conveniently known as the ‘glitazones’) includes **pioglitazone**, rosiglitazone and troglitazone. Troglitazone and rosiglitazone are withdrawn due to increased incidence of liver failure and increased cardiovascular risk, respectively in patients using it.

**Mechanism of action:** Thiazolidinediones reduce insulin resistance by binding to **peroxisome proliferator-activated receptor gamma (PPAR-γ)**.

- Highest levels of the PPAR-γ receptor are found in adipocytes. PPAR-γ is a nuclear receptor which regulates transcription of large numbers of genes including those involved in lipid metabolism (promote adipocyte differentiation, reduce hepatic fat accumulation and promote fatty acid storage) and insulin action.

### *Pioglitazone*

**Q. Write short note on side effects of pioglitazone.**

- **Dosage of pioglitazone:** 15–45 mg/day.
- **Combination therapy:** It can be combined with metformin and sulfonylureas.
- **Side effects:** Include
  - Weight gain of 2–3 kg (due to fluid retention as well as increase in adiposity), fluid retention and heart failure

- Mild rise in LDL and HDL levels
- Mild anemia and osteoporosis (increased propensity to bone fractures), bladder carcinoma
- Maximum effect may be seen only after 3–4 weeks.
- **Precautions:** Liver function should be periodically monitored as liver dysfunction may develop. It is contraindicated in liver disease and congestive cardiac failure.

## Other Drugs Used in Diabetes

- **Sodium-glucose co-transporter 2(SGLT2) inhibitors:** (e.g. dapagliflozin, Remogliflozin, empagliflozin, ertugliflozin canagliflozin). Sodium-dependent glucose co-transporters (SGLT) are found in the intestinal mucosa of the small intestine and the proximal tubules of the nephrons. SGLT2 inhibition is independent of glucose-dependent insulin secretion by the pancreatic  $\beta$  cells. The adverse effects of SGLT2 inhibitors may include fatigue, hypoglycemia, increased urine output, increased hematocrit, and **mycotic genital or urinary tract infections**. Other side effects include hypotension, acute kidney injury, bone fracture and auto-amputations.
- **Amylin agonist: Pramlintide** is a synthetic pancreatic hormone amylin. It is to be injected before each meal.
- **Bile acid-binding resins: Colesevelam** is a bile acid sequestrants, act in the GI tract to reduce glucose absorption. Side effects can include constipation, nausea, and dyspepsia.
- **Dopamine agonist: Bromocriptine** is an ergot-derived dopamine agonist that has been used for the treatment of hyperprolactinemia and Parkinson disease. A quick release formulation of bromocriptine is used for the treatment of type 2 diabetes mellitus. Bromocriptine (up to 4.8 mg daily) as monotherapy or as adjunctive therapy to sulfonylureas was minimally effective in reducing HbA<sub>1c</sub>. Common side effects include nausea, vomiting, dizziness, and headache.

## ***Lipase Inhibitors (Orlistat)***

- It produces weight-loss which improve glucose tolerance and slows the rate of progression to type 2 diabetes.

## Drugs in Pipeline

- **Glucokinase activators:** Piragliatin
- **Dual PPAR ( $\alpha$  and  $\gamma$ )agonists:** Alogliptazar
- **Chromium (Cr), sodium tungstate, vanadium, prooxyfan,  $\beta$ -sitosterol**
- **S-Allylcysteine** (a natural constituent of fresh garlic)
- **Otelixizumab**, an anti-CD3 monoclonal antibody, is known to stimulate C-peptide levels and reduce insulin requirement in type 1 diabetes.

**Box 3.7:** Goals of insulin therapy.

- Elimination of primary symptoms of hyperglycemia and glycosuria
- Prevention of diabetic ketoacidosis (DKA) and hyperosmolar coma
- Restoration of lost lean body mass
- Improvement of physical performance and sense of well-being
- Reduction of frequent infections
- During pregnancy: decrease fetal malformation, maternal and fetal morbidity
- Delay, arrest or prevent macrovascular or microvascular complications

## Insulin Treatment

**Q. Write short essay/note on:**

- **Role of insulin in the management of diabetes/insulin therapy.**
- **Classify insulins. Give a brief account of the commonly used insulins.**
- **Insulin indication and types/Indications for short, intermediate and long acting insulins.**

Insulin is necessary for all patients with type 1 DM and many patients with type 2 DM. Goals of insulin therapy is mentioned in Box 3.7.

## General Indications for Insulin Therapy (Table 3.12)

**Table 3.12:** Indications for insulin therapy.

<ul style="list-style-type: none"><li>• Type 1 DM</li><li>• Diabetic ketoacidosis (DKA)</li><li>• Hyperosmolar hyperglycemic state</li></ul>	<p>Diabetes under following conditions</p> <ul style="list-style-type: none"><li>• Pregnancy (preferably prior to pregnancy)</li><li>• Acute severe illness needing hospitalization</li><li>• Perioperative/intensive care unit setting</li><li>• Patients with acute coronary syndrome (MI)</li><li>• Patients on high dose corticosteroids</li></ul>
--	--

- Inability to tolerate or contraindication to oral antiglycemic agents
- Newly diagnosed type 2 diabetes with significantly elevated blood glucose levels (patients with severe symptoms or DKA)
- Patient no longer achieving therapeutic goals on combination antiglycemic therapy

## Insulin Preparations

Classification of insulin preparations (Table 3.13)

**Table 3.13:** Various ways of classification of insulin preparations.

<i>Basis of classification</i>	<i>Types</i>
Source	Bovine, porcine and human insulins
Purity	Conventional, single peak and monocompotent insulins
Time course of action	Rapid, intermediate and long-acting insulins
Strength	40 and 100 units/mL
Newer insulin analogues	Glargine, detemmer, etc.
Bolus insulin (mealtime or prandial)	Regular insulin, lispro, aspart, glulisine
Basal insulin	NPH (isophane insulin), glargine, detimer

## Properties of Various Insulin Preparations

The commonly used insulin preparations and their duration of action are presented in Table 3.14.

**Table 3.14:** Duration of action (in hours) of various insulin preparations.

<i>Class</i>	<i>Type</i>	<i>Onset of effect (hours)</i>	<i>Peak effect (hours)</i>	<i>Effective duration of action (hours)</i>
Rapid acting	Insulin analogues: lispro, aspart, glulisine	<0.25	0.5–1.5	2–4
Short-acting	Regular (crystalline, soluble, plain)	0.5–1	2–3	3–6
	Semilente	0.5–1	2–6	10–12
Intermediate	Isophane (NPH)	2–4	4–10	10–16
	Lente (excess zinc)	1–3	6–12	18–24

	ions)#			
Long-acting	Protamine zinc (PZI)	2-4	14-24	36
	Ultralente	2-4	18-24	36
	Insulin analogues: glargine, detemir	1-4	None	18-24

#Lente (intermediate acting) insulin is mixtures of semilente and ultralente in the ratio of 30:70, respectively.

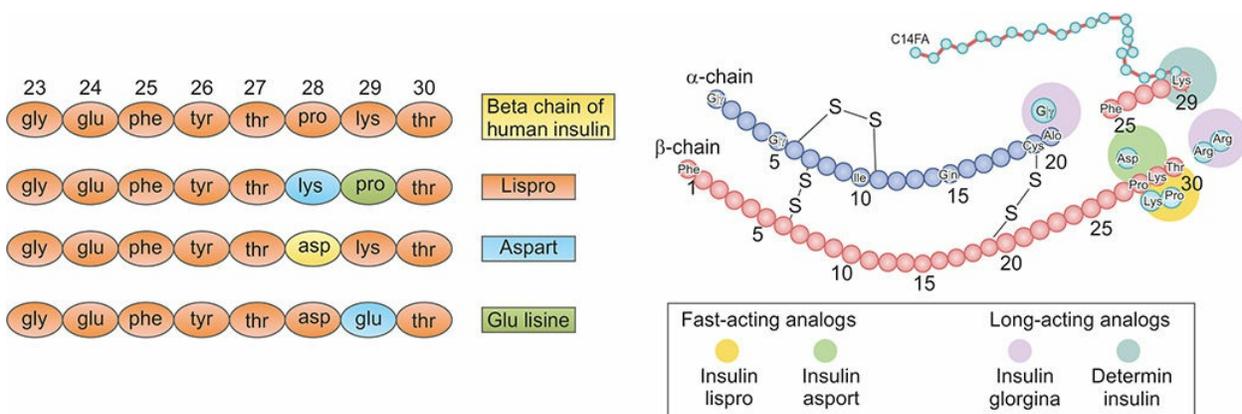

### Insulin Analogs/Newer Insulins (Table 3.15 and Fig. 3.5)

**Q. Write short note on human insulin analogs and advantages of newer insulins/insulin analogs.**

Insulin analogs are prepared by modifying human insulin and have replaced soluble and isophane insulins, especially type 1 diabetes mellitus. Insulin analogs have more flexibility and convenience. In contrast to soluble insulin (which should be injected 30 minutes before eating), rapid-acting insulin analogues can be given immediately before, during or even after meals. Long-acting insulin analogues (better than isophane insulin) maintain ‘basal’ insulin levels for up to 24 hours, and may be given once daily.

**Table 3.15: Insulin analogs.**

Short acting	Long acting
Lispro	Glargine
Aspart	Detemir
Glulisine	Degludec

**Fig. 3.5:** Amino acid structure of insulin and insulin analogs.

Patients on regular insulin regimens may develop repeated episodes of hypoglycemia between meals (during some part of the day) and particularly at night. Insulin analogues are useful in such patients. The various preparations include:

### ***Insulin Lispro***

- It is first human insulin analog produced by recombinant DNA technology utilizing a non-pathogenic strain of *E.coli*.
- **Glucose-lowering activity:** More **rapid onset** of action (<15 minutes), early peak (60–90 minutes) and a **shorter duration** of glucose-lowering activity (<5 hours).
- **Disadvantages:** Because of its short duration of action
  - Patient needs to take this insulin analog just before or after meals.
  - Patients need additional use of longer-acting insulin to maintain glucose control.

### ***Insulin Aspart and Insulin Glulisine***

- They are also short-acting insulin analogs similar to lispro.

### ***Insulin Glargine***

- It is a human ‘**peakless**’ bioengineered insulin analog that has a **long duration of action** and has an acidic pH.
- **Glucose-lowering activity:** After a lag time of 4 to 6 hours, the flat peakless effect last for 24 hours.
- **Mechanism of action:** After injection into the subcutaneous tissue, **acidic form of insulin becomes neutral and forms micro-precipitate**. They **release small amounts** of insulin **very slowly**. It results in a relatively constant concentration for 24 hours without a pronounced peak.
- **Advantages:** It is given **once daily** as subcutaneous injection generally at bedtime. **Hypoglycemia does not develop**.
- **Disadvantages:** As insulin glargine is in acid form, it may cause **increased pain at the injection site**. Its acid nature also **limits its ability to mix with other insulins**.

### ***Insulin Detemir***

- It is a long acting, basal soluble human insulin analog and has a neutral

pH.

### *Advantages*

- Because of its neutral pH, it causes **least pain** at the site of injection.
- It binds to albumin via its fatty acid chain which allows this analog to remain liquid and soluble following injection. It has **prolonged mode of action** due to its attachment to fatty acid.
- **Neither renal nor hepatic impairment exert influence** over its pharmacological effects.
- **No gain of weight.**
  - It is effective when administered once or twice daily and **combined with** the basal **soluble analogue** insulin and/or with **oral hypoglycemic drugs** or **pre-meal short acting insulin regimen**. Insulin detemir and the rapid-acting analog insulin aspart or lispro, it closely mimic near normal insulin profiles and **improves glycemic control than more conventional insulin therapy**.

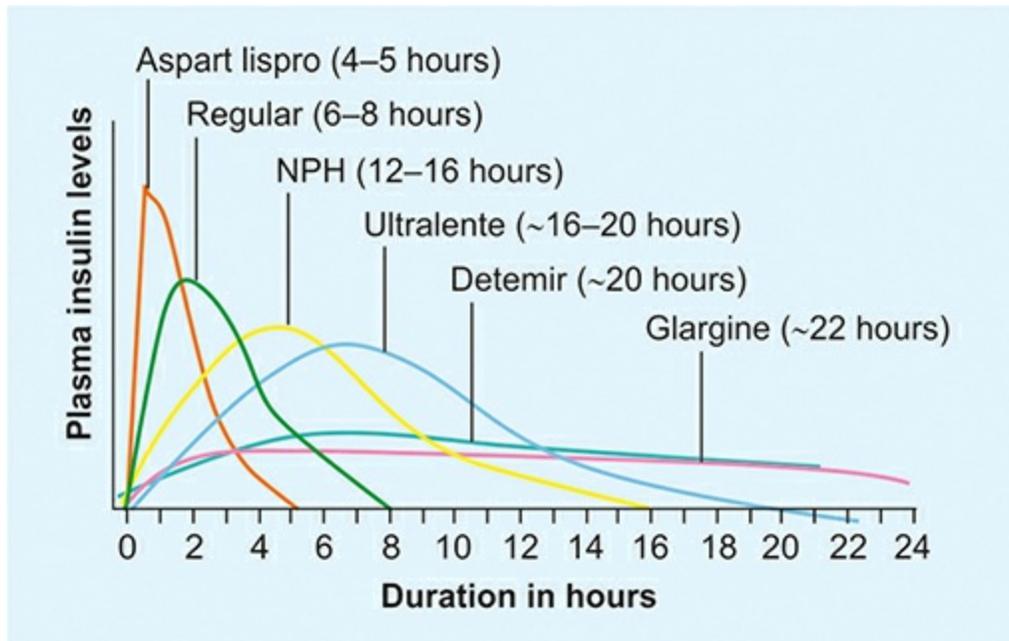

### *Insulin Degludec*

- It is a long acting (>40 hours) human insulin analog.
- It forms soluble multi-hexamers at the site of subcutaneous injection and releases monomers slowly to give an ultra-long peakless pharmacokinetic (PK) profile. It reduces variability of concentration in the plasma with once daily regimen.

### *Advantages of Degludec*

- **Peakless insulin**
- Excellent improvement in HbA<sub>1c</sub>, superior fasting plasma glucose (FPG) reduction
- Less hypoglycemia. Reduction of up to 36% in nocturnal hypoglycemia
- Flexibility: Dosing flexibility: **administration any time on any day.**

Schematic representation of duration of action of insulin profiles in diabetes mellitus is depicted in Figure 3.6.

**Fig. 3.6:** Insulin therapy in diabetes mellitus. Schematic representation of duration of action of insulin profiles.

Merits and demerits of newer insulin/insulin analogs (Table 3.16).

**Table 3.16:** Merits and demerits of newer insulin/insulin analogs.

<i>Merits</i>	<i>Demerits</i>
<ul style="list-style-type: none"> <li>• Better mimicking of physiological insulin secretion</li> <li>• Better control of glucose levels in the fasting, inter-digestive and post prandial period</li> <li>• Lesser risk of hypoglycemia (especially nocturnal)</li> <li>• No need to be injected half an hour before meals</li> <li>• More predictable action profile independent of dose/site of injection/exercise</li> <li>• Greater flexibility with short acting analogues</li> <li>• Compliance is improved with long acting analogues as once a day insulin</li> </ul>	<ul style="list-style-type: none"> <li>• No significant different in adverse effects when compared to standard insulins</li> <li>• Worsening retinopathy with Lispro (homologous to IGF-1)</li> <li>• Carcinogenicity: Concerns over Glargine carcinogenicity</li> <li>• High cost</li> </ul>

**Q. Write short note on advantages/merits and demerits of newer insulin/insulin analogs.**

### ***Inhaled Insulin***

- Inhaled human insulin powder was introduced in 2006 and its absorption was through the alveolar surface in the lungs. However, because of adverse effects and cost, it was withdrawn in 2007.
- Inhalation was done with each meal along with single injection of long-acting insulin to provide basal levels of insulin.
- **Side effects:** Cough, dry mouth, sore throat and shortness of breath, and hypoglycemia.

### Insulin Regimens (Table 3.17)

**Three insulin regimens** include (i) conventional insulin therapy, (ii) multiple subcutaneous injections (MSI) and (iii) continuous subcutaneous insulin infusion (CSII). The choice of regimen depends on the degree of glycemic control desired, the severity of insulin deficiency, the patient's lifestyle, and their ability to adjust the insulin dose. Most of type 1 diabetes requires two or more injections of insulin daily. In type 2 diabetes, insulin is usually started as once-daily long-acting insulin, either alone or in combination with oral hypoglycemic agents.

**Table 3.17: Insulin regimens.**

Once-daily insulin regimen	Long acting peakless insulin + oral hypoglycemic agents
Twice daily insulin regimen	Intermediate insulin (NPH) given twice daily
Sliding scale- premixed/split- mix regimen	Combination of premixed insulin (30:70/50:50) given twice daily or combination of short and long acting analogues given three to four times a day
Basal-bolus regimen/multiple daily injection therapy	Basal-long acting or intermediate acting insulin (NPH, detemir/glargine) once daily usually at night AND Bolus-separate injections of short or rapid acting insulin (Regular, Aspart/lispro/glulisine) at each meal.
Continuous subcutaneous insulin infusion / insulin pump therapy	Pump delivers a constant feed of insulin into the body via a cannula subcutaneously At meal times, an increased burst (bolus) of insulin can be delivered.

**Conventional insulin therapy:** It is the simplest regimen and used commonly. In this regimen, **intermediate-acting insulin** (lente), with **or**

**without the addition of small amounts of regular insulin** are injected subcutaneously **once or twice** per day.

- **Insulin mixtures:** In this, intermediate-acting insulin along with small doses of regular insulin is administered to achieve better euglycemic status.
- **Split lente regimen:** If the total daily requirement of insulin exceeds 50 or 60 units, or when there is a need for better control, the intermediate acting insulin (lente) is administered in two doses/day. Two-thirds of the total required dose is taken before breakfast (7–8 AM) and the remaining one-third before dinner (7–8 PM).

**Multiple subcutaneous injections (MSI):** Insulin is injected subcutaneously several times a day into the anterior abdominal wall, upper arms, outer thighs and buttocks.

- In this regimen, **intermediate or long acting insulin** is administered in the evening as a **single dose/day** together **with regular insulin prior to each meal**.
- It achieves overall control and may reduce the rate of development of long-term complications.
- **Commonly used schedule:** Calculate the total daily dose of insulin required at 0.6–0.7 units/kg body weight.
  - **25% of the calculated dose** is administered as **intermediate-acting insulin at bedtime**.
  - **75% of the calculated dose** is administered as **regular insulin in three divided doses** (40% before breakfast, 30% before lunch and 30% before dinner).

**Continuous subcutaneous insulin infusion (CSII)/alternative insulin therapies:** ‘Open-loop’ systems are small battery-powered portable **insulin pumps** which provide continuous subcutaneous, intraperitoneal or intravenous infusion of insulin.

- In this regimen, a **small battery-driven insulin pump** is worn externally and connected to a butterfly needle, which is inserted into the anterior abdominal wall.
- It mimics the physiological basal plus prandial pattern of insulin secretion and can achieve excellent glycemic control. The rate of insulin infusion can be programmed to match the patient’s diurnal variation in

requirements. About **40% of the total daily required dose** is given at **basal rate; the remainder is given as preprandial boluses.**

- **Advantages:**

- Ease of taking multiple boluses if desired.
- Availability to program the basal rate of insulin delivery especially useful in dawn phenomenon.
- Improved control over multiple dose insulin (MDI).
- Reduced risk of severe hypoglycemia and hypoglycemic attacks can be easily treated.

- **Disadvantages:**

- Needs a high degree of patient motivation
- Expensive- high cost
- Infection at infusion sites
- High incidence of ketoacidosis
- Hypoglycemia especially nocturnal and may be fatal.
- Risk of mechanical malfunctioning

- **Artificial pancreas project** aims to close the loop by using miniaturized glucose sensors to communicate wirelessly with the insulin pump. This would automatically adjust its insulin rate. However, this is not used in clinical practice at present.

## Insulin Delivery Systems

**Q. Write short note on newer insulin delivery device.**

- **Insulin syringes:** These are available as disposable plastic syringe in various sizes (i.e. 40 U/mL or 100 U/mL). Insulin can be administered using a fine needle (can be re-used several times). They can be used easily and has enhanced accuracy.
- **Insulin pen:** An insulin pen holds a prefilled cartridge contain desired type of insulin and has a fine disposable needle that can be changed for each injection. It is suitable for multiple dosing.
- **Implanted insulin pump therapy:** Controlled pumps can be implanted in the peritoneal cavity. Insulin released into the peritoneal cavity is mostly absorbed and delivered into the splanchnic system.
- **External insulin pump therapy:** Portable insulin infusion pump or

continuous subcutaneous insulin infusion (CSII) are alternative insulin delivery devices (refer above).

## Complications of Insulin Therapy

**Q. Write short essay/note on adverse/side effects (complications) of insulin therapy.**

- **Hypoglycemia during insulin treatment:** It is the most common complication of insulin therapy and causes anxiety for both patients and relatives. It occurs due to imbalance between injected insulin and a patient's normal diet, activity and basal insulin requirement. The risk of hypoglycemia is more before meals, during the night, and during exercise. Irregular eating habits, unusual exertion and alcohol excess may precipitate hypoglycemic episodes.
- **At the injection site**
  - **A shallow injection** causes intradermal (rather than subcutaneous) delivery of insulin resulting in **painful, red lesions** or even scarring. Abscess at injection site is extremely rare.
  - **Local allergic reactions:** May occur at the injection site early in therapy. These include local itching, erythematous and indurated lesions, and discrete subcutaneous nodules. They usually resolve spontaneously.
  - Fatty lumps, called as **lipohypertrophy**, may develop due to overuse of a single injection site due to lipogenic effects of the injected insulin. It may occur with any type of insulin.
  - **Insulin resistance and anti-insulin antibodies:** Most common cause of mild insulin resistance is obesity. Insulin resistance may be associated with antibodies directed against the insulin receptor.
- **Weight gain:** Many patients may gain weight on insulin treatment, especially if the insulin dose is increased inappropriately. This may be prevented by diet restriction, exercise, and addition of metformin.
- Generalized allergic (urticaria and anaphylactic) reactions are very rare.

## Pancreatic Transplantation

**Q. Write short note on pancreatic transplantation.**

Other option available in patients with type 1 diabetes mellitus includes

whole pancreas transplantation and islet cell transplantation. Both transplantation can restore normoglycemia without exogenous insulin therapy and survival rates of these patients are consistent with other organ transplantation procedures.

- **Whole pancreas transplantation:** At present, it is usually performed only in patients with end-stage renal failure who require a combined pancreas/kidney transplantation and in whom diabetes control is particularly difficult (e.g. because of recurrent hypoglycemia).
- **Transplantation of isolated pancreatic islets:** It is performed by harvesting pancreatic islets from cadavers (two or three pancreata are usually necessary). These islets cells are injected into the portal vein and they seed themselves into the liver.
- **Management of type 1 diabetes, nonobese type 2 diabetes and obese type 2 diabetes** are summarized in Boxes 3.8, 3.9 and 3.10 respectively.

**Box 3.8:** Summarized management of type 1 diabetes.

- **Insulin therapy:** Oral hypoglycemic agents (OHAs) are ineffective and patient should be started on insulin therapy. It can be split dose insulin therapy or intensive insulin therapy.
- Usually need multiple injections for acceptable glycemic control.

**Box 3.9:** Summarized management of nonobese type 2 diabetes.

- **Lifestyle modification:** If hyperglycemia is mild, following diabetic-diet can occasionally restore normal metabolic control.
- **Monotherapy:** When diet therapy is not sufficient, a trial of sulfonylurea is often effective in reducing sugar levels.
- **Two drug therapy:** Next step involved combination therapy with metformin, Thiazolidinedione/Dipeptidyl peptidase IV inhibitors/Glucagon-like peptide-1 receptor agonists/sodium-glucose co-transporter 2 inhibitors can be the next addition for sugar control.
- **Insulin therapy:** When patient fails the combination of these three drugs, insulin therapy is indicated. Usually patients have enough baseline insulin to allow use of single long acting insulin to take care of sugar control.

**Box 3.10:** Summarized management of obese type 2 diabetics.

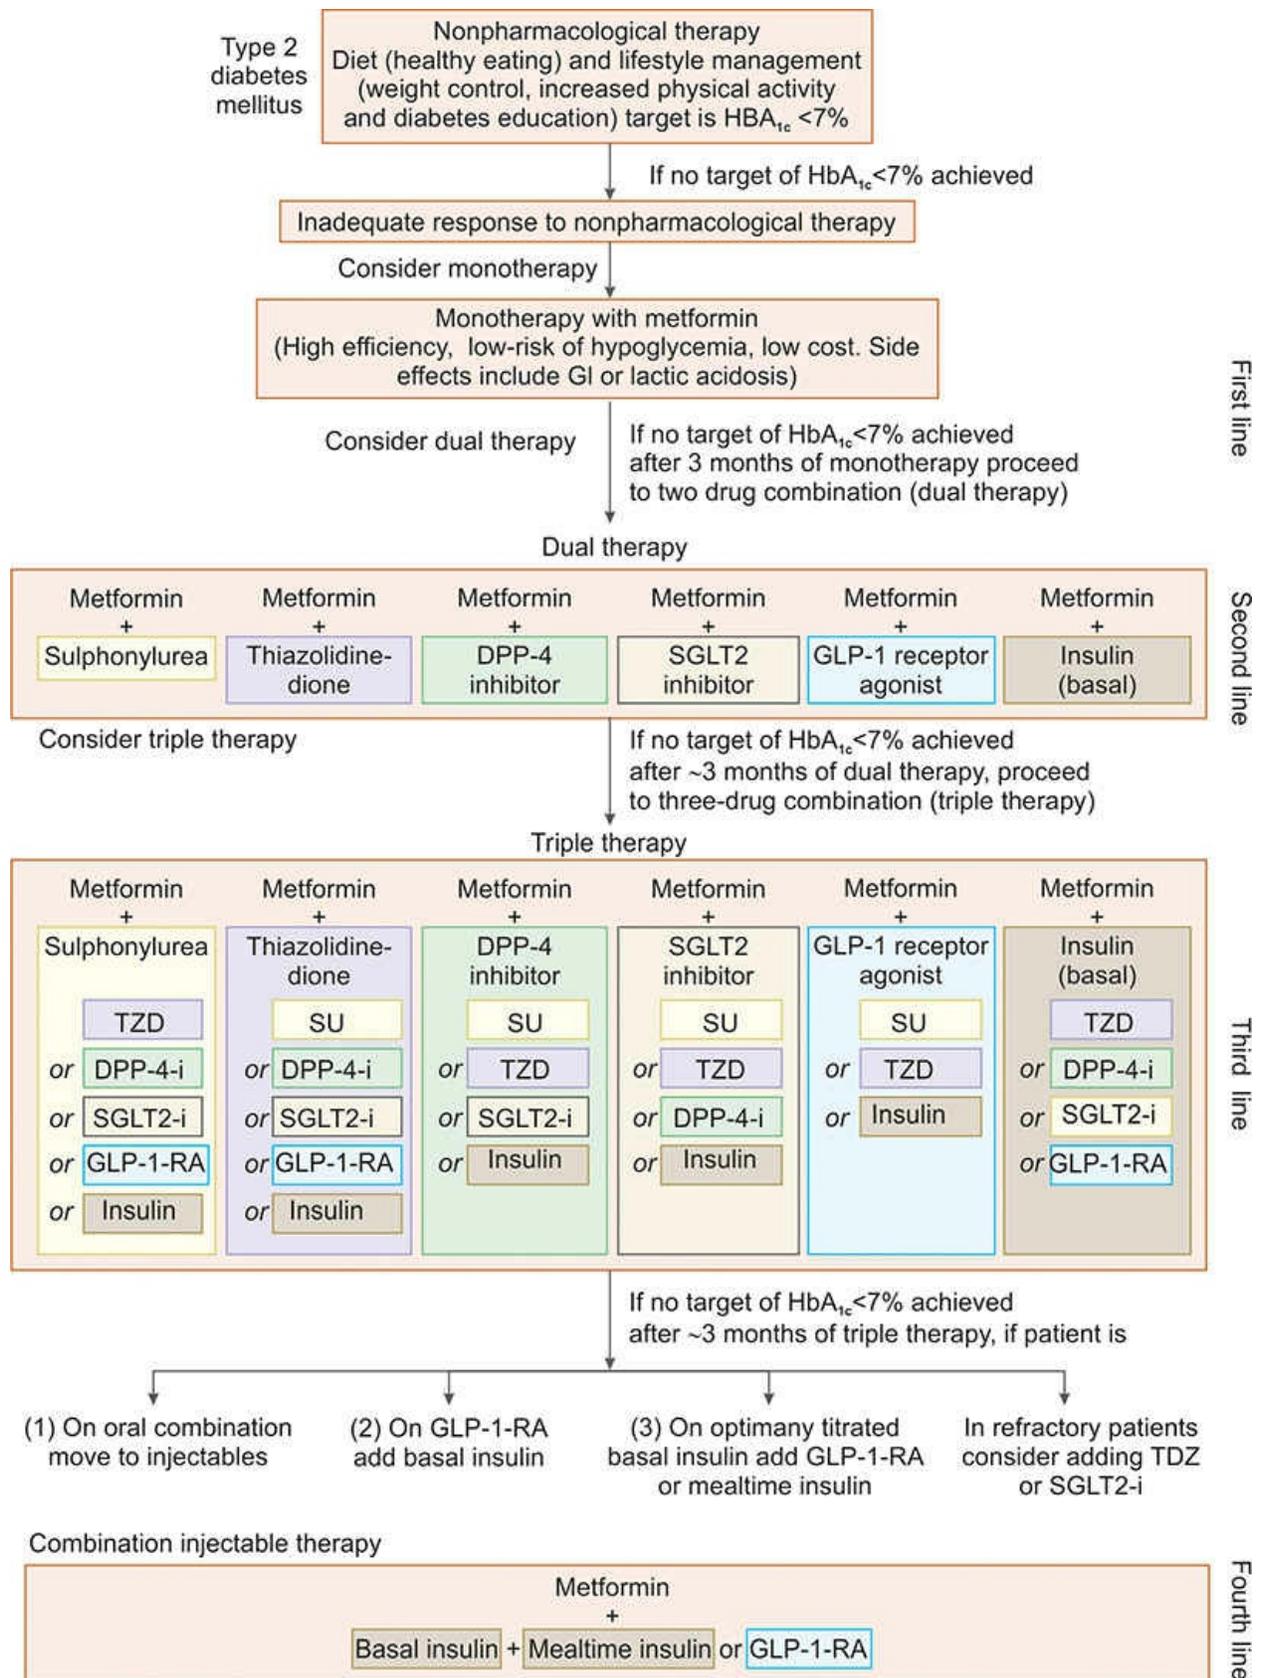

- **Weight reduction:** First step is weight reduction to improve tissue sensitivity to insulin.
- **Monotherapy:** Among oral hypoglycemic agents (OHAs) monotherapy with **alpha-glucosidase inhibitors or metformin** may be started, as they are not associated with weight gain or drug-induced hypoglycemia.
- **Two drug therapy:** If metformin therapy is inadequate, **sulfonylurea may be added.**
- **Three drug therapies:** If this combination of metformin and sulfonylurea is ineffective in controlling sugar levels then **addition of thiazolidinediones/Dipeptidyl peptidase IV inhibitors/**

Glucagon-like peptide-1 receptor agonists/sodium-glucose co-transporter 2 inhibitors should be considered.

- **Insulin therapy** should be instituted if the combination of these three drugs fails to restore euglycemia. Generally, the sulfonylurea is discontinued when insulin therapy is instituted but the patient can stay on the metformin and thiazolidinediones. Usually patients have enough baseline insulin to allow use of single long acting insulin to take care of sugar control.

Algorithm of therapy for type 2 diabetes mellitus is depicted in Flowchart 3.1.

**Flowchart 3.1:** Stepwise approach for the management of type 2 diabetes.

(DPP-4-i: dipeptidyl peptidase 4 inhibitor; GLP-1-RA: glucagon-like peptide 1 receptor agonist; SGLT2-i: sodium and glucose transporter 2 inhibitor; SU: sulphonylurea; TZD, thiazolidinedione)

## Glycosylated Hemoglobin (HbA<sub>1c</sub>) and Fructosamine

### **Q. Write short essay/note on glycosylated hemoglobin (HbA<sub>1c</sub>).**

#### *Glycosylated hemoglobin (HbA<sub>1c</sub>)*

- HbA<sub>1</sub> is a minor component of adult hemoglobin (HbA) and its important subgroup is glycosylated hemoglobin (HbA<sub>1c</sub>). HbA<sub>1c</sub> has an irreversibly attached glucose and is known as glycosylated hemoglobin.
- **Normal level:** Glycosylated hemoglobin is expressed as a percentage of the normal hemoglobin (standardized range 4–6.1%). In general, the goal of diabetic treatment is to obtain a value below 7%. It should be as close to normal (<6%) as possible without significant hypoglycemia.
- **Significance:** The percentage of glycosylated hemoglobin can be measured and its value provides an excellent assessment of overall state of **glycemic control during the preceding 3 months.**
- **Factors that influence HbA<sub>1c</sub> level:**
  - **Blood glucose level:** The level of HbA<sub>1c</sub> is dependent on the prevailing glucose level in the blood (exposure of the red cell to glucose). If young RBCs are exposed to extremely high blood glucose (>400 mg/dL) for several hours, HbA<sub>1c</sub> level increases. Thus, in patients with diabetes mellitus, it is useful in assessing the blood glucose control, higher the count poorer is the control.
  - **Disease associated with altered RBC survival:** Glycation of hemoglobin occurs only when the RBC circulates in serum. Older RBCs have more glycosylated hemoglobin than reticulocytes. Total HbA<sub>1c</sub> reflects the mixture of both old and younger RBCs. In patients with hemolytic anemia such as thalassemia, the measured HbA<sub>1c</sub> level will be lower, independent of glycemia. Conversely, if the circulating RBCs are older (e.g. aplastic anemia), then measured HbA<sub>1c</sub> level will be higher, regardless of glycemic status.
- Although the glycosylated hemoglobin level provides a rapid assessment of glycemic control, blood glucose level should also be tested to know the

control.

### ***Glycosylated Plasma Proteins ('Fructosamine')***

- It may also be measured as an index of diabetic control. It measures glycation of all serum proteins and the major component being **glycosylated albumin**. Since albumin accounts for most of the protein in blood, the measurement of fructosamine, for practical purposes, measures glycosylated albumin. As albumin has a turnover of about 2 weeks, fructosamine reflects **glycemia over the preceding 2–3 weeks** (shorter period).
- It is **useful in diabetic patients with anemia or hemoglobinopathy and in pregnancy** (when hemoglobin turnover is changeable).

**Table 3.18:** Complications of diabetes.

#### ***ACUTE METABOLIC COMPLICATIONS***

- Diabetic ketoacidosis (DKA)
- Hyperosmolar hyperglycemic state (hyperosmolar non-ketotic diabetic coma)
- Lactic acidosis
- Hypoglycemia

#### ***CHRONIC (LONG-TERM) COMPLICATIONS***

##### **A. Vascular Complications**

###### **1. Microvascular**

- Ophthalmic
  - Diabetic retinopathy (non-proliferative and proliferative)
  - Cataract
  - Glaucoma
- Peripheral neuropathy
  - Sensory
  - Motor
  - Sensory motor
  - Autonomic neuropathy
- Renal
  - Nephropathy: Microalbuminuria, macroalbuminuria
  - Chronic kidney disease

###### **2. Macrovascular**

- Coronary artery disease
- Peripheral vascular disease
- Cerebrovascular disease

## B. Nonvascular Complications

- Gastroparesis
- Infections
- Skin changes (dermatological complications)
- Hearing loss.

# COMPLICATIONS OF DIABETES

Classification of complications of diabetes is presented in Table 3.18.

**Q. Write short essay/note on:**

- **Classify and enumerate the complications of diabetes**
- **Chronic complications of diabetes mellitus.**

## Acute Complications of Diabetes (Table 3.18)

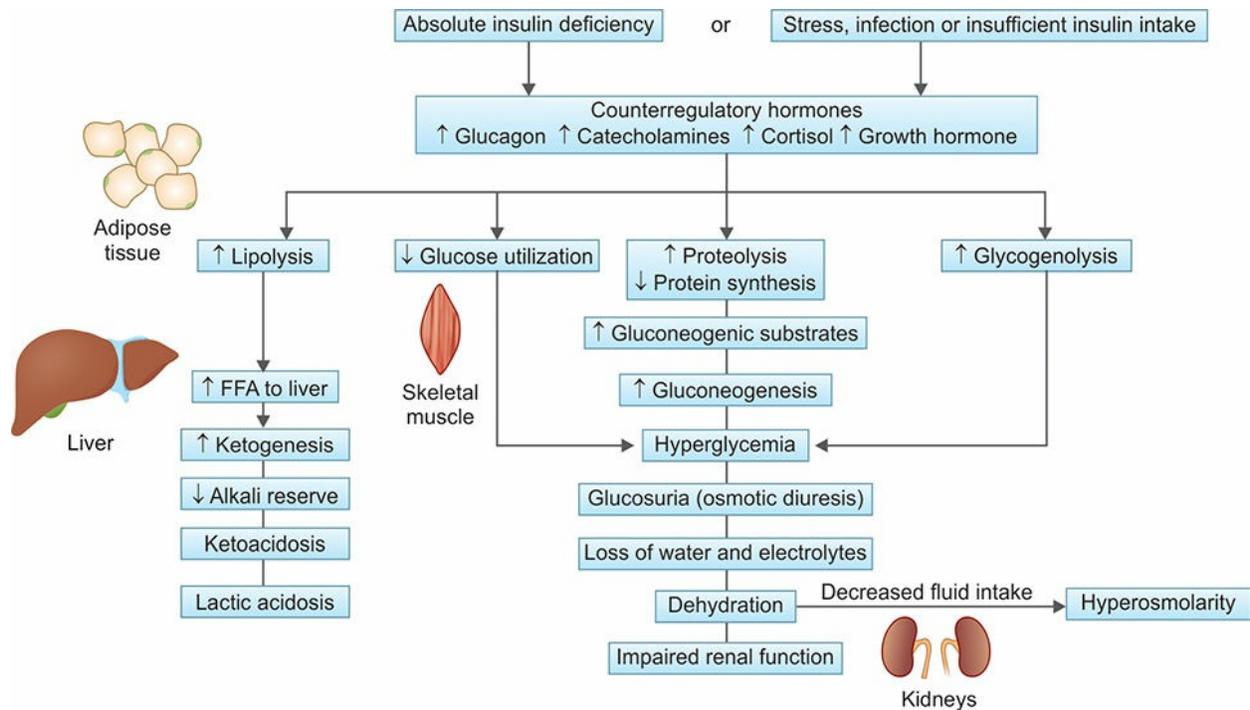

**Q. Write short essay/note on acute complications of diabetes mellitus.**

### *Diabetic Ketoacidosis*

**Q. Discuss the precipitating causes, pathogenesis, clinical features, diagnosis, complications and management of diabetic ketoacidosis (DKA).**

**Q. Write short essay/note on diabetic ketoacidosis (DKA).**

**Diabetic ketoacidosis (DKA)** is a medical emergency and a serious complication of diabetes. More **common and marked in type 1 diabetes** and is rare but may also occur in type 2 diabetes. It is usually seen in previously undiagnosed diabetes mellitus. Precipitating factors are listed in Box 3.11.

**Fig. 3.7:** Pathogenesis of diabetic ketoacidosis.

**Mechanism/pathogenesis (Fig. 3.7):** Cardinal biochemical features of DKA: **(1) hyperglycemia, (2) hyperketonemia (and ketonuria), and (3) metabolic acidosis.** DKA develops due to the combined effects (1) relative or absolute **insulin deficiency** and (2) counter-regulatory **glucagon excess.** Other hormones such as catecholamines (e.g. epinephrine), cortisol, and growth hormone are also be produced in excess.

**Box 3.11:** Precipitating factors of diabetic ketoacidosis (DKA) in a known patient with DM.

- Infections (pneumonia, urinary tract infections, sepsis, gastroenteritis)
- Inadequate insulin
- Infarction (cerebral, coronary, mesenteric, peripheral)
- Severe stress (e.g. physical, emotional)
- Hyperthyroidism, pheochromocytoma
- Drugs (e.g. thiazides, corticosteroids, cocaine)
- Pregnancy.

*Consequences of insulin deficiency and glucagon excess*

- **Severe hyperglycemia:** The blood glucose levels of 500 to 700 mg/dL.
- **Diuresis and dehydration:** Hyperglycemia causes a hyperosmolar state,

which induces an **osmotic diuresis** leading to volume depletion **and dehydration** (characteristic features of ketoacidosis). There is loss of electrolyte, particularly of sodium and potassium.

**Q. Write short essay/note on ketone bodies.**

- **Activation of the ketogenic machinery:**
  - **Lipolysis:** Insulin deficiency stimulates lipoprotein lipase which breaks down fat stores (lipolysis) and increases the free fatty acids (FFA) levels in the plasma.
  - **Generation of ketone bodies in liver:** In DKA, hyperglucagonemia (excess of glucagon) alters hepatic metabolism of free fatty acid to favor ketone body formation. This is through activation of the enzyme **carnitine palmitoyltransferase 1**. The free fatty acids are esterified to fatty acyl coenzyme A in the liver. In the mitochondria of liver cells, fatty acyl coenzyme A molecules are oxidized to ketone bodies (**acetoacetic acid,  $\beta$ -hydroxybutyric acid** and minor amount of acetone). These ketone bodies accumulate in the body fluids.
- **Ketonemia and ketonuria:** When the **rate of production of ketone bodies exceeds the rate of utilization** by peripheral tissues, it results in **ketonemia and ketonuria**.
- **Metabolic acidosis:** Acetoacetic acid and  $\beta$ -hydroxybutyric acid are strong acids and are responsible for the acidotic state. If the excretion of ketone bodies in the urinary is compromised by dehydration, it results in **systemic metabolic ketoacidosis (high anion gap)**.

### ***Clinical features of DKA***

- DKA may present as the initial symptom complex that leads to a diagnosis of type 1 DM for the first time, but more commonly, it develops in patient with already diagnosed diabetes mellitus.
- Clinical features of diabetic ketoacidosis are those of uncontrolled diabetes with acidosis. Patients typically present with **polyuria, polydipsia** and other symptoms of progressive hyperglycemia.
- **Other clinical features** include **nausea, vomiting, weakness, weight loss**, lethargy, anorexia, leg cramps, blurred vision, and shortness of breath. Vomiting is an ominous symptom because it precludes oral replacement of fluid losses; severe volume depletion may follow quickly.

- **Abdominal pain** is classically periumbilical and sometimes may be so severe that may be confused with a surgical acute abdomen (such as acute pancreatitis or ruptured viscus).

### *Physical findings in DKA*

- Findings secondary to **dehydration and acidosis**: These include **dry skin** and mucous membranes, **reduced jugular venous pressure, tachycardia, hypotension** (postural or supine), cold extremities/peripheral cyanosis, depressed mental function, and **Kussmaul (deep, rapid hyperventilation) respirations**.
- **Fruity** (sickly-sweet) **smell** of ketones on the patient's **breath** allows an instant diagnosis.
- **Hypothermia**: Body temperature is either normal or low in uncomplicated DKA. Presence of fever suggests infection.
- Mental apathy, confusion or a reduced conscious level may be observed.
- Abdominal tenderness.
- **Symptoms and signs of cerebral edema**: Headache, altered sensorium, seizures, bowel/bladder incontinence, papilledema, bradycardia, hypertension and respiratory arrest.

**Complications**: Acute gastric dilatation/erosive gastritis, cerebral edema, hyperkalemia/hypokalemia, hypoglycemia, infections, myocardial infarction, mucormycosis, and ARDS.

### *Investigations*

- **Urine examination**: Shows glucose and ketones.
- **Plasma levels** of following is to be estimated:
  - **Glucose** levels are raised (hyperglycemia) often markedly.
  - **Ketone bodies** are raised.
- **Serum electrolytes**:
  - **Potassium** levels are normal or raised in the initial stages despite a total body deficit of potassium. This is because, metabolic acidosis shifts potassium from intracellular compartment to extracellular compartment. The levels drop once the treatment is started.
  - **Sodium** levels are usually low, particularly if the patient has repeated vomiting and continued to drink water (pseudohyponatremia).

- **Bicarbonate** levels are low. Value  $<12$  mmol/L indicates severe acidosis.
- **Phosphorus** level may be high initially despite a total body deficit of phosphorus.
- **Blood:**
  - **Leukocytosis** invariably occurs in DKA; this represents a stress response and may not necessarily indicate infection.
  - **ABG:** Reveals high anion gap metabolic acidosis.
  - **Blood urea nitrogen (BUN)** is usually raised due to prerenal failure produced from volume depletion.
  - **Infection screen:** Full blood count, blood and urine culture, C-reactive protein, chest X-ray.
  - Serum amylase may be elevated.
- **ECG: To rule out myocardial infarction.**

**Diagnostic criteria for DKA (Table 3.19):** Diagnostic criteria for diabetic ketoacidosis include **plasma glucose  $>250$  mg/dL, arterial pH  $<7.3$ , serum bicarbonate  $<15$  mEq/L, ketonemia and/or ketonuria, and anion gap of  $>12$  mEq/L** (usually present in DKA).

**Table 3.19: Diagnostic criteria for diabetic ketoacidosis and the hyperosmolar hyperglycemic state.**

Features	Diabetic ketoacidosis (DKA)			Hyperosmolar hyperglycemic state (HHS)
	Mild	Moderate	Severe	
Mental status	Alert	Drowsy	Stupor or coma	Stupor or coma
Urine or serum ketone bodies	Positive			Negative to trace
Plasma glucose level (mg/dL)	$>250$			$>600$
Effective serum osmolality (mOsm/kg)	Variable			$>320$
Arterial pH	7.25–7.30	7.00–7.24	$<7.00$	$>7.30$
Serum bicarbonate (mEq/L)	15–18	10–15	$<10$	$>15$
Anion gap	$>10$	$>12$	$>12$	$<12$

(mEq/L)

## Management

Goals of therapy of diabetic ketoacidosis (Box 3.12).

**Box 3.12:** Goals of therapy of diabetic ketoacidosis.

- Rehydration
- Reduction of hyperglycemia
- Correction of electrolyte imbalance
- Correction of acid-base imbalance
- Investigation and correction of precipitating factors
- Treatment of complications

**Fluid resuscitation:** It is a critical part of treating patients with DKA as it is a state of severe dehydration.

- Intravenous solutions to replace extravascular and intravascular fluids and electrolyte losses. The usual fluid deficit is minimum 3–5 L and should be replaced intravenously. They dilute levels of both the glucose and the circulating counter regulatory hormones.
- Fluid itself leads to correction of acidosis to some extent.
- Fluid administration should be as follows:
  - **0.9% NaCl** (15–20 mL/kg/hr)
  - Administer 1–3 L during the first hour.
  - Administer 1 L during the second hour.
  - Administer 1 L during the following 2 hours.
  - Administer 1 L every 4 hours, depending on the degree of dehydration and central venous pressure readings.
  - 0.45% NaCl infused at 4–14 mL/kg/hr is appropriate if the corrected serum sodium is elevated.

### **Insulin recommendations**

- Insulin is needed to help switch from a catabolic state to an anabolic state. Insulin helps in uptake of glucose in tissues and the reduction of gluconeogenesis as well as free fatty acid and ketone production.
- In adult patients (if  $K^+ < 3.3$  mEq/L), an IV bolus of **regular insulin** continuous infusion at a dose of 0.1 U/kg/hr (5–7 units/h in adults), should be administered.
- If plasma glucose does not fall by 50 mg/dL from the initial value in the 1st hour, check hydration status; if acceptable, the insulin infusion may be doubled every hour until a steady glucose decline between 50 and 75 mg/h is achieved.
- When the plasma glucose reaches 250 mg/dL in DKA or 300 mg/dL in HHS, it may be possible to decrease the insulin infusion rate to 0.05–0.1 unit/kg/hr (3–6 units/h), and dextrose (5–10%) may be added to the intravenous fluids.
- Initiate subcutaneous insulin at least 2 hour before interruption of insulin infusion. Rapid acting insulin analogues (glulisine, as part) can be given in place of regular insulin.

### **Potassium repletion**

- $K^+ > 5.2$  mEq/L
  - Do not give  $K^+$  initially, but check serum  $K^+$  with basic metabolic profile every 2 hours.

– Establish urine output ~50 mL/hour.

- $K^+$  <3.3 mEq/L: Hold insulin and give  $K^+$  20–30 mEq/hr until  $K^+$  >3.3 mEq/L.
- $K^+$  = 3.3–5.2 mEq/L: Give 20–30 mEq  $K^+$  in each L of IV fluid to maintain serum  $K^+$  4–5 mEq/L.

#### **Correction of acid base balance**

- Its role is controversial.
- **Sodium bicarbonate is only infused if decompensated acidosis starts to threaten the patient's life**, especially when associated with either sepsis or lactic acidosis.
- It is **recommended for patients in shock and/or if pH is <6.9**.
- When arterial pH is 6.9–7.0, one ampule 7.5% sodium bicarbonate (44 mEq/L) should be added to 200 mL of sterile water and administered intravenously at the rate of 200 mL/hour. If pH is below 6.9, 2 ampules of sodium bicarbonate in 400 mL of sterile water given at the same rate of 200 mL/hour. Once the pH reaches 7.1, no further bicarbonate should be given.

**Box 3.13:** Criteria for resolution of diabetic ketoacidosis (DKA).

- Glucose <200 mg/dL
- Serum bicarbonate  $\geq$ 18 mEq/L, and
- Venous pH of >7.3.
- Plasma osmolality effectively has fallen below 315 mOsmol/kg
- The patient is able to eat

**Phosphorus repletion:** A sharp drop of serum phosphorus can also occur during insulin treatment and no treatment is usually necessary.

**Treatment of concurrent infection:** In the presence of infection, the administration of proper antibiotics is guided by the results of culture and sensitivity studies. It may be advisable to starting empirical antibiotics on suspicion of infection until culture results are available. Criteria for resolution of DKA is mentioned in Box 3.13.

## ***Hyperglycemic Hyperosmolar State (HHS)***

**Q. Write short essay on:**

- **Precipitating factors, clinical features, laboratory findings and management of hyperglycemic hyperosmolar state (HHS).**
- **Hyperosmolar non-ketotic (HONK) diabetic coma.**
- It is **metabolic emergency** which usually occurs as a complication of **uncontrolled type 2 diabetes mellitus**. Patients usually present in **middle or later life** (presently it is increasingly seen in younger adults), often with previously undiagnosed diabetes.
- This syndrome has a high mortality rate (>50%).

**Characteristics of hyperglycemic hyperosmolar state (HHS):** It is a

syndrome characterized by:

- **Severe hyperglycemia** [ $>30$  mmol/L (600 mg/dL)]
- **Hyperosmolality** (serum osmolality  $>320$  mOsm/kg)
- Extreme **dehydration in the absence of significant hyperketonemia** ( $<3$  mmol/L) **or ketoacidosis** (pH  $>7.3$ , bicarbonate  $>15$  mmol/L).

**Box 3.14:** Precipitating factors for hyperglycemic hyperosmolar state (HHS).

- Infections
- Cerebrovascular accidents
- Myocardial infarction
- Concurrent medication: e.g. thiazide diuretics, steroids, immunosuppressive agents, phenytoin and osmotic agents like mannitol
- Peritoneal dialysis and hemodialysis
- Tube feeding of high-protein formulas/consumption of glucose-rich fluids/parenteral nutrition

*Precipitating factors for HHS are listed in Box 3.14.*

*Pathogenesis (Fig. 3.8)*

- A **partial or relative insulin deficiency** results in **decreased utilization of glucose** by skeletal muscle, fat and liver which in turn induces hyperglucagonemia and **increases hepatic glucose output**.
- Massive glycosuria results in large amount of water loss which along with decreased intake due to associated illness results in **severe dehydration**. As plasma volume decreases, renal insufficiency develops, and limits the renal glucose loss. This increases **further increase in blood glucose levels**. **Severe hyperosmolality** develops that causes **mental confusion and finally coma**.

*Clinical features*

- **Onset:** It is usually more **insidious** in onset compared to diabetic ketoacidosis (DKA). It presents with a several-week history of polyuria, weight loss and diminished oral intake.
- **Dehydration:** Characteristic **clinical features** on presentation are **due to volume depletion and extreme dehydration**.
- **Central nervous system manifestations:** These include alteration in the level of consciousness ranging from mental confusion, stupor or coma, **convulsions** (sometimes Jacksonian in type), hemiballism/hemichorea and transient hemiplegia. Impairment of consciousness is directly related to the

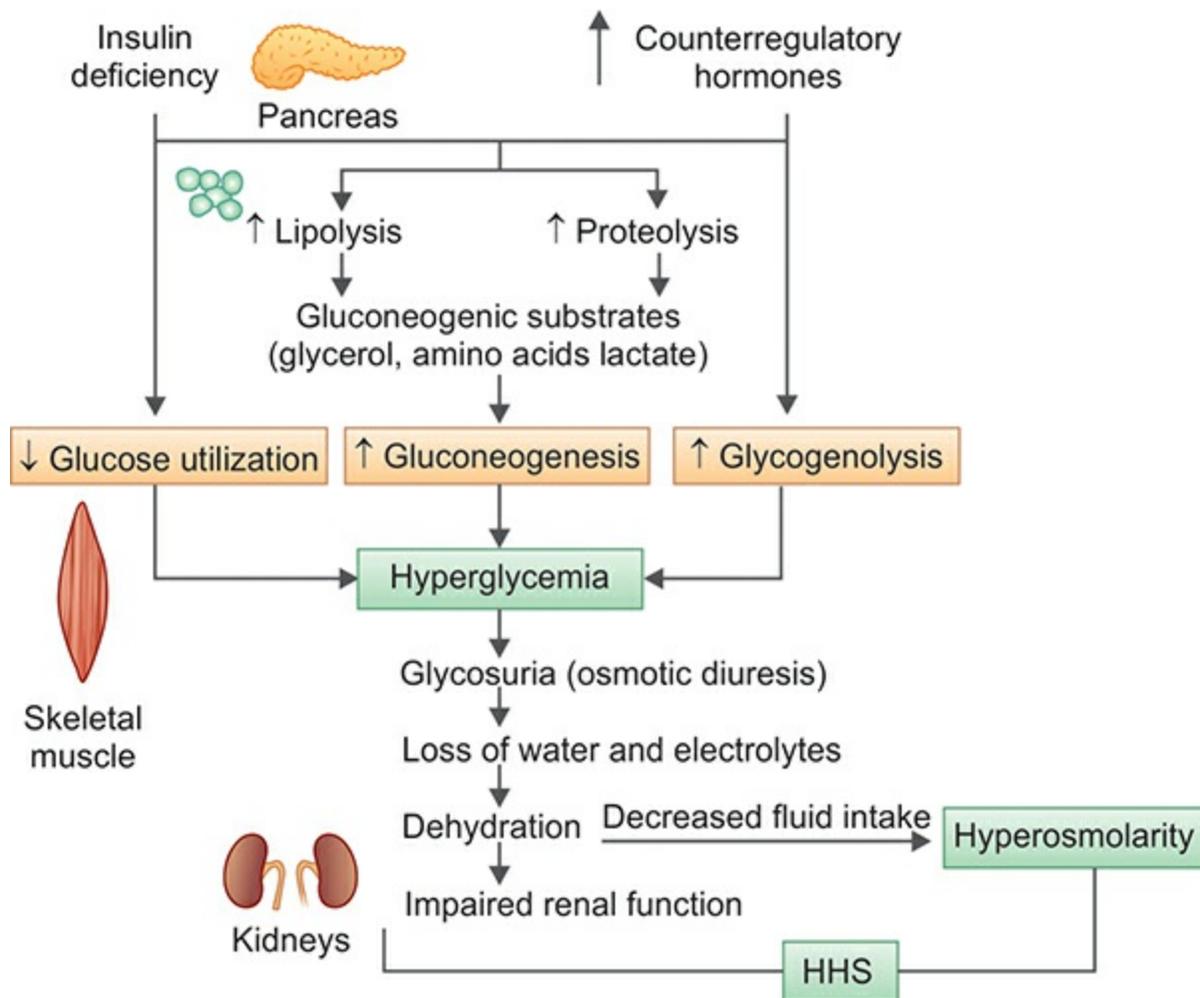

degree of hyperosmolality.

- Infections, particularly pneumonia or pyelonephritis and gram-negative sepsis are very common.
- Hyperosmolar state may predispose to stroke or myocardial infarction.
- Bleeding and acute pancreatitis may accompany HHS.

**Physical examination:** Shows severe dehydration, hyperosmolality, hypotension, tachycardia and altered mental status.

#### *Laboratory findings*

- **Plasma glucose:** Markedly raised and usually **around 1000 mg/dL** (range 600–2400 mg/dL)
- **Serum osmolarity:** Usually extremely high.
- **Prerenal azotemia** with raised BUN (blood urea nitrogen) and creatinine.
- **Plasma bicarbonate:** A mild metabolic acidosis with **marginal decrease** in plasma bicarbonate (about 20 mmol/L) is seen. Marked decrease in plasma bicarbonate (<10 mmol/L) indicates lactic acidosis.
- **Diagnostic criteria for HHS (refer Table 3.19).**

**Fig. 3.8:** Pathogenesis of hyperglycemic hyperosmolar state (HHS).

### Management

- **Fluid replacement.** The average fluid deficit is much higher than DKA and is about **10 L**. It should be corrected intravenously. Initially 2–3 L isotonic (0.9%) saline should be administered over 1–2 hours. Subsequently, half-strength (0.45%) saline should be given. Once the plasma glucose reaches 300 mg/dL, use 5% dextrose-saline solution.
- **Insulin:** Regular insulin should be administered as low-dose intravenous infusion as in DKA. The goal is to achieve the plasma glucose around 200 mg/dL.
- **Potassium supplementation** is needed early (as in DKA).
- **Lactic acidosis:** Treat with intravenous sodium bicarbonate.
- **Infections:** With suitable antibiotics.
- **Anticoagulants:** To prevent thrombosis.

**Differentiate between diabetic ketoacidosis and hyperglycemic hyperosmolar state (Table 3.20)**

**Q. How will you differentiate between diabetic ketoacidosis (DKA) and**

## hyperglycemic hyperosmolar state (HHS)?

**Table 3.20:** Differentiate between diabetic ketoacidosis and hyperglycemic hyperosmolar state.

<i>Features</i>	<i>Diabetic ketoacidosis (DKA)</i>	<i>Hyperglycemic hyperosmolar state (HHS)</i>
<b>Clinical features</b>		
Type of diabetes	Both type 1 or 2 DM	Type 2 DM
Evolution/onset	Over hours	Over days
Fruity (acetone) odor of breath	Observed	Not present
Kussmaul's respiration	Seen	Not seen
Abdominal pain/tenderness	Present	Absent
<b>Laboratory findings</b>		
Plasma glucose level	>250 mg/dL	>600 mg/dL
Serum sodium	Normal or low (<140 mmol/L)	Usually high (>155 mmol/L)
Blood/urine ketones	Moderate ketonuria or ketonemia	Absent/Minimal ketonuria and ketonemia
Arterial pH	<7.3	>7.3
Serum bicarbonate	<15 mEq/L	>15 mEq/L
Serum osmolality	Variable	>320 mosm/L
Anion gap	>12	Variable
Fluid deficit	6 liters	>10 liters
Mortality rate	1%	20–30%

## Hypoglycemia

**Q. Discuss the etiology, pathogenesis, clinical features and management of hypoglycemia.**

**Q. Write short essay/note on hypoglycemic coma.**

**Whipple's triad:** It is the most convincing documentation of hypoglycemia.

- **Symptoms** consistent with **hypoglycemia**
- **Low plasma concentration** of blood glucose  $\leq 70$  mg/dL (3.9 mmol/L) measured with a precise method (not a glucose monitor)
- **Relief of symptoms** after the **plasma glucose level is raised**.

**Box 3.15:** Causes of hypoglycemia in adults.

- Drugs: Insulin or insulin secretagogues, alcohol and others
- Critical illness: Hepatic, renal or cardiac failure, sepsis, malaria, inanition
- Hormone deficiency: Cortisol, glucagon and epinephrine (in insulin-deficient diabetes)
- Non-islet cell tumor
- Endogenous hyperinsulinism: Insulinoma, functional beta-cell disorders (nesidioblastosis), noninsulinoma pancrcreatogenous hypoglycemia, post-gastric bypass hypoglycemia, insulin autoimmune hypoglycemia, antibody to insulin, antibody to insulin receptor, insulin secretagogue
- Accidental, surreptitious or malicious hypoglycemia

### *Causes/etiology (Box 3.15)*

#### **Q. Write short essay/note on causes of hypoglycemia.**

**Significance:** Hypoglycemia is a dangerous complication, and more serious than hyperglycemia. Prolonged hypoglycemia may cause permanent damage to the brain.

#### *Pathogenesis*

Whenever blood glucose level falls, three primary physiological defence mechanisms come into action:

1. **Suppression of endogenous insulin release** from pancreatic  $\beta$  cells.
2. **Increased release of glucagon** from pancreatic  $\alpha$  cells.
3. **Activation of the autonomic nervous system** with release of catecholamines.

In addition, stress hormones, such as cortisol, catecholamines (adrenaline and noradrenaline) and growth hormone (GH), are also increased in the blood.

**Mechanism of hypoglycemia in diabetes:** It may be due to:

- **Insulin excess** (exogenous in patient on insulin therapy)
- **Counter-regulatory failure:**
  - In type 1 DM, in the early stages itself there is loss of capacity to increase glucagon release in response to hypoglycemia.
  - Subsequently, many patients also lose the capacity to release catecholamines in response to hypoglycemia. This is due to diabetic autonomic neuropathy.

#### *Clinical features*

- **Blood glucose level and symptom development:** Symptoms due to

hypoglycemia usually occur with a plasma glucose at:

- level of 60 mg/dL in non-diabetic individuals
- higher levels (80 mg/dL) in poorly controlled diabetic patients
- lower levels in well-controlled diabetic patients.

- **Symptoms** fall into two main groups:

- **Related to acute activation of the autonomic nervous system (neurogenic symptoms):** These are produced by excessive secretion of adrenaline and symptoms include sweating, tremor, tachycardia, anxiety and hunger. Adrenergic symptoms predominate, when hypoglycemia is of rapid onset (e.g. insulin reactions).
- Those **secondary to glucose deprivation of the brain (neuroglycopenia):** It causes dizziness, headache, clouding of vision, blunted mental acuity, and loss of fine motor skill, confusion, abnormal behavior, convulsions and loss of consciousness. Central nervous system symptoms predominate, when hypoglycemia is of gradual onset. Patients with longstanding diabetes may not develop warning adrenergic symptoms (**hypoglycemic unawareness**) due to severe neuropathy and are at a greater risk of central nervous dysfunction.

- **Daytime vs nocturnal hypoglycemia:**

- **Daytime hypoglycemic episodes** present with sweating, nervousness, tremor and hunger.
- **Nocturnal hypoglycemic episodes** develop during sleep and present with night sweats, unpleasant dreams and early morning headache. Frequently, nocturnal hypoglycemia is asymptomatic.

### Management

- **Oral carbohydrate:** If hypoglycemia is detected early, it may be corrected by ingestion of carbohydrate (preferably in an easily absorbable form).
- **Intravenous dextrose:** It is given in serious hypoglycemia, when there is impaired mental functions, and prolonged hypoglycemia is anticipated (e.g. with depot-insulin and oral sulfonylureas like chlorpropamide). Initially, 50 mL of 50% dextrose is administered, followed by infusion of 5–10% dextrose. Oral carbohydrate should be given as soon as the patient is able to eat.
- **Glucagon:** Glucagon in the dose of 0.5–1 mg subcutaneously or intramuscularly may be given when there is severe hypoglycemia. It may be repeated if necessary after 10 minutes. Glucagon stimulates hepatic glycogenolysis. But it may not be effective in severe and prolonged hypoglycemia due to depot-insulins. It should not be used for the treatment of hypoglycemia due to oral hypoglycemic drugs.

- **Octreotide:** It is useful for patients who develop recurrent hypoglycemia following dextrose infusion.
- **Other measures** are aimed at preventing recurrence of hypoglycemia. These include adjusting the dose of oral hypoglycemic drugs, changing the timing of insulin injections, adjustments in diet and physical activity/exercise, etc.

## ***Somogyi Phenomenon***

### **Q. Write short note on Somogyi phenomenon.**

- The Somogyi phenomenon (post-hypoglycemic hyperglycemia) is rebound hyperglycemia that follows an episode of hypoglycemia. It is due to counter-regulatory hormone release.
- **Significance:** The correction of the morning hyperglycemia is by reducing, and not increasing the evening dose of intermediate-acting insulin.

### *Clues to the presence of Somogyi phenomenon*

- **Worsening of diabetic control** in the **presence of increasing insulin doses.** It manifests as morning fasting hyperglycemia, in response to unrecognized nocturnal hypoglycemia.
- **Excessive hunger and weight gain** in presence of worsening hyperglycemia.
- **Nocturnal hypoglycemia:** Subtle manifestation such as mild nocturnal sweating, morning headache and hypothermia.
- **Plasma glucose and urine glucose:** Shows wide fluctuations over short time intervals, and not related to meals.
- **Confirmation of Somogyi phenomenon:** By documentation of hypoglycemia at 3 AM and hyperglycemia in the morning (fasting). Improvement in diabetic control after a decrease in the insulin dose.

## ***Dawn Phenomenon***

### **Q. Write short note on Dawn phenomenon.**

- It is closely related to the Somogyi phenomenon in that there is fasting hyperglycemia, without nocturnal hypoglycemia.
- **Mechanism:** Nocturnal surge of GH release or increased clearance of insulin in the mornings.

- **Confirmation:** Documenting of hyperglycemia at 3 AM and in the morning (fasting).
- **Significance:** Correction of the fasting hyperglycemia depends on increasing and not decreasing the insulin.

**Box 3.16:** Causes of coma in a diabetic patient.

1. Diabetic coma
  - Ketosis producing diabetic ketoacidosis (DKA)
  - Nonketonic hyperglycemic-hyperosmolar coma (NKHHC)
  - Lactic acidosis (LA)
2. Hypoglycemic coma (HC)
3. Other comorbid conditions: Metabolic encephalopathies or infection related

Differential diagnosis of morning hyperglycemia is mentioned in Table 3.21.

**Q. List the differences in coma due to hypoglycemia and diabetic coma/ketoacidosis in type 1 DM.**

Differences between hypoglycemic and hyperglycemic/diabetic coma are presented in Table 3.22.

Causes of coma in diabetes (Box 3.16).

**Table 3.21:** Differences diagnosis of morning hyperglycemia.

<i>Feature</i>	<i>Dawn phenomenon</i>	<i>Somogyi effect</i>
Definition	Recurring early morning hyperglycaemia	Early morning hyperglycaemia due to treatment with excessive amount of exogenous insulin
Casuse	Decrease of insulin secretion between 3 a.m. and 5 a.m.	Nocturnal hypoglycemia due to excessive dose of insulin
Diagnosis (3 a.m. and 5 a.m. glucose level)	High/normal plasma glucose level	Low plasma glucose level

**Table 3.22:** Differences between hypoglycemic and hyperglycemic/diabetic coma.

<i>Features</i>	<i>Hypoglycemic coma</i>	<i>Hyperglycemic coma</i>
<b>Physical findings</b>		
Volume of pulse	Full	Weak

Respiration	Shallow or normal	Rapid and deep (air hunger)
Blood pressure	Normal/may be raised	Decreased
Skin	Clammy, sweating	Dry
Tongue	Moist	Dry
Tissue turgor	Normal	Reduced
Eyeball tension	Normal	Reduced
Breath acetone	Not present	May be present
Reflexes	Brisk	Diminished
<b>Laboratory findings</b>		
Glucose in urine	Absent/ present (depends on time of last voiding)	Present
Plasma glucose level	Reduced	Raised >200 mg/dL
Plasma acetone	Negative	Usually present
Plasma bicarbonate	Normal	Low <20 mg/L
Plasma CO <sub>2</sub>	Normal	Diminished
Blood pH	Normal	<7.35

**Q. Write short essay/note on the cause of coma in diabetes.**

## CHRONIC COMPLICATIONS OF DIABETES

Pathogenesis of chronic complications of diabetes is multifactorial and includes: (1) hyperglycemia (glucotoxicity) is the main mediator, (2) insulin resistance and (3) obesity.

### Hyperglycemia

#### *Effects of Hyperglycemia (Fig. 3.9)*

These can be brought out by four **distinct metabolic pathways**.

1. **Formation of advanced glycation end products (AGEs):** Increased intracellular glucose leads to **markedly increased** formation of advanced glycosylation end products. AGEs can **directly cross-link extracellular matrix proteins** and its consequences are:
  - a. **Basement membrane thickening.**
  - b. **Trapping of LDL in the intima accelerating atherogenesis.**
  - c. Glomerular dysfunction, endothelial dysfunction, altered extracellular matrix composition.
2. **Activation of protein kinase C (PKC):** In patients with hyperglycemia,

intracellular hyperglycemia stimulates synthesis of diacyl glycerol (DAG) from glycolytic intermediates. DAG activates intracellular protein kinase C. PKC activation produces:

- a. **Proangiogenic molecules** such as **vascular endothelial growth factor (VEGF)** causes **neovascularization** characteristic of **diabetic retinopathy**.
  - b. **Profibrogenic factors** (e.g. **TGF- $\beta$** ) results in **increased production of extracellular matrix and basement membrane material**.
  - c. Plasminogen activator inhibitor (PAI-1) **reduces fibrinolysis** and **favors vascular occlusion** (by forming atherosclerotic plaques or thrombus).
3. **Disturbances in polyol pathways:** Some tissues (e.g. nerves, lenses, kidneys, blood vessels) do not require insulin for glucose transport. Persistent hyperglycemia increases the intracellular glucose in these tissues and excess intracellular glucose is metabolized by the enzyme aldose reductase to sorbitol (polyol) to fructose.
- a. This **reaction uses NADPH** (the reduced form of nicotinamide dinucleotide phosphate) as a cofactor.
  - b. NADPH is also necessary for the regeneration of reduced glutathione (GSH). GSH protects against injury by free radicals.
  - c. Reduced NADPH  $\rightarrow$  decrease in GSH  $\rightarrow$  increases cells **susceptibility to oxidative stress**.
4. Hyperglycemia increases the flux through the **hexosamine pathway** and generates fructose-6-phosphate. Which results in glycosylation of proteins such as endothelial nitric oxide synthase or by changes in gene expression of transforming growth factor  $\beta$  (TGF- $\beta$ ) or plasminogen activator inhibitor-1 (PAI-1).

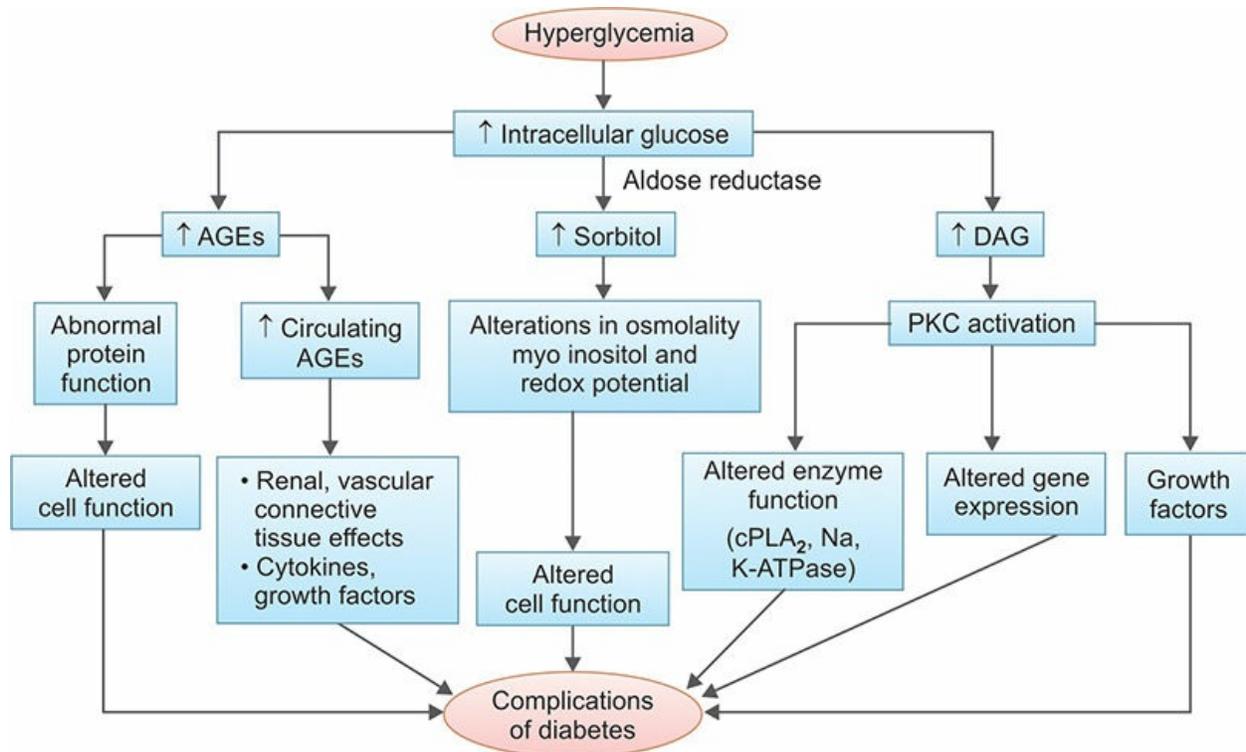

Fig. 3.9: Pathogenesis of chronic complications of DM due to hyperglycemia.

## Symptoms of Hyperglycemia (Box 3.17)

**Q.** Write short note on symptoms of hyperglycemia.

## Cardiovascular Complications of Diabetes

**Q.** Write short essay/note on the cardiovascular complications of diabetes.

The lesions of large- and medium-sized muscular arteries are the **most common causes of mortality** in long-standing diabetes. These include:

### Box 3.17: Symptoms of hyperglycemia.

- Excessive thirst, dry mouth
- Polyuria, nocturia
- Tiredness, fatigue, lethargy, weight loss
- Pruritus vulvae/balanitis due to genital candidiasis
- Blurring of vision
- Nausea, headache, mood changes, irritability, difficulty in concentrating, apathy
- Hyperphagia (especially for sweet foods)

**Atherosclerosis:** Diabetes is one of the major modifiable risk factor for

atherosclerosis and other cardiovascular morbidities. The main cardiovascular complications of diabetes are accelerated atherosclerosis. The **atherosclerosis is more severe and occurs at earlier age**. Diabetics have **increased levels of plasminogen activator inhibitor (PAI-1)**, which **inhibits fibrinolysis and favors development of atherosclerotic plaques**. **Renal arteries** also develop **severe atherosclerosis**. The atherosclerotic lesions can manifest in a variety of ways:

- **Myocardial infarction:** It is due to atherosclerosis of the coronary arteries and is the **most common cause of death in diabetics**. Diabetics have greater risk of coronary artery disease and cardiovascular complications than nondiabetics. Risk for cardiovascular disease is more even in pre-diabetics.
- **Gangrene of the lower/upper (Fig. 3.10) extremities:** Patient may also present with intermittent claudication. Gangrene may result from advanced vascular disease and is more common in diabetics.
- **Renal vascular insufficiency.**
- **Cerebrovascular accidents (stroke).**

**Fig. 3.10:** Diabetic gangrene of right index finger.

**Box 3.18:** Renal changes in diabetes mellitus.

---

- Glomerular lesions
  - Diffuse widespread thickening glomerular basement membrane (GBM)
  - Nodular glomerulosclerosis (Kimmelstiel-Wilson nodules)
  - Insudative lesions: Fibrin caps and capsular drop
- Pyelonephritis: Acute and chronic including necrotizing papillitis
- Tubular lesions: Armani-Ebstein lesions
- Renal vascular lesions (arteriosclerosis and atherosclerosis)

## Diabetic Nephropathy

**Q. Write short essay/note on:**

- **Clinical features, diagnosis and management of diabetic nephropathy.**
- **Kimmelstiel-Wilson lesions.**

Diabetic nephropathy is the term used for **collective lesions that often occur together in the diabetic kidney**. About **30–40% of all diabetics** develop nephropathy and is **leading cause of chronic kidney disease (CKD) and end-stage renal disease (ESRD)**. It is a leading cause of death and disability in diabetes and is more common in type 1 DM than 2 DM. Renal changes in diabetes mellitus are listed in Box 3.18.

**Pathogenesis:** Diabetic glomerulosclerosis represents a part of the generalized diabetic microangiopathy that involves small vessels throughout the body. Like other microvascular complications of DM, the pathogenesis of diabetic nephropathy is related to chronic hyperglycemia.

**Clinical features:** The natural history of diabetic nephropathy follows a fairly predictable sequence of events.

- **Glomerular hyperperfusion and renal hypertrophy** develops in the first years after the onset of DM. It is associated with an **increase of the glomerular filtration rate (GFR)**. It shows nephromegaly (enlargement of kidneys).
- During the first 5 years of DM, **thickening of the glomerular basement membrane**, glomerular hypertrophy, and expansion of mesangial volume occur as the GFR returns to normal.
- **Microalbuminuria:** After 5–10 years, many patients start excreting **small amounts of albumin in the urine**. It is the **earliest manifestation** of diabetic nephropathy in which the urine has low amounts of albumin (>20

mg/day, but <300 mg/day). Microalbuminuria defined as the **persistent elevation of the urinary albumin excretion of 20–300 mg/L** (or 20–200 micrograms/min) in an early morning urine sample. It is also a well-established marker for increased cardiovascular morbidity and mortality in either type 1 or type 2 diabetics. Normal individual excrete albumin <20 mg/day. It indicates early and possibly reversible glomerular damage. Type 2 diabetes is more likely to have microalbuminuria (or overt nephropathy) at diagnosis. This is because of the long duration of abnormal glucose metabolism in type 2 DM. Hence, patients with type 2 DM should be screened at the time of diagnosis for the presence of microalbuminuria.

- **Nephropathy with macroalbuminuria:** Without specific interventions, diabetics will develop **overt nephropathy with macroalbuminuria** (>300 mg of urinary albumin per day), usually associated with hypertension. From this stage, the renal disease is irreversible. There is a steady decline in glomerular filtration rate at a rate of about 1 mL/minute/month. The stage of macroalbuminuria may progress to nephrotic syndrome.
- **End-stage renal disease:** The overt nephropathy may progress to end-stage renal disease. Patient develops azotemia, renal failure and uremia.

Different stages of diabetic nephropathy are mentioned in Table 3.23.

**Table 3.23: Classification of diabetic nephropathy.**

<i>Stage</i>	<i>Urinary albumin (mg/g Cr) or urinary protein (g/g Cr)</i>	<i>GFR (eGFR) (mL/min/1.73 m<sup>2</sup>)</i>
Stage 1 (pre-nephropathy)	Normoalbuminuria (<30)	≥30
Stage 2 (incipient nephropathy)	Microalbuminuria (30–299)	≥30
Stage 3 (overt nephropathy)	Macroalbuminuria (≥300) or persistent proteinuria (≥0.5)	≥30
Stage 4 (kidney failure)	Any albuminuria/proteinuria status	<30
Stage 5 (dialysis therapy)	Any status on continued dialysis therapy	

### ***Causes of Microalbuminuria other than Diabetes***

- **Essential hypertension:** In hypertensive patients, microalbuminuria predicts cardiovascular morbidity and mortality.

**Screening for microalbuminuria:** It can be done in a variety of ways. Microalbuminuria can be assessed by radioimmunoassay or by using special dipsticks.

- **Measurement of albumin-to-creatinine ratio:** This is most easily obtained with minimal collection errors. A ratio of  $>30$  mg albumin/g creatinine is considered elevated on a spot urine test.
- **Albumin from a 24 hours urine sample:** Urinary albumin  $>30$  mg/24 hours is diagnostic.

### Management

- **Prevention:** Control of glycemia can reverse microalbuminuria in some patients. Stop smoking and control dyslipidemia.
- **Management of diabetic nephropathy**
  - **Aggressive treatment of hypertension:** Hypertension can accelerate nephropathy. The target for blood pressure is below 130/80 mm Hg with an optimal target of below 120/80 mm Hg in patients with proteinuria or renal insufficiency. This is likely to slow down the rate of deterioration of renal failure considerably.
  - **Angiotensin converting enzyme (ACE) inhibitors** or an **angiotensin receptor II antagonist** is the drugs of choice. They can retard the progression of nephropathy at this stage of microalbuminuria. These drugs should be given to normotensive patients with persistent microalbuminuria and they reduce microalbuminuria. They can be used if creatinine is  $<3$  mg/dL.
  - Other drugs include aliskiren, eplerenone, trandolapril, thiazide diuretics, calcium channel blockers (Verapamil), cilnidipine,  $\beta$ -blockers and  $\alpha$ -blockers can also be used.
  - **Avoid oral hypoglycemic agents partially excreted via the kidney** (e.g. glibenclamide and metformin).
  - Low-protein diets: may be beneficial because high-protein diets can accelerate glomerulosclerosis.
  - Pentoxifylline, fenofibrates lower proteinuria and maybe used as adjunct.

## Ophthalmologic Complications of Diabetes Mellitus

**Q. Write short essay/note on ocular complications of diabetes mellitus.**

Diabetes can produce different lesions in the eye. These include:

1. **Diabetic retinopathy** (damage to the retina and iris) can lead to blindness.
2. **Cataract** is denaturation of the protein and other components of the lens of the eye and leads to opacity of lens. Cataract develops early in diabetics than in the general population. Sustained very poor control of diabetes and ketosis can cause an acute cataract (snowflake cataract). Fluctuations in blood glucose level can cause refractive variability due to

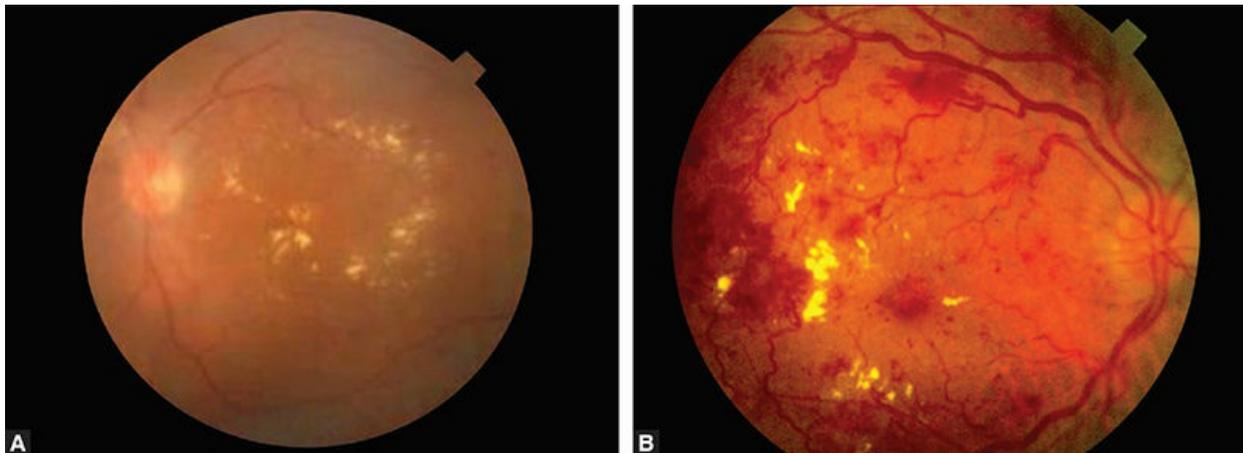

osmotic changes within the lens (the absorption of water into the lens can produce temporary hypermetropia). This clinically presents as fluctuating difficulty in reading and it resolves with control of the diabetes.

3. **External ocular palsies (refer Fig. 15.28):** The 6th and the 3rd cranial nerves (**Tolosa-Hunt syndrome**) are the most commonly affected. These nerve palsies usually recover spontaneously within 3–6 months.
4. Glaucoma.

### **Diabetic Retinopathy (Figs. 3.11A and B)**

**Q. Write short essay/note on diabetic retinopathy.**

Diabetic retinopathy (DR) is the most commonly diagnosed complication of diabetes mellitus. In developed countries, it is one of the most common causes of blindness between 30 and 65 years of age. Its prevalence increases with the duration of diabetes and develops in **~60–80% of diabetics, about 15–20 years after diagnosis.**

**Figs 3.11A and B:** (A) Moderate nonproliferative diabetic retinopathy (NPDR) with hard exudates; (B) Proliferative diabetic retinopathy (PDR).

**Table 3.24: Features of diabetic retinopathy.**

<b>Nonproliferative/simple background (NPDR)</b>	<b>Proliferative (PDR)</b>
<ul style="list-style-type: none"> <li>• Develops late in the first decade or early in the second decade</li> <li>• Increased capillary permeability</li> <li>• Marked retinal vascular microaneurysms, capillary closure and dilatation</li> <li>• Hemorrhages: Dot (capillary microaneurysms) and blot (leakage of blood into deeper retinal</li> </ul>	<ul style="list-style-type: none"> <li>• New blood vessel formation/neovascularization</li> <li>• Preretinal or subhyaloid hemorrhage</li> <li>• Vitreous hemorrhage</li> <li>• More numerous microaneurysms and hemorrhages</li> <li>• Changes in caliber of venous vessel</li> </ul>

layers)

- Cotton wool spots/cytoid bodies (caused by microinfarcts within the retina due to occluded vessels)
- Hard exudates (exudation of plasma rich in lipids and protein)
- Arteriovenous shunts and dilated veins
- Retinal fibrosis/scar (retinitis proliferans)
- Traction retinal detachment

### **Risk factors for diabetic retinopathy (Box 3.19)**

**Lesions of diabetic retinopathy (Table 3.24):** Diabetic retinopathy (DR) can be classified into two stages: (1) non-proliferative/simple background and (2) proliferative (Table 3.24).

**Diabetic macular edema (DME):** In addition to proliferative and non-proliferative diabetic retinopathy, patients may also develop clinically significant macular edema (CSME). This can develop at any stage of DR and is characterized by increased vascular permeability and hard exudates in the central retina. CSME is the most common cause of loss of vision in diabetes mellitus.

**Box 3.19:** Risk factors for diabetic retinopathy.

#### **Diabetes mellitus**

- Of long duration
- Poor glycemic control
- With nephropathy/renal disease
- Hypertension
- Hyperlipidemia
- Pregnancy
- Others: obesity, smoking, puberty in type 1 DM

#### *Investigations*

- **Fundus fluorescein angiography (FFA):** In this a fluorescent dye is injected into a vein of upper arm and photographed in transit through the retinal vessels. It helps to identify the extent of the potentially sight threatening diabetic retinopathy.
- **Optical coherence tomography (OCT):** It is used to image the content of the layers of the retina at the macula and to measure retinal thickness. It helps in detecting macular edema and other macular abnormalities.

#### **Treatment**

- **Prevention:** By intensive glycemic and BP control in both type 1 or type 2 DM.

- **Screening:** Regular eye examinations in all patients with DM.
- Diabetic retinopathy is treated by **laser photocoagulation**.
- Proliferative retinopathy is usually treated with **pan retinal laser photocoagulation**. Pars plana vitrectomy is performed for the treatment of non-resolving vitreous hemorrhage and retinal detachment. Intravitreal hyaluronidase, chondroitinase, and plasmin has shown promise in clearing vitreous hemorrhage
- **Vascular endothelial growth factor (VEGF) inhibitors** such as bevacizumab, ranibizumab, and aflibercept are useful as adjunct therapy to panretinal photocoagulation and/or vitrectomy for selected cases of PDR and DME.

## Diabetic Neuropathy

**Q. Write short essay/note on:**

- **Different neurological complications/manifestations of diabetes mellitus.**
- **Classification, clinical manifestations and management of diabetic neuropathy.**

Diabetes can involve the **peripheral nervous systems** in a number of ways.

**Box 3.20:** Classification of diabetic neuropathy.

- **Polyneuropathy**
  - Symmetrical, mainly sensory and distal
  - Asymmetrical, mainly motor and proximal (including amyotrophy)
- **Mononeuropathy and mononeuritis multiplex**
  - Cranial nerve lesions
  - Isolated peripheral nerve lesions
- **Autonomic (visceral) neuropathy**
  - Cardiovascular
  - Gastrointestinal
  - Genitourinary
  - Sudomotor
  - Vasomotor
  - Pupillary
- **Polyradiculopathies**
  - Diabetic amyotrophy (lumbar polyradiculopathy)
  - Thoracic polyradiculopathy
  - Diabetic neuropathic cachexia
- **Treatment-induced neuropathy of diabetes**

**Risk factors:** Similar to other complications of DM, the development of neuropathy is related to the duration of diabetes and the degree of glycemic

control. Other risk factors are greater body mass index (BMI) and smoking.

**Classification of diabetic neuropathy:** There are various classifications of diabetic neuropathy and one of them is presented in Box 3.20.

## ***Polyneuropathy***

### *Distal symmetric sensorimotor polyneuropathy*

- It is the most common form of diabetic neuropathy. It affects **both motor and sensory function** of the lower extremities. It can be divided into two types:
  - **Asymptomatic:** It is a relatively asymptomatic form. It is diffuse, distal, usually involves the lower extremities and later it may involve the upper extremities with a **‘glove and stocking’** type of distribution.
  - **Acute painful neuropathy:** It is a diffuse, painful neuropathy and is less common. It presents with burning or crawling or dull aching sensation or excruciating, lancinating pain in the feet, shins and anterior thighs. The pain is typically worse at night and pressure from bedclothes may be intolerable and partially relieved by movement. Hyperesthesia may be severe.
- In both forms, physical findings are: Loss of vibration sense, loss of tendon reflexes in the lower limbs (especially ankle jerk) and ‘glove and stocking’ impairment of all sensation.
- With progression patients may complain of a feeling of ‘walking on cotton wool’ and loss of balance while washing the face (‘Washbasin sign’) or walking in the dark owing to impaired proprioception. It may be associated with involvement of other sensation like joint position, touch, pain and temperature, later leading to weakness and wasting of muscles.
- **Sequelae of neuropathy:** Involvement of motor nerves to the small muscles of the feet results in interosseous wasting. Unbalanced traction by the long flexor muscles results in a characteristic shape of the foot, with a high arch and clawing of the toes. This can lead to abnormal distribution of pressure on walking, producing callus formation under the first metatarsal head or on the tips of the toes. Complications include unrecognized trauma, beginning as blistering due to an ill-fitting shoe and neuropathic ulceration. Sometimes, **neuropathic arthropathy (Charcot’s joints)** may develop in the ankle.

*Asymmetrical Motor Diabetic Neuropathy (diabetic amyotrophy/Brunns-Garland syndrome)*

**Q. Write short essay/note on diabetic amyotrophy.**

- Usually develops in older individuals with diabetes.
- It presents with **asymmetrical, severe and progressive weakness and atrophy of the proximal (quadriceps) muscles of the lower limbs**. It is associated with **severe pain**, mainly on the anterior aspect of the leg, and hyperesthesia and paresthesias.
- Sometimes there may be marked wasting and weight loss ('neuropathic cachexia'). The patient may appear extremely ill and be unable to get out of bed. Tendon reflexes may be diminished or absent on the affected side(s).
- This neuropathy is probably due to the acute infarction of the lower motor neurons of the lumbosacral plexus. Other lesions of this plexus (e.g. neoplasms and lumbar disc disease) must be excluded, before a diagnosis is made.
- It is seen in patients with poor glycemic control and resolves with optimization of metabolic control.
- Management is mainly supportive.

***Mononeuropathy and Mononeuritis Multiplex***

Mononeuropathy characterized by dysfunction of isolated cranial or peripheral nerves is less common than polyneuropathy in DM.

- **Nerve involvement:** Diabetic mononeuropathy can involve a single **peripheral or cranial nerve** and affect either **motor or sensory function**. Usually affects 3rd, 6th, 4th (Tolosa-Hunt) or 7th (Bell's palsy) cranial nerves and the **femoral and sciatic nerves** (in order of frequency). Third nerve involvement is characterized by diplopia and normal pupillary constriction to light (pupil-sparing). Rarely, other single nerves are involved and produce paresis and paresthesias in the thorax and trunk (truncal radiculopathies). Simultaneous involvement of more than one nerve (mononeuropathy multiplex) may also occur.
- **Presentation:** Unlike the gradual progression of distal symmetrical and autonomic neuropathies, the mononeuropathies present as **rapid, severe pain and motor weakness** in the distribution of a single nerve. However,

eventually they recover.

- **Nerve compression palsies:** Mononeuropathies can present with or without nerve compression. Nerve compression is more common in diabetes. Compression may affect the median nerve (presents the clinical picture of **carpel tunnel syndrome**), lateral popliteal nerve (**foot drop**) or less commonly the ulnar nerve (**wrist drop**). Compression palsies may be due to glycosylation and thickening of connective tissue and/or increased susceptibility of nerves affected by diabetic microangiopathy.

**Table 3.25:** Clinical features of diabetic autonomic neuropathy.

<i>System involved</i>	<i>Clinical features</i>
Cardiovascular	Postural hypotension, resting tachycardia, fixed heart rate, impaired Valsalva maneuver, painless myocardial infarction, sudden cardiac death
Gastrointestinal	Dysphagia (due to esophageal atony), abdominal fullness, nausea, vomiting, gastroparesis, nocturnal diarrhea, constipation, fecal incontinence
Genitourinary	Difficulty in micturition, urinary incontinence, recurrent infection, impotence, erectile dysfunction, retrograde ejaculation
Sudomotor	Gustatory sweating, nocturnal sweat without hypoglycemia, fissures in feet, anhidrosis
Vasomotor	Feet feel cold (due to loss of skin vasomotor responses), dependent pedal edema (due to loss of vasomotor tone and increased vascular permeability)
Pupillary	Decreased pupil size, delayed or absent reflexes to light, resistance to mydriatics Argyll-Robertson pupil
Metabolic	Hypoglycemia unawareness

### ***Autonomic Neuropathy (Table 3.25)***

- Autonomic neuropathy may affect both the sympathetic and parasympathetic nervous systems
- DM-related autonomic neuropathy can involve one or more systems, including the cardiovascular, gastrointestinal, genitourinary, sudomotor, and metabolic systems (Table 3.25).
- It may result in loss of awareness of hypoglycemia and can cause disabling postural hypotension.

#### **Management**

***Strict glycemic control, Foot care***

- **Mononeuropathies are usually self-limiting** and do not require any specific therapy. Explanation and reassurance about remission within months may be necessary.
- **Neuritic pain** of diabetic neuropathy may be treated with non-steroidal anti-inflammatory drugs (opiates-tramadol, oxycodone), tricyclic antidepressants (amitriptyline, imipramine), duloxetine, venlafaxine, mexiletine, valproate and anticonvulsants (e.g. phenytoin, carbamazepine, gabapentin or pregabalin). Duloxetine is an antidepressant, potent dual reuptake inhibitor of serotonin and noradrenaline is useful in refractory cases.
- Transcutaneous nerve stimulation (**TENS**): Beneficial in some patients.
- Topical **capsaicin** containing creams: May be occasionally beneficial.
- **Orthostatic/postural hypotension**: Responds to sleeping with the head of the bed raised, avoiding sudden upright position, full-length elastic support stockings and increased salt intake. Rarely, fludrocortisone,  $\alpha$ -adrenoceptor agonist (midodrine) are needed.
- **Gastroparesis**: Patient is advised to take frequent small meals and prokinetic agents. Dopamine antagonists (metoclopramide, domperidone), erythromycin and gastric pacemaker; percutaneous enteral (jejunal) feeding may be necessary in some cases.
- **Diarrhea**: In diabetics often responds to diphenoxylate, loperamide or broad spectrum antibiotics (e.g. tetracyclines). Rarely clonidine and octreotide may be needed.
- **Constipation**: Can be treated by stimulant laxatives (senna).
- **Atonic bladder**: By intermittent self-catheterization.
- **Excessive sweating**: By anticholinergic drugs (propranolol, poldine, oxybutinin), clonidine, or topical antimuscarinic agent (glycopyrrolate cream)
- **Erectile dysfunction**: Treatment includes:
  - Psychological counselling; psychosexual therapy
  - Phosphodiesterase type 5 inhibitors: Oral therapy with sildenafil, vardenafil, tadalafil
  - Dopamine agonist (apomorphine) through sublingual route
  - Prostaglandin E<sub>1</sub> (alprostadil): Injected into corpus cavernosum or intraurethral administration of pellets
  - Vacuum tumescence devices
  - Implanted penile prosthesis

#### ***Specific treatment to reverse neuropathy***

- **$\alpha$ -Lipoic acid**: It is a natural cofactor of dehydrogenase complex and is an antioxidant (redox modulating agent). It may ameliorate both somatic and autonomic diabetic neuropathies.
- **Aldolase reductase inhibitors (e.g. epalrestat)**: They decrease the flux of glucose through polyol pathways, inhibit accumulation of sorbitol and fructose, and prevent reduction of redox potential. However, they are not effective.
- **Carnitine** may be useful in few cases.
- **Methylcobalamin** may provide some benefit.
- **Ruboxistaurin, a protein kinase C beta inhibitor**, is an emerging treatment for diabetes microvascular complications.

## **Dermatological Complications of Diabetes Mellitus (Box 3.21)**

**Q. Write short note on dermatological complications of diabetes mellitus.**

### Box 3.21: Dermatological complications of diabetes mellitus.

- Skin infections: Due to immune dysfunction, e.g. carbuncles and furuncles and intertrigo (Fig. 3.12)
- Balanoposthitis (Fig. 3.13)
- Vaginal candidiasis/balanitis (Fig. 3.14): Due to immune dysfunction
- Diabetic ulcers: Due to peripheral neuropathy and ischemia
- Xanthomatoses: Due to hyperlipoproteinemia
- Necrobiosis lipoidica diabetorum (NLD)
- Diabetic dermopathy (shin spots)
- Tight waxy skin the dorsum of the hands with joint contractures in type 1 DM—digital sclerosis
- Acanthosis nigricans
- Acrocordans/skin tags: Marker of insulin resistance
- Granuloma annulare
- Diabetic blisters: Bullosis diabetorum

### Musculoskeletal Complications in Diabetes (Box 3.22)

**Q. Write short note on musculoskeletal complications of diabetes.**

#### Box 3.22: Musculoskeletal complications in diabetes.

- Diabetic muscle infarction: Painful muscle swelling, usually in thigh
- Neuropathic arthropathy (Charcot joint)
- Carpal tunnel syndrome
- Dupuytren's contracture
- Flexor tenosynovitis
- Adhesive capsulitis (frozen shoulder)
- Diabetic cheroarthropathy—'prayer sign', 'table top test'
- Diabetic sclerodactyly

### Gestational Diabetes Mellitus (GDM)

**Q. Write short essay/note on gestational diabetes mellitus (GDM), its significance and management.**

Gestational diabetes mellitus (GDM) is defined as **glucose intolerance (diabetes) that develops or is first recognized during pregnancy.** Typically it is asymptomatic and usually remits after delivery. However, there is an increased risk of type 2 diabetes in later life and maintaining a low bodyweight and keeping physically active can reduce this risk.

Risk factors for GDM, low risk groups for GDM and importance of

diagnosis of GDM are mentioned in Boxes 3.23, 3.24 and 3.25 respectively.

**Box 3.23:** Risk factors that predispose to gestational diabetes mellitus.

Women with

- Previous history of gestational diabetes
- Obesity (overweight) and pregnancy at older age
- History of large for gestational age babies
- Ethnic groups at particular risk

**Box 3.24:** Low-risk groups for gestational diabetes mellitus.

Women with

- Age below 25 years
- Normal weight before pregnancy
- Member of an ethnic group with a low prevalence of diabetes
- No diabetes in first degree relatives
- No history of abnormal glucose tolerance or poor obstetrical outcome

**Box 3.25:** Importance of diagnosis of gestational diabetes mellitus.

**Fetal risk with GDM**

- Fetal macrosomia
- Intrauterine fetal death
- Respiratory distress
- Hypoglycemic fetuses
- Polyhydramnios
- Hypocalcemia
- Increased incidence of shoulder dystocia
- Fetal hyperbilirubinemia
- Transient tachypnea of the newborn

**Risk for offspring of women with GDM:** Increased risk of obesity and diabetes

**Risk for women with GDM:** Increased risk of obesity and diabetes in future.

- Increased incidence of preeclampsia
- Cesarean section

**Fig. 3.12:** Intertrigo (intertriginous dermatitis) characterized by inflammation of skin folds.

**Fig. 3.13:** Balanoposthitis.

**Fig. 3.14:** Candida balanitis.

### Oral glucose tolerance test (OGTT)

- Diagnosis is based on an oral glucose tolerance test (OGTT) performed at 24–28 weeks of gestation in women with moderate to high risk.
- **Method:** 100 g glucose is dissolved in 300–400 mL of water and consumed over 5 minutes. The quantity of glucose is more than usual glucose load of 75 g and is recommended because there is an increased turnover of glucose in pregnancy.

**Table 3.26:** Criteria for diagnosis of gestational diabetes mellitus.

Time (Hour)	Upper limit of normal values (mg/dL)	
	Whole blood (O'Sullivan)	Plasma (Carpenter and Coustan)
0 (fasting)	85	95
1	160	180
2	140	155
3	125	140

(Two or more of these values must be abnormal).

## Criteria for diagnosis of GDM (Table 3.26)

### Management

**Aim:** To normalise the maternal blood glucose and reduce excessive growth of fetus.

- **Insulin:** Initiate insulin therapy when target glucose levels exceed despite nutritional therapy. Insulin does not cross the placenta.
- **Dietary modification:** Reduce the consumption of quick-acting refined carbohydrate. Treatment for other patients with diet in the first instance, although most may require insulin at some stages during pregnancy.
- Many oral hypoglycemic drugs cross the placenta and should be avoided because of the potential risk to the fetus. However, *metformin* or *glyburide/glibenclamide* are considered safe to use in pregnancy.

### Follow-up

Though the sugar levels normalize after delivery, it is advised to repeat a OGTT 6 weeks postpartum.

## Metabolic Syndrome

### Q. Write short essay or note on:

- **Metabolic syndrome/insulin resistance syndrome and its components.**
- **Clinical diagnosis, risks and treatment of insulin resistance syndrome (syndrome X).**

Metabolic syndrome (also known as the *insulin resistance syndrome*, *Reaven syndrome*, *dysmetabolic syndrome*, and *syndrome X* syndrome) is a proinflammatory, prothrombotic state that consists of a **cluster of clinical findings and laboratory abnormalities**.

**Table 3.27: Risks associated with metabolic syndrome.**

- |   |   |
|---|---|
| <ul style="list-style-type: none"><li>• Cardiovascular diseases (atherosclerotic vascular disease, specifically coronary artery disease)</li><li>• Type 2 diabetes mellitus</li><li>• Non-alcoholic fatty liver disease</li></ul> | <ul style="list-style-type: none"><li>• Sleep disorders: obstructive sleep apnea</li><li>• Polycystic ovary syndrome (PCOS).</li><li>• Hyperuricemia</li><li>• Chronic kidney disease</li><li>• Erectile dysfunctions</li></ul> |
|---|---|

- **Clinical findings:** Include obesity (central, abdominal, or visceral), increased sympathetic nervous system activity, hypertension. Risk factors associated with metabolic syndrome is listed in Table 3.27. These clinical features include acanthosis nigricans, skin tags–acrocordans, ovarian hyperandrogenism [polycystic ovary syndrome (PCOS)], and

lipodystrophy.

- **Laboratory abnormalities:** Cardiovascular risk factors and includes hyperglycemia, dyslipidemia (high TGs, low HDL), glucose intolerance, insulin resistance (the common etiologic factor), hyperinsulinemia (compensatory).
- **Pathogenesis:** The basic defect is insulin resistance.
  - Insulin resistance is **the decrease/failure of target (peripheral) tissues to insulin action**. Insulin is unable to produce its numerous actions, in spite of unimpaired secretion from the  $\beta$  cells.
  - **Main factors** in the development of insulin resistance are combination of genetic susceptibility and **obesity**. The obesity accompanying type 2 DM is central obesity and central adipose tissue is more ‘lipolytic’ than peripheral sites. Insulin resistance is induced by free fatty acids, adipokines, and chronic inflammation in adipose tissue.
  - **Consequences of insulin resistance**
    - ◆ **Decreased uptake of glucose in muscle** results in post-prandial hyperglycemia. The defects in the uptake are due to defect in the receptors present in target tissues and usually at the post-receptor level.
    - ◆ **Reduced glycolysis and fatty acid oxidation** in the liver.
    - ◆ **Inability to suppress hepatic gluconeogenesis**
- **Clinical diagnosis** (Box 3.26): Individual on medical treatment for dyslipidemia or hypertension, and those with isolated systolic or diastolic hypertension are included in the above criteria.

### Box 3.26: Diagnostic criteria for metabolic syndrome.

Presence of at least three of the following

- Abdominal obesity (waist circumference >80 cm in women and >90 cm in men)
- **Body mass index  $>30 \text{ kg/m}^2$  and/or waist/hip ratio  $>0.09$  in men,  $>0.85$  in women**
- Raised triglyceride (TG) levels ( $\geq 150 \text{ mg/dL}$ ) or on treatment for TG
- Reduced high density lipoproteins- HDL cholesterol level ( $<40 \text{ mg/dL}$  in males and  $<50 \text{ mg/dL}$  in females) or on treatment for HDL
- Raised blood pressure (systolic  $\geq 130 \text{ mm Hg}$  or diastolic  $\geq 85 \text{ mm Hg}$ ).
- Raised fasting glucose level ( $110\text{--}125 \text{ mg/dL}$ ); type 2 DM or impaired glucose tolerance and/or insulin resistance, denoted by hyperinsulinemia relative to glucose levels

### Management

Currently there is no evidence that treatment of insulin resistance reduces mortality and morbidity in metabolic syndrome. However, treatment of insulin resistance consists of:

- Lifestyle changes and exercise
- Diet: Low in calories and high in fibers
- Reduction of weight
- Treatment and control of diabetes, hypertension and lipid abnormalities.

# **Infectious Diseases**

# CHAPTER

# 4

## PYREXIA (FEVER) OF UNKNOWN ORIGIN

- Q. Define pyrexia of unknown origin (PUO). Discuss briefly your approach to a case of PUO or fever of unknown origin (FUO).**
- Q. Describe types, investigation and differential diagnosis of a case of pyrexia of unknown origin.**
- Q. Mention the etiology of pyrexia of unknown origin and discuss the investigation in a case of pyrexia of unknown origin.**

### Definition

The definition of FUO (classical) was given by Petersdorf and Beeson in 1961. According to new classification, PUO is divided into four types:

1. **Classic pyrexia of unknown origin (PUO)** is classically defined as:
  - **Duration: Fever of at least 3 weeks duration.**
  - **Temperature: Daily temperature** persistently elevated **above 101°F (38.3°C).**
  - **Remains undiagnosed** despite after a thorough history-taking, physical examination, and the following obligatory (intelligent and intensive) investigations (or at least three outpatient visits or 3 days in hospital).
  - **No known immunocompromised state** (e.g. HIV or other immunosuppressing conditions).
2. **Nosocomial PUO:**
  - **Temperature:** Daily temperature persistently elevated **above 101°F (38.3°C)** developing on several occasions.
  - In a **hospitalized patient (>24 hours) who is receiving acute care**

**but no fever or incubating on admission.**

- It is mandatory that the cause of fever is not found at least on 3 days of intelligent investigations, including at least 2 days incubation of cultures.
3. **Neutropenic PUO:**
- A temperature of  $>38.3^{\circ}\text{C}$  ( $101^{\circ}\text{F}$ ) developing on several occasions.
  - **Neutrophil count is below 500/mL** or is expected to fall to that level in 1 or 2 days.
  - It is mandatory that the cause of fever is not found at least on 3 days of intelligent investigations, including at least 2 days incubation of cultures.
4. **HIV-associated PUO:**
- A temperature of more than  $38.3^{\circ}\text{C}$  ( $101^{\circ}\text{F}$ ) developing on several occasions.
  - Duration of fever is more than 4 weeks for outpatients or more than 3 days for hospitalized patients.
  - **HIV infection confirmed.**
  - It is mandatory that the cause of fever is not found at least on 3 days of intelligent investigations, including at least 2 days incubation of cultures.

## **Etiology**

*Classic PUO is usually not due to a rare disease, but due to atypical presentation of common diseases. Common causes of prolonged fever are:*

### **Infections (40% Cases)**

Most common infections causing PUO are **tuberculosis, malaria, typhoid, HIV**. Other causes are:

#### **1. Bacterial**

- **Abscesses:** Most commonly in the subphrenic space, liver, right lower quadrant, retroperitoneal space or the pelvis in women.
- **Tuberculosis (TB):** Disseminated tuberculosis occurring in **immunocompromised** patients, presents with more constitutional symptoms than localizing signs. **Chest X-ray** may be normal.
- **Urinary tract infections (UTIs)** are rare causes. Perinephric abscesses

occasionally fail to communicate with the urinary system resulting in a normal urinalysis.

- **Infective endocarditis:** Culture-negative endocarditis occurs in 5–10% of endocarditis. The HACEK (*H. parainfluenzae*, *H. aphrophilus*, and *H. paraphrophilus*), *Actinobacillus actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella spp.*) group are responsible for 5–10% cases of infective endocarditis and are the most common causes of gram-negative endocarditis in individuals without any abuse of intravenous drugs.
- **Hepatobiliary infections: Cholangitis** may develop without local signs and with only mildly elevated or normal liver function tests especially in the elderly patients.
- **Osteomyelitis.**
- **Brucellosis:** Should be considered in patients with persistent fever and a history of contact with cattle, swine, goats or sheep, or patients who consume raw milk products.
- **Borrelia recurrentis** is responsible for tick borne relapsing fever.
- Other spirochetal diseases that can cause PUO include *Spirillum minor* (**Rat-bite fever**), *Borrelia burgdorferi* (**Lyme disease**), and *Treponema pallidum* (**syphilis**).

## 2. Viral

- **Herpes viruses**, such as **cytomegalovirus** and **Epstein-Barr virus** (EBV) can cause prolonged febrile illnesses with constitutional symptoms without any significant organ manifestations, particularly in the elderly.
- **HIV:** Prolonged fever may be the only manifestation in patients with advanced HIV infection.

3. **Fungi:** Immunosuppression, the use of broad-spectrum antibiotics, the presence of intravascular devices and total **parenteral nutrition** all predispose individual to disseminated fungal infections.

## 4. Parasites:

- **Malaria**
- **Toxoplasmosis:** It should be considered in febrile patients with lymph node enlargement.

- **Trypanosoma**, leishmania and **amoeba** species may rarely cause PUO.
5. **Rickettsial organisms:** *Coxiella burnetii* may cause chronic infections; chronic **Q fever** or Q fever endocarditis may be identified in patients with a PUO.
  5. **Psittacosis:** Infection by the causative organism, *Chlamydophila* should be considered in a patient with PUO who has a history of contact with birds. **Lepidopterism** (fever with rash due to exposure to scales and toxic fluids of adult moths, butterflies or its caterpillars).

### **Neoplasms**

Primary or metastatic neoplasms constitute 20% of cases of PUO (Table 4.1).

### **Collagen Vascular Disease/Autoimmune Disease**

Constitute 20% of cases of PUO (Table 4.1).

**Table 4.1: Neoplasms and collagen vascular diseases causing PUO.**

<i>Neoplasms-primary or metastatic (20% cases)</i>	<i>Collagen vascular disease/autoimmune disease (20% cases)</i>
<ul style="list-style-type: none"> <li>• <b>Hematological</b> <ul style="list-style-type: none"> <li>– Lymphoma</li> <li>– Chronic leukemia</li> </ul> </li> <li>• <b>Non-hematological</b> <ul style="list-style-type: none"> <li>– Renal cell cancer</li> <li>– Hepatocellular carcinoma</li> <li>– Pancreatic cancer</li> <li>– Colon cancer</li> <li>– Myelodysplastic syndrome</li> <li>– Sarcomas</li> <li>– Atrial myxoma</li> <li>– Malignant histiocytosis</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Adult onset Still’s disease, Macrophage activation syndrome (MAS)/hemophagocytic lymphohistiocytosis (HLH)</li> <li>• Polymyalgia rheumatica</li> <li>• Temporal arteritis</li> <li>• Rheumatoid arthritis</li> <li>• Rheumatic fever</li> <li>• Inflammatory bowel disease</li> <li>• Reiter’s syndrome</li> <li>• Systemic lupus erythematosus</li> <li>• Vasculitides <ul style="list-style-type: none"> <li>– Polyarteritis nodosa</li> <li>– Giant cell arteritis</li> <li>– Kawasaki disease</li> </ul> </li> </ul>

(PUO: pyrexia of unknown origin)

### **Psychogenic Fevers**

- **Habitual hyperthermia:** It is seen in young females, characterized by temperatures of 99 °F to 100.5 °F that occurs regularly or intermittently for years. No organic cause can be found.
- **Afebrile PUO:** In this, patient always complains of feverishness but the temperature recorded is always less than <38.3°C.
- **Exaggerated circadian rhythm:** Normal person usually have an evening rise of temperature which is not normally apparent. In this condition, it becomes evident.
- **Hysterical fever:** In this, the patient is thinks and believes that he is always having fever.
- **Malignant hyperthermia:** It is a rare life-threatening condition triggered by exposure to certain drugs used for general anesthesia (especially all volatile anesthetics), nearly all gaseous anesthetics, and neuromuscular blocking agent like succinylcholine.
- **Neuroleptic malignant syndrome (NMS):** It is a rare, life threatening, neurological disorder, most often caused by an adverse reaction to neuroleptic or antipsychotic drugs. It presents with muscle rigidity, fever, and autonomic instability.

### ***Periodic Fevers***

For example, Familial Mediterranean fever.

### ***Miscellaneous***

Constitute 10% cases (Table 4.2).

**Table 4.2: Miscellaneous causes of PUO (10% cases).**

<ul style="list-style-type: none"> <li>• Drugs: penicillin, phenytoin, captopril, allopurinol, erythromycin, cimetidine, etc. All drugs can cause fever except DIGITALIS</li> <li>• Hyperthyroidism, Pheochromocytoma, Addison’s disease</li> <li>• Alcoholic hepatitis</li> <li>• Sarcoidosis</li> <li>• Inflammatory bowel disease</li> </ul>	<ul style="list-style-type: none"> <li>• Deep venous thrombosis/pulmonary thromboembolism</li> <li>• Hemolytic anemia</li> <li>• Thyroiditis</li> <li>• Granulomatous hepatitis</li> <li>• Cyclic neutropenia</li> <li>• Kikuchi–Fujimoto disease</li> <li>• Cerebrovascular accidents (CVA)—Intracranial bleeds</li> </ul>
---	---

(PUO: pyrexia of unknown origin)

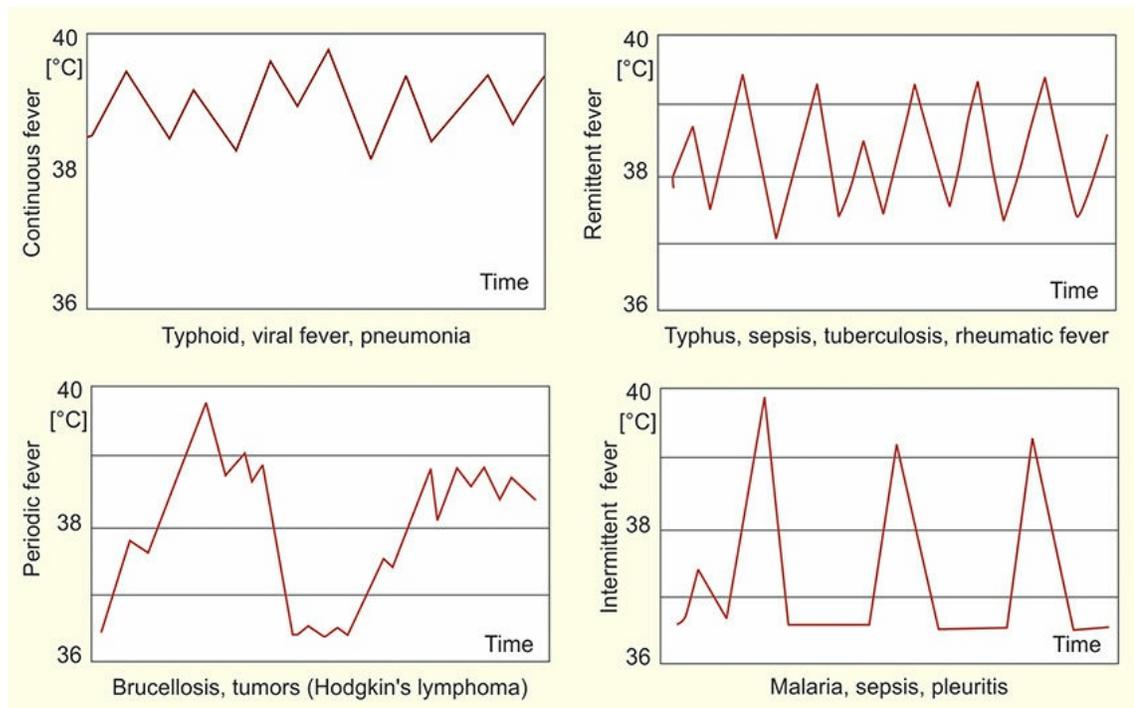

## ***Undiagnosed (10% Cases)***

About 10–15% of patients remain undiagnosed despite extensive investigations and in 75% of these the fever resolves spontaneously. In the remainder, other signs and symptoms make the diagnosis clear.

## **Clinical Approach to PUO**

### ***History Taking***

1. **Onset:**
  - **Acute:** Malaria, pyogenic infection
  - **Gradual:** TB, typhoid fever
2. **Character:** High grade fever is seen in urinary tract infections (UTI), malaria, thrombosis, drug fever.
3. **Pattern (Fig. 4.1):**
  - **Sustained/persistent:** Typhoid fever, drugs
  - **Intermittent fever:**
    - Daily spikes: Malaria, abscess, tuberculosis (TB), Schistosomiasis
    - Double quotidian, Twice-daily spikes: Leishmaniasis, gonococcal endocarditis, adult onset Still's disease
    - Saddle back fever: Leptospirosis, dengue, borrelia
    - Relapsing/recurrent fever: Non-falciparum malaria, brucellosis, Hodgkin's lymphoma
4. **Antecedents:** Prior to onset of fever:
  - **Dental extraction:** Infective endocarditis
  - **Urinary catheterization:** UTI, bacteremia

**Fig. 4.1:** Patterns/types of fever.

## 5. Associated symptoms:

- **Chills and rigors:** Bacterial, rickettsial and protozoal disease (malaria), influenza, lymphoma, leukemia, drug-induced
- **Night sweats:** TB, Hodgkin's lymphoma
- **Loss of weight:** Malignancy, TB
- **Cough and dyspnea:** Miliary TB, multiple pulmonary emboli, AIDS patient with PCP (Pneumocystis pneumonia), CMV (Cytomegalovirus)
- **Headache:** Giant cell arteritis, typhoid fever, sinusitis, meningitis, drug fever
- **Joint pain:** Rheumatoid arthritis, systemic lupus erythematosus (SLE), vasculitis, adult onset Still's disease
- **Abdominal pain:** Cholangitis, biliary obstruction, perinephric abscess, Crohn's disease, dissecting aneurysm, gynecological infection
- **Bone pain:** Osteomyelitis, lymphoma
- **Sore throat:** Infectious mononucleosis, retropharyngeal abscess, streptococcal infection
- **Dysuria, rectal pain:** Prostatic abscess, UTI
- **Altered bowel habit:** Inflammatory bowel disease (IBD), typhoid

fever, schistosomiasis, amebiasis

- **Skin rash:** Gonococcal infection, polyarteritis nodosa (PAN), non-Hodgkin's lymphoma (NHL), dengue fever, connective tissue disorders.
5. **Review past medical history:** Malignancy (e.g. leukemia, lymphoma, hepatocellular carcinoma), HIV infection, diabetes mellitus, inflammatory bowel disease, collagen vascular disease [e.g. systemic lupus erythematosus (SLE), rheumatoid arthritis (RA)], giant cell arteritis, tuberculosis, heart disease (e.g. valvular heart disease)
  7. **Past surgical history:** Post-splenectomy/post-transplantation, prosthetic heart valve, catheter, AV fistula, recent surgery/operation
  3. **Drug history**
    - **Immunosuppressive drug/corticosteroid**
    - **Anticoagulants**
    - **Before the fever: Drug fever** occur within 3 months after starting, taking drugs may cause hypersensitivity and low grade fever, usually associated with rash.
      - **Due to the allergic reaction**, direct effect of drug which impairs temperature regulation (e.g. phenothiazine), antiarrhythmic drug (e.g. procainamide, quinidine); antimicrobial agent (e.g. penicillin, cephalosporin, hydralazine), phenytoin.
    - **After the fever:** May modify clinical pictures, mask certain infection, e.g. subacute bacterial endocarditis (SBE), antibiotic allergy.
  9. **Family history:** Whether anyone in family has similar problem (e.g. tuberculosis, familial Mediterranean fever)
  1. **Social history**
    - **Travel:** Amebiasis, typhoid fever, malaria, schistosomiasis
    - **Residential area:** Malaria, leptospirosis, brucellosis
    - **Occupation**
      - Farmers, veterinarian, slaughter-house workers = Brucellosis
      - Workers in the plastic industries = polymer-fume fever
      - Contact with domestic/wild animal/birds : Brucellosis, psittacosis (pigeons), leptospirosis, Q fever, toxoplasmosis
    - **Diet history**

- Unpasteurized milk/cheese = Brucellosis
- Poorly cooked pork = Trichinosis
- IVDU (intravenous drug user) = HIV-AIDS related condition, endocarditis
- Sexual orientation = HIV, sexually transmitted disease (STD), pelvic inflammatory disease (PID)
- Close contact with TB patients.

### Physical Examination (Table 4.3)

**Table 4.3: Various physical examination in pyrexia of unknown origin (PUO).**

<i>General</i>	<i>Hands</i>	<i>Arms</i>
<ul style="list-style-type: none"> <li>• Pattern of fever (continuous, intermittent, remitting, relapsing)</li> <li>• Patient is ill/not ill</li> <li>• Weight loss (presence indicates chronic illness)</li> <li>• Skin rash</li> </ul>	<ul style="list-style-type: none"> <li>• Stigmata of infective endocarditis</li> <li>• Vasculitis changes</li> <li>• Clubbing</li> <li>• Presence of arthropathy</li> <li>• Raynaud’s phenomenon</li> </ul>	<ul style="list-style-type: none"> <li>• Drug injection sites (IVDU)</li> <li>• Epitrochlear and axillary nodes (lymphoma, sarcoidosis, focal infection)</li> <li>• Skin rash, nodules</li> <li>• Intravenous cannula—phlebitis</li> </ul>

## Investigations (Tables 4.4, 4.5 and Box 4.1)

**Table 4.4: Laboratory investigations in pyrexia of unknown origin.**

<b>Stage 1: Screening tests</b>	<b>Stage 2: Laboratory investigations</b>
<ul style="list-style-type: none"> <li>• Full blood count with peripheral smear</li> <li>• ESR and CRP</li> <li>• Renal function tests</li> <li>• Liver function tests</li> <li>• Blood culture</li> <li>• Serum virology for HIV, dengue, leptospira, widal test</li> <li>• Urinalysis and culture</li> <li>• Blood culture</li> <li>• Sputum culture and sensitivity</li> <li>• Stool routine and occult blood</li> <li>• Chest X-ray</li> <li>• Mantoux test</li> <li>• Ultrasound abdomen, pelvis, neck (if adenopathy, thyroid)</li> <li>• Malarial smear in endemic areas</li> </ul>	<ul style="list-style-type: none"> <li>• Repeat blood counts, chemistry</li> <li>• Protein electrophoresis</li> <li>• CT (chest, brain, abdomen, pelvis)</li> <li>• Autoantibody screen (ANA, RF, ANCA, anti-ds DNA)</li> <li>• ECG</li> <li>• Thyroid function tests</li> <li>• Bone marrow examination with culture</li> <li>• Lumbar puncture</li> <li>• Coagulation workup</li> <li>• Serum ferritin (adult onset Still's disease)</li> <li>• Consider PSA, CEA, LDH</li> <li>• Temporal artery biopsy</li> <li>• Paul Bunnell test and brucella agglutination test</li> <li>• Weil Felix reaction</li> </ul>

**Table 4.5: Various radiological investigations and its usefulness in PUO.**

<b>Radiological investigations</b>	<b>Usefulness in the diagnosis of</b>
Chest X-ray	Tuberculosis, malignancy, <i>Pneumocystis pneumonia</i>
CT of abdomen or pelvis with contrast agent	Abscess, malignancy
MRI of brain	Malignancy, autoimmune disorders

PET scan	Malignancy, inflammation
Transthoracic or transesophageal echocardiography	Bacterial endocarditis
Galium 67 scan	Infection, malignancy
Indium-labelled leukocytes	Occult septicemia
Technetium Tc 99m	Acute infection and inflammation of bone and soft tissue
Venous Doppler study	Venous thrombosis

### Treatment

- Treat the underlying cause identified after investigations.
- Use empirical broad-spectrum antibiotics.
- Therapeutic trial of aspirin/steroids.
- Naprosyn challenge for malignancy/lymphoma.
- Empirical antitubercular treatment.

### Box 4.1: Stage 3: Laboratory investigations in PUO.

- Echocardiography
- PET scan (Indium-labelled WBC scan)
- IVU (intravenous urogram)
- Liver biopsy
- Exploratory laparotomy
- Bronchoscopy

## BACTERIAL INFECTIONS

### Streptococcal Infections

Streptococci are gram-positive cocci 1  $\mu\text{m}$  in diameter, non-motile and non-sporing. Many strains are capsulated.

Various products secreted by streptococci, which aid in their pathogenicity include *streptolysin O* and *S*, *deoxyribonucleases*, *hyaluronidase* and *erythrogenic toxins*.

### *Streptococcal Pharyngitis*

- Incubation period is 2–4 days.
- **Clinical features:** Presents with abrupt onset of sore throat, dysphagia, headache, malaise, anorexia, and fever. The posterior pharyngeal wall is red and edematous. The tonsils are enlarged, red and covered with

yellowish exudate, which can be easily removed with a swab. Anterior cervical lymph nodes are enlarged and tender.

- **Complications:** **Rheumatic fever** and **poststreptococcal glomerulonephritis** are two major immunologically triggered complications of streptococcal infection of the upper oropharyngeal regions.

**Treatment:** Pharyngitis responds readily to penicillin, erythromycin, cephalosporins (first generation given orally) or clindamycin 600–900 mg given 8th hourly.

## ***Scarlet Fever***

Characterized by the development of an **erythematous rash** on the second day of illness. The primary lesion is in the throat. The rash is seen over the neck and trunk, the palms and soles are generally spared. The rash blanches on pressure. The rash subsides with extensive desquamation after 4–5 days.

### **Treatment**

Streptococcal lesions respond promptly to penicillin. A single intramuscular injection of benzathine penicillin G 600,000 units for children less than 25 kg and 1.2 million units for all others. Phenoxymethylpenicillin (penicillin V) 250 mg orally four times daily for 7-10 days is also equally effective. Erythromycin 250 mg 6 hourly for 7–10 days is given to patients allergic to penicillin. If suppuration develops, surgical drainage of the pus may be required.

## ***Erysipelas***

**Acute spreading infection of the skin and the subcutaneous tissue** by streptococci. Face is commonly affected. The disease sets in abruptly with malaise, chills, headache and vomiting. The skin lesions are erythematous with clear advancing margins which may show vesicles. The part is tender and local lymph node enlargement may occur.

## ***Streptococcal Impetigo***

- It is inflammation of the skin characterized by isolated pustules which become crusted. Sites of predilection are around the mouth and nostrils.
- If left untreated they may ulcerate to produce shallow ulcers with crusts or scabs which may lead to pigmentation and scarring. This stage is called ecthyma.

## ***Cellulitis***

This is spreading inflammation of the subcutaneous tissue due to entry of the organism through the abrasions of the skin. There is pain, tenderness, erythema, fever, and often regional lymphadenopathy.

### ***Lymphangitis***

Acute lymphangitis may follow local trauma. This condition presents in the form of linear red streaks radiating from the site of entry to the draining lymph nodes.

### ***Streptococcal Bacteremia***

Irrespective of the focus of entry and primary lesion, streptococcal bacteremia gives rise to metastatic foci of infection such as suppurative arthritis, osteomyelitis, peritonitis, endocarditis, meningitis, or visceral abscesses.

### ***Necrotizing Fasciitis (Syn: Streptococcal Gangrene) (Fig. 4.2)***

- This is a progressing destructive lesion of the subcutaneous tissue leading to necrosis of fascia and adipose tissue, but often sparing the skin. The organisms enter through trivial wounds, but within 24 hours the part is hot, swollen, tender and edematous. The edema and violaceous hue spreads in all directions.

**Fig. 4.2:** Necrotizing fasciitis—due to *Streptococcus*.

- It is more common in diabetes, immunocompromised individuals and those with local conditions impairing the vitality of the part, e.g. vascular occlusions, chronic edema and infective lesions. Increase in the fascial compartmental pressure further jeopardises the vascularity. Within 48

hours bullae develop, which go on to gangrene within 4–5 days. The gangrenous area gets demarcated. General symptoms include severe prostration, toxemia, mental clouding and delirium. If the diagnosis is missed, mortality is high.

### ***Streptococcal Myositis***

- This is an uncommon lesion. Infection reaches the muscles by the bloodstream. Onset is with severe pain and swelling of muscles. Muscle compartment syndromes may develop. If unrecognized, mortality is over 80%.
- It should be differentiated from spontaneous gas gangrene. Presence of superficial crepitus favors the diagnosis of gas gangrene.

**Treatment:** Includes the administration of broad-spectrum antibiotics and early surgical debridement.

### ***Pneumonia and Empyema***

Streptococcal pneumonia usually follows a viral infection, and it manifests as bronchopneumonia. In many cases empyema develops as a complication.

### ***Streptococcal Toxic Shock Syndrome***

Infection by group A streptococcus may lead to vascular collapse and organ failure. M-protein which is a constituent of the cell wall is the virulence factor, which plays the major role in the pathogenesis of toxic shock syndrome. It forms large aggregates with fibrinogen, in blood and tissues. These activate polymorphonuclear leucocytes intravascularly and this leads to the production of toxic shock syndrome.

### ***Other Pathogenic Strains of Streptococci***

*Group B streptococcus (Syn: Streptococcus agalactiae)*

This is a major pathogen found in the female genital tract, rectum and also throat. **Chorioamnionitis, septic abortion** and **puerperal sepsis** may occur during pregnancy. Urinary tract infection may occur in both sexes. Hematogenous spread may result in endocarditis, pneumonia, empyema, meningitis and peritonitis. Immunocompromised hosts and elderly subjects are more susceptible.

## *Streptococcus viridans*

Viridans streptococci account for more than 40% cases of **infective endocarditis**. *Streptococcus mutans* which colonizes dental plaques is an important cause of dental caries.

## *Enterococci*

Causes urinary tract infections, biliary tract infections, septicemia, peritonitis, infective endocarditis and abdominal suppuration.

## Staphylococci

### **Q. Write short note on:**

- **Diseases caused by Staphylococci.**
- **Drugs used for treating Staphylococcal septicemia.**
- ***Staphylococcus aureus***: Causes pyogenic lesions such as boils, carbuncles, wound infection, abscesses, impetigo, mastitis, osteomyelitis, pneumonia, septicemia and pyemia.
- ***Coagulase negative staphylococci***: It causes infection of cardiac and vascular prostheses, endocarditis, ventriculitis (cerebral), peritonitis in continuous ambulatory peritoneal dialysis, septicemia, and cystitis. Various diseases caused by Staphylococci are listed in Table 4.6.
- ***Staphylococcus epidermidis*** is a common infective agent in implanted prosthetic devices. Most of the infections are acquired from hospital.

**Table 4.6: Diseases caused by staphylococci.**

#### Superficial Lesions

- |   |  |
|---|--|
| <ul style="list-style-type: none"><li>• Furuncle, carbuncle, impetigo, ecthyma, sycosis barbae</li><li>• Follicular Impetigo of Bockhart</li><li>• The scalded skin syndrome (Syn: pemphigus neonatorum, Ritter's disease, toxic epidermal necrolysis) (Fig. 4.3)</li></ul> | <ul style="list-style-type: none"><li>• Staphylococcal pneumonia</li><li>• Osteomyelitis/septic arthritis</li><li>• Staphylococcal bacteremia</li><li>• Staphylococcal food poisoning</li><li>• Endocarditis</li><li>• Toxic shock syndrome</li><li>• Tropical pyomyositis</li></ul> |
|---|--|

### ***Treatment of Staphylococcal Infections***

- Antistaphylococcal antibiotics of the first choice:
  - Oxacillin (methicillin)
  - Cephalosporins of first generation (cefazolin, cephalothin)

- Antistaphylococcal antibiotics of the second choice: For MRSA/VRSA
  - lincosamides (e.g. clindamycin), glycopeptides (vancomycin, teicoplanin), quinupristin/dalfopristin, chloramphenicol, minocycline, rifampin, trimethoprim sulfamethoxazole, fosfomycin, linezolid, daptomycin, tigecycline, dalbavancin.
  - Oritavancin, Telithromycin, Ceftobiprole medocaril anti-MRSA cephalosporin antibiotics.

**Fig. 4.3:** Staphylococcal scalded skin syndrome.

## Community-acquired Methicillin-resistant *Staphylococcus aureus* (CA-MRSA)

**Q. Write short note on community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA).**

- It is a type of staphylococcal bacteria that is resistant to certain antibiotics, such as methicillin, oxacillin, penicillin and amoxicillin. It was first identified in 1968.
- The infection does not occur in individuals who are hospitalized or had any medical procedure. On the other hand, HA-MRSA occurs in the hospital setting.
- Outbreaks of CA-MRSA have occurred among categories such as: athletic teams (e.g. football, wrestling, rugby, fencing), military barracks, correctional facilities, dormitories, daycares and schools.
- **Factors that favor for MRSA transmission (5 Cs)**
  - Crowding
  - Compromised skin (abrasions, cuts)
  - Contaminated surfaces

- Frequent, skin-to-skin Contact
- Lack of Cleanliness
- **Feature:** It tends to cause more aggressive skin and soft tissue infections, necrotizing pneumonia, septic shock and bacteremia.

**Treatment** of methicillin-resistant *Staphylococcus aureus* (MRSA) (Table 4.7).

**Table 4.7:** Treatment of methicillin-resistant *Staphylococcus aureus*.

<b>Drug</b>	<b>Traditional dosage</b>
Doxycycline (mild cases oral)	100 mg IV or per oral 12 hourly
Trimethoprim sulfamethoxazole (mild cases oral)	160 mg per oral 12 hourly 2.5 mg/kg IV 12 hourly
Clindamycin	300–400 mg per oral 6 hourly 600–900 mg IV 8 hourly
Daptomycin	4 mg/kg IV per day 6 mg/kg IV per day
Linezolid	600 mg per oral or IV 12 hourly
Minocycline	100 mg IV or per oral 12 hourly
Quinupristin-dalfopristin	7.5 mg/kg IV 12 hourly
Telavancin	10 mg/kg IV per day
Tigecycline	100 mg IV (initial) then 50 mg IV 12 hourly
Vancomycin	1 g IV 12 hourly

## PNEUMOCOCCAL INFECTIONS

Diseases caused by pneumococci are listed in Box 4.2.

**Box 4.2:** Diseases caused by pneumococci.

- Pneumococcal pneumonia
- Extrapulmonary pneumococcal lesions
  - *Pneumococcal meningitis*
  - *Pneumococcal peritonitis*

### **Treatment of Pneumococcal Infections**

- Pneumococci are generally susceptible to penicillin, but resistant strains are frequent. It is advisable to send the sputum for sensitivity tests before starting specific therapy. Benzyl penicillin

is the drug of choice for uncomplicated pneumococcal infections.

- Multiple-drug-resistant pneumococci respond to vancomycin 2 g/day given IV in divided doses or cefotaxime or ceftazidime. Levofloxacin is also effective.

## Meningococcal Infections

### *Meningococcal Meningitis (Syn: Cerebrospinal Fever)*

- Meningococemia may be fulminant or chronic.
- **Fulminant meningococemia:** This is characterized by abrupt onset, severe constitutional disturbances, peripheral vascular collapse, shock, and sometimes myocarditis. In some cases the illness may progress rapidly so that toxemia and shock may occur within hours. These features are collectively called **Waterhouse-Friderichsen syndrome**. This syndrome is caused by hemorrhage into the adrenal glands resulting in acute adrenal failure. Toxic vasculitis aggravates the hypotension. Complications include endocarditis, allergic polyarthritis, pneumonia and osteomyelitis.

#### Treatment

- Penicillin G is the antibiotic of choice and should be administered intravenously in a dose of 24 million units daily in divided doses. Addition of glucocorticoids early in treatment favors prompt recovery and prevents complications considerably.
- Ampicillin in a dose of 200–400 mg/kg body weight daily is also equally effective. The third generation cephalosporins, especially cefotaxime and ceftriaxone are equally effective.

## Diphtheria

### **Q. Discuss the clinical manifestations, complications, diagnosis and management of diphtheria.**

- Diphtheria is a nasopharyngeal (respiratory diphtheria) and/or skin infection (cutaneous diphtheria) caused by *Corynebacterium diphtheriae*.
- *Corynebacterium diphtheriae* is a gram-positive bacillus. *Corynebacterium diphtheriae* remains localized at the site of infection but releases a powerful soluble **exotoxin** that damages the heart muscle and the nervous system.

### *Mode of Transmission*

- It is through airborne/droplet infection from active cases or carriers. Infection may also transmit through skin lesions.
- Incubation period: 2–7 days.

## ***Pseudomembrane***

The diagnostic pathologic feature is mucosal ulcers coated by pseudomembrane. The **pseudomembrane** has a well-defined edge which appears as 'wash-leather', elevated, firm, grayish-green (black in advanced stages) adherent membrane. It is surrounded by a zone of inflammation.

## ***Clinical Features***

- Its manifestations may be local (due to the membrane) or systemic (due to exotoxin).
- Insidious in onset with a sore throat and fever being the usual manifestation. The fever is moderate but there is usually marked tachycardia.

## ***Respiratory diphtheria***

- **Pharyngeal diphtheria:** It is characterized by marked tonsillar and pharyngeal inflammation and the presence of a pseudomembrane. There may be regional often tender lymphadenopathy (cervical lymph nodes), and along with marked edema of submandibular areas produces the so-called '**bull-neck**' appearance (swelling of the neck). Pharyngeal diphtheria is associated with the greatest toxicity.
- **Laryngeal diphtheria:** It usually represents extension of the membrane from the pharynx. Extension and sloughing of membranes may produce fatal airway obstruction. It usually presents with a husky voice, a brassy cough and later dyspnea and cyanosis due to respiratory obstruction.
- **Nasal diphtheria:** It is restricted to the nasal mucosa and is characterized by the presence of a unilateral, serosanguineous (frequently blood-stained) nasal discharge.

## ***Cutaneous diphtheria***

It is uncommon but occurs in individuals with poor personal hygiene and with burns. It produces round, deep, 'punched-out' skin ulcers with undermined edges and is covered by a gray-yellow or gray-brown adherent membrane. The ulcers occur more commonly on the lower and upper extremities, head and trunk. Constitutional symptoms are not common.

## ***Complications***

- **Airway (laryngeal) obstruction:** It may occur with advanced diphtheria.

Airway obstruction may be either due to the sloughed pseudomembrane or extension of the pseudomembrane to the larynx or into the tracheobronchial tree (bronchopulmonary diphtheria). It is mainly observed in children because of their small airways.

- **Cardiac complications:** These include **myocarditis** with arrhythmias, cardiac failure and ECG changes. They often develop weeks after initial episode of diphtheria. These are usually reversible.
- **Neurological complications** occur in 75% of cases.
  - **Palatal palsy** may develop after 10 days.
  - **Polyneuropathy** with weakness and paraesthesia may develop 3–5 weeks after the onset of diphtheria.
  - **Paralysis of accommodation** may manifest as difficulty in reading small print.
  - Encephalitis can occur rarely.
- **Other complications** include pneumonia, renal failure, encephalitis, cerebral infarction and pulmonary embolism.

## Diagnosis

- **Clinical diagnosis**
- **Confirmation of diagnosis:**
  - Demonstration of *Corynebacterium diphtheriae* on methylene blue-stained preparations.
  - Bacterial culture of *Corynebacterium diphtheriae* on Loeffler's medium and toxin studies (Elek test).

## Management

- Patients should be hospitalized with close monitoring of cardiac and respiratory function. Patient should be **isolated** and strict bed rest.
- **Diphtheria antitoxin** is the only specific treatment. It is produced from hyperimmune horse serum and it neutralizes circulating toxin
  - It must be given as early in the course of diphtheria as possible without awaiting the result of a throat swab. Because any delay in administration can be dangerous because toxin once fixed to the tissues can no longer be neutralized by antitoxin.
  - **Dose:** It is administered intravenously over 60 minutes after an initial test dose to exclude any allergic reaction. 20,000 to 40,000 units for pharyngeal/laryngeal disease of <48 hours duration, 40,000 to 60,000 units for nasopharyngeal disease, and 80,000 to 120,000 units for >3 days of illness or diffuse neck swelling (“bull neck”).
  - **Adverse reactions:** It can cause two types of reactions, an immediate anaphylactic reaction and delayed serum sickness. The immediate anaphylactic reaction is treated with adrenaline

and an antihistamine.

- **Antibiotics** should be given concurrently to eliminate *C. diphtheriae* and thereby remove the source of toxin production. Benzylpenicillin (1200 mg 4 times daily IV) or amoxicillin (500 mg 3 times daily) is given for 2 weeks. Patients allergic to penicillin are given erythromycin (500 mg four times daily for 14 days).
- **Tracheostomy** or intubation may be needed for respiratory distress.
- **Immunization:** Primary diphtheria does not produce immunity against infection. Hence, following recovery all sufferers should be immunized with diphtheria toxoid. Close contacts should be protected by erythromycin prophylaxis and also by immunization. Vaccines include DPT (diphtheria, pertussis, tetanus) and DT (diphtheria, tetanus).
- **Contact prophylaxis:** Single dose of penicillin G benzathine (600,000 units intramuscularly—IM) or oral erythromycin (500 mg four times daily for 7–10 days).

## TETANUS

### Q. Write a short essay/note on tetanus.

- Tetanus is due to infection by toxin secreting clostridium namely *Clostridium tetani*. The organism is found in soil derived from animal and human excreta.

**Mode of infection:** Infection enters the body through a contaminated wound (injury may be trivial). It can also develop as complication in intravenous drug misusers. Neonatal tetanus may develop following contamination of the umbilical stump, often after dressing the area (unhygienic practices) with dung (e.g. in many developing countries) or site of circumcision, causing tetanus neonatorum.

### Q. Write a short note on the actions of tetanospasmin.

**Pathogenesis:** During circumstances unfavorable to the growth of *Clostridium tetani*, it forms spores and remain dormant for years in the soil. Spores germinate and organism multiplies only in the anaerobic conditions. Thus, it may multiply in areas of tissue necrosis or wherever the oxygen tension is reduced by the presence of other organisms (e.g. aerobic organism). *Clostridium tetani* is not invasive and remain localized. Its clinical manifestations are due to the potent neurotoxin (exotoxin) called tetanospasmin.

**Incubation period:** Varies from 2 days to several weeks after injury. Shorter the incubation period, the more severe the attack and the worse the prognosis.

## Clinical Features

**Q.** Write a short essay/note on the clinical features of tetanus.

**Generalized tetanus** is the most common form of tetanus.

- **Lockjaw:** General malaise is rapidly followed by the most important symptom namely trismus. It is due to spasm of the masseter muscles, which causes difficulty in opening the mouth and in masticating.
- **Risus sardonicus:** When the tonic rigidity involve the muscles of the face, neck and trunk, contraction of the frontalis and the muscles at the angles of the mouth produces characteristic grinning expression known as ‘risus sardonicus’.
- **Opisthotonus:** Varying degree of rigidity develops in the muscles at the neck and trunk. The back is usually slightly arched (‘opisthotonus’) and the abdominal wall appears board-like.
- **Severe disease:**
  - If the disease is severe, **painful, violent, exhausting, reflex spasms** (convulsions) develop, usually within 24–72 hours of the initial symptoms and lasts for a few seconds to 3–4 minutes. The interval between the first symptom and the first spasm is known as the ‘onset time’.
  - The **spasms can be spontaneous or may be induced by stimuli** such as movement or noise or by light. Laryngeal spasm can impair respiration; esophageal and urethral spasm can produce dysphagia and urinary retention, respectively. Patients are mentally alert.
  - **Autonomic involvement** may produce cardiovascular complications (e.g. tachycardia, a labile blood pressure, sweating and cardiac arrhythmias).
- **Death:** Spasms gradually increase in frequency and severity and death may occur from exhaustion, hypoxia, cardiac arrest, asphyxia, respiratory failure or aspiration pneumonia or exhaustion. Mild cases with rigidity usually recover.

**Local tetanus** is a milder form of the disease in which the pain, stiffness, increased tone or spasms of the muscles develop only near the infected wound. Prognosis is good and recovery usually occurs if treatment is commenced at this stage.

**Cephalic tetanus:** Uncommon but fatal. It usually develops due to entry of *C. tetani* through the middle ear. Cranial nerve abnormalities (e.g. seventh nerve) are usual.

**Neonatal tetanus** is usually develops due to infection of the umbilical stump. Characterized by failure to thrive, poor sucking, grimacing and irritability followed by intense rigidity and spasms. Mortality is almost 100%. It can be prevented by immunizing all women of childbearing age, and providing clean delivery facilities.

## Investigations/Diagnosis

- Diagnosis is usually made on clinical grounds.
- **C. tetani:** Rarely possible to isolate from wounds (original locus of entry).

**Differential diagnosis:** Phenothiazine over dosage, strychnine poisoning, meningitis and tetany.

## Q. Write a short essay/note on the treatment of tetanus.

### Management/Treatment of Tetanus

#### Suspected tetanus

- **Care of the wound:** Clean the wound and debrided if necessary, to remove the source of toxin.
- **Human tetanus immunoglobulin:** In the dose of 250 units should be given along with an intramuscular injection of tetanus toxoid. If the patient is already immunized a single booster dose of the tetanus toxoid is given; otherwise the full three dose course of adsorbed vaccine is given.

#### Established tetanus

Management of established disease should be started as soon as possible.

- **Prevent further toxin production:** Debridement of wound and antibiotics (see below).
- **General supportive medical and nursing care.** Patient is isolated in a quiet, well ventilated and darkened room. Maintain hydration and nutrition and treat secondary infections.
- **Control of spasm:** Nurse in a quiet room, avoid unnecessary stimuli. Benzodiazepines/IV diazepam are used to control spasms and sedate the patient. If spasms continue, paralyze patient and ventilate. Baclofen may be useful.
- **Intubation and mechanical ventilation:** If the airway is compromised.
- **Magnesium sulfate infusion:** Reduces the need for antispasmodics.
- **Antibiotics and antitoxin:** Given even in the absence of an obvious wound. Drug of choice is intravenous metronidazole. Other antibiotic include penicillin (Benzylpenicillin 600 mg IV 4 times daily) and cephalosporins.
- **Neutralization of absorbed toxin:** Human tetanus immunoglobulin (HTIG) 3000 to 6000 IU should be given by intramuscular injection to neutralize any circulating toxin. If HTIG is not available, immune equine tetanus immunoglobulin 10,000 IU should be given intramuscularly: but there is a high incidence of severe allergic reactions.
- If the patient recovers active immunization should be instituted, as immunity following tetanus is incomplete.

## Anthrax

### Q. Write short essay on anthrax.

- Anthrax is a zoonotic disease caused by *Bacillus anthracis*.
- *Bacillus anthracis* is a gram-positive bacillus with a central spore. It produces toxins and is responsible for the clinical features of disease **that** most closely correlated with its virulence.

### ***Mode of Transmission***

It is through direct contact (inoculation of the spores) with an infected animal particularly herbivores. Infection is most frequent as an occupational disease in farmers, butchers and dealers in wool and animal hides. Spores of *Bacillus anthracis* can also be ingested or inhaled. Deliberate release of anthrax spores is an important bioterrorist weapon.

**Incubation period:** 1–10 days.

### ***Clinical Manifestations***

It depends on the route of entry of the anthrax spores.

#### *Cutaneous anthrax*

### Q. Write short essay on cutaneous anthrax and malignant pustule.

- It is the most common type of anthrax. It follows inoculation of spores into the subcutaneous of the exposed skin. Occupational exposure to anthrax spores during processing of hides and bone products results in cutaneous anthrax.
- Skin lesions (**Hide porter's disease**) begin as a small, itching, erythematous, maculopapule on an edematous hemorrhagic base. The lesion is initially painless despite edema. It enlarges to form a vesicle filled with sero-sanguinous fluid, and is surrounded by gross edema ('**malignant pustule**'). The vesicle ulcerates and dries to form a central depressed thick black '**eschar**' surrounded by blebs. Despite marked edema, pain is infrequent.
- It is self-limiting illness in the majority of patients, but occasionally perivascular edema and regional lymphadenopathy may be associated with marked toxemia.

### *Inhalational anthrax (Woolsorter's disease)*

#### **Q. Write short essay on inhalation anthrax and Woolsorter's disease.**

- It is extremely rare and follows inhalation of spores into the lung producing '**Woolsorter's disease**'.
- Bioterrorism-related anthrax also due to inhalation of spores.
- It begins with fever, non-productive cough, dyspnea, headache and retrosternal discomfort. Patient develops bronchopneumonia. Symptoms of septicemia may develop 3–14 days following exposure. Pleural effusions (hemorrhagic) are common and **meningitis** may occur.
- Chest X-ray shows broncho-pneumonia, widening of the mediastinum and pleural effusions.
- Without rapid and aggressive treatment at the onset of symptoms, the mortality ranges from 50 to 90%.

### *Gastrointestinal anthrax*

- It is associated with ingestion of undercooked, contaminated meat products.
- The cecum is involved and it manifests as a severe gastroenteritis. The symptoms include nausea, vomiting, anorexia, and fever followed in 2–3 days by severe abdominal pain and bloody diarrhea.
- Toxemia, shock and death may develop rapidly.

### **Diagnosis**

- **Demonstrating the organism:** A stained smear of fluid taken from the edge of a skin lesion may demonstrate the organism. The organism may also be demonstrated in stools, laryngeal secretions, sputum and CSF.
- **Culture** of blood and other body fluids: *Bacillus anthracis* can be cultured in mice, rabbits or guinea pigs.
- **Serological examination:** ELISAs for detecting antibodies to both the organism and a toxin.
- **Chest X-ray** may show mediastinal widening, bronchopneumonia and pleural effusion.

### **Treatment**

- **Systemic anthrax with meningitis:** Ciprofloxacin (400mg TDS) PLUS meropenem plus linezolid/clindamycin.

- **Anthrax related to bioterrorism:** Ciprofloxacin is the drug of choice. Dose is 400 mg IV ciprofloxacin BID. Once the patient stabilizes, ciprofloxacin is given orally in a dose of 500 mg BID. Duration of treatment is 60 days.
- **Raxibacumab, Obiltoxaximab:** 40-80 mg/ kg Human monoclonal antibody directed against the protective antigen has been shown in animal studies to improve survival in inhalation anthrax. Anthrax Immunoglobulin is available to treat inhalational anthrax.

### Prevention and Control

- **Prophylaxis:**
  - Ciprofloxacin (500 mg twice daily) is recommended for individuals with high risk of exposure to anthrax spores.
  - Doxycycline (100 mg BID) for 60 days.
- Vaccination of animals and persons at risk.
- When an infected animal dies, it should be burned and the area in which it was housed must be disinfected.

## Plague

### Q. Write short essay/note on plague.

- Plague is caused by a small gram-negative, non-motile bacillus namely *Yersinia pestis*.
- 11 *Yersinia* species—3 human pathogens namely *Y. pestis*, *Y. pseudotuberculosis*, *Y. enterocolitica*.
- One of three WHO quarantinable diseases.
- Plague is also called as '**black death**'. Historically, 3 plague pandemics have caused more than 200 million deaths, including the Black Death epidemic in 14th century Europe (Justinian 541 AD, Black Death 1346, China 1855).
- Use for biological warfare.

### Source of Infection

The main reservoirs are woodland rodents (sylvatic rats) that spread infection to the domestic rat species (*Rattus rattus*) and finally infected rat fleas (*Xenopsylla cheopis*). These fleas bite humans when there is a sudden reduction in the rat population.

### Route of Infection

- **Rat flea bite:** Most common route in humans is after bite of a plague-infected rat flea.
- **Direct contact** with infected tissues or fluids from sick or dead plague-

infected animals. Hunters and trappers can develop plague from handling rodents.

- **Droplet infection:** Plague pneumonia or by laboratory exposure.
- **Incubation period:** 3–6 days (Shorter in pneumonic plague).

### ***Clinical Features***

**Type of plague:** Four clinical forms are recognized: bubonic, septicemic, pneumonic and cutaneous.

#### *Bubonic plague*

- Most common form of the disease and occurs in about 90% of infected individuals.
- Onset is usually **acute/sudden**, with a high fever, rigor, chills, severe headache, dry skin, myalgia, nausea, vomiting and when severe, prostration. This is rapidly followed painful lymphadenopathy. Characteristically these lymph nodes are tender and suppurate in 1–2 weeks. Most common site for lymphadenopathy is the inguinal region or axilla. The swollen lymph nodes and surrounding tissue constitute the characteristic '**bubo**' called so because they are rarely fluctuant.
- Other manifestations include apathy, confusion, fright, anxiety, oliguria or anuria, tachycardia, toxemia, and hypotension. The spleen is usually palpable.
- Without treatment, complications such as secondary septicemia, secondary pneumonia and meningitis may occur. Mortality rate for untreated cases is 60%.

#### *Septicemic plague*

- It may be primary without signs of primary disease (primary septicemic plague) or secondary as a complication of untreated bubonic plague or pneumonic plague (secondary septicemic plague).
- Primary septicemic plague presents as an acute fulminant infection characterized by high fever, chills and malaise, but without any lymph node enlargement. Elderly individuals are more prone. The patient is toxic and may develop gastrointestinal symptoms, such as nausea, vomiting, abdominal pain and diarrhea. Patients may develop hypotension, septic shock, renal failure, ARDS and disseminated intravascular coagulation (DIC).

- Gangrene of acral regions (tip of the nose or the fingers and toes) may develop due to thrombosis of small artery in advanced stages (hence named Black Death).
- Left untreated, it deteriorates rapidly and the mortality approaches 100%.

### *Pneumonic plague*

- It may occur as a primary infection in the lung or as secondary infection (as a complication of the bubonic and septicemic plague—secondary pneumonia).
- Primary form: Develops within 1–6 days of exposure. It begins suddenly with features of a fulminant pneumonia. Patient develops malaise, high fever, vomiting, abdominal pain, diarrhea and marked prostration. Soon followed by cough, dyspnea, copious blood-stained, frothy, highly infective sputum marked respiratory distress/failure, cyanosis and septic shock. Without antibiotics, death occurs in almost all patients within 2 or 3 days.
- Chest X-ray: Shows bilateral infiltrates that may be nodular and progress to an ARDS-like picture.

### *Cutaneous plague*

It presents either as a pustule, eschar or papule or an extensive purpura. It can develop necrosis and gangrene.

## ***Investigations and Diagnoses***

Diagnosis is based on clinical, epidemiological and laboratory findings.

- **Demonstration of organism:** For rapid diagnosis, smears are prepared from blood, sputum, bubo aspirate (lymph node aspirate) and cerebrospinal fluid. They are stained with Gram, Giemsa or Wayson's stains (contains methylene blue) and examined under microscopy. *Y. pestis* is seen as bipolar staining coccobacilli, giving a 'safety pin' appearance.
- **Culture of organism:** From blood, sputum and bubo aspirates.
- **Serological diagnosis:** A presumptive diagnosis in an appropriate clinical setting is possible by a rapid antigen detection test (by immunofluorescence, using *Y. pestis* F1 antigen-specific antibodies).
- **Septicemic plague:** Often associated with laboratory findings of DIC.

- **Chest X-ray:** In pneumonic plague, it shows evidence of multilobar consolidation, cavities or bronchopneumonia.
- **Blood:** WBC count 20,000/mm<sup>2</sup> and/or thrombocytopenia in about 50% of patients.

### Treatment/Management

If the diagnosis is suspected on clinical and epidemiological grounds, urgent treatment is required even before the results of culture studies are available.

#### 1. First choices

- **Streptomycin:** 30 mg/kg per day IM (up to a total dose of 2 g) in two divided doses for 10 days.
- **Gentamicin** as effective OD dosing and less toxic.

#### 2. Second choices

- Tetracyclines: Doxycycline
- Fluoroquinolones: Ciprofloxacin, Levofloxacin, Ofloxacin, Moxifloxacin
- Chloramphenicol: 1st choice for meningitis +/- aminoglycoside

Supportive treatment of ARDS, DIC, and shock.

### Prophylaxis

- **Control of rats and flea**
- Avoid handling and skinning of wild animal in endemic areas.
- **Prevention of human-to-human transmission:** Patients with plague pneumonia should be isolated until at least 4 days of antibiotic treatment have been administered. For the other types of the plague, patients should be isolated for the first 48 hours or until clinical improvement begins. Attendants must wear gowns, masks and gloves and health care workers should use high-efficiency respirators.
- **Chemoprophylaxis:** Close contact with a patient with pneumonic plague should receive postexposure antibiotic prophylaxis (doxycycline 100 mg or ciprofloxacin 500 mg twice daily) for 7 days.
- **Vaccine:** A partially effective formalin-killed vaccine is available for those who travel to plague-endemic areas and individuals at occupational risk.

## Botulism

### Q. Write a short essay/note on botulism.

- Botulism is caused by neurotoxin (botulinum) produced by *Clostridium botulinum*.
- It produces a neurotoxin which is the most potent poison known and cause disease after ingestion of even picogram (as low as 0.05 g) amounts. There are seven types of toxins which are labeled as A to G.

### *Mode of Infection*

- **Ingestion:** It can contaminate many foodstuffs such as canned or bottled foodstuff, in which it can multiply. Most cases of botulism are due to consumption of contaminated food being served undercooked. Contaminated honey causes infant botulism, in which the organism colonizes the gastrointestinal tract.
- **Inoculation:** Wound botulism can develop in injection drug-users.
- **Incubation period:** Two hours to 8 days.

## ***Classification***

- **Food-borne botulism:** It occurs due to ingestion of toxin present in the contaminated food (fish, canned food) and it is the most common type of botulism.
- **Infantile botulism:** It develops due to ingestion of spores, which germinate in the gut and produce toxin.
- **Wound botulism:** It follows the contamination of wounds, street heroin injection contaminated with *C. botulinum*. Other types are inhalational and iatrogenic botulism.

## ***Clinical Features***

### *Food-borne botulism*

- Initial symptoms are related to gastrointestinal symptoms such as nausea and diarrhea. These are rapidly followed **neurotoxic effects** of toxin. The toxin causes **mainly bulbar and ocular palsies** (difficulty in swallowing, blurred or double vision, ptosis), progressing to **symmetrical descending limb weakness**, diaphragmatic paralysis, respiratory paralysis and death. **No sensory deficits** seen except blurring of vision.
- **Absence of fever** and patients are alert, remains responsive, though mild drowsiness may be present.
- Heart rate is normal or slow and blood pressure is normal.
- Parasympathetic dysfunction: Rare and may produce dry mouth, paralytic ileus and dilated, nonreactive pupils.

### *Infantile botulism*

- Characterized by onset of constipation, followed by weakness in sucking, crying or swallowing. Later there is progressive bulbar and muscle weakness of the extremities.

### Wound botulism

- It is similar to food-borne botulism except that GI upset does not occur.

### Diagnosis

- Diagnosis of botulism is usually based on clinical features.
- **Detection of toxin:** In blood (foodborne) or stools (infant botulism) or in the contaminated food.
- Culture of organism from wound.

**Differential diagnosis:** GB (Guillain-Barré) syndrome, myasthenia gravis, tick paralysis, diphtheria and hypermagnesemia.

#### Treatment

- It is mainly general supportive care with mechanical ventilation, prevention of secondary infection and administration of antitoxin (not available in India). Equine serum heptavalent botulism antitoxin and human-derived botulism immune globulin are available in United States.
- Antibiotics are of no much use. However, penicillin G and metronidazole are used. The overall mortality is high, but those who survive the acute paralysis fully recover.

## Whooping Cough

**Q. Describe the etiology, clinical features, complications, diagnosis and management of whooping cough.**

- Whooping cough (pertussis) is an acute infection of the respiratory tract caused by *Bordetella pertussis*. *Bordetella pertussis* is a gram-negative coccobacillus.
- The term pertussis means ‘violent cough’ which is the most prominent feature of the illness.

**Mode of spread:** Pertussis is highly contagious and spreads by droplet infection.

**Incubation period:** 7–10 days.

**Age group:** Classic case is seen in childhood, with 90% occurring below 5 years of age.

### Clinical Features

#### Catarrhal phase

This first stage is highly infectious characterized by upper respiratory catarrh

with rhinitis, lacrimation (conjunctivitis), low-grade fever and an unproductive cough. This stage lasts about 1–2 weeks.

### *Paroxysmal phase*

It is called so because of the characteristic paroxysms of coughing.

- **Whoop:** During this stage, the cough becomes spasmodic, more frequent and severe with repetitive bouts of 5–10 coughs. The coughing paroxysms episode may be terminated by a **classic inspiratory audible whoop**. The whoop is due to rapid inspiration against a closed glottis at the end of a paroxysm. It is observed only in younger patients in whom the lumen of the respiratory tract is narrowed due to mucus secretion and mucosal edema. These paroxysms usually terminate in vomiting. Early paroxysmal stage is also infectious.
- **Other features** include conjunctival suffusion and petechiae and ulceration of the frenulum of the tongue. Lymphocytosis is observed.
- This stage lasts for about 2 weeks and may be associated with many complications (Table 4.8).

**Table 4.8: Complications of pertussis.**

<i>Respiratory</i>	<i>Other complications</i>	
<ul style="list-style-type: none"> <li>• Apnea (in children)</li> <li>• Bronchopneumonia</li> <li>• Atelectasis</li> <li>• Bronchiectasis (sequelae)</li> <li>• Rib fractures</li> <li>• Pneumothorax</li> </ul>	<ul style="list-style-type: none"> <li>• Encephalitis</li> <li>• Convulsions (due to cerebral anoxia)</li> <li>• Conjunctival hemorrhage</li> </ul>	<ul style="list-style-type: none"> <li>• Subdural hematoma</li> <li>• Direct inguinal hernia</li> <li>• Rectal prolapse</li> <li>• Weight loss</li> </ul>

### *Convalescence phase*

It follows the paroxysmal phase during which slow resolution of whoop occurs. This phase can last 1–3 months, and cough may persist for several weeks to months.

### **Complications (Table 4.8)**

#### **Diagnosis**

- **Clinical diagnosis** is not difficult if the classic symptoms, characteristic whoop and a history of contact with an infected individual are present.

- **Blood:** Peripheral blood may show lymphocytosis.
- **Culture of nasopharyngeal secretions** is the gold standard for diagnosis.
- *B. pertussis* DNA detection by PCR assay.
- Direct fluorescent antibody test.

### Management

#### Antibiotics

- Erythromycin for 7–14 days is the recommended treatment.
- CDC recommends azithromycin for five days (500 mg day 1, followed by 250 mg day 2 through 5) or clarithromycin (500 mg twice daily for seven days).
- Trimethoprim/sulfamethoxazole reduces pertussis transmission and is an alternative treatment for patients who are allergic to macrolides.
- Cough suppressants are not effective.
- Others: Steroids, antihistamines,  $\beta$ -agonists and immunoglobulins are not beneficial.

#### Prevention

- **Isolation of patient:** Patients should be isolated to prevent contact with others, e.g. in hostels and boarding schools.
  - Catarrhal phase: If antibiotics have been given during catarrhal phase, patient is infectious until 5 days after starting antibiotics.
  - Paroxysmal phase: Patient is contagious till 3 weeks after the paroxysmal stage ends if not treated during catarrhal stage.
- **Chemoprophylaxis:** Risk of transmission of *B. pertussis* within households is high. Hence, close contacts of patients should receive macrolides, especially if they are not vaccinated.
- **Active immunization:** Pertussis is an easily preventable disease with active immunization by DPT vaccine. Immunity begins to decline 4–12 years after vaccination, and may make adolescent and adult susceptible to infection. Rarely, the vaccine can produce convulsions and neurological damage. Currently acellular effective vaccines with few adverse reactions are available. A triple vaccine containing tetanus toxoid, reduced diphtheria toxoid and acellular pertussis (Tdap) is available for use in adolescents and adults.

## Enteric Fever

**Q. Describe the etiology, clinical features, investigations, diagnosis, complications and treatment of typhoid fever.**

**Q. Write short note on enteric fever (typhoid and paratyphoid fever).**

**Enteric fever** is the general term, which includes **both typhoid and paratyphoid** fever. It is an acute systemic illness characterized by fever, headache and abdominal discomfort.

### Causative Agent

- Enteric fevers are caused by *Salmonella typhi* and *Salmonella paratyphi*.

*Salmonella* are gram-negative, flagellate, motile, non-sporulating, facultative anaerobic bacilli (rods). Boiling or chlorination of water and pasteurization of milk destroy the bacilli.

- Typhoid fever (enteric) is an **acute systemic disease** caused by infection with *Salmonella typhi* (also known as *Salmonella enterica* serovar Typhi). Paratyphoid fever is a clinically similar but milder disease caused by *Salmonella paratyphi* (*Salmonella enterica* serovar Paratyphi A, B or C).

## ***Source of Infection***

**Humans** are the only natural reservoir and include:

1. **Patient suffering from disease:** Infected urine, feces, or other secretions from patients.
2. **Chronic carriers of typhoid fever:** *S. typhi* or *S. paratyphi* colonizes in the **gallbladder, urinary bladder, or biliary tree.**

**Mode of transmission:** From **person-to-person contact.**

- **Ingestion of contaminated food** (especially dairy products) and shellfish or **contaminated** food, mild or **water.** Chronic carriers, often food handlers transmit the disease.
- **Direct spread:** Rare by **finger-to-mouth contact** with feces (fecal-oral route), urine, or other secretions is rare.

**Incubation period:** Usually **10–14 days and for paratyphoid** it is shorter.

## ***Pathogenesis***

- The typhoid bacilli (*Salmonella*) are **ingested through contaminated food or water** are able to **survive in gastric acid of the stomach** and reach mucosa of small intestine.
- In the small intestine, they penetrate the **ileal mucosa**, reach the submucosa and are **phagocytosed by the macrophages in the Peyer's patches.**
- They are **carried to the mesenteric lymph node** via lymphatics **and** enter the **bloodstream via the thoracic duct causing** bacteremia.
- They colonize reticuloendothelial tissues (**liver, gallbladder, spleen, bone marrow**), and multiply further and re-enter bloodstream causing **massive bacteremia** (occurs towards the end of incubation period) and disease clinically manifests.

- In the intestine, the bacilli are localized to the **Peyer's patches and lymphoid follicles** of the terminal ileum. They cause inflammation, plateau-like elevations of Peyer's patches and necrosis, which results in characteristic **oval typhoid ulcers**.

### *Clinical Features*

- Onset is gradual and nonspecific. Patients usually present with fever, anorexia, headache, abdominal pain, bloating, nausea and vomiting.
- **Fever:** The temperature rises in a step-ladder fashion (**step-ladder fever**) to 40–41 °C for 4 or 5 days in some cases. The hallmark of typhoid fever is continuous, persistent fever, often lasting 4–8 weeks in untreated patients.
- Early intestinal manifestations include constipation (especially in adults) or mild diarrhea (in children).

### *Physical findings*

- In the early stages abdominal tenderness, hepatosplenomegaly, lymphadenopathy and a scanty maculopapular rash ('rose spots') are found.
- **Rose spots** or 'rose-red spots': These are small 2–4 mm, pale-red maculopapular lesions on the skin that fade/blanch on pressure appear on the chest and abdomen, which occur during first week and usually last only 2–3 days. They result from bacterial embolism and Salmonella can be cultured from the biopsy of these lesions.
- **Mild hepatosplenomegaly:** Spleen is soft and palpable (around the 7th–10th day) may be accompanied by tender hepatomegaly.
- **Relative bradycardia:** The pulse is often slower than would be expected from the height of the fever.
- **Intestinal manifestations:** By the end of 1st week, constipation is succeeded by diarrhea and abdominal distension, with tenderness in the right iliac fossa. The stools are loose and greenish in color and characteristically described as 'pea-soup'. Intestinal complications often develop in the 3rd or 4th week of illness.

If untreated by the end of 2nd week: Patient may be profoundly ill.

By 3rd week: Toxemia increases and patient may develop coma and die.

The 4th week of the illness is characterized by gradual improvement.

## Complications of Typhoid (Box 4.3)

**Q. Write short note on complications of typhoid fever.**

**Box 4.3:** Complications of typhoid.

- **General complications:** Toxemia, dehydration, peripheral circulatory failure, DIC.
- **Intestinal complications:** The most common intestinal complication is ileus. **Perforation** of typhoid ulcer and **hemorrhage from the ulcer** may occur at the end of the second week or during the third week of the illness.
- **Extraintestinal complications:**
  - **Neurological:** Delirium (**muttering delirium**), psychosis, **seizures**, coma vigil, catatonia, meningitis, encephalopathy, GB syndrome peripheral neuritis and deafness.
  - **Miscellaneous:** **Myocarditis**, endocarditis, pericarditis, pneumonia, **cholecystitis**, pyelonephritis, glomerulonephritis, osteomyelitis, arthritis, periostitis, hepatitis, thrombophlebitis. Patients with **sickle cell disease are susceptible to *Salmonella* osteomyelitis.**
- **Carrier state:** Persistence of bacilli in the **gallbladder or urinary tract** may result in passage of bacilli in the feces or urine and causes a 'carrier state' which is the source of infection to others. After clinical recovery, about 5–10% will continue to excrete *S. typhi* for several months and they are termed convalescent carriers.

## Laboratory Diagnosis (Box 4.4)

**Q. Write short note on:**

- **Laboratory diagnosis of typhoid fever.**
- **Widal test.**

**Box 4.4:** Laboratory diagnosis of typhoid fever.

- **Total leukocyte count:** It shows **leukopenia with relative lymphocytosis. Eosinophils are usually absent.**
- **Isolation of Bacilli:**
  - **Blood culture:** This is the “Gold Standard “ investigation for diagnosis of typhoid. The maximum positivity of blood culture is in **first week** of fever in 90% of patients and remains positive in second week till the fever subsides. Blood culture rapidly becomes negative on treatment with antibiotics. During early phase, bone marrow culture aspirate is more sensitive than blood culture, even after a brief prior antibiotic treatment.
  - **Stool cultures:** It is almost as valuable as blood culture and become positive in the **third week.**
  - **Urine culture:** It reveals the organism in approximately 25% of patients by **third week.**
- **Widal test/reaction:** Classic Widal test **measures** agglutinating **antibodies against O, H and Vi antigens** of *S. typhi* and H antigens of *S. paratyphi* A and B, but **lacks sensitivity and specificity.** Widal test (immunological reactions) becomes positive from **end of the first week till fourth week.** There are many false-positive (anamnesic reaction) and occasional false-negative Widal reactions. Vi antigen is alone detected in the carrier state. The mean sensitivity, specificity, NPV and PPV of Widal test remains below 80%. Therefore, Widal test should not be used as a

diagnostic tool to rule out typhoid fever unless supported by invasive clinical pictures and other confirmatory tests.

- **Other serologic tests:** They are available for the rapid diagnosis of typhoid fever with a higher sensitivity.
- **Molecular methods:** PCR detects flagellin, somatic gene and Vi gene.

### **Q. Write short note on:**

- **Treatment and prevention of typhoid fever**
- **Chronic carrier state in typhoid**
- **New drugs with dosage and duration used to treat enteric fever.**

#### **Treatment**

- **General management:** These include bed rest, isolation, and maintenance of nutrition and fluid intake.
- **Antibiotic therapy:** Several antibiotics are effective in enteric fever and various drug regimens are presented in Table 4.9. It must be guided by culture and sensitivity report.
- **Multidrug resistant strains:** Certain strains of *S. typhi* (especially in India) are resistant to chloramphenicol, amoxicillin and cotrimoxazole are called as multidrug resistant strains. These should be treated with ciprofloxacin.
- **NARST-nalidixic acid resistant *Salmonella typhi*:** Sometimes, strains that are sensitive to ciprofloxacin *in vitro* may not respond to ciprofloxacin. They are usually resistant to nalidixic acid when tested *in vitro* (NARST-nalidixic acid resistant *Salmonella typhi*). These patients need treatment for longer duration with ciprofloxacin or with ceftriaxone.
- **Corticosteroids:** It is indicated in patients with severe toxemia, central nervous system manifestations and DIC. Intravenous dexamethasone is given in the dose of 3 mg/kg as a loading dose, followed by 1 mg/kg every 6 hourly for 24 hours.
- **Treatment of complications:** Intestinal perforation and hemorrhage occur in the 3rd or 4th week of illness are managed accordingly.

#### **Carrier state in typhoid**

- **Asymptomatic carrier state:** About 3–5% of patients develop long-term asymptomatic carrier state. Many carriers does not give history of typhoid fever and are probably had an undiagnosed mild infection.
- **Chronic carriers:** These carriers are usually older than 50 years and females with gallstones. *S. typhi* resides in the gallbladder, urinary bladder and even within the gallstones. They are intermittently excreted into the stool, thereby contaminating water or food. Vi antigen is positive in carriers.
- Chronic carriers should be given ciprofloxacin/ampicillin for 4 weeks. Cholecystectomy may be needed in some patients.

#### **Prevention**

- **Improved sanitation and living conditions:** It is most important method to prevent typhoid fever. These measures include good hygiene, clean water, proper sewage disposal and proper water treatment. Travellers are advised to avoid drinking untreated water, ice in drinks and eating ice creams.

**Vaccination:** Three available typhoid vaccines are:

- **Inactivated injectable:** two in number
  - Heat-killed, phenol-extracted, whole-cell vaccine—because of several adverse reactions, this is not used at present.
  - Vi-polysaccharide-parenteral administration in individuals >2 years; single dose.
- **Oral live attenuated vaccines:** Ty21a, a live, attenuated vaccine containing the *S. typhi* strain Ty21a is oral administered in individuals >6 years; one capsule every other day for 3 doses.

**Table 4.9: Various antibiotic regimens in typhoid fever.**

<b>Drug</b>	<b>Dosage and duration of treatment</b>
Ceftriaxone	75 mg/kg/day for 7–14 days
Chloramphenicol	3–4 g/day till the fever subsides, followed by 2 g/day, for a total duration of 14 days.
Amoxicillin	4–6 g/day in four divided doses of 14 days
Cotrimoxazole	Trimethoprim 640 mg + sulfamethoxazole 3200 mg in two divided doses daily for 14 days
Ciprofloxacin	500–750 mg twice daily for 14 days
Ofloxacin	400–800 mg/day for 14 days
Cefotaxime	50–75 mg/kg/day for 7–14 days
Cefixime	20 mg/kg/day for 10–14 days
Azithromycin	1 g once a day for 7 days
Aztreonam	50–100 mg/kg/day for 14 days

## Food Poisoning

**Q. List the causes of food poisoning. Discuss briefly the manifestations, diagnosis and management of food poisoning.**

- Food poisoning is an **illness contracted by eating contaminated food.**
- In most cases, food that causes food poisoning is contaminated by bacteria, such as salmonella or *Escherichia coli* (*E. coli*), or a virus, such as the norovirus. Some toxins can cause food poisoning within a short time. Vomiting is the main symptom of food poisoning.
- Box 4.5 lists the food infection vs intoxication.
- Each year about 6.5–33 million foodborne illness occurs. Campylobacter cause 1–6 million cases/year. Salmonella causes 2–4 million illnesses/year. *E. coli* causes about 21,000 cases each year.

**Box 4.5:** Food infection vs intoxication.

- **Food infection**

- Bacteria are consumed
- Body reacts by raising temperature—fever
- Longer incubation
- **Food intoxication**
  - Toxin contaminated food is eaten
  - Shorter incubation

## Causes of Food Poisoning (Table 4.10)

**Table 4.10:** Causes of food poisoning.

<p><b>Infective (bacteria or their toxins)</b></p> <ul style="list-style-type: none"> <li>• Due to toxin           <ul style="list-style-type: none"> <li>– Preformed toxins, e.g. <i>Staphylococcus aureus</i>, <i>Bacillus cereus</i></li> <li>– Enterotoxins released in the intestine, e.g. <i>Vibrio cholerae</i>, <i>E. coli</i>, <i>Clostridium perfringens</i>, <i>Clostridium difficile</i></li> </ul> </li> <li>• Due to intestinal mucosal damage           <ul style="list-style-type: none"> <li>– Invasion of mucosa, e.g. roovirus</li> <li>– Invasion and destruction of mucosa, e.g. <i>Shigella</i>, <i>Yersinia enterocolitica</i>, <i>Salmonella</i>, <i>Entamoeba histolytica</i>, <i>Bacillus anthracis</i>.</li> </ul> </li> </ul>
<p><b>Noninfective</b></p> <ul style="list-style-type: none"> <li>• Allergic type, e.g. shellfish.</li> <li>• Non-allergic type, e.g. scombrototoxin (fish), fungi (<i>Amanita Phalloides</i>).</li> <li>• Chemicals, e.g. detergents, pesticides.</li> </ul>

Various organism causing food poisoning and their symptoms are summarized in Table 4.11.

**Table 4.11:** Various organism causing food poisoning and their symptoms.

<b>Organism</b>	<b>Incubation</b>	<b>Symptoms</b>	<b>Foods</b>
<i>Campylobacter jejuni</i>	2–5 days	Diarrhea, vomiting, headache, fever, muscle pain	Poultry, dairy products, water
<i>Salmonella enteritidis</i>	12–36 hours	Abdominal cramps, headache, fever, nausea, diarrhea	Poultry, meat, eggs and egg products, sliced melons
<i>Escherichia coli</i>	3–4 days	Diarrhea, vomiting, mild fever	Undercooked ground beef, unpasteurized cider
<i>Listeria monocytogenes</i>	3 to 70 days	Flu-like, meningitis, encephalitis,	Unpasteurized milk, ice cream, ready-to-eat,

		spontaneous abortion	lunch meats
<i>Clostridium perfringens</i>	10–12 hours	Abdominal pain, nausea, diarrhea, fever, headache, vomiting usually absent	Stews, gravies, beans
<i>Clostridium botulinum</i> (intoxication)	4 hours to 8 days	Vomiting; constipation; diplopia, dysphagia, dysarthria, paralysis, death	Baked potatoes, fish, garlic/oil mixtures, low-acid canned foods
<i>Staphylococcus aureus</i> (intoxication)	1 to 7 hours	Nausea, retching, abdominal cramps, diarrhea	Ready-to-eat, reheated foods, dairy products, protein foods
<i>Bacillus cereus</i> (intoxication)	30 min. to 6 hours (emetic) or 6 to 15 hours (diarrheal)	Nausea, vomiting, watery diarrhea	Rice products, starchy foods, casseroles, puddings, soups
Hepatitis A	10–50 days	Sudden fever, vomiting, jaundice	Water (ice), shellfish, ready-to-eat, fruit juices, vegetables
Norwalk virus	10–50 hours	Nausea, diarrhea, headache, mild fever	Water, shellfish, raw vegetables and fruits
Rotavirus	1–3 days	Vomiting, diarrhea, mild fever	Ready-to-eat, water and ice
<i>Giardia lamblia</i>	3–25 days	Fatigue, nausea, weight loss, abdominal cramps	Water, ice, raw vegetables
<i>Cryptosporidium parvum</i>	1–12 days	Severe diarrhea, may have no symptoms	Water, raw foods, unpasteurized cider, ready-to-eat

## Clinical Feature and Diagnosis

The symptoms will be different depending on what type of contamination is responsible. Common symptoms of food poisoning are listed in Box 4.6.

### Management

- The symptoms of food poisoning subside in 2 to 3 days.
- The goal of treatment is to replace fluids and electrolytes lost through vomiting and diarrhea. If dehydration is severe and cannot be managed at home, patient needs to be admitted, intravenous saline and supportive treatment (antiemetics, antipyretics, probiotics, antimotility agents) advised.
- Antibiotics to be used sparingly only in infective cases.

### Box 4.6: Common symptoms of food poisoning.

- Severe vomiting
- Diarrhea

- Headache
- Fever
- Abdominal pain
- Tiredness

## DYSENTERY

Dysentery is defined as an acute inflammation of the large intestine (colitis) characterized by diarrhea with blood and mucus in the stools. Two causes are bacillary and amebic infections.

### Bacillary Dysentery (Shigellosis)

**Q. Write short essay on the etiology, clinical presentation, diagnosis and management of acute bacillary dysentery.**

**Q. Write short essay on clinical features of Shigellosis**

- Bacillary dysentery is an acute **necrotizing infection** of the **distal small bowel and colon** caused mostly by one of *Shigella* species. *Shigella* species that cause colitis are classified into four major subgroups namely: *dysenteriae* (most virulent), *flexneri*, *boydii* and *sonnei*. Bacillary dysentery is one of the **most common causes of bloody diarrhea**. Other organisms causing bacillary dysentery include *E. coli* O157:H7, *Salmonella*, *Campylobacter*, etc.
- *Shigella* **produces toxin** (endotoxin as well as an exotoxin) that has cytotoxic, neurotoxic, and enterotoxic effects. When inflammation is severe, ileus, toxic megacolon, gross hemorrhage, and perforation may develop.
- **Source of infection: Humans** are the only natural reservoir.
- **Mode of transmission:** By **ingestion** through fecal-oral route or via fecally contaminated water and food. It can be acquired by oral contact with any contaminated surface (e.g. clothing, towels, unwashed hands after defecation or skin surfaces) or flies.
- **Incubation period:** It ranges from **1 to 3 days**.

### Clinical Features

- **Severity of infection:** Disease severity varies from mild to severe. *S. sonnei* produces mild infection, *S. flexneri* infection is usually more

severe, and *S. dysenteriae* may produce fulminating infection resulting in death within 48 hours.

- Symptoms start 24–48 hours after ingestion and usually presents as frequent small quantity of stools containing blood, mucus and purulent exudate with little fecal material (dysentery). This is accompanied by fever, colicky abdominal pain and tenesmus. Severe cases may show signs of systemic toxicity, dehydration and electrolyte disturbances.
- Physical examination may show tenderness over the colon in the left iliac fossa and hyperactive bowel sounds.

### **Complications (Table 4.12)**

#### **Diagnosis**

- **Stool culture** is required for confirmation of *Shigella* infection.
- **Sigmoidoscopy** shows red and swollen mucosa covered by mucopus on the surface. The submucous veins are obscured.
- Enzyme immunoassay used for detecting Shiga toxins in stools.
- PCR for *Shigella* DNA in stools.

**Table 4.12: Complications of bacillary dysentery.**

<b>Intestinal</b>	<b>Extraintestinal</b>
<ul style="list-style-type: none"><li>• Rectal prolapse</li><li>• Toxic megacolon</li><li>• Colonic perforation</li></ul>	<ul style="list-style-type: none"><li>• Bacteremia</li><li>• Meningismus, seizures</li><li>• Transient peripheral neuropathy</li><li>• Reiter syndrome</li><li>• Hemolytic-uremic syndrome (HUS)</li><li>• Thrombotic thrombocytopenic purpura</li></ul>

#### **Management**

- Fluid and **electrolyte** deficits should be corrected by oral rehydration therapy or, if diarrhea is severe, by intravenous replacement of water and electrolyte loss.
- **Antibiotic therapy:** Infections caused by *S. dysenteriae* and *S. flexneri* should be given ciprofloxacin (500 mg twice daily for 3 days). Second-line agents include azithromycin and ceftriaxone.
- **Antidiarrheal medication** should be avoided. Codeine or loperamide may be given to control diarrhea in adults without dysentery.

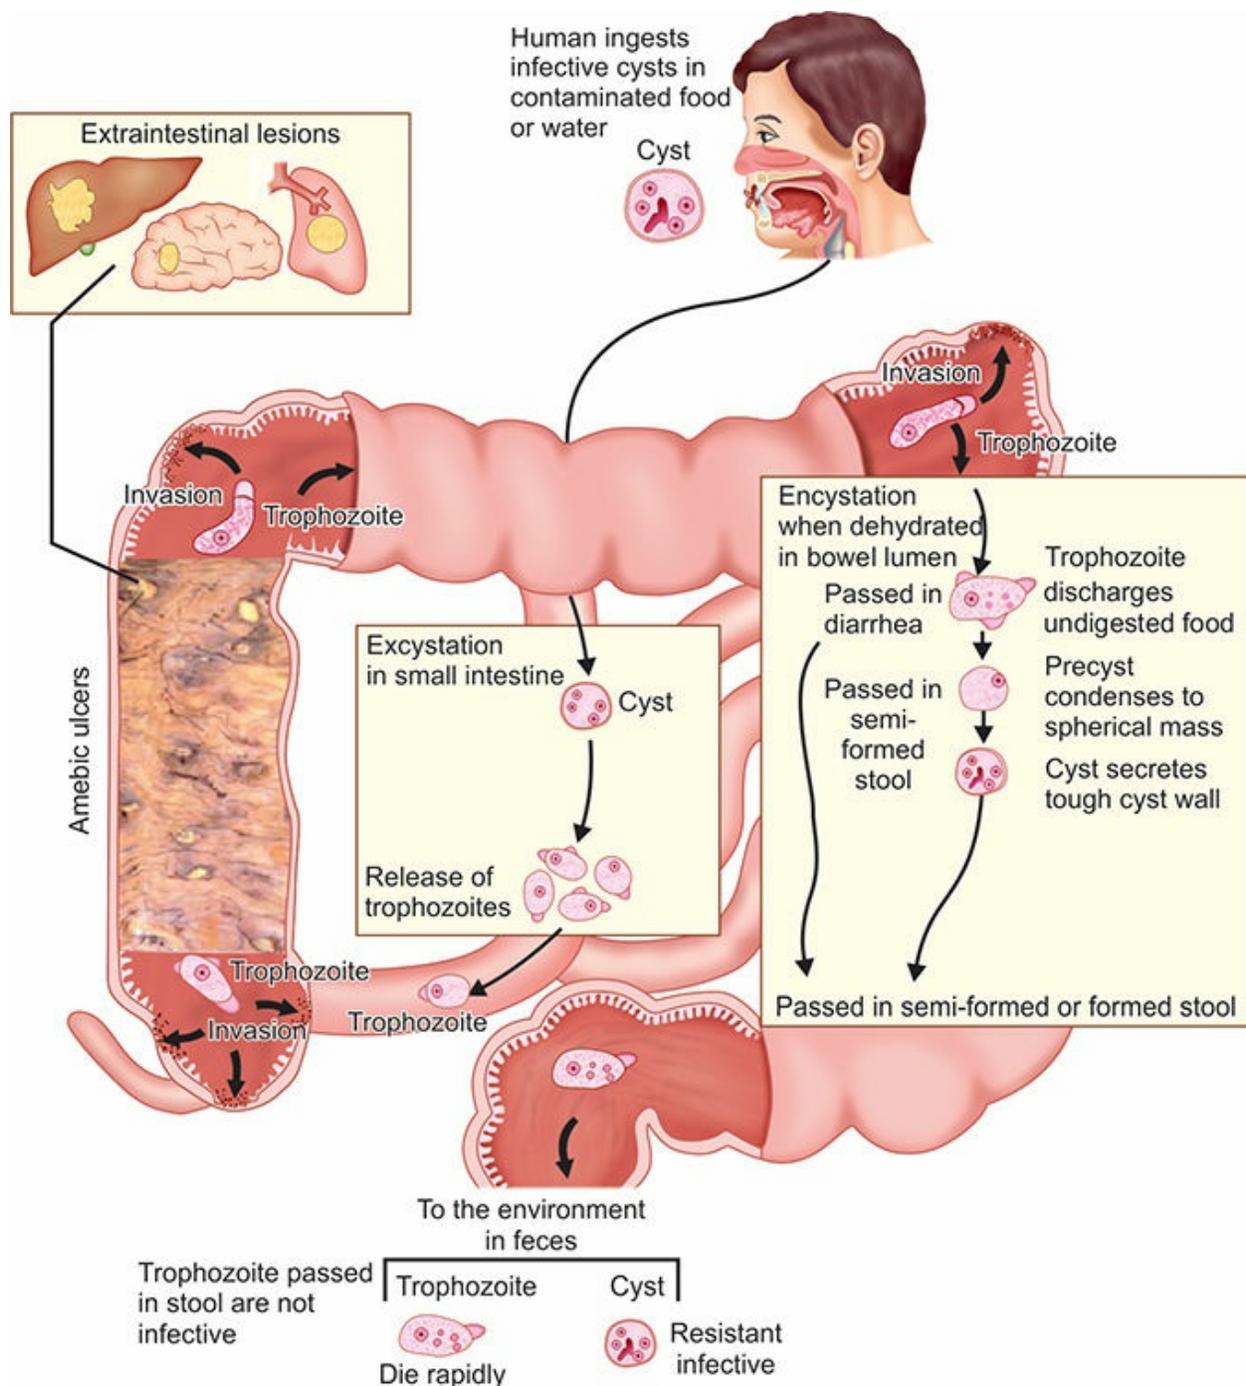

Fig. 4.4: Pathogenesis of amebiasis.

## Amebiasis

**Q. Discuss the etiology, pathogenesis, clinical features, diagnosis, investigations, complications and treatment of amebic dysentery/intestinal amebiasis.**

## ***Etiology***

- Amebiasis is an **infection caused by protozoan *Entamoeba histolytica***
- *E. histolytica* has three distinct stages:
  1. **Trophozoite stage:** Amebic trophozoites are seen in the stools of patients with acute symptoms.
  2. **Precyst stage:** In the colon, the trophozoite develops into a cyst through an intermediate form termed the precyst.
  3. **Cyst stage: Amebic cysts are the infecting stage** and are found only in stools. They are spherical and have thick chitin walls, and usually four nuclei.
- **Source of infection: Humans** are the only known reservoir for *E. histolytica*. It is reproduced in the colon of infected individual and passes in the feces.
- **Mode of infection:** It is **acquired by fecal-oral route** through ingestion of materials contaminated with human feces containing *E. histolytica*. Pathogenesis of amebiasis is depicted in Figure 4.4.
- **Incubation period:** About 2–6 weeks.

## **Amebic Colitis**

**Q. Write a short note on amebic colitis/intestinal amebiasis.**

Amebic colitis can present in two forms: Amebic dysentery and non-dysenteric amebic colitis.

### ***Amebic Dysentery***

#### *Pathogenesis*

- The amebic cysts are passed in the stool of infected individuals and the **cysts can contaminate water, food, or fingers**. These cysts are tetra-nucleated and can remain viable for weeks to months. However, these are destroyed in temperature below 5°C or above 40°C.
- Amebic dysentery results from ingestion (fecal-oral transmission) of *E. histolytica* cysts. **Amebic cysts colonize the epithelial surface of the terminal ileum and** undergo further nuclear division, and release trophozoites. The trophozoites are carried to the large intestine and may colonize any part of the large intestine, but **most frequently in the cecum**

**and ascending colon causing amebic colitis.** They produce the characteristic ‘flask-shaped’ amebic ulcers with a narrow neck and broad base. These patients pass both cysts and trophozoites in the stool.

- Most often, the amebic infection remains subclinical. However, antibody response usually occurs even without local invasion. These asymptomatic patients should be treated to prevent transmission of infection to others and development of amebic colitis at a later period.
- **Ameboma** is a common complication of amebic dysentery. It is a localized granuloma which presents as a palpable mass in the rectum or causes a filling defect in the colon on radiography.
- **Trophozoite may penetrate blood vessels and reach the liver through portal vein.** In the liver they multiply and produce amebic liver **abscesses** in about 40% of patients with amebic dysentery. The liquid contents of this abscess have a characteristic pinkish color, which may later change to chocolate-brown (like anchovy sauce).
- They can also travel to lungs and brain.

*Clinical features of intestinal amebiasis (amebic dysentery)*

**Q. Write short essay on the clinical features and treatment of intestinal amebiasis.**

- It may produce **dysentery of varying severity.** It presents with intermittent diarrhea consisting of **foul smelling** (offensive), **loose, watery stools** that may contain **mucus and blood.** Sometimes diarrhea alternate with constipation.
- **Other symptoms include abdominal pain/cramp** (especially right lower quadrant which may simulate acute appendicitis), flatulence and weight loss. Sometimes it is accompanied by systemic symptoms such as headache, fever, nausea and anorexia. Less commonly, it may present as acute amebic dysentery, resembling bacillary dysentery or acute ulcerative colitis.
- **Physical examination:** There may be tenderness over the cecum (amebic typhlitis), ascending colon and over the left iliac fossa (**amebic point or Manson-Barr point**) and tender hepatomegaly.

*Complications (Table 4.13)*

*Diagnosis*

- **Microscopic examination of stool:** Presence of motile trophozoites containing red blood cells (hematophagous trophozoites) in fresh sample of stool will confirm the diagnosis. If a fresh stool sample cannot be examined immediately, it should be preserved with a fixative such as polyvinyl alcohol or kept cool (4°C). Presence of amebic cysts alone does not imply disease.
- **Sigmoidoscopy** and barium enema may show the characteristic ‘flask-shaped’ ulcers with normal surrounding mucosa. The aspirated material or scrapings from the ulcer or biopsy of the ulcer may show the trophozoites. Colonic exudate obtained by sigmoidoscopy may microscopically show trophozoites.
- **Serologic tests:** Indirect hemagglutination test, ELISA or counter immunoelectrophoresis can detect antibodies in the blood. They are more useful in extraintestinal amebiasis.
- Amebic fluorescent antibody test is positive in about 90% of patients with liver abscess and in 60–70% with active colitis.
- Detection of *E. histolytica* antigen or DNA in a stool sample.

**Diagnosis of amebic liver abscess:** It is often suspected on clinical grounds (discussed on pages 848-9).

**Table 4.13:** Complications of amebiasis.

<i>Intestinal complications</i>	<i>Extraintestinal complications</i>
<ul style="list-style-type: none"> <li>• Massive hemorrhage</li> <li>• Ameboma</li> <li>• Perforation and peritonitis</li> <li>• Toxic megacolon in fulminant cases</li> <li>• Postdysenteric colitis</li> <li>• Rectovaginal fistula</li> <li>• Chronic infection with stricture formation</li> </ul>	<ul style="list-style-type: none"> <li>• Amebic liver abscess</li> <li>• Pleuropulmonary amebiasis</li> <li>• Hepaticobronchial fistula</li> <li>• Amebic pericarditis</li> <li>• Cutaneous amebiasis</li> </ul>

### ***Non-dysenteric Amebic Colitis***

- Usually presents as recurrent bouts of diarrhea with or without mucus, but without any visible blood.
- **Stools examination** shows *E. histolytica* cysts or non-hematophagous trophozoite (trophozoites with no ingested RBCs).

**Table 4.14: Differences between amebic dysentery and bacillary dysentery.**

<b>Features</b>	<b>Amebic dysentery</b>	<b>Bacillary dysentery</b>
<b>Macroscopic</b>		
Number of motions	6–8 motions/day	Over 10 motions/day
Amount of stool	Relatively copious	Relatively small
Odour	Offensive	No odour
Nature	Blood and mucus mixed with feces	Blood and mucus, no feces
Color	Dark red	Bright red
Reaction	Acidic	Alkaline
Consistency	Not adherent to the container	Adherent to the container
<b>Microscopic</b>		
RBC	In clumps	Discrete or in rouleaux
Pus cells	Few	Numerous
Macrophages, Ghost cells	Very few	Numerous
Eosinophils, Pyknotic bodies	Present	Scarce
Causative agent	Trophozoites of <i>E. histolytica</i>	Motile bacteria
Charcot-Leyden crystals	Present	Absent

**Q. Write a short note on treatment of amebiasis.****Treatment**

- **Invasive intestinal amebiasis:**

- Metronidazole 500–750 mg three times daily for 7–10 days or long-acting nitroimidazoles like tinidazole or ornidazole (both in doses of 2 g daily for 3 days). Other options include secnidazole or nitazoxanide (500 mg twice daily for 3 days).
- After treatment of the invasive disease, luminal amebicide such as diloxanide furoate, diiodohydroxyquin or paromomycin should be given to clear luminal cysts or parasite. Alternative agents include iodoquinol, and nitazoxanide.

- **Hepatic amebiasis** (refer pages 848-9).

**Q. Write short note on uses of metronidazole.**

Box 4.7 lists the uses of metronidazole.

**Box 4.7:** Uses of metronidazole.

- Amebiasis
- Giardiasis
- *Trichomonas vaginalis*

- Anerobic bacterial infections
- Pseudomembranous enterocolitis
- Ulcerative gingivitis
- *Helicobacter pylori* gastritis/peptic ulcer

**Differences between amebic dysentery and bacillary dysentery (Table 4.14).**

**Q. Enumerate the differences between amebic dysentery and bacillary dysentery.**

## Brucellosis

**Q. Write short essay/note on brucellosis (abortus fever; Malta fever; undulant fever; Mediterranean fever). Name species that cause brucellosis.**

- Brucellosis (Malta fever, undulant fever, Mediterranean fever, Rock fever of Gibraltar) is a zoonotic disease.
- Brucellosis is an infection caused by one of the four species of *Brucella*: *Brucella melitensis* (goats, sheep and camels), *Brucella abortus* (cattle), *Brucella suis* (pigs) and *Brucella canis* (dogs). *Brucella* is a gram-negative organism.
- Natural reservoir of brucellosis is animals.

### ***Mode of Infection***

- **Ingestion:** Infected animals may excrete *Brucella* in their milk, and human infection is acquired by ingesting contaminated dairy products (especially unpasteurized raw milk), uncooked meat.
- **Direct infection:** Animal urine, feces, vaginal discharge and uterine products may act as sources of infection and they may enter humans through abraded skin.
- **Inhalation of infectious aerosols**
  - Pens, tables, slaughter houses
  - Conjunctival splashes, injection
- **Person-to-person transmission is very rare**, particularly mother-to-child.

### ***Clinical Features***

**Q. Write short essay on clinical features and treatment of brucellosis.**

Brucellosis involve many organ systems and has a very insidious onset with varying clinical signs. The most common sign in all patients is an intermittent/irregular fever with variable duration, which is termed as *undulant fever*.

*Acute brucellosis (<2 months)*

- Incubation period of acute brucellosis is 1–3 weeks.
- Acute onset in nearly 50% cases and presents with fever, malaise, headache, chills, fatigue, weakness, backache, generalized myalgia and night sweats. Patients also have anorexia, lose weight, cough and arthralgias.
- **Fever:** It is classically high swinging **undulant** pattern with rigors, although continuous and intermittent patterns may be seen.
- **Physical findings** are non-specific and include splenomegaly (20% of cases may lead to hypersplenism and thrombocytopenia), lymphadenopathy (15% cases) and hepatomegaly (10% cases), sacroiliitis and arthritis.
- A few may develop localized brucellosis in the form of osteomyelitis, splenic abscess, epididymo-orchitis, pneumonia, meningoencephalitis pleural effusion and endocarditis.

*Subacute brucellosis (2–12 months)*

Features are similar to acute form, but less severe.

*Chronic brucellosis (>12 months)*

- This is characterized by low-grade fever easy fatigability, myalgia, arthralgia, occasional bouts of fever and neuropsychiatric manifestations (e.g. depression).
- Splenomegaly is usually observed.
- Bone and joint complications are the most common complications and include uveitis, sacroiliitis, spondylitis, peripheral arthritis, osteomyelitis and bursitis.

**Diagnosis**

- **Culture:** Definitive diagnosis depends on the isolation of the Brucella.
- **Serological tests** may also aid diagnosis and are of greater value in

chronic disease. In **Brucella agglutination test**, a four-fold or greater rise in titer of agglutination antibody (IgM) is highly suggestive of brucellosis. Raised serum IgG level indicates current or recent infection; a negative test excludes chronic brucellosis.

- **Other tests** include ultrasound and CT, bone radiographs, radionuclide scans and species-specific PCR tests.

#### Treatment

- **Regimen A:** Doxycycline 100 mg PO BID for 6 weeks + streptomycin 1 g IM qd (means one a day) for the first 14–21 days
- **Regimen B:** Doxycycline 100 mg PO BID + rifampin 600 to 900 mg (15 mg/kg) PO qd for 6 weeks

#### Prevention and Control

- Careful attention to hygiene when handling infected animals, eradication of infection in animals and pasteurization of milk.
- No vaccine is available for humans.

## Cholera

### Q. Write a short essay/note on cholera and cholera sicca.

- Cholera is an acute illness caused by the curved, flagellated, halophilic gram-negative bacillus, *Vibrio cholerae*.
- *Vibrio cholerae* colonizes in the small intestine. It causes explosive, severe watery diarrhea with rapid depletion of extracellular fluid and electrolytes.
- *Vibrio cholerae*: It is killed by temperatures of 100°C in a few seconds but can survive in ice for up to 6 weeks. The **major pathogenic strain** has a **somatic antigen (O1)** and has **two biotypes: classical and El Tor**. **New classical toxigenic strain, serotype O139** (Bengal serogroup) is still major cause of cholera in our country.

### Mode of Transmission

**By the feco-oral route:** Infection spreads via the stools or vomitus of symptomatic patients. Contaminated drinking water is the major source of the dissemination, although contaminated foodstuffs (shellfish and food contaminated by flies), and hands of contact carriers may contribute in epidemics.

**Incubation period** is about 12–48 hours.

## ***Pathogenesis***

- In the small intestine *Vibrio cholerae* proliferates and produces a powerful **exotoxin**. The exotoxin causes massive secretion of isotonic fluid into the intestinal lumen.
- Cholera toxin also releases serotonin (5HT, 5 hydroxy tryptamine) from enterochromaffin cells in the gut. This activates a neural secretory reflex in the enteric nervous system.
- *V. cholerae* also produces other toxins (zona occludens toxin, ZOT and accessory cholera toxin, ACT) and are responsible for pathogenesis of cholera.
- Severe depletion of extracellular fluid produces hypotension, metabolic acidosis and hypokalemia.
- In severe cases, massive fluid loss may lead to hypovolemic shock and acute tubular necrosis resulting in renal failure.

## ***Clinical Features***

- Majority with cholera may have a mild illness that cannot be distinguished clinically from diarrhea due to other infective causes. Severe cases, present abruptly with severe, painless, watery diarrhea without pain or colic, followed by vomiting (vomiting may be absent).
- **Rice-water stool:** Following the evacuation of normal gut fecal contents, characteristic ‘rice water’ stool is passed, consisting of clear fluid with flecks of mucus.
- **Loss of fluid and electrolytes:** Leading to intense dehydration with muscular cramps. The features of hypovolemic shock include cold, clammy and wrinkled (‘washer women’ skin) skin with loss of skin turgor, tachycardia, hypotension and peripheral cyanosis. Features of dehydration include sunken eyes, hollow cheeks and a diminished urine output. The blood pressure drops, and the pulse becomes rapid and thready. Death from acute circulatory failure may occur unless fluid and electrolytes are promptly replaced. Rapid improvement occurs with proper treatment.
- **Cholera sicca:** Occasionally, a very **severe form of the cholera** occurs with **accumulation of fluid into the dilated bowel**. This **kills the patient before typical gastrointestinal symptoms** appear. It is called as ‘cholera sicca’.

## Diagnosis

- **Clinical diagnosis** can be easily made during an epidemic. Otherwise, the diagnosis requires bacteriological confirmation.
- **Stool examination: ‘Hanging drop’ preparation** of the freshly passed stool shows the characteristic rapidly motile (shooting star motility) *V. cholerae* (this is not diagnostic, as *Campylobacter jejuni* may give a similar appearance).
- **Culture** of the stool or a rectal swab can isolate and identify the *V. cholerae* and also establish antibiotic sensitivity.

### Q. Write a short essay/note on treatment of cholera.

#### Treatment/Management

1. **Appropriate and effective rehydration therapy:** Maintenance of circulation by replacement of water and electrolytes is the mainstay of treatment.
  - **Intravenous therapy** is required if there is severe dehydration. Ringer-Lactate is the best fluid for intravenous replacement and should contain sodium chloride 5 g/L, potassium chloride 1 g/L and sodium bicarbonate (4 g/L) (‘Dhaka solution’). Initial fluid deficit should be replaced within 3–4 hours. Patients with severe cholera may need 200–300 mL/kg of isotonic fluids in the initial 24 hours. It should be continued till the patient is hemodynamically stable and vomiting subsides.
  - **Oral rehydration:** Once the vomiting stops and the patient is hemodynamically stable, fluid should be given orally up to 500 mL hourly. *Oral rehydration solutions (ORS)* are based on the observation that glucose (and other carbohydrates) increases absorption of sodium and water in the small intestine, even in the presence of secretory loss due to toxins.
  - Oral rehydration solutions with resistant starch, based on either rice or cereal, shorten the duration of diarrhea and improves prognosis.
  - Total fluid needed may exceed 50 L over a period of 2–5 days. Accurate assessment can be made by the use of a ‘cholera cot’, which has a reinforced hole under the patient’s buttocks, beneath which a graded bucket is placed.
2. **Antibiotics:** Three days treatment with tetracycline 500 mg 6 hourly, a single dose of doxycycline 300 mg or ciprofloxacin 1 g in adults or cotrimoxazole one tablet daily reduces the duration or excretion of *V. cholerae*. It also reduces the total volume of fluid required for replacement. Other alternative drugs include erythromycin, and furazolidone.
3. In children, zinc supplementation may reduce the severity of diarrhea.

**Prognosis** is good with adequate treatment and there is gradual return to normal of clinical and biochemical parameters within 1–3 days.

#### Prophylaxis

- **Vaccination:** It is recommended by the WHO during potential or actual outbreak situations.
  - Parenteral vaccination with a killed suspension (WC-rBS) of *V. cholerae* has some protective role.
  - Both live attenuated and whole cell killed vaccine (both oral) are available. Oral vaccines containing killed *V. cholerae* and the B subunit of cholera toxin are of limited efficacy.
- **Chemoprophylaxis** by tetracycline 500 mg twice a day for 3 days. Mass single-dose vaccination

along with tetracycline is also advised.

## Leprosy

**Q. Discuss the etiology, clinical features, diagnosis and management of Hansen's disease (leprosy).**

**Definition:** Leprosy (Hansen's disease) is a **chronic, granulomatous**, slowly progressive, destructive infection affecting skin and nerves, caused by *Mycobacterium leprae*.

**Mode of transmission:** 1. Inoculation/inhalation and 2. Intimate contact

**Incubation period:** Generally 2–7 years.

### ***Bacteriological Considerations***

- *Mycobacterium leprae* is an acid and alcohol fast, intracellular bacillus.
- Lepra bacilli survive and grow better at a temperature below that of the internal organs (close to 30°C rather than 37°C). Hence, it affects sites such as skin, peripheral nerves, the mucosa of the upper airways, and other tissues (bone, eyes, testis and some viscera).
- *Mycobacterium leprae* can be grown in the foot-pads of mice and **nine banded armadillos**, **cannot be cultured** on artificial media or in cell culture.

### ***Classification (Fig. 4.5)***

**Q. Write short note on classification of leprosy.**

In the early stage, disease may be indeterminate, and may either spontaneously undergo remission or develop into overt leprosy.

1. **Ridley and Jopling (1966) classification:** It depends on the clinicopathological spectrum of the disease, which is **determined by the immune resistance of the host**.

- **Tuberculoid leprosy (TT):** It is the polar form that has maximal immune response. It is characterized by single or few sharply demarcated skin lesions with predominant peripheral nerve involvement. The bacilli are usually absent or difficult to demonstrate.
- **Borderline tuberculoid (BT):** In this type the immune response falls between BB and TT.

- **Borderline leprosy (BB):** It exactly falls between two polar forms of leprosy.
- **Borderline lepromatous (BL)** has the immune response that falls between BB and LL.
- **Lepromatous leprosy (LL):** It is the other polar form with least immune response. This is characterized by extensive, diffuse and bilaterally symmetrical skin lesions that contain numerous bacilli. The peripheral nerves are better preserved than in the tuberculoid form.
- **Indeterminate type:** When the biopsy sample shows definite diagnostic evidence of leprosy (both nerve involvement and acid-fast bacilli) but clinically not fitting to the leprosy spectrum.

### 3. WHO classification:

- Paucibacillary: All cases of tuberculoid leprosy and some cases of borderline type.
- Multibacillary: All cases of lepromatous leprosy and some cases of borderline type bacilli are present in large numbers, and hence the term multibacillary (MB).

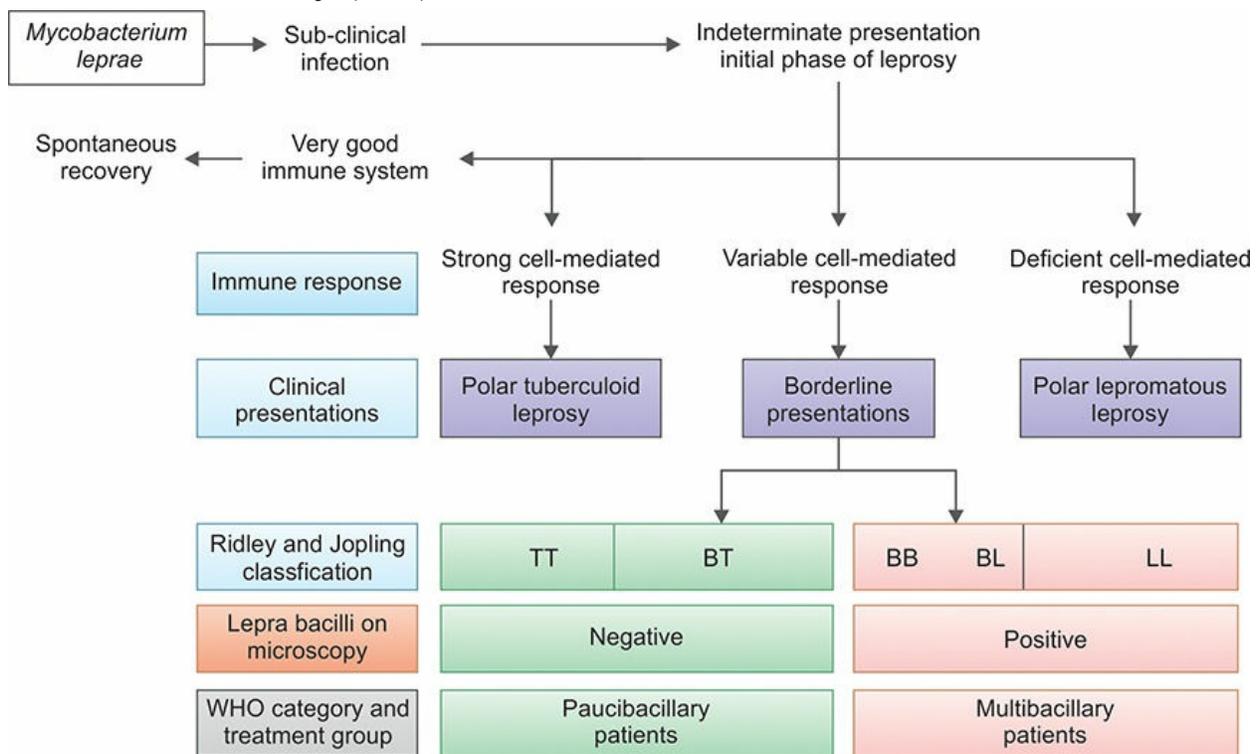

Fig. 4.5: Classification of leprosy.

## Clinical Features

### Tuberculoid leprosy (TT)

#### **Q.** Write short essay on clinical features of tuberculoid leprosy.

- **Skin lesions:** The early features consist of one or few, localized, well-demarcated, dry, elevated, **hypoesthetic, red or hypopigmented** macule (Fig. 4.6A). Later, the lesions become larger, margins elevated and circinate or gyrate. Fully developed lesions are anesthetic and show loss of sweat glands and hair follicles.

**Figs. 4.6A and B:** Lesions of tuberculoid leprosy: (A) Hypopigmented macules on face; (B) Visible greater auricular nerve thickening.

- **Nerve involvement** occurs early and **is the dominating feature** in tuberculoid leprosy. It is usually asymmetric and the involved nerves (Fig. 4.6B) are thickened and palpable. Routinely, the nerves such as ulnar, peroneal (lateral popliteal) and greater auricular nerves should be palpated. Sometimes, TT may present with only nerve involvement without any skin lesions (**neural leprosy or pure neuritic leprosy**). Consequences (complications) of nerve involvement are:
  - **Sensory nerve involvement** produces sensory dysfunctions like glove and stocking anesthesia (more common in LL), chronic non-healing plantar ulcers, and repeated injuries to hands and feet (leading to **autoamputation** of fingers or toes).
  - **Motor nerve involvement** produces muscle weakness, wasting and later paralysis followed by contractures. Nerve involved and their consequences are as follows:
    - ♦ **Ulnar nerve:** Claw hand (main en griffe) (Fig. 4.7)

Fig. 4.7: Bilateral claw hand.

- ◆ **Median nerve:** Ape hand (main de singe)
- ◆ **Lateral popliteal nerve:** Foot drop
- ◆ **Posterior tibial nerve:** Claw toes or hammer toes.
- **Autonomic involvement** produces anhidrosis or hyperhidrosis.
- **Cranial nerve involvement:** Facial nerve is commonly affected and results in facial paralysis, lagophthalmos, exposure keratitis and corneal ulcerations (may lead to blindness). Trigeminal nerve involvement may develop early causing loss of corneal reflex. Greater auricular nerve (Fig. 4.6B), supraorbital, supratrochlear and infraorbital nerves are also thickened.

### *Lepromatous leprosy (LL)*

#### **Q. Write short essay on:**

- **Clinical features of multibacillary/lepromatous leprosy**
- **Complications of lepromatous leprosy.**
- **Nasal symptoms** are the early features of LL and include anosmia, nasal stuffiness, crust formation and blood-stained nasal discharge.
- **Skin lesions** include **multiple, symmetric, macules, papules, plaques or nodules**. The macules are often hypopigmented. The borders of the lesions are ill-defined, centers indurated, raised and convex ('inverted saucer' appearance). There is also diffuse infiltration between the lesions. The nodular skin lesions may ulcerate. The lesions are more common on the face (cheeks, nose and eyebrows) (Fig. 4.8A), ears, wrists, elbows,

buttocks and knees. With progression, the nodular lesions in the face and ear lobes (Fig. 4.8B) may coalesce to produce thickening of face and corrugated forehead. This produces a lion like appearance known as **leonine facies** (Fig. 4.8C). This may be accompanied by loss of eyebrows and eyelashes.

**Fig. 4.8A to C:** Lesions of lepromatous leprosy: (A) Facial involvement; (B) Nodular lesions on ear; (C) Leonine facies.

- **Nerve involvement** of major nerve trunks is less prominent in LL. In advanced disease, **loss of sensation with ‘glove and stocking’** anesthesia is common. Mononeuritis multiplex can also occur.
- Lepromatous leprosy without visible skin lesions but with diffuse dermal infiltration and a demonstrable thickening of dermis is called *diffuse lepromatosis*.
- **Bone involvement:** It may develop in hands, feet (phalanges, metatarsals and tarsal bones) and skull. It causes slow absorption of distal phalanges resulting in shortening of fingers. In the skull, it may produce atrophy of the anterior nasal spine (leading to nasal collapse) and atrophy of maxillary alveolar process (causing loosening and loss of upper incisors). These changes in the skull produce ‘facies leprosa’.
- **Other features:**
  - **Bilateral edema** of legs and ankles.
  - **Saddle nose:** Swollen and broad nose, septal perforation and nasal collapses produces saddle nose deformity.
  - **Teeth:** Loosening of upper incisor teeth which may later fall off.
  - **Anterior chamber of the eye** involvement results in keratitis,

iridocyclitis and **blindness**.

- **Upper airways:** Chronic nasal discharge, laryngitis, palatal perforation and hoarseness (voice change).
- **Testes:** Usually severely involved, leading to destruction of the seminiferous tubules, testicular atrophy, impotence, infertility and gynecomastia.
- **Painless lymphadenopathy** involving inguinal and axillary lymph nodes.
- **Renal lesions:** Secondary glomerulonephritis, interstitial nephritis, pyelonephritis and renal amyloidosis.

Complications of lepromatous leprosy are summarized in Table 4.15.

**Table 4.15: Complications of lepromatous leprosy.**

- **Permanent nerve damage with sensory loss** (usually begins in extremities)
  - Leading to skin ulcers
  - ‘Glove and stocking’ anesthesia
  - Mononeuritis multiplex.
- **Infection of skin ulcers**
- **Disfiguration of the face** (leonine facies)
- **Eye damage:** Keratitis, iridocyclitis and blindness
- **Upper airways:**
  - Nasal damage: Anosmia, nasal stuffiness, crust formation and blood-stained nasal discharge.
  - Laryngitis, palatal perforation and hoarseness (voice change).
- **Muscle weakness:** Claw-like hands or an inability to flex the feet
- **Bone involvement:**
  - Hands and feet: Slow absorption of distal phalanges (shortening of fingers).
  - Skull: Nasal collapse and atrophy of maxillary alveolar process, saddle nose
- **Testes:** Testicular atrophy, impotence, infertility and gynecomastia.
- **Renal lesions:** Secondary glomerulonephritis, interstitial nephritis, pyelonephritis and renal amyloidosis

### *Borderline leprosy*

- Clinical features are poorly defined and it overlaps with features of other subtypes.

### ***Reactions in Leprosy or Lepra Reactions***

Immunity in leprosy may change spontaneously or following treatment. The course of leprosy may be interrupted by lepra reactions which comprise

several common immunologically mediated inflammatory states. There are two types of lepra reactions. Both types of reactions can occur in untreated patients, but more often develop as complications of chemotherapy.

*Type I lepra reaction*

**Q. Write short note on:**

- **Lepra reactions and their management**
- **Erythema nodosum leprosum (ENL).**

**Borderline leprosy** (BT, BB or BL) is the **most unstable form of leprosy** where **immune status may shift up or down** and type I reaction occur in 50% of these patients. These are delayed hypersensitivity reactions and may be of two types:

*Downgrading reaction or reversal reaction*

- **Downgrading reaction:** If type I lepra reactions precede the initiation of appropriate antimicrobial therapy, they are termed as downgrading reactions. It is associated with decrease of immunity and histologically the disease moves (usually from borderline) towards lepromatous leprosy.
- **Upgrading/reversal reaction:** If type I lepra reactions occur after the initiation of antimicrobial therapy, they are termed as reversal reactions. It is associated with improved immunity and histologically the disease moves (usually from borderline) towards tuberculoid leprosy. It develops usually in the first months or years after the initiation of therapy but may also occur after several years.

**Manifestations:** Existing skin lesions (i.e. macules, papules, and plaques) develop classic signs of inflammation in the form of erythema and swelling and new skin lesions may appear. Peripheral nerves inflammation (i.e. neuritis) causes pain and exquisitely tenderness of nerves. Irreversible nerve damage may occur suddenly (24 hours) unless the reaction is treated promptly.

**Type lepra reaction or erythema nodosum leprosum**

It **occurs mostly in lepromatous** leprosy (BL/LL) particularly within 2 years of institution of chemotherapy. It develops due to wide spread immune-complex deposition (type III hypersensitivity reactions) and over production of tumor necrosis factor (TNF- $\alpha$ ).

## Manifestations

- **Crops** of painful, tender inflamed, red, subcutaneous papules or plaque (on the face and limbs) that resolve spontaneously in a few days to a week but new crops may appear.
- Severe reactions may be accompanied by low-grade fever, malaise, lymphadenopathy symptoms of neuritis and arthralgia.
- **Other features** include uveitis, iritis, orchitis, myositis, glomerulonephritis, edema, anemia, leukocytosis and abnormal liver function tests.

## Diagnosis of Leprosy

### **Q. Write short note on lepromin test.**

- **Clinical diagnosis** is by cardinal sign of leprosy: Hypopigmented/reddish patches with loss of sensation and thickening of peripheral nerves.
- **Slit-skin smears:** The smears are made from skin lesions (earlobes and dorsum of the ring or middle finger) by scraped-incision method and the dermal material (fluid obtained) on to a glass slide and stained for AFB. It is useful in borderline Lepromatous (BL) and LL.
- **Nasal secretions** for acid-fast bacilli (AFB) from LL show numerous bacilli.
- **Lepromin test:** Lepromin is an antigen extract of dead *M. leprae*. The test is performed like the tuberculin test by intradermal injection of lepromin but is read after 4 weeks. It is **not a diagnostic test** for leprosy. It is **used for classifying** the leprosy based on the immune response. It is **interpreted** as follows:
  - **Lepromatous leprosy** shows **negative lepromin test** due to suppression of cell-mediated immunity.
  - **Tuberculoid leprosy** shows **positive lepromin test** because of delayed hypersensitivity reaction.
  - **Borderline leprosy:** Negative or weakly positive responses.
- **Skin biopsy:** Involvement of peripheral nerves in a skin biopsy taken from the affected area is pathognomonic, even in the absence of bacilli. Lepra bacilli can be demonstrated in LL and BL types by Fite-Ferraco stain.

- **Serological test** is not sensitive or specific enough for diagnosis.
  - Hypergammaglobulinemia is common in LL and can give false-positive serological tests (VDRL, rheumatoid factor and antinuclear antibodies).
  - IgM antibodies to PGL-1 (phenolic glycolipid-1) may be found in 95% of LL and in 60% of TT. However, these antibodies may also be present in normal individuals.
- **PCR testing** for *M. leprae* DNA: Detection of *M. leprae* DNA is possible in all types of leprosy using the polymerase chain reaction, but not sensitive or specific enough for diagnosis. It can be used to assess the efficacy of treatment.

**Q. Write short essay on:**

- **Management of multibacillary/lepomatous leprosy**
- **WHO regimen of treatment of leprosy**
- **Drug therapy/treatment of leprosy**
- **Treatment of borderline/lepomatous leprosy.**

**Treatment**

**Drugs**

- Main drugs available include dapsone (100 mg), rifampicin (600 mg), clofazimine (100 mg), ethionamide (500 mg) and thiacetazone (150 mg). Other drugs effective against leprosy are ofloxacin, minocycline and clarithromycin.
- **Side effects** of various drugs are as follows:
  - **Dapsone:** Hemolysis, agranulocytosis, hepatitis and exfoliative dermatitis.
  - **Clofazimine:** They are mainly found in the skin (e.g. reddish pigmentation of skin, ichthyosis) and intestinal tract (e.g. diarrhea, cramping abdominal pain).

**Treatment regimens for leprosy**

There are two recommended regimens for multibacillary and one for paucibacillary leprosy (Table 4.16).

**Table 4.16: Treatment (WHO) regimens for leprosy.**

**Multibacillary leprosy (MB):** Treatment is for 1 year

**Regimen 1**

- Dapsone 2 mg/kg daily (maximum 100 mg)
- Clofazimine 50 mg daily or 100 mg three times a week
- Rifampicin, 450 mg (for patients <35 kg) or 600 mg (for patients >35 kg), on 2 consecutive days in a month

### Regimen 2

- Dapsone 100 mg daily (self-administered)
- Clofazimine 50 mg daily (self-administered) + 300 mg once a month (supervised)
- Rifampicin 600 mg once a month (supervised)

### Paucibacillary leprosy (PB)

- Dapsone 100 mg given daily
- Rifampicin 600 mg given once a month under supervision

Duration of treatment is 6 months, and the patient should be followed up for 5 years

Box 4.8 lists the dapsone resistance cases.

**Box 4.8:** Dapsone resistance cases.

- Clofazimine alone or
- Clofazimine + ethionamide 500 mg daily and rifampicin given on the first 2 days of each month.

Treatment of lepra reactions is listed in Box 4.9.

**Box 4.9:** Treatment of lepra reactions.

During lepra reactions, the chemotherapy for leprosy is maintained.

1. Type 1 lepra reaction (reversal reaction):
  - **Mild cases:** Aspirin 600 mg 6 hourly.
  - **Severe cases:** Start with prednisone 40–80 mg daily and reduce gradually over 3–9 months.
2. Type 2 lepra reaction (erythema nodosum leprosum)
  - **Mild cases:** Aspirin 600 mg 6 hourly
  - **Severe cases:** Prednisone 1 mg/kg/day. If there is no response to steroids, add clofazimine (300 mg/day) or thalidomide (100 mg 4 times daily). The doses are slowly reduced over 1–3 months. If there is involvement of eyes, 1% hydrocortisone drops or ointment and 1% atropine drops is given.

## Leptospirosis

**Q.** Write short essay on the etiology, clinical features, complications, investigations/laboratory diagnosis, complications and treatment of leptospirosis.

**Q.** Write a short note on leptospirosis.

Leptospirosis is a globally important zoonotic disease caused by the spirochaete *Leptospira interrogans*.

**Synonyms:** Autumn fever, seven-day fever, Canefield fever, Swamp fever, Weil's disease, rice-field fever, Swineherd's disease.

## ***Etiology***

- *Leptospira* consists of two species: (1) pathogenic *Leptospira interrogans* (now designated *L. interrogans sensulato*) and (2) saprophytic/free-living *Leptospira biflexia* (now designated *L. biflexia sensulato*).
- Leptospirosis is the term used for an infection with any of the subtypes or subgroups of *Leptospira interrogans*.

**Epidemiology:** Leptospirosis is the most widespread important zoonosis in the world.

## ***Source of Infection***

Leptospirosis is ubiquitous in wildlife and in many domestic animals. Reservoirs of organisms include **rodents** (most frequent), foxes, skunks, dogs and domestic livestock. Many animals shed the organism into the urine in massive numbers for long period but infection is asymptomatic in these animals. Outbreaks of leptospirosis may occur with flooding.

## ***Mode of Transmission***

- **Direct contact:** Human infection occur either by direct contact with urine or tissue of an infected animal. Transmission may occur through cuts, abraded skin, and mucous membranes (nasopharynx, oral mucosa, conjunctiva, vagina). Prolonged immersion in contaminated water favors invasion, as the spirochete can survive in fresh water for months and for up to 24 hours in sea water.
- **Ingestion** of contaminated water, soil or vegetation.

**Incubation period** is usually 1–2 weeks (7–14 days) but ranges from 1 to 30 days.

## ***Pathogenesis (Fig. 4.9)***

Typically illness has two phases (biphasic illness)

1. **Leptospiremic (initial/first) phase** is named so because leptospirae are present in the blood and CSF during this phase. After entry of the organisms into the human, they proliferate and disseminate through blood into all organs (leptospiremic phase). The organisms can survive in the nonimmune host. They evade complement-mediated killing, resist ingestion and killing by neutrophils, monocytes and macrophages.
2. **Immune (second) phase:** During the immune phase, the antibodies

appear and leptospire disappear from the blood. However, the organism persists in various organs including liver, lung, kidney, heart, and brain.

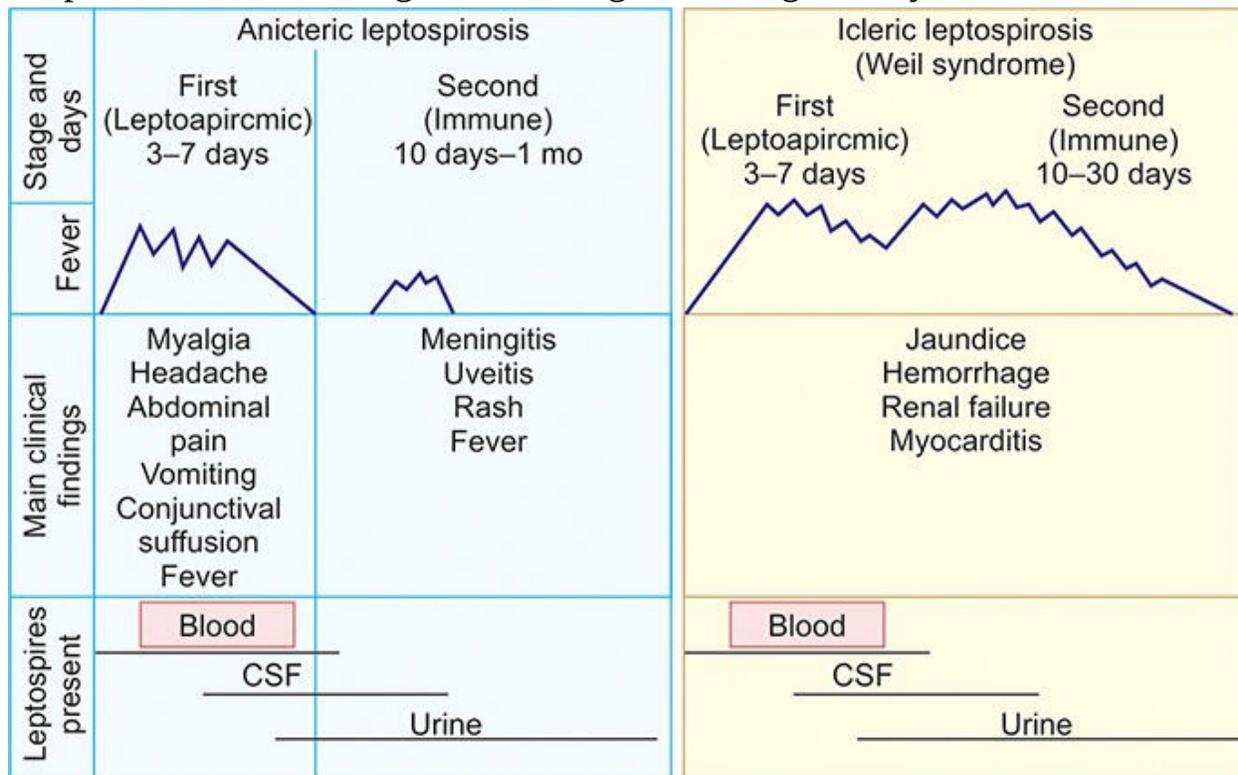

Fig. 4.9: Pathogenesis of leptospirosis.

## Clinical Features

### Q. Write a short note on the signs and symptoms of Weil's disease.

Most patients with mild leptospirosis are asymptomatic and do not seek medical attention.

1. **Leptospiremic phase:** It lasts for up to a week. It produces a nonspecific illness and commonly encountered symptoms include:
  - **Fever:** Usually high-grade with chills and rigors. May be accompanied by malaise, weakness.
  - **Severe headache:** retro-orbital or occipital.
  - **Myalgia:** Muscle pain occurs in most patients and is severe. The muscles of the thighs and lumbar areas (calf and back) show severe tenderness and may show cutaneous hyperesthesia (causalgia).
  - **Conjunctival suffusion/congestion** (Fig. 4.10) is very helpful, notable sign for detecting the disease. It is characterized by pericorneal

reddening or hyperemia (redness without exudate) without conjunctivitis.

**Fig. 4.10:** Conjunctival suffusion and jaundice in leptospirosis.

**Other less common features** include anorexia, nausea, vomiting, abdominal pain, cough, pharyngitis, uveitis lymphadenopathy, hepatosplenomegaly and skin rashes.

## 2. *Immune (second) phase*

- In many patients, the first (leptospiremic) phase is followed by a period of apparent recovery, after which the symptoms worsen again for another 2–5 days (immune phase).
- During the second phase, meningitis and iridocyclitis are more common.
- **Meningitis:** Presence of headache, fever, neck stiffness may suggest meningitis. The CSF is usually show normal number of cells in the first 7 days of illness, although the organisms may be seen. With the onset of antibodies (during immune phase) in the serum aseptic meningitis develops in about 90% of patients, with abnormalities in CSF (refer investigations below).
- **Other manifestations** which are less frequent include change in the level of consciousness, encephalitis, cranial nerve palsies and acute dilatation of the gallbladder with cholecystitis.

## *Weil's Syndrome*

**Q. Write a short note on Weil's syndrome.**

Weil's syndrome is not a specific subgroup of leptospirosis, but indicates severe leptospirosis. It can develop during the second (immune) phase of

leptospirosis or as a progressive illness.

### *Components of Weil's syndrome*

It is dramatic life-threatening event, characterized by:

1. **Jaundice:** The first manifestation of severe leptospirosis is usually jaundice. It develops between 5th and 9th days. Jaundice is deep and is not due to hepatocellular damage, but probably due to cholestasis or sepsis. Hepatic dysfunction such as acute hepatitis and sometimes fulminant may develop.
2. **Renal failure:** Primarily due to impaired renal perfusion and acute tubular necrosis. It presents as oliguria or anuria (acute renal failure) with the presence of albumin, blood and casts in the urine.
3. **Hemorrhagic manifestations** are common, and include purpura, petechiae appearing on oral, vaginal or conjunctival mucosa and large areas of bruising. In severe cases there may be epistaxis, hemoptysis, hematemesis and melena (due to gastrointestinal bleeding), hemorrhage into adrenal glands, pleural, pericardial or subarachnoid spaces (subarachnoid hemorrhage). Thrombocytopenia is common cause of hemorrhagic manifestation.
4. **Pulmonary syndrome:** Adult respiratory distress syndrome (ARDS), pulmonary hemorrhage, pneumonia, effusion.
5. **CNS:** Meningoencephalitis, subarachnoid hemorrhage, seizures.
5. **Other features:** DIC, hemolytic anemia, myocarditis and arrhythmias, and multiple organ dysfunction syndrome (MODS).

### ***Investigations***

- **Urine examination:**
  - During early part of the illness shows microscopic hematuria, pyuria and proteinuria.
  - **Demonstration of organism:** The tightly coiled spirochete may be visualized in the urine by phase contrast or dark-field microscopy.
- **Blood:**
  - **Total leucocyte count** may vary, but polymorphonuclear leukocytosis (neutrophilia of more than 70%) with shift to left is very frequent.
  - **Anemia** may develop due to intravascular hemolysis, azotemia and blood loss caused by hemorrhage.

- **Thrombocytopenia** in severe infection.
- **Elevated markers of inflammation:** Raised **erythrocyte sedimentation rate** and C-reactive protein level.
- Raised **blood urea nitrogen (BUN) and hyperkalemia** occur with renal failure.
- **Coagulation studies** may show a prolonged prothrombin time which is reversible with vitamin K administration.
- **Creatinine phosphokinase (CPK)** are elevated in 50% of patients during the first week of illness. This helps in differentiating leptospirosis from viral hepatitis.
- **Liver function tests** show raised AST and ALT (up to five times normal), conjugated hyperbilirubinemia and raised alkaline phosphatase. Marked elevations of bilirubin and mild elevated transaminases level are characteristically found in Weil's syndrome.
- **Chest radiograph** may reveal patchy bronchopneumonia and a small pleural effusion.
- **Electrocardiographic abnormalities** include bradycardia, low voltage and nonspecific ST-T wave changes.
- **CSF examination:** It may be abnormal in up to 90% of patients. Cell counts are increased (but  $<500/\text{mm}^3$ ) with predominance of neutrophils. Protein levels may be normal or raised and glucose level is normal. In severe jaundice, xanthochromia can be seen.
- **Serological tests:**
  - **IgM antibodies** may be detected in blood by microscopic agglutination test (MAT), during the immune (second) phase of illness. IgM ELISA and immunofluorescent techniques are easy to perform and rapid immunochromatographic tests are specific but are of moderate sensitivity in the first week of disease.
  - **Demonstration of leptospiral antigen** by radioimmunoassay or ELISA.
- **Culture:** Diagnosis can be confirmed by culture (on Fletcher's medium) of the blood or CSF during the first week (leptospiremic phase) of illness or of the urine from the second week onwards. It may take several weeks.
- **Detection of leptospiral DNA** by PCR in blood during early symptomatic disease and in urine from the eighth day of illness.

Modified Faine’s Criteria (Table 4.17) includes clinical, epidemiological and laboratory criteria. A score of more than 26 indicates current leptospirosis.

**Table 4.17: Modified Faine’s Criteria 2012 for the diagnosis of leptospirosis.**

<b>Part A: Clinical data</b>	<b>Score</b>
• Headache	2
• Fever	2
• Fever >39°C	2
• Conjunctival suffusion	4
• Meningism	4
• Myalgia	4
• Conjunctival suffusion + meningism + myalgia	10
• Jaundice	1
• Albuminuria/nitrogen retention	2
• Hemoptysis/dyspnea	2
<b>Part B: Epidemiological factors</b>	
• Rainfall	5
• Contact with contaminated environment	4
• Animal contact	1
<b>Part C: Bacteriological and Laboratory Findings</b>	
<i>Isolation of leptospira in culture – Diagnosis certain</i>	
PCR	25
Positive serology	
• ELISA IgM positive	15
• SAT positive	15
• Other rapid tests	15
• MAT – single positive in high titer	15
• MAT – Rising titer /seroconversion (paired sera)	25
<i>Presumptive diagnosis of leptospirosis is made of:</i>	
• Part A or Part A and Part B score : 26 or more	
• Part A, B, C (Total) : 25 or more	
• A score between 20 and 25 suggests leptospirosis as a possible diagnosis.	

## Treatment

**Antibiotic therapy:** Leptospirosis is highly susceptible to a broad range of antibiotics. Early antibiotic therapy may prevent the development of major organ system failure or lessen its severity, but it should be given whatever the stage of the infection.

- **Mild disease:** Oral treatment with following for 7 days effective when started within 4 days of onset of symptoms.
  - Doxycycline (100 mg orally twice daily) or
  - Ampicillin (750 mg four times daily)
  - Amoxicillin (500 mg four times daily)
  - Azithromycin (500 mg once daily).
- **Severe leptospirosis** should be treated with intravenous penicillin as soon as the diagnosis is considered.
  - Intravenous penicillin (1.5 million units intravenous 6 hourly) or
  - Ceftriaxone 1 g twice a day IV
  - Cefotaxime 1 g IV four times a day.
- **Treatment of complications/general care of the patient**
  - Blood product transfusion for hemorrhage, anemia and thrombocytopenia.
  - ARDS may require mechanical ventilation. Renal failure may require dialysis. Intravenous corticosteroid is useful for the vasculitic nature of severe leptospirosis, particularly in the setting of pulmonary hemorrhage.

## Melioidosis

### Q. Write short note on Melioidosis.

- **Melioidosis** (Whitmore disease) is caused by *Burkholderia pseudomallei*; which is an aerobic, gram-negative motile bacillus, with 'safety pin' appearance. It is an opportunistic pathogen found in water and moist soil and produces exotoxin.

### Mode of Transmission

- **Contact with contaminated soil or water:** It is the most common route of acquiring the disease.
- **Other routes** include aspiration or ingestion of contaminated water and inhalation of dust from soil. Transmission between infected animals and/or infected people is very rare. Person-to-person transmission may rarely occur through sexual contact with an individual with prostatic infection.

**Incubation period** varies from two days to months to many years. *B. pseudomallei* can survive in phagocytic cells. Hence, melioidosis can result after a latent period.

**Risk factors:** Immunosuppressive events or chronic diseases such as diabetes, chronic alcohol use, chronic renal disease, and chronic lung disease.

### ***Clinical Features***

- Most infections are asymptomatic.
- **Acute pulmonary infection:** It is the most common form which resembles tuberculosis with presentations of lobar or multilobar pneumonia, necrotizing lesions, and pleural effusions.
- **Focal infection:** Melioidosis can be limited to a focal infection. Localized lesions may occur in the skin (as a result of infected wounds) or various internal organs (as a result of septicemic spread). Many times focal infections become chronic conditions like lymphadenopathy, parotitis, cystitis, osteomyelitis, prostatitis, spondylitis and septic arthritis.
- **Severe systemic form:** It manifests as severe septicemic form. This can be non-disseminated (only involving one organ) or disseminated. Rarely melioidosis can produce encephalomyelitis.

### ***Diagnosis***

- It is **difficult** and has been called the great imitator (especially tuberculosis) because there are no pathognomonic lesions. Any organ can be affected and the lesions have no distinguishing characteristics.
- **Isolation of the organism** from blood, sputum, tissues or wound exudates by culture can help to diagnose the disease.
- **Serological tests** for titers may also be used for diagnosis. Serological tests available include agglutination tests, indirect hemagglutination, complement fixation, immunofluorescence and enzyme assays. Improved methods for rapid diagnosis are being evaluated.

### **Treatment**

- **Systemic antibiotics:** Initial intensive therapy with one of the following regimens:
  - Ceftazidime (2 g IV every six hours)
  - Meropenem (1 g IV every eight hours)
  - Imipenem (1 g IV every six hours)

Addition of TMP-SMX (trimethoprim sulfamethoxazole) twice daily during the intensive phase and to be continued for 2–3 months.

- **Surgical drainage of skin wounds** can be effective for localized infection.
- **Long-term treatment** and **multiple drugs** will be necessary for chronic and severe cases. Relapses, as soon as 6 months after treatment, are common.

## RICKETTSIAL DISEASES

- Rickettsiae are obligate intracellular gram negative parasites.
- Most are zoonoses spread to humans by arthropods (except Q fever).
- Rickettsiae replicate within the cytoplasm of endothelial cells and smooth muscle cells of capillaries, arterioles and small arteries causing necrotizing vasculitis.
- Most are febrile infections with a characteristic rash.
- An **eschar** is the characteristic lesion that develops at the site of inoculation.
- Among the major group of rickettsioses, the commonly reported diseases in India are: (1) *Scrub typhus*, (2) *Murine (endemic) typhus*, (3) *Indian tick typhus* and (4) *Q fever* (Table 4.18).

**Table 4.18:** Examples of rickettsial diseases and their features.

Diseases	Rickettsial agent	Insect vector	Mammalian reservoir	Clinical features
<b>Typhus Group</b>				
Epidemic typhus	<i>R. prowazekii</i>	Louse	Human	Fever/chills, myalgia, headache, rash (No eschar) all over body except palm, sole and face
Murine typhus (Endemic typhus)	<i>R. typhi</i>	Flea	Rodents	Fever, myalgia, headache, rash (No eschar), trunk, extremities, milder form of illness
Scrub typhus	<i>R. tsutsugamushi</i>	Mite	Rodents	Fever, headache, <b>rash with eschar*</b> cigarette burn sign (Figs. 4.11A and B), lymphadenopathy
<b>Spotted Fever Group</b>				
Indian tick typhus	<i>R. conorii</i>	Tick	Rodent, Dog	Fever, headache, <b>rash with eschar</b> , first appear on wrist and ankle
Rocky mountain spotted fever	<i>R. rickettsii</i>	Tick	Rodents, Dogs	Fever, headache, rash (No eschar)—first appear on wrist and ankle, palms and soles involved, systemic complications—respiratory, cardiovascular, central nervous, renal and hepatic system

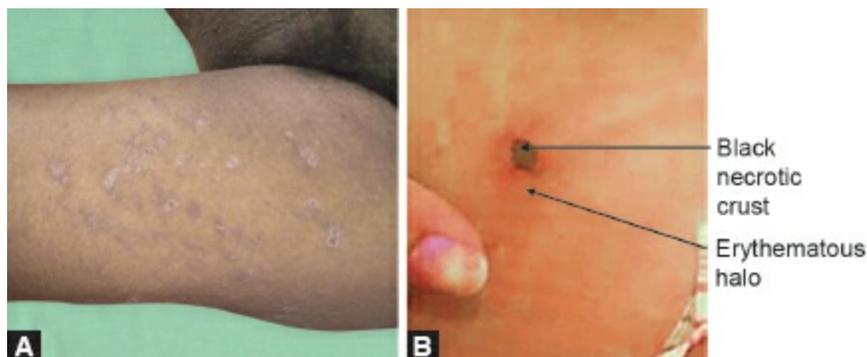

Rickettsial pox	<i>R. akari</i>	Mite	Mice	Mild illness, fever, headache, vesicular rash with eschar, lymphadenopathy, resemblance to chicken pox
<b>Others</b>				
Q fever	<i>C. burnetii</i>	Nil	Cattle, sheep, goats	Fever, headache, fatigue, pneumonia, endocarditis, no rash
Trench fever	Rochalimaea/Bartonella quintana	Louse	Human	Fever, splenomegaly, bone pains, maculopapular rash.

\* In scrub typhus, the eschar begins as a small papule, then enlarges, undergoes central necrosis, and eventually acquires a blackened crust with an erythematous halo that resembles a cigarette burn. The eschar resembling ‘**cigarette burn mark**’ is seen in 95% of cases and is most important diagnostic clue of scrub typhus.

Box 4.10 lists the investigations in rickettsial disease.

### Box 4.10: Investigations in rickettsial disease.

- Polymerase chain reaction (PCR)
- Serological tests
  - **Indirect fluorescent antibody (IFA) test** (Titer  $\geq$  1: 200)
  - **Complement fixation test**
  - **Weil Felix Test**
  - IgM ELISA test: Highly specific test.

**Fig. 4.11A and B:** (A) Multiple eschar with rash in typhus;(B) Cigarette-burn sign—eschar in typhus.

### Treatment

- Tetracycline is the drug of choice.
- Doxycycline 100 mg BID PO  $\times$  7–15 days.
- Chloramphenicol 500 mg qid PO  $\times$  7–15 days.
- IV Chloramphenicol 150 mg/kg per day for 5 days.
- Coxiella endocarditis : Combination therapy
  - Tetracycline + Co-trimoxazole

## VIRAL INFECTIONS

### Measles (Rubeola)

**Q. Discuss the etiology, clinical features, complications and prevention of measles (rubeola).**

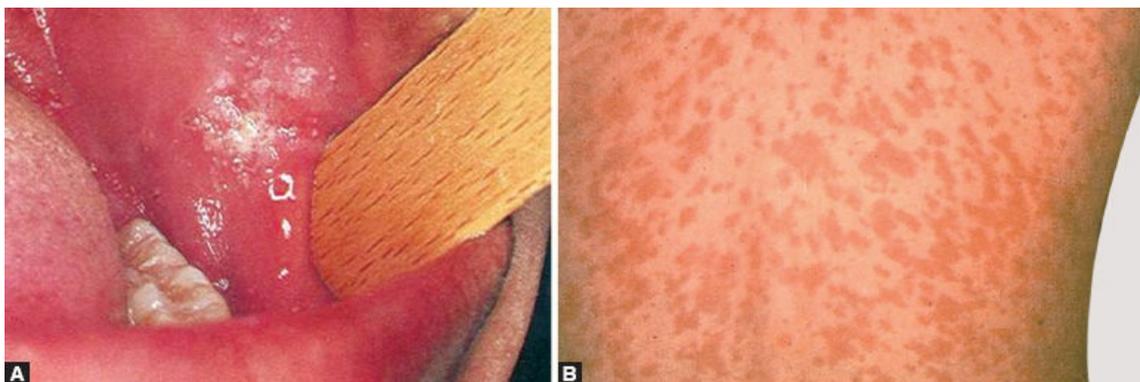

- Measles virus, the cause of measles is an RNA virus of the genus *Morbillivirus* in the family Paramyxoviridae.
- Measles is highly contagious; approximately 90% of susceptible household contacts acquire the disease.
- Maximal dissemination of virus occurs by droplet spray during the prodromal period (catarrhal stage).

### *Clinical Features*

Measles has three clinical stages

#### 1. Incubation stage

- This stage lasts for about 6–21 days to the first prodromal symptoms and another 2–4 days to the appearance of the rash.
- **Period of infectivity** is from *4 days before and 2 days after* the onset of rash. Patients with compromised immunity can shed virus for the entire duration of illness.

**Fig. 4.12A and B:** (A) Koplik spots—pathognomonic of measles which appears as grayish white dots on the buccal mucosa; (B) Maculopapular rashes in measles.

- #### 2. Prodromal stage with an enanthem (Koplik spots) and mild symptoms
- Usually lasts 3–5 days and is characterized by low-grade to moderate

fever, dry cough, coryza and conjunctivitis.

**Q. Write short note on Koplik's spot.**

**Koplik spots (Fig. 4.12A): Pathognomonic sign** of measles are grayish white dots, usually as small as grains of sand, that have slight, reddish areolae; occasionally they are hemorrhagic.

- Usually tends to occur opposite the lower molars but can spread irregularly over the rest of the buccal mucosa.
- Rarely, they are found within the midportion of the lower lip, on the palate, described as 'grains of salt on a red background' and on the lacrimal caruncle.
- They appear usually within 12–18 hours and disappear rapidly.
- Koplik's spots begin to slough when the exanthem appears.
- The conjunctival inflammation and photophobia may suggest measles before Koplik spots appear. In particular, a **transverse line of conjunctival inflammation**, sharply demarcated **along the eyelid margin**, may be of diagnostic assistance in the prodromal stage.

**3. Final stage with a maculopapular rash (Exanthem) (Fig. 4.12B) accompanied by high fever.**

- Usually starts as faint macules on the upper lateral parts of the neck, behind the ears along the hairline, posterior parts of the cheek.
- Individual lesions become increasingly maculopapular as the rash spreads rapidly over the entire face, neck, upper arms, and upper part of the chest within approximately the first 24 hours.
- During the succeeding 24 hours, the rash spreads over the back, abdomen, entire arm, and thighs.
- As it finally reaches the feet on the 2nd–3rd day, it begins to fade on the face. Associated lymphadenopathy, conjunctivitis and pharyngitis.
- In hemorrhagic measles (**black measles**), bleeding may occur from the mouth, nose, or bowel.
- **Complete absence of rash (modified measles) is rare** except:
  - In patients who have received immunoglobulin (Ig) during the incubation period.
  - In some patients with HIV infection.

- Occasionally in infants younger than 9 months of age who have appreciable levels of maternal antibody.

## **Diagnosis**

- Diagnosis is usually apparent from the characteristic clinical picture; laboratory confirmation is rarely needed.
- Testing for measles IgM antibodies is recommended in some situations. Measles IgM is detectable for 1 month after illness, but sensitivity of IgM assays may be limited in the first 72 hours of the rash illness.

## **Complication (Table 4.19)**

They are more common in older children and adults.

### **Treatment**

There is **no specific antiviral therapy** and it is entirely **supportive**.

- **Antipyretics** (acetaminophen or ibuprofen) for fever
- **Bed rest**
- **Maintenance of an adequate fluid intake**
- **Vitamin A supplementation:** Recommended by the American Academy of Pediatrics for children:
  - From 6 months to 2 years of age who are hospitalized for measles and its complications.
  - Older than 6 months of age with measles and immunodeficiency.
  - Recommended regimen as a single dose of:
    - ◆ 100,000 IU orally for children 6 months to 1 year
    - ◆ 200,000 IU for children 1 year and above
    - ◆ Children with ophthalmologic evidence of vitamin A deficiency should be given additional doses the next day and 4 week later.
- **Treatment of secondary bacterial infections:** Prompt identification and treatment of secondary bacterial infections (with appropriate antibiotics).
- **Measles encephalitis:** Aerosolized and IV ribavirin may be useful.

### **Prevention**

- **Passive immunization** with intramuscular injection of human normal immune globulin (0.25 mL/kg; maximum: 15 mL) is effective for prevention and attenuation of measles within 6 days of exposure. Indications for passive immunization are mentioned in Table 4.20.
- **Active immunization:** It is achieved by giving subcutaneous injection live attenuated measles virus. All children aged 12–15 months should be given measles vaccination. It can be given simultaneously in combination with rubella and mumps vaccines (MMR vaccine). Further MMR dose is given at the age of 4 years. This vaccination offer protection for at least 15 years. Contraindications for measles vaccination are listed in Box 4.11.

**Box 4.11:** Contraindications for measles vaccine.

- Pregnant women
- Children with primary immunodeficiency
- Untreated tuberculosis, cancer, or organ transplantation
- Those receiving long-term immunosuppressive therapy
- Severely immunocompromised HIV-infected children

**Table 4.19: Complications of measles.**

**Due to virus replication**

- Acute laryngotracheobronchitis (croup) in young children
- Giant-cell pneumonitis in immunocompromised children

**Due to secondary bacterial infections**

**Common**

- Otitis media
- Bronchitis
- Bronchopneumonia
- Gastroenteritis

**Others**

- Noma/cancrum oris
  - Gangrenous stomatitis
  - Diarrhea due to undernutrition

**Less common:**

- Transient hepatitis
- Myocarditis
- Conjunctivitis
- Keratitis
- Corneal ulcers

**Postinfectious: Rare CNS complications**

- Early: Postmeasles encephalomyelitis
- Late: Measles inclusion body encephalitis (MIBE) and subacute sclerosing panencephalitis (SSPE)

**Others**

- Guillain-Barré syndrome
- Hemiplegia
- Cerebral thrombophlebitis
- Retrobulbar neuritis
- Exacerbate underlying *Mycobacterium tuberculosis*
- Measles pneumonia in HIV-infected patients is often fatal

**Table 4.20: Indications for passive immunization.**

- Prophylaxis for susceptible household and nosocomial contacts younger than 1 year of age
- Immunodeficient patients (including HIV infected persons previously immunized with live attenuated measles vaccine)
- Pregnant females
- If measles is diagnosed in a household member, to be given to all unimmunized children in the household
- Debilitated children, especially those with a malignant disease
- Patients with active tuberculosis

## Rubella (German Measles)

### Q. Write short note on:

- **Rubella (German measles, 3 day measles)**
- **Rubella syndrome and congenital rubella syndrome.**

Rubella is infection caused by a **Rubella virus** which is an enveloped RNA virus and member of the Togaviridae family. The name is derived from the Latin, meaning *little red*.

- **Mode of spread via respiratory droplet infection:** Maximum infectivity from up to 10 days before the onset to 2 weeks after the onset of the rash.
- After an incubation period of 14–21 days, the primary symptom of rubella virus infection is the appearance of a rash (exanthema) on the face which spreads to the trunk and limbs and usually fades after three days.
- The skin manifestations are called ‘**blueberry muffin lesions.**’

### *Clinical Features*

Depends on age of the patient and divided into acquired and congenital rubella. Symptoms are mild or absent in children under 5 years.

#### 1. **Acquired rubella**

- **Prodromal or catarrhal phase:** Characterized by malaise, fever, headache, and mild conjunctivitis. Lymphadenopathy (particularly suboccipital, postauricular and posterior cervical lymph nodes) may be observed during the second week after exposure. **Forschheimer spots** (small petechial lesions on the soft palate) are suggestive but not diagnostic. Splenomegaly may be found.
- **Eruptive or exanthematous phase:** Occurs within 7 days of the initial symptoms. Characterized by **pinkish red, macular rashes** first appear behind the ears and on the forehead and then spread downwards to the

trunk and limbs. These rashes usually last for 2 to 3 days. May be associated with polyarthritis and generalized lymphadenopathy which may persist for 2 weeks.

**Complications** are rare. These include secondary bacterial infection of lung, arthralgia (commoner in females), hemorrhagic manifestations due to thrombocytopenia and postinfectious encephalitis.

## 2. **Congenital rubella syndrome**

It is the most serious consequence of rubella virus infection of mother during first trimester pregnancy. Box 4.12 lists the classical triad of congenital rubella syndrome.

**Box 4.12:** Classical triad of congenital rubella syndrome.

- Cataract
- Cardiac abnormalities
- Deafness

- **Mode of spread:** From the transplacental transmission of the virus from an infected mother to the fetus.
- **Consequences** (Table 4.21): The complications of rubella infection of the mother include miscarriage, fetal death, premature delivery or live birth with congenital defects. Infants infected with rubella virus in utero may have many defects. Most common are related to the eyes, ears, and heart. This combination of severe birth defects is known as congenital rubella syndrome.

**Table 4.21:** Congenital malformations associated with rubella syndrome.

**Congenital heart diseases:** Patent ductus arteriosus, ventricular septal defect, pulmonary stenosis

**Eye diseases:** Corneal clouding, cataracts, chorioretinitis, microphthalmia, blindness

**CNS:** Mental retardation, microcephaly

**Deafness**

**Others:** Hepatosplenomegaly, myocarditis, interstitial pneumonia and metaphyseal bone lesions.

- **First trimester infections** lead to abnormalities in 85% of cases and greater damage to organs.

- **Second trimester infections** lead to defects in 16%. > 20 weeks of pregnancy fetal defects are uncommon.
3. **Expanded rubella syndrome** additionally includes the following manifestations:
- Hepatosplenomegaly
  - Thrombocytopenic purpura
  - Intrauterine growth retardation
  - Myocarditis
  - Interstitial pneumonia
  - Humoral and cellular immunodeficiency.

### ***Diagnosis***

Diagnosis is clinically made. However, laboratory diagnosis is needed especially in pregnancy.

- Detection of rubella specific IgM by ELISA in serum, confirmed by demonstration of IgG seroconversion (or a rising titer of IgG) in a serum taken 14 days later.
- Detection of viral genome in throat swabs (or oral fluid), urine and the products of conception (in the case of intrauterine infection).

#### **Treatment**

- No specific therapy is available.
- Symptom based treatment is given for various manifestations such as fever and arthralgia.

#### **Prevention**

- **Passive immunization:** Human immunoglobulin can reduce the symptoms but does not prevent the teratogenic effects.
- **Active immunization:** Active immunization is by giving live attenuated rubella vaccine.
  - Aim of vaccination: To reduce the frequency of infection and thereby decrease the chance of exposure to infection by susceptible pregnant females.
  - **Indications:** Should be given to all children at the age of 15 months along with mumps and measles vaccine (MMR vaccine). A second dose is given to young females between the age of 11 to 13 years and all seronegative females of child-bearing age.
  - **Contraindications**
    - ◆ Contraindicated during pregnancy or if there is a likelihood of pregnancy within 3 months of immunization. It is because of likely risk of vaccine-virus induced fetal damage.
    - ◆ Patients with immune deficiency diseases or those on immunosuppressive drugs.

## **Mumps**

**Q. Write short essay/note on mumps and its prevention.**

- Mumps is an acute systemic viral infection caused by paramyxovirus (RNA virus) and is characterized by swelling of the parotid glands.
- **Mode of spread:** The virus is transmitted by the respiratory route (1) by droplet infection, (2) by direct contact or (3) through saliva and fomites. Humans are the only natural hosts of the mumps virus. The peak infectivity is 2–3 days before the onset of the parotitis and for 3 days afterwards.
- **Incubation period** is about 15–20 days (average 18 days).

### *Clinical Features*

**Q. Write short essay/note on clinical manifestations of mumps.**

Primarily affects school-aged children and young adults (peaks at 5–9 years of age) and is uncommon before 2 years of age.

- **Prodromal symptoms:** Nonspecific and includes malaise, low-grade fever, myalgia, anorexia, headache, anorexia, and tenderness at the angle of the jaw.
- **Parotid gland enlargement:** Prodromal symptoms are followed by severe pain over the parotid glands due to parotitis. Parotitis produces either unilateral or bilateral parotid swelling (75% of cases). It is accompanied by obliteration of the space between the earlobe and the angle of the mandible. The chief complaints at this stage are difficulty in eating, swallowing and talking. Submandibular gland involvement is less frequent.

### *Complications of Mumps (Table 4.22)*

**Table 4.22: Complications of mumps.**

- Epididymo-orchitis (30%) in adults can lead to infertility
- Oophoritis
- Mumps pancreatitis
- Mumps meningitis (5 to 10%), encephalitis. CSF reveals a lymphocytic pleocytosis
- Mumps myocarditis
- Others: Mastitis, hepatitis, polyarthritis, transient hearing loss, labyrinthitis, and electrocardiographic abnormalities
- Abortion (if infection occurs in the first trimester of pregnancy)

- Thrombocytopenic purpura

**Q. Write short essay/note on complications of mumps.**

**Treatment**

- Mumps is generally a benign, self-resolving illness.
- Treatment is symptom-based and supportive. Adequate nutrition and mouth care. Analgesics to relieve pain.

**Prevention**

- MMR vaccine: To be given at the age of 15 months.

**Diagnosis**

- On the basis of the clinical features. In atypical cases diagnosis is confirmed by following investigations:
  - **Serological test:** Demonstration of a mumps-specific IgM response in a blood or oral fluid during infection is diagnostic.
  - **Demonstration virus:** Culture of virus or identification by genome (PCR) or antigen detection assays, from saliva, throat swab, urine and CSF.

**Herpes Viruses Infecting Humans**

**Q. Write short note on common herpes viruses infecting humans. Enumerate the diseases caused by them.**

Herpes viruses are double-stranded DNA viruses. The various diseases caused by them are listed in Table 4.23.

**Table 4.23: Disease caused by various herpes viruses in human beings.**

<i>Virus</i>	<i>Diseases</i>
Herpes simplex	
• Type 1	Herpes labialis (herpes febrilis/cold sore—Fig. 4.13A), keratoconjunctivitis, dendritic corneal ulcer, pulp space infections (whitlows), encephalitis with temporal lobe involvement, genital herpes (40%), pneumonitis, tracheobronchitis, ulcerative stomatitis, esophagitis
• Type 2	Genital herpes (60%), neonatal infections
Cytomegalovirus	Congenital infections (intrauterine growth retardation), perinatal infections, infections in the immunocompromised patients (pneumonitis, retinitis)

Epstein-Barr virus (EBV)	Infectious mononucleosis, Burkitt's lymphoma, nasopharyngeal carcinoma, hairy leukoplakia in AIDS patients
Varicella-zoster virus	Chicken pox, herpes-zoster (shingles)
Human herpes virus 6	Exanthem subitum (sixth disease), Roseola subitum-slapped cheek appearance (Fig. 4.13B)
Human herpes virus 7	Exanthem subitum (sixth disease)
Human herpes virus 8	Kaposi's sarcoma, multicentric Castleman's disease

**Figs. 4.13A and B:** (A) Herpes labialis/febrilis caused by herpes simplex type 1 virus; (B) Roseola subitum-slapped cheek appearance in human herpes virus 6 infection.

## Infectious Mononucleosis (Glandular Fever)

**Q. Write short essay/note on etiology, clinical features, investigations, complications and treatment of infectious mononucleosis (glandular fever).**

### *Etiology*

- Caused by Epstein-Barr virus (EBV). It is a herpes virus that infects and replicates in B lymphocytes in the submucosal lymphoid tissue of nasopharynx and oropharynx.
- **Age:** Peak incidence in 14–16 years for females and 16–18 years for males. Subclinical infection is very common.
- **Mode of transmission** is largely through saliva (e.g. kissing hence the nickname kissing disease).
- **Incubation period:** 7–10 days.

### *Clinical Features*

- Usually presents with non-specific prodromal symptoms followed by the classical triad of (1) fever, (2) severe pharyngitis and tonsillitis, and (3) lymphadenopathy (particularly posterior cervical lymph node enlargement but sometimes generalized) and hepatosplenomegaly.

Other features: Petechial rashes on palate and maculopapular skin rash, the latter develops in 90% of patients who have received ampicillin or amoxicillin (inappropriately) for the sore throat.

- **Gianotti-Crosti syndrome:** A symmetrical rash on the cheeks with, multiple erythematous papules, which may coalesce into plaques, and persists for 15–50 days.

### ***Investigations***

- **Peripheral blood smear:** In >90% of cases  $\frac{2}{3}$  are **lymphocytes, 20–40% atypical lymphocytes**. The atypical lymphocytes are large, with larger eccentric and folded nuclei with a lower nuclear-to-cytoplasm ratio.
- **Liver function tests: Raised liver enzymes**
- **Serological Tests**
  - **Demonstration of heterophile antibodies:** The following tests will be useful for demonstration of heterophile antibodies.
    - ◆ **Paul Bunnell test** is characteristically positive: Sheep red blood cells agglutinate in the presence of heterophile antibodies.
    - ◆ **Monospot test** is a sensitive slide test: Horse red cells agglutinate on exposure to heterophile antibodies.
  - **Demonstration specific antibodies against EBV antigens:** These are demonstrated by ELISA.
    - ◆ Antibody against viral capsid antigens (anti-VCA): These antibodies are initially of IgM type and later of IgG type (which persists for life).
    - ◆ Antibodies to Epstein-Barr nuclear antigen (EBNA): This can be demonstrated by polymerase chain reaction (PCR).

### ***Complications of EBV Infection (Table 4.24)***

**Table 4.24:** Complications of EBV infection.

- Chronic fatigue syndrome.
- Hematological complications:
  - Hemolytic anemia and thrombocytopenia.
  - Aplastic anemia, thrombotic thrombocytopenic purpura of hemolytic-uremic syndrome, disseminated intravascular coagulation (DIC).
- Glomerulonephritis, interstitial nephritis, hepatitis, myocarditis, pericarditis.

- Splenic rupture.
- Cardiac: Myocarditis, pericarditis.
- Hepatic: Reyes syndrome.
- Skin: Ampicillin associated rash (Jarisch-Herxheimer reaction), oral hairy leukoplakia.
- Neurologic complications, e.g. meningitis, encephalitis, transverse myelitis and Guillain-Barré (GB) syndrome.
- Airway obstruction due to marked enlargement tonsils/severe pharyngeal edema.

## ***EBV Associated Oncogenesis (Table 4.25)***

### **Treatment**

- Infectious mononucleosis is usually a **self-limiting disease** and **majority requires no specific treatment** and recovery rapidly.
- **Symptomatic treatment** includes rest, acetaminophen, etc.
- Corticosteroids are indicated when there is neurological complications (e.g. meningitis, encephalitis, severe hemolysis, marked thrombocytopenia and marked tonsillar enlargement causing respiratory obstruction).

### **Table 4.25: EBV associated oncogenesis.**

#### **Benign EBV-associated proliferations**

- Oral hairy leukoplakia, primarily in adults with AIDS
- Lymphoid interstitial pneumonitis, in children with AIDS.

#### **Malignant EBV-associated proliferations**

- Nasopharyngeal carcinoma
- Burkitt lymphoma
- Hodgkin disease
- Lymphoproliferative disorders
- Leiomyosarcoma in immunodeficient including AIDS

## **Chickenpox (Varicella)**

### **Q. Discuss the clinical features, complications and management of chickenpox.**

- Chickenpox is caused by ubiquitous and extremely contagious primary infection with varicella-zoster virus (also called as human herpes virus 3). It is usually a benign illness of childhood (5 to 9 years of age).
- Varicella zoster virus (VZV) is a dermatropic and neurotropic virus and is a member of the family Herpesviridae.
- It causes two distinct clinical entities: varicella (chickenpox) and herpes zoster (shingles). Primary infection is chicken pox and usually occurs in

childhood. The virus remains latent; which reactivate later in life giving rise to herpes zoster.

### ***Mode of Transmission***

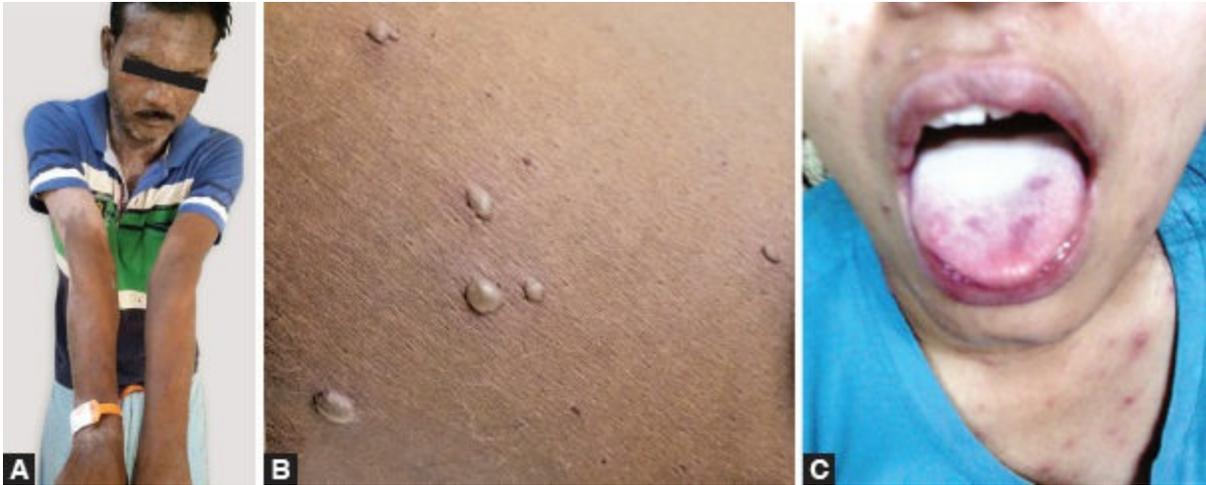

- By droplet infection from the upper respiratory tract.
- Direct contact with discharge from ruptured lesions on the skin.

Humans are the only reservoirs of VZV. Chicken pox is contagious till pustules disappear.

- **Incubation period** is about 10–21 days.

### ***Clinical Features***

- **Distribution of skin lesions:** Chicken pox presents with characteristic rash on the 2nd day of illness that first appears on the trunk followed by the face (Fig. 4.14A), and finally on the limbs. Maximum lesions are found on the trunk and minimum on the periphery of the limbs (centripetal distribution).
- **Appearance of skin lesions:**
  - Rash appear first as **small pink macules** and **progress to papules, vesicles (Fig. 4.14B) and pustules within 24 hours**. Finally these lesions dry up and form scabs.
  - New lesions develop in crops every 2–4 days and each crop is associated with fever. Thus, lesions at all stages of development are seen in any area at the same time.
  - Infectivity lasts from up to 4 days before the lesions appear till the last vesicles crust over.
  - In immunocompromised patients the skin lesions are hemorrhagic and are numerous. Dissemination to other organs is quite common.
- Enanthem are rash/small spots on the mucous membranes (Fig. 4.14C) may also be seen.

**Figs. 4.14A and C:** Lesions in chickenpox: (A) Involvement of face and body; (B) Vesicles; (C) Chickenpox exanthema (widespread) and enanthem (rash/small spots on the mucous membranes).

## Complications of Chickenpox (Table 4.26)

**Table 4.26:** Complications of chickenpox.

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• Secondary bacterial infection of skin lesions</li> <li>• CNS (rare)               <ul style="list-style-type: none"> <li>– Cerebellar ataxia</li> <li>– Encephalitis</li> <li>– Aseptic meningitis</li> <li>– Transverse myelitis</li> <li>– Guillain-Barré syndrome</li> </ul> </li> <li>• Varicella pneumonia (interstitial)</li> </ul> | <ul style="list-style-type: none"> <li>• Myocarditis</li> <li>• Acute glomerulonephritis</li> <li>• Corneal lesions</li> <li>• Arthritis, osteomyelitis</li> <li>• Bleeding diatheses</li> <li>• Hepatitis</li> <li>• Reye's syndrome with aspirin use</li> <li>• Perinatal varicella</li> <li>• Congenital varicella (extremely uncommon)</li> </ul> |
|--|---|

**Q. Write short note on complications of chickenpox/varicella.**

### Diagnosis

- Mainly clinical, by recognition of the skin rash.
- If needed, it may be confirmed by:
  - Detection of antigen (direct immunofluorescence) or DNA (PCR) of fluid aspirated from vesicles.
  - Serology is used to identify seronegative individuals at risk of infection
  - Isolation of virus by culture of vesicular fluid.
  - Tzanck smear: Prepared by scraping of the base of the vesicular lesion.

It shows multinucleated giant cells and epithelial cells with eosinophilic intranuclear inclusion bodies. Its sensitivity is low (60%).

## **Q. Write short note on treatment of chickenpox/varicella.**

### **Management**

- No treatment is needed in majority of patients.
- Medical management of immunologically normal patient is by prevention of avoidable complications. These include good hygiene (daily bathing), meticulous skin care (to avoid secondary bacterial infection).
- Avoid aspirin use in children to prevent Reye's syndrome.
- Symptomatic treatment for itching/pruritus includes antihistamines and local calamine lotion.
- Secondary bacterial infection is managed with local antiseptic or systemic antibiotics (e.g. cloxacillin).

### **Antiviral Therapy**

- Not required for uncomplicated primary VZV infection in children.
- **Drugs used:** Antiviral drugs that are used include acyclovir (15 mg/kg by mouth five times daily), valacyclovir (1 gm three times daily) or famciclovir (250 mg three times daily) and famciclovir (500 mg TID) for 5–7 days.
- **Indications:** Though in healthy children, antiviral drugs may reduce the duration of disease when administered within 24 hours of symptoms. However, they are usually not recommended but are indicated in the following cases:
  - For uncomplicated chickenpox when the patient presents within 24–48 hours of onset of vesicles.
  - All patients with complications.
  - Immunocompromised patients and pregnant women, regardless of duration of vesicles. More severe disease in immunocompromised patients requires initial parenteral therapy. Immunocompromised patients may shed virus for a prolonged period and may require prolonged treatment.

### **Prevention**

Three methods for the prevention of VZV infections are:

1. **Live attenuated vaccine:** It is given to prevent chicken pox in immunocompetent children and adults who are at a high risk of infection. It is contraindicated in pregnant or immunocompromised patients.
2. **Passive prophylaxis using zoster immune globulin (ZIG) or varicella-zoster immune globulin (VZIG):**
  - It may be given to individuals who are susceptible, those patients having high risk of severe disease or complication of chicken pox (e. g. immunocompromised, steroid treated or pregnant women with history of significant exposure). It should be given within 96 hours of exposure.
  - It is given prophylactically to newborn infants, infant whose mother develops chicken pox within 5 days before or within 48 hours after delivery.
3. **Antiviral therapy:** As prophylaxis to individuals at high risk and not eligible for vaccine or after 96 hours of exposure. They significantly reduce the severity of disease if not completely preventive.

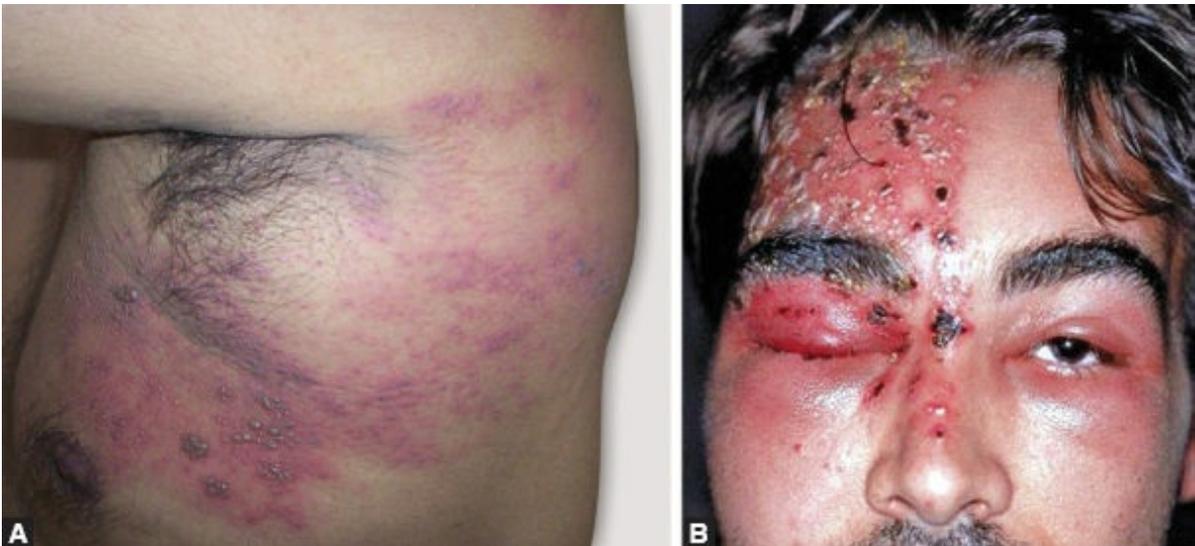

## Shingles (Herpes Zoster)

**Q. Write short essay on clinical features, diagnosis and management of herpes zoster.**

Initial infection with VZV produces chicken pox. After this initial infection, VZV persists in latent form in the dorsal root ganglion of sensory nerves or cranial nerve ganglia. Shingles arises from the reactivation of his latent virus later in life.

### *Clinical Features*

- **Age:** It may occur at any age but most common in the elderly.
- **Skin lesions:** The onset of the skin rash is usually preceded (3–4 days before discrete vesicles occur in the skin) by severe pain (**burning discomfort**) in the affected dermatome. Though **rash is similar to chickenpox**, classically they are unilateral and restricted to a sensory nerve (i.e. dermatomal) distribution (Fig. 4.15A). This is associated with a brief dissemination of virus causing viremia and can produce distant satellite ‘chickenpox’ lesions. Virus is from freshly formed vesicles may also cause chickenpox in susceptible contacts. Chickenpox may be contracted from a patient suffering from shingles but not vice versa. Occasionally, paresthesia may develop without rash (‘zoster sine herpette’).

**Figs. 4.15A and B:** (A) Herpes zoster–dermatomal involvement; (B) Ramsay Hunt syndrome.

- **Dermatome involved:** Most commonly involves **thoracic dermatomes**

or **ophthalmic division of the trigeminal nerve** (vesicles may develop on the cornea and can produce corneal ulceration leading to blindness). Bowel and bladder dysfunction may develop with sacral nerve root involvement. Occasionally it may cause cranial nerve palsy, myelitis or encephalitis.

### ***Complications of Shingles (Herpes Zoster)***

**Q. Write short note on complications of herpes zoster.**

- **Herpes zoster ophthalmicus**, leading to loss of vision
- **Ramsay Hunt syndrome (Fig. 4.15B)**: It develops due to geniculate ganglion involvement and characterized by involvement of cranial nerves (V and VII). A triad of (1) ipsilateral facial paralysis/palsy (ipsilateral loss of taste and buccal ulceration), (2) ear pain, and (3) vesicles/rashes in the external auditory canal and auricle is seen. It may be mistaken for Bell's palsy.
- **Postherpetic neuralgia is seen in 10–15%** of people with shingles. It results in troublesome persistent pain for 1–6 months or longer, following healing of the skin rash. It is more common in elderly patients.
- **Granulomatous cerebral angiitis** is a cerebrovascular complication. It leads to a stroke-like syndrome in patients with shingles, especially in an ophthalmic distribution.

**Q. Write short note on drugs used for the treatment of herpes zoster.**

#### **Management**

- **Early therapy with aciclovir or related agents** (refer treatment of chicken pox above on page 153) reduce both early- and late-onset pain, especially in patients above 65 years.
- **Postherpetic neuralgia: Analgesics** along with **amitriptyline** 25–100 mg daily or gabapentin (start with 300 mg daily and slowly increasing to 300 mg twice daily or more). **Capsaicin cream** (0.075%) may be of some help.

### **Human Papillomaviruses**

**Q. Write short note on human papillomavirus.**

Human papillomavirus (HPV) is a non-enveloped, double-stranded DNA virus with strong tropism for stratified squamous epithelial cells of skin and mucous membranes.

## Types of HPV

- **High-risk types** cause dysplastic lesions and invasive carcinoma in the cervix (e.g. HPV-16, HPV-18).
- **Low-risk types** are responsible for condylomata acuminata (genital wart) and low-grade cervical lesions (e.g. HPV-6, HPV-11).

## Mode of Infection

- **Direct contact:** Usually mode of infection via direct contact with skin or mucous membrane lesion.
- **Sexual contact:** Anogenital HPV are usually transmitted sexually. Most important risk factor is number of sexual partners.
- **Autoinoculation**
- **Incubation period** for genital HPV varies from weeks to months.

## Lesions/Diseases Caused by HPV (Table 4.27)

Majority of HPV infections are subclinical and about 80% resolves spontaneously within 12 months.

**Table 4.27: Lesions/diseases caused by HPV.**

<p><b>Verrucae plantaris</b></p> <ul style="list-style-type: none"> <li>• Sites: Hands (verrucae palmaris) and feet (verrucae plantaris)</li> <li>• Color: Skin colored</li> <li>• Nature: Flat or dome-shaped papules, surface rough and hyperkeratotic</li> <li>• Usually asymptomatic</li> </ul>	<p><b>Anogenital malignancies:</b> Caused by high-risk HPV</p> <ul style="list-style-type: none"> <li>• Intraepithelial neoplasms: Cervix, vulva, vagina, anus and penis.</li> <li>• Penile carcinoma</li> <li>• Cervical carcinoma: Squamous cell carcinoma</li> </ul>
<p><b>Verrucae plana</b></p> <ul style="list-style-type: none"> <li>• Sites: Mainly face, hands or distal forearms</li> <li>• Nature: Flat, reddish or skin-colored papules</li> </ul>	<p><b>Oral lesions:</b> Asymptomatic or cause papilloma</p> <p><b>Head and neck cancers:</b></p> <p>Sites: Oropharynx, tonsils, base of tongue and soft palate</p>
<p><b>Condyloma acuminatum</b></p> <ul style="list-style-type: none"> <li>• Cause: Low risk HPV</li> <li>• Sites: External (Fig. 4.16) or internal genitalia, perianal, the anal canal, perineum</li> <li>• Nature: Multiple, flat or raised exophytic papillomas, may be with pedicle or broad based, usually self-limited</li> </ul>	<p><b>Periungual warts</b></p> <p>Site: At nail fold; often painful</p> <p><b>Skin cancers</b> (squamous cell carcinoma and basal cell carcinoma)</p> <ul style="list-style-type: none"> <li>• HPV may act synergistically with ultraviolet light</li> <li>• Usually not caused by high-risk HPV</li> </ul>

**Fig. 4.16:** Condyloma acuminatum on the external genitalia of male.

## ***Diagnosis***

- On clinical presentation and appearance.
- **Biopsy:** Necessary to confirm dysplasia or carcinoma.
- **Acetic acid test:** HPV infections can be visualized after application of 3–5% acetic acid with a cotton swab. HPV-positive lesions appear white within 5 minutes.
- **Endoscopic examination (colposcopy, proctoscopy):** To visualize condyloma, dysplasia and carcinomas.
- Molecular methods: To detect HPV viral DNA (e.g. hybrid capture 2 DNA test).
- PCR to detect HPV viral DNA.

## **Treatment/Therapy**

No specific antiviral treatment available

- **Verrucae**
  - **Keratolysis:** Mechanical removal with a sharp knife and application of salicylic acid: lactic acid: collodion (1:1:4). Vaseline is applied to the surrounding normal skin to prevent its corrosion by chemicals.
  - **Cryotherapy:** Liquid nitrogen is used to freeze warts.
- **Anogenital warts**
  - **Podophyllotoxin:** Application causes death of infected cells. It is applied by patient himself at home twice/day for 3 consecutive days in cycles of several weeks. Serious systemic side effects can develop if it is applied to large areas and absorbed systemically. It is contraindicated during pregnancy.
  - **Imiquimod:** Induces the production of antiviral cytokines (e.g. interferon and tumor necrosis

- factor- $\alpha$ ). A 5% cream to be applied thrice weekly for up to 4 months.
- **Ablation:** Either by surgery, laser and electrocauterisation.
- **Cryotherapy** by using liquid nitrogen.
- **Trichloroacetic acid:** Topical application of 50–90% trichloroacetic acid produces coagulation of cell protein and cell death.
- **5-Fluorouracil** can be applied as cream.

#### HPV Vaccines

- HPV vaccines induces high titers of antibodies which can neutralize infectious viruses. They can prevent about 70% of cervical dysplasias (which can progress to cancer if not treated).
- Types of HPV vaccines: Quadrivalent vaccine and bivalent vaccine.

## Arthropod-Borne Viruses (Arboviruses)

**Q. Write short essay/note on:**

- **Classification of arboviruses**
- **Major clinical syndromes caused by arboviruses.**

Arthropod-borne viruses are called as arboviruses. Diseases caused by arboviruses are listed in Table 4.28 and manifestations of a few diseases are listed in Table 4.29.

**Table 4.28: Examples of diseases caused by arthropod-borne.**

<i>Family</i>	<i>Common diseases</i>	<i>Family</i>	<i>Common diseases</i>

## Dengue

**Q. Describe classic dengue (break bone fever), dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS).**

**Q. Write short essay on the clinical features, diagnosis and management of dengue hemorrhagic fever.**

Dengue is the most rapidly spreading febrile illness caused by flavivirus and transmitted by mosquitoes. It is the commonest arthropod-borne viral infection in humans in the world.

### *Source of Infection*

- Humans suffering from dengue are main amplifying host of the virus and infective during the first 3 days of the illness (the viremic stage). About 2 weeks after feeding (day time) on an infected individual, mosquitoes become infective and remain so for life. Dengue is usually endemic.

## ***Mode of Transmission***

- All are transmitted by the daytime *Aedes* mosquito biting. *Aedes aegypti* is the most common mosquito involved in transmission which breeds in stagnant water (e.g. collections of water in containers, water-based air coolers and tire dumps).

**Incubation period:** 4–10 days following the mosquito bite.

## ***Classification of Dengue***

*WHO (2008) Classification of Dengue*

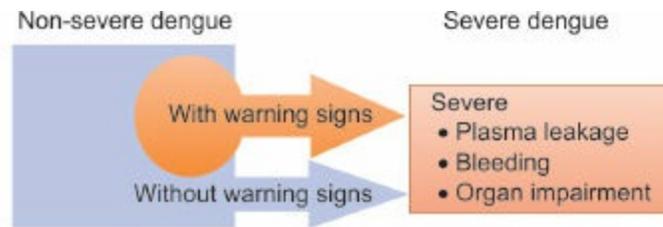

- **WHO (2008)** classifies dengue into non-severe dengue (with and without warning signs) and severe dengue, the criteria for the same is presented in Figure 4.17. Even non-severe dengue patients without warning signs may develop severe dengue. **WHO (2016) has revised the** classification and is presented in Table 4.30.

*Consequences of dengue virus infection is presented in Flowchart 4.1.*

*Presently, expanded dengue has been defined and its features are presented in Flowchart 4.2.*

## ***Pathogenesis of Severe Dengue***

- Severe dengue is characterized by plasma leakage, hemoconcentration, bleeding and organ impairment.
- **Plasma leakage:** The cause of plasma leakage probably due to functional endothelial cell activation/dysfunction. The endothelial cell dysfunction in turn may be mediated by activation of infected monocytes and T cells, the complement system and mediators, monokines, cytokines and soluble receptors.
- **Bleeding:** It may due to thrombocytopenia and associated platelet dysfunction or disseminated intravascular coagulation. Thrombocytopenia may be due to increased destruction or consumption (peripheral sequestration and consumption).

Criteria for non-severe dengue		Criteria for severe dengue
Without warning signs	With warning signs	
<b>Probable dengue</b> <ul style="list-style-type: none"> <li>• Live in/travel to endemic area</li> <li>• Fever and two of the following criteria: <ul style="list-style-type: none"> <li>- Nausea, vomiting</li> <li>- Rash</li> <li>- Aches and pains</li> <li>- Tourniquet test positive</li> <li>- Leukopenia</li> <li>- Any warning sign</li> </ul> </li> </ul> <b>Laboratory—confirmed dengue</b> (important when no sign of plasma leakage)	<b>Warning signs</b> (requires strict observation and medical intervention) <ul style="list-style-type: none"> <li>• Abdominal pain or tenderness</li> <li>• Persistent vomiting</li> <li>• Clinical fluid accumulation</li> <li>• Mucosal bleed</li> <li>• Lethargy, restlessness</li> <li>• Liver enlargement &gt;2 cm</li> <li>• Laboratory: Increase in hematocrit concurrent with rapid decrease in platelet count</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Severe plasma leakage</b> leading to <ul style="list-style-type: none"> <li>- Shock (DSS)</li> <li>- Fluid accumulation with respiratory distress</li> </ul> </li> <li>• <b>Severe bleeding</b> as evaluated by clinician</li> <li>• <b>Severe organ involvement</b> <ul style="list-style-type: none"> <li>- Liver: AST or ALT <math>\geq 1000</math></li> <li>- CNS: Impaired consciousness</li> <li>- Heart and other organs</li> </ul> </li> </ul>

Fig. 4.17: WHO (2008) classification and levels of severity in dengue case.

<i>DF/DHF</i>	<i>Grade</i>	<i>Signs and symptoms</i>	<i>Laboratory</i>
DF		Fever with two of the following: <ul style="list-style-type: none"> <li>• Headache</li> <li>• Retro-orbital pain</li> <li>• Myalgia</li> <li>• Arthralgia/bone pain</li> <li>• Rash</li> <li>• Hemorrhagic manifestations</li> <li>• No evidence of plasma leakage</li> </ul>	<ul style="list-style-type: none"> <li>• Leucopenia (WBC <math>\leq 5000</math> cells/mm<sup>3</sup>)</li> <li>• Thrombocytopenia (Platelet count <math>&lt;150,000</math> cells/mm<sup>3</sup>)</li> <li>• Rising hematocrit (Hct) (5–10%)</li> <li>• No evidence of plasma loss</li> </ul>
DHF	I	Fever and hemorrhagic manifestation (positive tourniquet test) and evidence of plasma leakage	Thrombocytopenia $<100,000$ cells/mm <sup>3</sup> ; Hct rise $\geq 20\%$
DHF	II	As in Grade I plus spontaneous bleeding	Thrombocytopenia $<100,000$ cells/mm <sup>3</sup> ; Hct rise $>20\%$
DHF*	III	As in Grade I or II plus circulatory failure (weak pulse, narrow pulse pressure ( $\leq 20$ mm	Thrombocytopenia $<100000$ cells/mm <sup>3</sup> ; Hct rise $\geq 20\%$

		Hg), hypotension, restlessness)	
DHF*	IV	As in Grade III plus profound shock with undetectable BP and pulse	Thrombocytopenia <100000 cells/mm <sup>3</sup> ; Hct rise ≥20%

Source: <http://www.who.int/csr/resources/publications/dengue/Denguepublication/en/>

(DHF: dengue hemorrhagic fever; Hct: hematocrit)

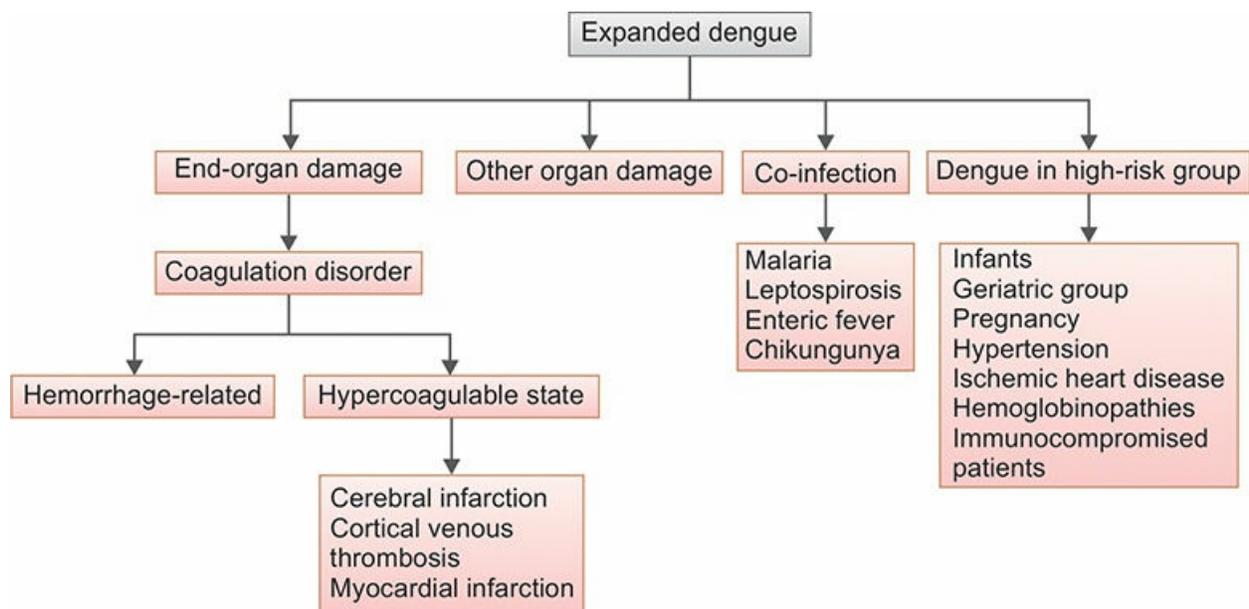

\*: DHF III and IV are DSS = Dengue shock syndrome.

**Flowchart 4.1:** Manifestations of dengue infection.

(DHF: dengue hemorrhagic fever)

**Flowchart 4.2:** Expanded dengue syndrome

## ***Clinical Features***

Dengue is a systemic and dynamic disease. It has a wide clinical spectrum and includes both severe and non-severe clinical manifestations. Asymptomatic infections are common (especially in children), but it is more severe in infants and the elderly.

### *Phases of dengue*

After the incubation period, dengue begins abruptly and is followed by the three phases: (1) febrile, (2) critical and (3) recovery.

#### **1. Febrile phase**

- Characterized by the abrupt onset of **high-grade fever** and this phase last for 2–7 days. Fever may be continuous or saddle-back (see below).
- It often accompanied by **facial flushing, skin erythema, generalized body ache ('break-bone fever'), myalgia, arthralgia, malaise, headache retrobulbar pain** (worsens on eye movements), **severe backache** (which is a prominent symptom), **anorexia, nausea and vomiting**. Some may have sore throat (pharyngitis), upper respiratory tract symptoms, and conjunctival suffusion. In children, high fever may produce febrile convulsions/seizures.
- **Saddle-back fever:** In few cases fever subsides and other symptoms disappear after 3–4 days. This remission may last for 2 days and then the fever returns together with others symptoms but milder. This biphasic or 'saddle-back' pattern is considered characteristic of dengue.
- **Mild hemorrhagic manifestations** such as petechiae and mucosal membrane bleeding (e.g. nose and gums) may be found.
- Liver is often enlarged and tender.

#### Laboratory findings

- The earliest laboratory abnormality which has a high probability of dengue is a **progressive decrease in total white cell count**.
- **Tourniquet test (Hess test)**
  - Sphygmomanometer (blood pressure) cuff is tied to the upper arm above the elbow and mark a circle of 5 cm diameter on the flexor aspect of forearm.
  - The cuff is inflated to 80 mm for 5 minutes.
  - Measure the number of petechiae present in the circle (already marked). A test is considered positive when 20 or more petechiae appear in the circle.

## 2. Critical phase

- Around the time of falling (defervescence = the period of abatement of fever) of fever (usually on days 3–7 of illness), an **increase in capillary permeability** along with **increase of hematocrit** levels may occur. This marks beginning of critical phase.
- **Consequences of plasma leakage are:**
  - **Pleural effusion** and **ascites** may develop.
  - **Shock** occurs when there is a critical volume of plasma leakage and is often preceded by warning signs.
  - **Body temperature** may be **subnormal** when shock occurs.
  - **Organ impairment:** If shock is prolonged, it causes hypoperfusion of organs and leads to progressive organ impairment, metabolic acidosis and disseminated intravascular coagulation (DIC). This in turn leads to severe hemorrhage and decrease of hematocrit in severe shock. Severe organ impairment (i.e. severe hepatitis, encephalitis or myocarditis) and/or severe bleeding may also develop without obvious plasma leakage or shock.
- *Non-severe dengue: Patients who improve after defervescence are said to have non-severe dengue.*
- *Dengue with warning signs: Patients who deteriorate will manifest with warning signs and are said to have dengue with warning signs. Cases of dengue with warning signs usually recover with early intravenous rehydration. However, some cases will progress to severe dengue.*

## 3. Recovery phase

- If the patient survives the 24–48 hour critical phase, a **gradual reabsorption of extravascular compartment fluid** takes place during the subsequent 48–72 hours.
- It is characterized by **improvement** in the general well-being, return of appetite, disappearance of gastrointestinal symptoms, stabilization of hemodynamic status and diuresis.
- **Other features:** Some patients may develop a rash of ‘isles of white in the sea of red’, and some may complain of generalized pruritus (particularly on hands and feet).
- **Findings**

- Bradycardia and electrocardiographic changes are common.
- **Hematocrit** stabilizes or may be low due to the dilutional effect of reabsorbed extracellular fluid (which leaked due to increased vascular permeability).
- **White blood cell count:** Usually begins to rise soon after defervescence.
- **Platelet count** recovery is later than that of white blood cell count.
- **Consequences of excessive intravenous fluids:** If excessive intravenous fluids are administered, massive pleural effusion and ascites may develop leading to **respiratory distress**. During any phase (critical and/or recovery phases), excessive fluid therapy may cause **pulmonary edema** or **congestive heart failure**.
- The various clinical problems during the different phases of dengue are presented in Table 4.31.

**Table 4.31:** Clinical problems during the different phases of dengue.

<i>Phase</i>	<i>Clinical problems</i>
Febrile	Dehydration; high fever may cause febrile seizures in young children
Critical	Shock from plasma leakage; severe bleeding; organ impairment
Recovery	Hypervolemia (only with excessive intravenous fluid therapy)

## **Severe Dengue**

### **Q. Write short note/essay on dengue shock syndrome.**

According to WHO severe dengue (Fig. 4.17) is defined by one or more of the following:

1. Plasma leakage that may lead to shock (dengue shock) and/or fluid accumulation, with or without respiratory distress.
2. Severe bleeding.
3. Severe organ impairment.

### *Mechanism of severe dengue*

#### *Dengue shock*

- **Time of occurrence:** Usually develops around defervescence on day **4 or 5 (range 3–7 days) of illness**. It is preceded by the warning signs.

- **Mechanism of shock:** In dengue, **progression of increased vascular permeability** (due to endothelial dysfunction) leads to worsening of **hypovolemia** and results in shock.
- **Consequences:** Initially compensatory mechanisms try to correct the process, but once they fail it goes into the decompensatory phase and organ dysfunction sets in.
  - Severe dengue may be associated with coagulation abnormalities, but they are not sufficient to cause major bleeding. When major **bleeding** develops, it is always associated with profound shock, **hypotension, thrombocytopenia, hypoxia and acidosis**. They can lead to multiple organ failure and advanced **disseminated intravascular coagulation**.
- Most deaths occur in patients with profound shock complicated by fluid overload. Complications of dengue are listed in Box 4.13.

#### Box 4.13: Complications of dengue.

- Dengue hemorrhagic fever and disseminated intravascular coagulation (DIC) hemophagocytic lymphohistiocytosis (HLH)
- Dengue shock syndrome, polyserositis acalculous cholecystitis, acute pancreatitis
- Cerebral hemorrhage or edema, cranial nerve palsies, rhabdomyolysis, hemolytic uremic syndrome
- Hepatitis, encephalitis, myocarditis, aseptic meningitis, GB syndrome, cortical venous thrombosis, pericarditis, atrial fibrillation, heart blocks, cardiomyopathy
- Vertical transmission (if infection occurs within 5 weeks of delivery).

## Diagnosis

### **Q. Write short note on diagnosis of dengue fever.**

- **Blood:** Increasing hemoglobin and hematocrit, leucopenia, thrombocytopenia and raised liver enzymes (AST or ALT).
- **Isolation of dengue virus** from the blood (within first 5 days of onset of symptoms) by tissue culture.
- **Detection of dengue virus RNA** by molecular methods like RT-PCR or nucleic acid sequence base amplification (NASBA) during the first few days of illness is diagnostic.
- **Detection of serum NS1 antigen** by enzyme-linked immunosorbent assay (ELISA) is highly specific but **less sensitive** than PCR. It is positive early in the course of illness.
- **Detection of virus specific IgM antibodies** or of rising IgG titers in

sequential serum samples (start after 5 days of onset).

- **In severe dengue:** Chest radiograph to look for pleural effusion, and ultrasound abdomen for ascites.

**Q. Write short essay on management of dengue fever.**

## Stepwise Approach to the Management of Dengue

At the first levels of care a stepwise approach should be applied as mentioned in Table 4.32.

### Step I: Overall assessment (Table 4.33).

**Table 4.32: A stepwise approach to the management of dengue (WHO).**

#### Step I. Overall assessment

#### Step II. Diagnosis, assessment of disease phase and severity

#### Step III. Management

- Management decisions: Depending on the clinical manifestations and other circumstances, patients may:
  - be sent home (Group A);
  - be referred for in-hospital management (Group B);
  - require emergency treatment and urgent referral (Group C).

**Table 4.33: Step I—overall assessment.**

<i>History</i>	<i>Physical examination</i>
<ul style="list-style-type: none"> <li>• Date of onset of fever/illness</li> <li>• Quantity of oral intake</li> <li>• Assessment for warning signs</li> <li>• Diarrhea</li> <li>• Change in mental state, seizure, dizziness</li> <li>• Urine output (frequency, volume and time of last voiding)</li> <li>• Other important relevant histories including coexisting conditions</li> </ul>	<ul style="list-style-type: none"> <li>• Mental state</li> <li>• Hydration status</li> <li>• Hemodynamic status</li> <li>• Tachypnea, acidotic breathing, pleural effusion</li> <li>• Abdominal tenderness, hepatomegaly, ascites</li> <li>• Rash and bleeding manifestations</li> <li>• Tourniquet test (Hess test)</li> </ul>

#### *Investigations*

- Complete blood count.
- Hematocrit in early febrile phase, establishes baseline, the patient's own hematocrit.
- Rapid decrease of white blood cell count makes dengue very likely.
- Rapid decrease in platelet count along with a rising hematocrit compared to the baseline is suggestive of progress to the plasma leakage/critical phase of disease.
- Other tests include liver function tests (LFT), blood glucose, serum electrolytes, urea and creatinine, bicarbonate or lactate, cardiac enzymes, ECG and urine specific gravity. A low serum albumin, high ferritin and a raised CRP (C-reactive protein) are indicative of progress to severe dengue.

Laboratory tests are performed to confirm the diagnosis. However, it is not necessary for the acute management of dengue.

## Step II: Diagnosis, assessment of disease phase and severity

On the basis of step I determine

- Whether the disease is likely to be dengue
- If dengue, which phase (febrile, critical or recovery)
- Whether there are warning signs
- Hydration and hemodynamic status of the patient
- Whether the patient requires admission.

## Step III: Management

### *Treatment of Group A patients (Can be managed at home)*

#### *Criteria for group A*

- Patients who are able to tolerate adequate volumes of oral fluids and pass urine at least once every 6 hours.
- Do not have any of the warning signs, particularly when fever subsides.

Strategies to be followed:

- Daily review of patients for disease progression (decreasing white blood cell count, defervescence and warning signs).
- **Treatment plan:**
  - **Fluid intake:** Encourage intake oral rehydration solution (ORS), fruit juice and other fluids containing electrolytes and sugar to replace losses from fever and vomiting.
  - **Control of fever:** Paracetamol for high fever and if patient is uncomfortable. Tepid sponge if fever is still high. Avoid use of NSAIDs (may aggravate gastritis or bleeding) and aspirin (may develop Reye's syndrome).
  - **To be brought to hospital immediately** if no clinical improvement or bleeding manifestations develop.

### *Treatment of group B patients*

Patients may require hospital management for close observation, particularly as they approach the critical phase.

**Criteria for group B patients:** These include patients with:

- Warning signs.
- Coexisting conditions (e.g. pregnancy, infancy, old age, obesity, diabetes mellitus, renal failure, chronic hemolytic diseases) that may make dengue or its management more complicated.
- Certain social circumstances (such as living alone, or living far from a health facility without reliable means of transport).

#### **Treatment plan:**

- Obtain the reference **hematocrit** before the start of fluid therapy.
- **Intravenous fluid:**
  - **Give only isotonic solutions** such as normal (0.9%) saline or Ringer's lactate.
  - Start with 5–7 mL/kg/hour for 1–2 hours, then reduce to 3–5 mL/kg/hour for 2–4 hours, and then reduce to 2–3 mL/kg/hour or less according to the clinical response.
  - **Reassess clinical status and repeat hematocrit.**
  - If hematocrit remains the same or rises only minimally, continue with the same rate (2–3 mL/kg/hour) for another 2–4 hours.
  - If vital signs are worsening and hematocrit is rising rapidly, increase rate to 5–10 mL/kg/hour

for 1–2 hours.

- Reassess clinical status, repeat hematocrit and review fluid infusion rates accordingly.
- Monitor hematocrit, platelet count, creatinine, electrolytes, liver function tests.

### **Treatment of group C patients**

**Criteria for group C patients:** These patients require emergency treatment and urgent referral when they are in the critical phase of disease or have severe dengue. The criteria include patients with **severe:**

- Plasma leakage leading to dengue shock and/or fluid accumulation with respiratory distress.
- Hemorrhages.
- Organ impairment (hepatic damage, renal impairment, cardiomyopathy, encephalopathy or encephalitis).

### **Treatment plan:**

All patients with severe dengue should be admitted to a hospital with intensive care facilities and blood transfusion.

**Intravenous fluid:** Judicious intravenous fluid resuscitation is the essential and usually sole intervention required.

- **Replacement of plasma losses** should be immediate and rapid with isotonic crystalloid solution or, in the case of hypotensive shock by colloid solutions. If possible, obtain hematocrit levels before and after fluid resuscitation.

### **Treatment of shock**

- Start intravenous fluid resuscitation with isotonic crystalloid solutions at 5–10 mL/kg/hour over 1 hour. Then reassess the patient's condition (vital signs, capillary refill time, hematocrit, urine output).
- If no improvement or shock worsens, fluid infusion rate can be increased. Vasopressors and inotropes need to be added.

### **Treatment of hemorrhagic complications**

- Avoid intramuscular injections.
- NSAIDs, antiplatelet agents, anticoagulants to be withheld temporarily.
- Platelets transfusion if platelet count drops below 10,000/mm<sup>3</sup> or patient develops bleeding manifestations.
- If coagulopathy present, transfuse plasma. Pack red cell transfusion if hemoglobin drops below 8 gm%. Steroids indicated if hemophagocytosis is diagnosed.

### **Management of complications appropriately**

#### **Prevention of dengue infections**

Prevention or reduction of dengue virus transmission depends on control of the mosquito vectors or interruption of human-vector contact.

- **Control of the mosquito vectors**
- **Interruption of human-vector contact**
- Currently, no vaccine or antiviral drug against dengue viral infections is available.

## **Chikungunya**

### **Q. Write short essay/note on chikungunya.**

- Chikungunya is a viral fever caused by an alphavirus.

- It is usually not fatal. However during 2005–2006 outbreak occurred in India, where more than 200 deaths were reported mainly related to CNS involvement and fulminant hepatitis.
- Chikungunya (in Swahili of African dialect) means ‘that bends up’. It was used in reference to the stooped posture developed due to the arthritic symptoms of the disease.

**Mode of spread:** By bites from *Aedes aegypti* mosquitoes.

**Source of infection:** Humans are the major reservoir of chikungunya virus.

**Incubation period:** 2–12 days.

**Epidemiology:** Observed in Tamil Nadu, Karnataka, Kerala, Andhra Pradesh, Rajasthan, Gujarat and Madhya Pradesh. Significant numbers of cases have been reported from northern India including Delhi.

## ***Clinical Features***

### *Symptoms*

- **Fever** (often severe): The fever usually lasts for 2–5 days and may be followed by an afebrile phase and then reappearance of fever (**saddleback pattern**).
- **Maculopapular rash:** Skin involvement is more common in children and occurs about 40–50% of cases. It may appear at the beginning or several days (day 2 or 3 of the disease) of the illness. It is usually a pruritic maculopapular rash predominating on the trunk and limbs.
- **Arthralgia or arthritis:** Adults are more prone to migratory polyarthrititis, which produces early morning pain and swelling, most often in the small joints of the ankles, feet, hands and wrists. However, larger joints may also be affected. Arthritis may persist for months and may become chronic (6 months to several years) in patients who are positive for human leucocyte antigen (HLA)-B27.
- **Other symptoms:** Constitutional symptoms and signs, such as abdominal pain, headache (last for a variable period), anorexia, nausea, conjunctival injection and slight photophobia. Occasionally, bleeding from skin (petechiae) and epistaxis may occur. Arthritis and skin pigmentation may persist for months to years after convalescence.

## ***Diagnosis***

- **Blood:** Leucopenia and thrombocytopenia may occur but is uncommon.
- **Raised aspartate amino transferases** and **C-reactive protein** may be found.
- **Demonstrating antibodies** using ELISA method for diagnosis.
- Molecular methods include **RT-PCR** to detect structural genes of virus in the blood sample.

#### Treatment

- **Symptomatic:** No specific treatment available. For arthralgias and arthritis **NSAIDs** (e.g. ibuprofen, diclofenac or naproxen) may be used. Rest is important to reduce morbidity.
- **Hydroxychloroquine** (200 mg once or twice a day) may be given to patients with prolonged joint pains.

## Japanese Encephalitis

### **Q.** Write short note on Japanese encephalitis.

- Japanese encephalitis is a mosquito borne encephalitis caused by a Flavivirus.
- **Mode of transmission:** It is a viral infection transmitted by infected *Culex tritaeniorhynchus* mosquitoes.
- **Source of infection:** It is a zoonotic disease maintaining Japanese encephalitis virus in nature by pig-mosquito-pig and bird-mosquito-bird cycles. *Culex tritaeniorhynchus* feeds mainly on the infected pigs and birds (e.g. herons and sparrows) and transmit the disease. Humans are accidental hosts.
- **Incubation period:** 5–15 days after the mosquito bite.
- **Epidemiology:** It is endemic in Bihar, Uttar Pradesh, Assam, Andhra Pradesh, Karnataka, Tamil Nadu, West Bengal and Odisha states of India. It is most frequent in the rice growing countries (where irrigated rice fields are present).

### **Clinical Features**

**Age group:** In endemic regions, the infection occurs in children between 3 and 15 years of age because of high background immunity in older individuals.

### **Presenting features**

- **Prodromal period:** Following incubation period, the illness starts with fever, severe rigors, headache, malaise nausea, diarrhea, vomiting, cough and myalgia that last for 1–6 days. Weight loss is prominent.
- **Acute encephalitic stage:** During this stage fever is high, there is neck rigidity, and neurological signs such as irritability, altered consciousness/behavior, hemiparesis and convulsions develop. Mental deterioration occurs over a period of 3 to 4 days and may terminate in coma.
- **Residual neurological defects features** such as cognitive and speech impairment, emotional liability, cranial nerve palsies (e.g. ocular palsies-deafness), hemiplegia, quadriplegia and Parkinsonian presentation (extrapyramidal signs in the form of rigidity, dystonia, choreoathetosis and coarse tremors) occur in about 70% of patients who have had CNS involvement.

Mortality ranges from 7% to 40% and is higher in children.

## **Diagnosis**

- **Blood:** Leukocytosis with neutrophilia.
- **Cerebrospinal fluid (CSF) examination:**
  - It shows **raised pressure** and cell count. During early stages neutrophils may predominate but a lymphocytic pleocytosis is typical. CSF **protein is moderately raised** in about 50% of case.
  - **Virus isolation** from CSF.
  - **Detection of viral antigens** in CSF by indirect immunofluorescence assay (IFA).
- **Serological tests:** Detect antibodies to viral antigens. The various tests include virus neutralization test, hemagglutination inhibition and complement fixation. **Antibody detection** in serum and CSF by IgM capture ELISA is a rapid diagnostic test.
- **EEG:** Persistent abnormalities are common (particularly in children).
- **Imaging studies** by CT scan may show low-density areas in the temporal lobes. MRI scan is more sensitive in detecting early abnormalities.

## **Treatment**

- Treatment is supportive/symptomatic and includes management of fever, raised intracranial tension and convulsions.

### *Prevention*

- **Control of the mosquito vectors**
- **Interruption of human-vector contact**
- **Vaccines:** These include vaccines containing purified formalin-inactivated virus derived from mouse brain (requires three doses on 0, 7 and 14 days) and cell-culture derived live attenuated.

## Smallpox (Variola)

### **Q. Write short essay on the clinical features, treatment and prophylaxis of smallpox.**

- It is a severe disease with high mortality caused by variola virus that belongs to the *Orthopoxvirus* genus.
- Smallpox was eradicated worldwide by a global vaccination program and the last case was reported in 1977. In 1980, WHO declared world free of smallpox.
- Interest in smallpox has re-emerged because of its potential as a bioweapon. Deliberate introduction of the smallpox virus through aerosolization can produce an epidemic in a few days.

**Mode of transmission:** Virus spread through the respiratory or oropharyngeal mucosa. The virus is present in contaminated aerosols, lesional tissue, body fluids or fomites. It may also spread through contact with lesions (which contains numerous viable virions)

**Incubation period:** 12–17 days. During incubation period, the viral proliferate within the lymph nodes and subsequently disseminated and seed the other lymphoid tissues throughout the body.

### ***Clinical Features***

***Prodromal period:*** It develops abruptly with high fever, headache, backache, prostration and malaise.

*Skin lesions (Described in Table 4.34)*

- **Contagious period:** The disease is most contagious during the period from the development of the rash up to the 10th day. However, the patient remains contagious till scabs fall off.
  - Within 2–3 weeks, the skin lesions develop into scabs that detach. Sometimes it may lead to scar formation or become hypopigmented.
  - **Uncommon presentations** are flat and hemorrhagic types of lesions.

- ◆ Smallpox: Characterized by soft, flat, confluent or semiconfluent lesions.
- ◆ Hemorrhagic smallpox: Characterized by widespread hemorrhages into skin and mucous membranes with a very high case-fatality rate.

Vaccination can modify course of disease with milder rash and lower mortality.

**Cause of death:** May be due to DIC, hypotension and multiorgan failure.

**Treatment**

- Symptomatic and there is no effective postexposure therapy.

**Prophylaxis by Vaccine**

- It is a live attenuated vaccine that employs another virus of *Orthopoxvirus* genus called vaccinia.
- Vaccination can prevent or reduce the severity of infection if given within 4 days of exposure. However, most countries do not have adequate stock of vaccine.

Differences between smallpox and chickenpox are presented in Table 4.34.

**Table 4.34:** Differences between smallpox and chickenpox.

<i>Features</i>	<i>Smallpox</i>	<i>Chickenpox</i>
Stages of skin rash	All rashes of the same stage	Rash in different stages occur simultaneously
Involvement of palms and soles	Affected	Not affected
Axilla	Free	Affected
Rash prominent on	Extensor surfaces and bony prominences	Mostly on flexor surfaces
Location of rash	Deep seated	Superficial
Type of skin lesion	Vesicles multilocular and umbilicated	<ul style="list-style-type: none"> <li>• Unilocular-dew drop appearance</li> <li>• Pleomorphic rashes</li> </ul>
Distribution of rash	Centrifugal	Centripetal
Relation to fever	Fever 2–4 days prior to rash	Fever at the time of rash
Mortality	2–10%	Very few

## RABIES

**Q. Describe etiology, clinical features, and treatment of rabies. Add a note on postexposure prophylaxis.**

Rabies is caused by a rhabdovirus (genotype 1, single stranded RNA virus of the *Lyssavirus* genus). The virus has a **marked affinity for central nervous tissue and the salivary glands** of a wide range of mammals. Established infection is invariably fatal.

**Mode of infection:** By **saliva** usually through the **bites or licks** of an infected animal on abrasions or on intact mucous membranes. Other forms of transmission (aerosolized exposure in bat infested caves, post organ transplant) are rare.

**Source of infection:** Humans are usually infected from dogs/fox (rarely cats) and bats.

**Incubation period in humans:** Varies from few weeks to several months. Unusually average is 1–3 months. In general, severe bites (especially on the head or neck), are associated with shorter incubation periods than those elsewhere.

## Clinical Features

- **Clinical varieties:** There are two distinct clinical varieties of rabies in humans: (1) Furious rabies (the classic variety) and (2) Dumb rabies (the paralytic variety).
- The only characteristic feature in the initial prodromal period is **the pain and tingling** (paraesthesia) **at the site of the bite**. There may be fever, malaise and headache.
- After a prodromal period of 1–10 days, marked anxiety, agitation or depressive features, hallucinations, and paralysis may develop. It may be accompanied by spitting, biting and mania, with lucid intervals in which the patient is markedly anxious.
- **Hyperexcitability** is the hallmark and is precipitated by auditory or visual stimuli. The characteristic **'hydrophobia' (fear of water)** develops in 50% of patients. In hydrophobia, though the patient is thirsty, attempts at drinking (or to eat) provoke violent/severe contractions of the diaphragm and other inspiratory (pharyngeal) muscles. **Aerophobia (fear of air) is pathognomonic** of rabies.
- Cranial nerve lesions and autonomic instability is common.
- **Examination:** It shows hyperreflexia, spasticity and features of sympathetic overactivity (pupillary dilatation and diaphoresis).

- Patient develops **convulsions, respiratory paralysis and cardiac arrhythmias**. Death usually occurs within 10–14 days of the onset of symptoms.

Dumb rabies presents with a symmetrical ascending paralysis similar to Guillain–Barré syndrome. It commonly develops after bites from rabid bats.

### ***Investigations/Diagnosis***

- Diagnosis is usually made on clinical grounds.
- **Skin punch biopsy:** To detect antigen with an immunofluorescent antibody test on frozen section.
- **Reverse transcription polymerase chain reaction (RTPCR):** Isolation of viral RNA
- **Isolation of viruses:** From saliva or the presence of antibodies in blood or CSF.
- **Corneal smear test:** It is unreliable.
- **Classic Negri bodies:** They can be demonstrated at postmortem in 90% of patients with rabies. These are eosinophilic, cytoplasmic, ovoid bodies, 2–10 nm in diameter, found in large numbers in the neurons of the hippocampus and the cerebellum.
- **Diagnosis on the biting animal:** By using RTPCR, immunofluorescence assay (IFA) or tissue culture of the brain.

### **Q. Write a short essay/note on treatment of rabies.**

#### **Treatment/Management**

##### ***Established disease***

- Once the CNS disease is established, treatment is symptomatic, as death is virtually inevitable. Only a few patients with established rabies survive.
- **Intensive care:** The patient should be isolated in a quiet, darkened room. Patients who received some postexposure prophylaxis should be given intensive care facilities to control cardiac and respiratory failure and nutritional support. Only palliative treatment can be given once symptoms have appeared.
- **Heavy sedation:** The patient should be heavily sedated with diazepam/ morphine, supplemented by chlorpromazine if needed. Sedation should be done liberally in patients who are excitable. Nutrition and fluids should be given intravenously or through a gastrostomy.
- Milwaukee Protocol using antivirals (Ribavirin and Amantidine) along with ketamine and midazolam infusion has been tried.

### **Q. Write a short note on prevention of rabies.**

## **Prevention**

### *Preexposure prophylaxis*

- High-risk individuals: Preexposure prophylaxis is indicated to individuals with a high-risk of contracting rabies. These include laboratory workers (who work with rabies virus), animal handlers (who handle potentially infected animals professionally), veterinarians and those who live at special risk in rabies-endemic areas.
- **Method:**
  - **Three doses** on days **0, 7 and 28** (1.0 mL) of **human diploid (HDCV) or chick embryo cell vaccine** given by deep subcutaneous or intramuscular route.
  - A **reinforcing dose after 12 months** and additional reinforcing doses are given every 3–5 years (depending on the risk of exposure).

**Q. Write a short note on postexposure prophylaxis of rabies.**

### *Postexposure prophylaxis*

- **Treatment of the wound:** The wounds should be thoroughly and carefully cleaned with a quaternary ammonium detergent or soap and water. Excise the damaged tissues, the wound left unsutured and open.
- Rabies can be prevented if treatment is started within a day or two of bite. For maximum protection hyperimmune serum and vaccine are needed.
- **Human rabies immunoglobulin** should be **given immediately** at dose is 20 IU/kg body weight; **half is injected /infiltrated around the bite wound and other half is given intramuscularly** at a different site from the vaccine. Hyperimmune animal serum can be given but hypersensitivity reactions (including anaphylaxis) are common.
- **Vaccine:**
  - **Human diploid cell strain vaccine (HDCV)** is the safest vaccine, free of complications. Six 1.0 mL doses of HDCV is should be given intramuscularly on days **0, 3, 7, 14, 30 and 90**.

## **Ebola Virus Disease**

**Q. Write short note on the clinical features and management of Ebola virus.**

Ebola virus disease (EVD), earlier known as **Ebola hemorrhagic fever**, is a severe, often **fatal illness** in humans. EVD outbreaks have a very high fatality rate of around 90%. EVD outbreaks occurred primarily in remote villages in Central and West Africa, near tropical rainforests.

**Source of infection:** Ebola virus is introduced into the human population through close contact with the blood, secretions, organs or other bodily fluids of infected animals. Humans recovered from the disease can transmit the virus through semen for up to 7 weeks after recovery from illness.

### **Mode of Transmission**

The natural host of the Ebola virus are the fruit bats of the *Pteropodidae*

family.

- **Spread of infection:** The virus spreads in the **human population through human-to-human transmission**, with infection resulting from **direct contact (through broken skin or mucous membranes) with the blood, secretions, organs or other bodily fluids of infected people**, and **indirect contact with environments contaminated with such fluids**.

### ***Clinical Features***

Acute EVD is characterized by **sudden onset of high grade fever**, associated with **severe weakness, muscle pain, headache, vomiting, diarrhea and skin rash**.

**Complications** include acute renal failure, hemorrhagic manifestations, DIC, hepatitis and MODS (multiple organ dysfunction syndrome).

**Diagnosis** is clinical and serological tests available.

**Treatment:** **Symptomatic** and supportive. Isolation is of paramount importance.

- Handling of dead bodies, animal carcasses needs to be emphasized.
- No vaccine available.

## **Swine Flu**

### **Q. Write short note on Swine Flu.**

- **Swine influenza virus (SIV)** refers to influenza cases that are caused by *Orthomyxovirus* endemic to pig populations. SIV strains have been classified either as influenza virus C or one of the various subtypes of the genus influenza virus A.
- In late March and early April 2009, cases of human infection with swine influenza A (H1N1) viruses were first reported in Southern California and near San Antonio, Texas.
- **Swine influenza is a respiratory disease of pigs** caused by type A influenza virus that regularly causes outbreaks of influenza in pigs that cause high levels of illness but low death rates in pigs. Swine influenza viruses may circulate among swine throughout the year, but most outbreaks occur during the late fall and winter months similar to outbreaks in humans. The classical swine flu virus (an influenza type A H1N1 virus) was first isolated from a pig in 1930.

- The disease originally was nicknamed swine flu because the virus that causes the disease originally jumped to humans from the live pigs in which it evolved. The virus is a ‘reassortant’—a mix of genes from swine, bird, and human flu viruses.

### ***Source of Infection***

- Droplets from cough or sneeze of an infected individual.
- Object contaminated by the cough or touch of an infected person.

Infected individual shed the virus from the day prior to illness onset until resolution of fever. Hence infected individuals should be considered to be contagious up to 7 days from the onset of illness.

### ***Signs and Symptoms (Table 4.35)***

Patients aged above 65, children below 5 years, pregnant women (especially during the third trimester) and those with underlying medical conditions (e.g. asthma, diabetes, obesity, heart disease), or those with weakened immune system (e.g. on immunosuppressive medications or infected with HIV) are at **high risk of serious complications**.

**Table 4.35:** Signs and symptoms of swine flu.

- |  |  |
|--|--|
| <ul style="list-style-type: none"> <li>• High grade fever</li> <li>• Unusual tiredness</li> <li>• Headache</li> <li>• Running nose</li> <li>• Sore throat</li> </ul> | <ul style="list-style-type: none"> <li>• Shortness of breath or cough</li> <li>• Loss of appetite</li> <li>• Aching muscles</li> <li>• Diarrhea or vomiting</li> </ul> |
|--|--|

The CDC criteria for suspected H1N1 influenza are listed in Table 4.36.

**Table 4.36:** The CDC criteria for suspected H1N1 influenza.

- Onset of acute febrile respiratory illness within 7 days of close contact with a person who has a confirmed case of H1N1 influenza A virus infection
- Onset of acute febrile respiratory illness within 7 days of travel to a community (within the United States or internationally) where one or more H1N1 influenza A cases have been confirmed
- Acute febrile respiratory illness in a person who resides in a community where at least one H1N1 influenza case has been confirmed.

(CDC: centers for disease control and prevention)

**Complications:** ARDS (adult respiratory distress syndrome) and MODS (multiple organ dysfunction syndrome).

### *Diagnosis*

A **confirmed case** of novel influenza A (H<sub>1</sub>N<sub>1</sub>) virus infection is defined as a person with an influenza-like illness with laboratory confirmed novel influenza A (H<sub>1</sub>N<sub>1</sub>) virus infection by one or more of the following tests:

1. Real-time RT-PCR
2. Viral culture from swabs (nasal, oral, secretions of respiratory tract) can be used for virus isolation.

### **Treatment**

- **Mainly supportive** and consists of bed rest, increased fluid consumption, cough suppressants, and antipyretics and analgesics (e.g., acetaminophen, nonsteroidal anti-inflammatory drugs) for fever and myalgias.
- **Severe cases** may need **intravenous hydration and other supportive measures.**

### *Antiviral Agents*

- They may also be considered **for treatment or prophylaxis.**
- **Neuraminidase inhibitors:** They **inhibit neuraminidase** which is a glycoprotein on the surface of influenza virus that destroys an infected cell's receptor for viral hemagglutinin. By inhibiting viral neuraminidase, **neuraminidase inhibitor agents decrease the release of viruses from infected cells** and, thus, **decrease the spread of virus.** Drugs include Oseltamivir and Zanamivir. Both are effective against both influenza A or B.

#### 1. **Oseltamivir (Tamiflu)**

- Must be administered within 48 hours of symptom onset to provide optimal treatment.
- **Adult dose**
  - **Treatment for acute illness:** 75 mg PO BID for 5 days
  - **Prophylaxis:** 75 mg PO qd (Please refer to duration of prophylaxis specific for postexposure).

#### 2. **Zanamivir (Relenza)**

- It is in powder form for inhalation via the Diskhaler oral inhalation device.
- **adult dose**
  - **Treatment for acute illness:** 10 mg inhaled orally BID for 5 days
  - **Prophylaxis of household contact:** 10 mg inhaled orally qd for 10 days (initiate within 36 hours)
  - **Prophylaxis for community outbreak:** 10 mg inhaled orally qd for 28 days (initiate within 5 days of outbreak)

Other antiviral agents (e.g. amantadine, rimantadine) are not recommended because of recent resistance to other influenza strains.

- **Vaccination:** Yearly vaccination with season specific strain vaccine before the annual flu season is recommended. Two types of vaccination are available namely intranasal and intramuscular. Monovalent/trivalent vaccines are available.

## Zika Virus

### **Q. Write short note on Zika Virus.**

- Zika virus (ZIKV) is an arbovirus, belongs to the flavivirus family.
- It is enveloped and icosahedral with a nonsegmented, single-stranded, positive-sense RNA genome. It was first identified in Zika forest of Uganda in 1947.

### ***Mode of Spread***

- Zika virus is transmitted by ***Aedes mosquito*** species such as *A. aegypti*, the extrinsic incubation period in mosquitoes is about 10 days. Rarely, mother to child transmission and one case of sexual transmission has been reported.
- The vertebrate hosts of the disease are monkeys and humans. The virus infects dendritic cells near the site of inoculation, and later spreads to lymph nodes and produces viremia.

**Incubation period:** 10 days.

### ***Clinical Features***

- It produces symptoms similar to a mild form of dengue fever with mild headaches, maculopapular rash, fever, malaise, conjunctivitis, and arthralgia. Within two to four days, the rash started fading, and fever resolved within three days.
- **Neurological complications:** Guillain–Barré syndrome and other neurologic complications.
- Congenital infection leads to microcephaly, chorioretinal atrophy, hydranencephaly, IUGR, hydrops fetalis. In January 2016 the US Centers for Disease Control and Prevention (CDC) issued travel guidance on affected countries, including the use of enhanced precautions, and guidelines for pregnant women including considering postponing travel to affected areas. Most dangerous time is during first trimester of pregnancy and damage to the brain of fetus.

### ***Diagnosis***

- **Sample to be tested:** Blood saliva and urine.
- **PCR:** Useful in the first 3–5 days after the onset of symptoms. It directly

detects the virus or specific viral antigens in the clinical specimen.

- **Serology test:** Detects the presence of antibodies and useful only after 5 days.

#### **Treatment**

- Only symptomatic. No specific antiviral drugs or vaccines are available.

#### **Prevention and control**

- Avoid travel to areas with an active infection.
- Control of mosquito.

## **Molluscum Contagiosum**

### **Q. Write short note on molluscum contagiosum.**

It is caused by a **DNA poxvirus** called the **molluscum contagiosum virus** (MCV). MCV has no nonhuman-animal reservoir (infecting only humans).

**Types:** **Four types** of MCV named MCV-1 to 4; MCV-1 is the most prevalent and MCV-2 is seen usually in adults.

**Mode of transmission:** The virus spread from person to person by touching of the affected skin. The virus also spreads by touching a surface with the virus on it, such as a towel, clothing, or toys.

**Age group:** Children and young adults are infected and also commonly seen in HIV patients.

**Appearance of lesions:** Lesions begin as small (3–6 mm) papules that are smooth, flesh-colored domes with a central dimple (umbilication). Inside the papule is a white, curd-like core that can be easily expressed. Occasionally, they may be complicated by secondary bacterial infections.

#### • **Site of lesions:**

- It can occur anywhere on the skin and mucous membranes, but are usually grouped in one or two areas. Occasionally, they may be widely disseminated.
- Common sites: Head, eyelids, trunk, and genitalia (predominant site in adults).

**Treatment:** Imiquimod and Retinoids have been used. Cryosurgery, curettage have also been used in the treatment.

# FUNGAL INFECTIONS

## Candidiasis (Moniliasis)

**Q. Write short note on candidiasis (moniliasis).**

Infection of skin or mucous membranes (e.g. oral cavity and vagina) by *Candida* is known moniliasis.

- **Most *Candida* infections occur when the normal commensal flora breach the skin or mucosal barriers. *Candida* resides normally in the skin, mouth, gastrointestinal tract, and vagina. *Candida* species usually live as benign commensals and does not cause disease in healthy individuals. *Candida* species (usually *C. albicans*), are the most common cause of human fungal infections. *Candidas* are small asexual fungi.**
- *Candida* species are the most common nosocomial pathogens. *Candida albicans* is the most common cause of candidiasis. Candidiasis may be superficial (non-invasive) or invasive (disseminate). Invasive candidiasis can also be due to non-albicans *candida* species (e.g. *C. glabrata*) and some of these are resistant to fluconazole.

### ***Lesions/Conditions Caused Due to Candida***

1. **Oral thrush (refer Fig. 5.7B):** It is characterized by white adherent, painless, discrete or confluent patches in the mouth. Conditions that predispose to oral *candida* infection include use of broad-spectrum antibiotics, xerostomia, immune dysfunction (e.g. diabetes, immunosuppressive therapy, HIV infection, etc.) or the presence of removable prostheses and lichen planus.
2. **Vulvovaginal candidiasis:** More common in diabetics. It presents with pruritus, pain, and vaginal discharge which is usually thin but may appear as whitish 'curds' in severe cases.
3. **Cutaneous candidiasis:** It may present as intertriginous infection (in the skin folds), paronychia (painful swelling at the nail-skin interface) balanitis (infection of the glans penis), Pruritus ani (infection surrounding the anus), vulval candidiasis (in diabetic females) and scrotal candidiasis.
4. **Chronic mucocutaneous candidiasis:** It is a heterogeneous infection of the hair, nails, skin, and mucous membranes which persists in spite of intermittent therapy. The onset is usually in infancy or within the first two

decades of life. It may be mild and limited to a specific area of the skin or nails or may be severe form (*Candida granuloma*). It occurs in immunocompromised patients with leukemias, lymphomas and AIDS.

5. **Deeply invasive candida infections:** It may or may not be due to hematogenous spread.
  - **Esophageal candidiasis (refer Fig. 5.7A):** Deep esophageal infection may result from penetration by organisms from superficial esophageal erosions. It present as a dysphagia and retrosternal pain
  - **Candidiasis of the urinary tract:** It presents with hematogenous renal abscess and bladder thrush. Kidney infection may develop from catheter.
  - **Hematogenous dissemination of candida (invasive candidiasis or candidemia):** *Candida* may enter into the intravascular compartment either from the gastrointestinal tract or, less often, from the skin through the site of an indwelling intravascular catheter. Then it may spread hematogenously to deep organs such as brain, chorioretina, heart, and kidneys. It presents with retinal abscesses (extending into vitreous), pulmonary candidiasis, endocarditis, chronic meningitis and arthritis.

**Table 4.37:** Treatment of candidiasis.

<i>Disease</i>	<i>Treatment</i>
Cutaneous	Topical azole or topical nystatin
Vulvovaginal	Oral fluconazole (150 mg) or azole cream/suppository or nystatin suppository
Thrush	Clotrimazole troches or Nystatin or fluconazole
Esophageal	Fluconazole tablets (100–200 mg/day) or itraconazole solution (200 mg/day) or caspofungin, micafungin, or amphotericin B Therapy should be extended for 3 weeks or 2 weeks after the symptoms subside, whichever is longer
Disseminated candidiasis	Ketoconazole 200–400 mg/day, fluconazole 200 mg/day or itraconazole 100 mg per day for 2 weeks
Severe disseminated candidiasis	Intravenous fluconazole (6 mg/kg/day) or amphotericin B Echinocandins (include caspofungin, micafungin and anidulafungin)

## Diagnosis

- **Visualization of hyphae or pseudohyphae** on wet mount (saline and 10% KOH) preparation or in scrapings from infected lesions under microscope.
- Tissue secretions stained with Gram's stain, periodic acid-Schiff stain, or methenamine silver stain may show candida in association with inflammation.
- In invasive disease from blood cultures.

**Treatment (Table 4.37):** Depends on the site and severity of infection.

## Superficial Mycoses

### **Q. Write short note on superficial mycoses and dermatophytes.**

Superficial mycoses are fungal infections of the outermost keratinized (cornfield) layers of the skin or hair shaft resulting in essentially no pathological changes.

Superficial mycoses along with their etiologic agent are as follows:

- **Pityriasis versicolor:** *Malassezia furfur*
- **Black piedra:** *Piedraia hortae*
- **White piedra:** *Trichosporon beigeli*
- **Tinea nigra:** *Exophiala werneckii*

## ***Pityriasis Versicolor***

**Etiology:** *Malassezia furfur* (*Pityrosporum orbiculare*) which is a lipophilic yeast.

- Normal flora of the superficial epidermis and clusters around the openings of hair follicles.
- Saprophytic on normal skin of trunk, head, neck and **appears in highest numbers in areas with increased sebaceous activity**. Causes superficial chronic infection of stratum corneum.

**Predisposing factors:** Malnutrition, burns, corticosteroid therapy, immunosuppression, depressed cellular immunity, excess heat and humidity. It is associated with increased sweating.

*Clinical presentation*

- Most common in **adolescent and young adult males**.
- **Multiple small, asymptomatic, red to fawn-colored, circular, macules, patches, or follicular papules.** It is hypopigmented. There may be tan to dark brown macules and patches.
- **Most common site: Back, underarm, upper arm, chest, neck** and occasionally on face.
- Microscopy of skin scrapings, shows ‘spaghetti and meatballs’ hyphae. Lesions fluoresce greenish yellow in Wood’s light.

**Treatment:** Topical selenium sulphide or 2% ketoconazole shampoo (apply and remove after 30–60 minutes and repeat daily for 7 days) or a topical imidazole cream (twice daily for 10 days). Oral ketoconazole or oral itraconazole (100 mg twice daily for 1 week) in resistant cases. Altered pigmentation persist for months even after successful treatment.

## ***Dermatophytes***

- Cutaneous fungi are called dermatophytes which are keratinophilic fungi —**they possess keratinase** allowing them to **utilize keratin as a nutrient** and energy source.
- They **infect the keratinized** (horny) **outer layer** of the scalp, glabrous skin, and nails causing tinea or ringworm by secreting keratinase—which degrades keratin with varied clinical manifestations and are caused by species of the fungal genera *Trichophyton*, *Epidermophyton*, and *Microsporum* (in order of commonality).
- **Lesions on skin** and sometimes nails have a **characteristic circular pattern** that was mistaken by ancient physicians as being a worm down in the tissue.
- These lesions are still today called ringworm infections even though the etiology is known to be a fungus rather than a worm.

**Clinical manifestations** of ringworm infections are called different names on basis of location of infection sites (Table 4.38).

**Table 4.38:** Terminology for ringworm infections and location of infection.

<b><i>Terminology</i></b>	<b><i>Location of ringworm infection</i></b>
Tinea capitis	Head, scalp, eyebrows, eyelashes
Tinea favosa	Scalp (crusty hair)
Tinea corporis	Body (smooth skin) (Fig. 4.18A)

Tinea cruris	Groin (jock itch) (Fig. 4.18B)
Tinea unguium	Nails
Tinea barbae	Beard
Tinea manuum	Hand (Fig. 4.18C)
Tinea pedis	Foot (athlete's foot)

## ***Kerion***

- Inflammatory reaction of tinea capitis caused by *Microsporum canis* or *Trichophyton mentagrophyte*.
- Presents as boggy indurated swellings with crusting and loose hairs.
- Hair follicles may discharge pus.
- In extensive lesions, fever, pain and regional lymphadenopathy is present.
- Kerion may be followed by scarring and alopecia in areas of inflammation and suppuration.

## ***Favus***

- Caused by *Trichophyton schoenleinii*.
- Characterized by the presence of yellowish, cup-shaped crusts known as scutula. Each scutulum develops round a hair, which pierces it centrally. The scutula have a distinctive mousy odor.
- Cicatricial alopecia is usually found in long-standing cases.

**Figs. 4.18A to C:** (A) Tinea corporis; (B) Tinea cruris; (C) Tinea manuum.

### **Treatment of mycoses**

- **Topical:** Miconazole, clotrimazole, econazole, terbinafine.
- **Oral:** Griseofulvin, ketaconazole, itraconazole, terbinafine.

# OPPORTUNISTIC MYCOSES

**Q. Write short essay/note on opportunistic mycoses.**

- Occurs in humans with a compromised immune system.
- Causative agents are normal resident flora that becomes pathogenic only when the host's immune defences are altered, as in immunosuppressive therapy, in a chronic disease (e.g. diabetes mellitus), or during steroid or antibacterial therapy that upsets the balance of bacterial flora in the body.

## Etiology (Table 4.39)

### Aspergillosis (refer pages 373-6)

- *Aspergillus* species are **ubiquitous saprophytes** in nature
- In nature >300 species of *Aspergillus* exist, few are important as human pathogens. These include (1) *A. fumigatus*, (2) *A. niger*, (3) *A. flavus*, (4) *A. terreus* and (5) *A. nidulans*.

**Table 4.39:** Common causative agents responsible for opportunistic mycoses.

|--|--|

## Clinical Syndromes

The *Aspergillus* species can cause a variety of clinical syndromes:

- **Pulmonary aspergillosis:** These include allergic asthma, bronchopulmonary aspergillosis, and aspergilloma.
- **Invasive aspergillosis**
- **Superficial infections:** Sinusitis, mycotic keratitis, otomycosis.

**Treatment:** Invasive aspergillosis is treated with intravenous amphotericin B, voriconazoles.

## Mucormycosis

- It represents a group of **life-threatening infections** caused by fungi of the order Mucorales.
- **Rhizopus oryzae** (in the family Mucoraceae) is by far the most

**common** cause of infection.

### ***Risk Factors***

- **Impaired immune system:** Mucormycosis typically **cause infection primarily in patients with diabetes or defects in phagocytic function** (e.g. associated with prolonged neutropenia or glucocorticoid treatment), solid organ or hematopoietic stem cell transplantation (HSCT), or malignancy.
- **Elevated levels of free iron:** Supports fungal growth in serum and tissues. Hence patients with raised levels of free iron also have increased risk. In iron-overloaded patients with end-stage renal failure, treatment with deferoxamine (iron chelator for the human host) predisposes to the development of rapidly fatal disseminated mucormycosis. Deferoxamine serves as a fungal siderophore, directly delivering iron to the mucorales.

### ***Clinical Categories***

Mucormycosis can be divided into at least six clinical categories based on clinical presentation and the involvement of a particular anatomic site. These are (1) rhinocerebral (most common in diabetics), (2) pulmonary (in patients undergoing hematopoietic stem cell transplant), (3) cutaneous, (4) gastrointestinal, (5) disseminated and (6) miscellaneous.

#### *Rhinocerebral mucormycosis*

- The **initial symptoms** of rhinocerebral mucormycosis are **nonspecific** and include **eye or facial pain** and **facial numbness** followed by the onset of **conjunctival suffusion, blurring of vision**, and soft tissue swelling.
- Fever may be absent in up to half of cases, while **white blood cell counts are typically elevated** as long as the patient has functioning bone marrow.
- If untreated, infection usually spreads from the ethmoid sinus to the orbit, resulting in compromise of extraocular muscle function and **proptosis**, typically with **chemosis**. Onset of signs and symptoms in the contralateral eye, with resulting bilateral proptosis, chemosis, vision loss, and ophthalmoplegia, is ominous and suggests the development of cavernous sinus thrombosis.
- Upon visual inspection, infected tissue may appear to be normal during the earliest stages of fungal spread and then progresses through an erythematous phase, with or without edema, before the onset of a

violaceous appearance and finally the development of a black necrotic eschar.

### **Definitive Diagnosis**

- Diagnosis requires a positive culture from a sterile site (e.g. a needle aspirate, a tissue biopsy specimen, or pleural fluid). A probable diagnosis of mucormycosis can be done by culture from a nonsterile site (e.g. sputum or bronchoalveolar lavage).
- Biopsy with histopathologic evidence of invasive mucormycosis is the most sensitive and specific modality for definitive diagnosis. Biopsy reveals characteristic wide (6- to 30- $\mu$ m), thick-walled, ribbon-like, aseptate hyphal elements that branch at right angles

#### **Treatment: Surgical debridement plus**

- Amphoterecin B deoxycholate: 1 mg/kg per day.
- Liposomal AmB (LAmB): 5–10 mg/kg per day. However, dose escalation of LAmB to 10 mg/kg per day for CNS mucormycosis may be considered in light of the limited penetration of polyenes into the brain.
- Amphotericin B lipid complex (ABLC): 5–7.5 mg/kg.
- Echinocandin-lipid polyene combinations in primarily diabetic patients with rhino-orbital-cerebral mucormycosis.

## **Mycetoma**

**Q. Write short note on mycetoma. Write short note actinomycosis.**

- Mycetoma is a **chronic suppurative infection** of the **deep soft tissues and bones**.
- **Most common site** is the **limbs** but can also occur in the abdominal or chest wall or head.

### **Etiology**

Caused by either (1) **aerobic or anaerobic branching gram-positive bacilli, *Actinomycetales*** (actinomycetoma—60%), or (2) by **true fungi, Eumycetes** (eumycetoma—40%).

1. **Actinomycetomas** are caused by **bacteria** such as *Actinomadura*, *Nocardia* and *Streptomyces* spp.
2. **Eumycetes:** Many **fungi** cause eumycetomas. Most common are *Madurella mycetomatis*, *M. grisea*, *Leptosphaeria senegalensis* and

*Scedosporium apiospermum*.

**Colored grains:** Both the above groups characteristically produce colored grains; the color depends on the causative organism. Examples include black grains by eumycetoma, red and yellow grains by actinomycetoma, and white grains by either of them. The disease develops mostly in the tropics and subtropics.

**Mode of infection:** It is acquired **by inoculation** (e.g. from a thorn) and most commonly affects the foot (**Madura foot**).

### ***Clinical Features***

- It begins as a **painless swelling** at the **implantation site**. It becomes chronic and progressively, grows and **spreads within the soft tissues**, and extends into the underlying **bone**. There is usually little pain without fever or lymphadenopathy.
- **Discharging sinuses (Fig. 4.19):** Nodules develop under the epidermis and rupture, producing sinuses through which grains (fungal colonies) may be discharged. Sinuses heal with scarring, while fresh sinuses appear at other places. It can cause progressive disability.
- Deeper soft tissue and bone involvement are less rapid and extensive in eumycetoma than actinomycetoma.

**Fig. 4.19:** Mycetoma.

### ***Diagnoses/Investigations***

- **Demonstration** of fungal grains in pus, and/or causative agent by histopathological examination of tissue.
- **Culture and sensitivity** is needed for identification species and susceptibility testing.
- **Serological tests:** Not available.

## Management

- **Actinomycetoma:** Treated with prolonged antibiotic combinations. Usual combination is streptomycin and dapson, with dapson replaced by co-trimoxazole in cases with intolerance or refractory cases. Other combination includes co-trimoxazole plus amikacin, with rifampicin added in refractory cases and to prevent recurrence.
- **Eumycetoma:** Usually treated with a combination of surgery and antifungal therapy. Most commonly used antifungal drugs are itraconazole and ketoconazole (both 200–400 mg/day). Other drugs include terbinafine monotherapy, voriconazole and posaconazole. Amphotericin B is usually not effective. Therapy is continued for 6–12 months or longer. In extensive and severe cases, amputation may be needed.

## Nocardiosis

- Nocardiosis is a gram-positive bacterial infection caused by aerobic actinomycetes of the genus *Nocardia* found in the soil.
- **Mode of infection:** It is an uncommon infection which occurs most frequently by **direct traumatic inoculation** or occasionally via inhalation or ingestion.

### Clinical features

- **Localized cutaneous infection:** It causes localized cutaneous ulcers or nodules, most frequently in the lower limbs. In tropical countries, chronic destructive infection can produce actinomycetoma (refer above on page 172), involving soft tissues and bone.
- **Systemic *Nocardia* infection:** Occurs mostly in immunocompromised individuals and results in suppurative disease with lung and brain abscesses.

**Microscopic appearance:** *Nocardia* spp. appears as long, filamentous, branching gram-positive rods. They are weakly acid-fast. They can be cultured but need prolonged incubation.

## Treatment

It depends on the result of culture and sensitivity.

- **Systemic infection:** Needs combinations of ceftriaxone, meropenem, amikacin and co-trimoxazole. They are to be given for 6–12 months or longer. Abscesses are drained surgically wherever possible.
- **Localized cutaneous infection:** Usually treated with a single drug for 1–3 months.

Treatment of actinomycetoma (refer above on page 172)

## *Actinomyces israelii*

- *Actinomyces israelii* can produce deep infection in the head and neck, and

suppurating disease in the pelvis associated with intrauterine contraceptive devices (IUCDs).

- **Treatment:** Penicillin or doxycycline.

## PROTOZOAL INFECTIONS

### Malaria

**Q.** Draw a neat labeled diagram of life cycle of the malarial parasite. Discuss the etiology, epidemiology, clinical features, complications, investigations and management of malaria.

**Q.** Discuss the clinical features, diagnosis and management of *P. falciparum* malaria (both uncomplicated and complicated *P. falciform* malaria).

- Malaria is a **protozoan disease** caused by *Plasmodium*. Human malaria is usually caused by one of four species of the genus *Plasmodium* namely (1) *P. falciparum*, (2) *P. vivax*, (3) *P. ovale* and (4) *P. malariae*. Occasionally a species of malaria usually found in primates namely *P. knowlesi* (simian parasite) can affect man.
- *P. falciparum* causes the most severe form of malaria than the other *Plasmodium* species. *P.vivax* is the most common cause of malaria in India.

**Mode of transmission:** By the bite of female anopheline mosquitoes. Malaria can also be transmitted through contaminated blood transfusions.

A comparison of the developmental characteristics of various species of *Plasmodium* is presented in Table 4.40.

**Table 4.40:** Developmental characteristics of various species of *Plasmodium*.

Features	<i>P. falciparum</i>	<i>P. vivax</i>	<i>P. ovale</i>	<i>P. malariae</i>
Duration of erythrocytic cycle	48 hours	48 hours	48 hours	72 hours
Type of red cells parasitized	All	Reticulocytes	Reticulocytes	Mature erythrocytes
Relapse	No	Yes	Yes	No

Drug resistance

Yes

+/-

No

No

## Life Cycle of the Malarial Parasite (Fig. 4.20) and Pathogenesis

### Q. Write short essay on life cycle of malarial parasite.

The life cycle of *Plasmodium* species is simple because it involves only humans and mosquitoes. However, the development of the parasite is complex, because it passes through several morphologically distinct forms. Malarial parasites pass its life cycle in two different hosts namely: (1) human (intermediate host) and (2) female anopheles mosquito (definitive host).

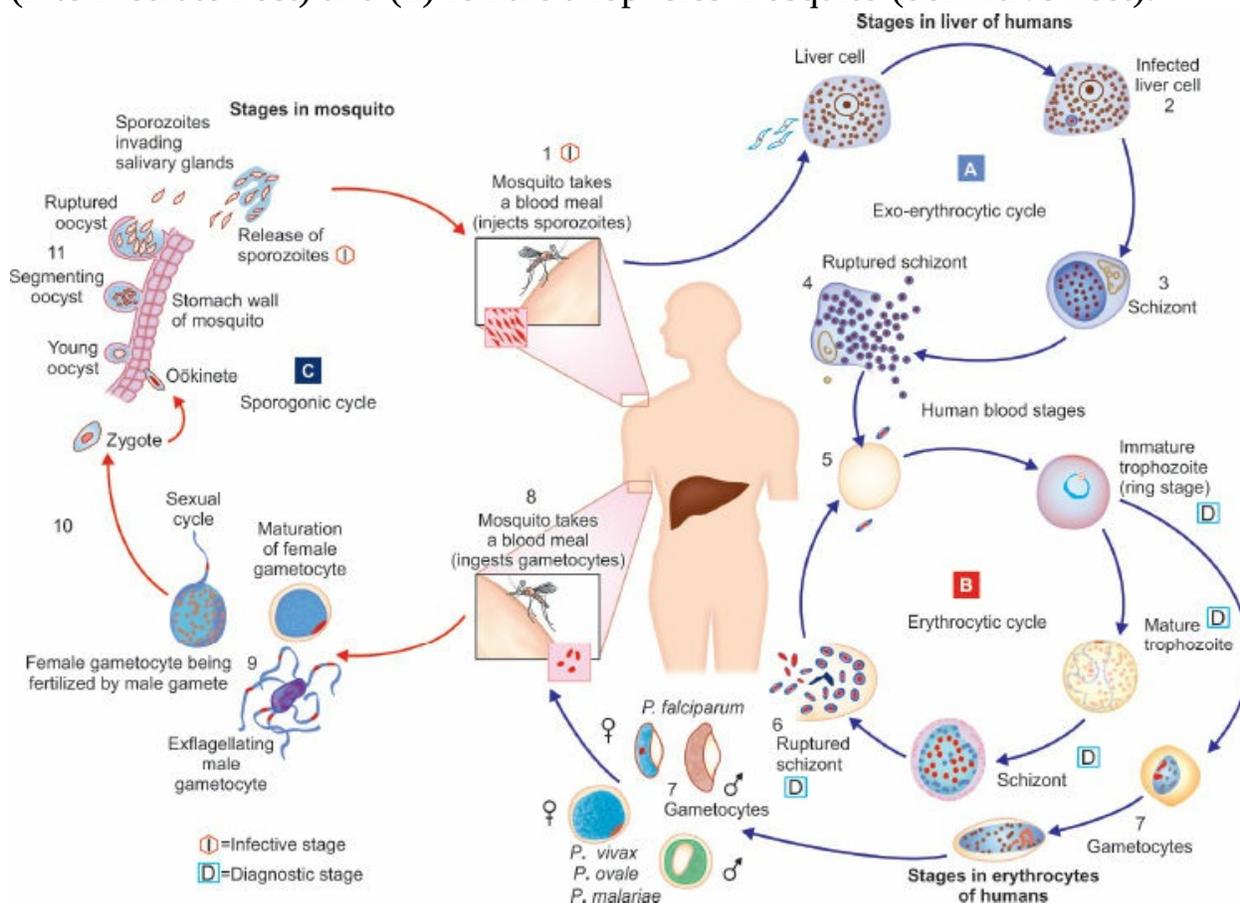

Fig. 4.20: Life cycle of malarial parasites (refer text for description).

### Human cycle (Fig. 4.20)

Human cycle (infection) starts with the introduction of infectious *sporozoite* by the bite of infected female anopheles mosquito. The *sporozoite* is found in the salivary glands of mosquitoes. During mosquito bite, the mosquito takes a blood meal and sporozoites are released into the human's blood. The different stages of human cycle are:

### *Pre-erythrocytic (Primary exoerythrocytic) stage*

Sporozites cannot directly enter erythrocyte to start its erythrocyte stage, but undergoes development inside liver cells. The infection of the liver and development of sporozites into merozoites is referred to as the pre-erythrocytic (exoerythrocytic) stage. Within minutes of entry of sporozites into the human blood, (those which are not destroyed by the immune response) they are carried via the bloodstream and are rapidly (within 30 minute) taken up by the liver. They enter liver cells and these malaria parasites multiply by asexual reproduction (intrahepatic schizogony), releasing about 30,000 *merozoites* (asexual, haploid forms) when each infected liver cells ruptures. This stage is asymptomatic and during this phase, the parasites are not found in the peripheral blood. The infected hepatocytes rupture and release merozoites into the bloodstream.

- During *P. falciparum* infection, rupture of swollen liver cells usually occurs within 8 to 12 weeks. *P. falciparum* and *P. malariae* have no persistent exoerythrocytic phase but a new outbreak of fever may result from multiplication of parasites in red cells which have not been eliminated by treatment and immune processes.
- In contrast, *P. vivax* and *P. ovale* releases merozoites into the bloodstream weeks to months after initial infection.

### *Hypnozoite (latent) stage*

The pre-erythrocytic phase disappears completely in *P. falciparum*, whereas a few parasites persist in the liver cells as dormant forms in *P. vivax* and *P. ovale*. The resting phase of parasite (latent phase) is called as hypnozoite. These hypnozoites are capable of developing into merozoites months or years later, causing relapsing malarial infection. Thus, the first attack of clinical malaria may develop long after the individual has left the endemic area.

### *Erythrocytic stage*

Once merozoites are released from the liver into the blood stream, they rapidly invade erythrocyte by penetration of the membrane. Within the red cells (erythrocytic stage) asexual division occurs.

- **Asexual forms:** In the red cells parasite develop through the stages of asexual forms changing from *merozoite* to *trophozoite*, to *schizont* and finally appearing as 8–24 new *merozoites*. These asexual forms of parasite can be demonstrated in the thick blood smears.

- *Ring form*: It is the first stage of the parasite in the red cell and is characterized by the presence of a single chromatin mass (ring form).
- *Trophozoite*: During this, the parasite assumes an irregular or ameboid shape.
- *Schizont*: It is the next stage the parasite has consumed two-thirds of the RBC's hemoglobin and has grown to occupy most of the cell. It shows multiple chromatin masses, each of which develops into a merozoite. Rupture of the schizont releases merozoites into the blood. This causes fever and the periodicity of fever depends on the species of parasite.
- *Merozoites*: Rupture of the red cell containing merozoites releases the merozoites into the bloodstream. These merozoites are capable of invading additional new erythrocyte and repeating the cycle. The characteristic clinical features of malaria such as paroxysmal fever, chills, and rigors develop during the release of these merozoites into the blood.

Each cycle of the above process is called erythrocytic schizogony. The periodicity of such cycle takes about 48 h in *P. falciparum*, *P. vivax* and *P. ovale* and about 72 h in *P. malariae*. *P. vivax* and *P. ovale* mainly attack reticulocytes and young erythrocytes, whereas *P. malariae* tends to attack old erythrocytes; *P. falciparum* will parasitize any stage of erythrocyte.

- **Sexual forms**: Most malaria parasites within the red cells develop into daughter merozoites. A few merozoites within erythrocytes develop not into trophozoites but undergo a different pathway of development into sexual forms called gametocytes (male and female *gametocytes*). These gametocytes are not released from the red cells until taken up by a feeding mosquito to complete the life cycle. These gametocytes are ingested by the mosquito during a blood meal when mosquito bites the infected human.

### *Mosquito cycle*

A female anopheles mosquito during its blood meal from an infected patient ingests both sexual and asexual forms of parasite, but it is only the mature sexual forms (gametocytes) capable of development.

- The male and female gametocytes of malarial parasite fuse inside the mid-gut (stomach) of the mosquito to form a **zygote**.
- The zygote matures to form an ookinete, which penetrates the gut wall and

form an **oocyst**.

- The oocyst matures and forms numerous **sporozoites**. These sporozoites have special predilection towards the **salivary glands** and reach maximum concentration in the salivary ducts of mosquito. The mosquito at this stage is capable of transmitting malarial infection.
- During the blood meal these sporozoites are **inoculated into the new human host**, thus completing the life cycle of *Plasmodium*.

### ***Protection Against Malaria***

- Red blood cells containing hemoglobin F, C or S impair growth of *P. falciparum* parasite. Patients with hemoglobin S especially heterozygotes (AS) are protected against the lethal complications of malaria.
- Attachment of merozoites to red blood cells is mediated via a specific erythrocyte surface receptor. In *P. vivax*, this receptor is related to the Duffy blood group antigen (Fy<sup>a</sup> or Fy<sup>b</sup>). Thus, an individual who is Duffy-negative (as most of the West African population) will be resistant to infection by *P. vivax*.

### ***Clinical Features***

Malaria is a very common cause of fever in tropical countries. The first symptoms of malaria are nonspecific.

#### *P. vivax and P. ovale malaria*

- **Incubation period** for *P. vivax* is 12–17 days, and for *P. ovale* is 15–18 days.
- **Prodromal symptoms** include headache, fatigue, abdominal discomfort, and muscle aches. These are more severe with *P. malariae* infections.
- **Fever:** The most common symptom of these ‘benign’ malarias is paroxysms of fever. Fever starts with a rigor. The febrile paroxysm synchronizes with erythrocytic stage of the parasite.
  - Tertian fever: In *P. vivax* and *P. ovale* malaria infections, the fever recurs every third day (tertian) interval (with 48 hours cycle between spikes).
- ***P. vivax*:** Patients suffering from *P. vivax* malaria may develop **anemia, thrombocytopenia and mild jaundice** with tender hepatosplenomegaly. **Splenic rupture is more common.** Occasionally, *P. vivax* malaria

presently develops complications similar to those of *P. falciparum* malaria.

- ***P. ovale***: The acute symptoms of *P. ovale* may be as severe as those of *P. vivax* infection, but **anemia is less severe** and the risk of **splenic rupture is less common**.
- ***P. vivax* and *P. ovale***: They have a persistent hepatic cycle and a few parasites persist in the liver cells as dormant forms. This may give rise to relapses.

#### *P. malariae* malaria

- **Incubation period: 18–40 days**
- **Prodromal symptoms** include headache, fatigue, abdominal discomfort, and muscle aches and may be more severe than *P. vivax*.
- **Fever**: The febrile paroxysm synchronizes with erythrocytic stage of the parasite.
  - Quartan fever: In *P. malariae* infections, the fever recurs every fourth day (quartan) interval (72 hours interval between spikes).
- It is associated with gross splenomegaly, but **splenic rupture is less common** and **anemia is less severe**. Chronic *P. malariae* infections cause **glomerulonephritis and nephrotic syndrome**. *P. malariae* does not relapse, but a persisting undetectable parasitemia may produce repeated exacerbations and the risk of **splenic rupture is less common**.

#### *P. falciparum* malaria (malignant tertian or subtertian malaria)

#### **Q. Write short essay on falciparum malaria.**

- It is the **most dangerous** type of malarias and patients may be either **‘killed or cured’**.
- **Incubation period**: 7–14 days (mean 12 days).
- **Prodromal symptoms**: Onset is often insidious, with malaise, headache, myalgia, anorexia and vomiting.
- **Fever**: Patients develop mild fever having no particular pattern and may last for several days before the onset of the classical ‘malarial paroxysms’.
  - A high irregularly spiking unremitting fever or daily (quotidian) paroxysm is more commonly seen in falciparum malaria but usually due to mixed infection (falciparum plus vivax).

- **Physical findings:** Patient is often anemic and jaundiced with moderate tender hepatosplenomegaly.
- **Neurological complications** can manifest as acute headache, irritability, agitation, seizures, psychosis and impaired consciousness.

Box 4.14 lists the jaundice in malaria.

#### Box 4.14: *Jaundice in malaria.*

Causes: Jaundice may be due to severe hemolysis and hepatic involvement (malarial hepatopathy) by malaria.

- **Hemolysis:** The malarial parasite, especially *P. falciparum* infects a large number of RBCs. These are destroyed in the spleen and result in hemolytic anemia. It produces elevation of serum bilirubin (dominant unconjugated fraction) level without any significant elevation of the liver enzymes.
- **Malarial hepatitis (malarial hepatopathy):** This term is used to describe dysfunction of liver cells in severe and complicated malaria. However, inflammation of the liver parenchyma is never observed

### Severe manifestations and complications of falciparum malaria

#### Q. Write short essay on:

- **Complications of malaria**
- **Complications of falciparum malaria.**
- WHO defines complicated falciparum malaria as one of the features shown in the Table 4.41 along with presence of asexual forms of *P. falciparum* in the peripheral smear. Acute renal failure, acute respiratory distress syndrome and jaundice are uncommon in children.
- At highest risk of complications from malaria are nonimmune people, and children and pregnant females who live in endemic regions.

#### *Cerebral malaria*

#### Q. Write short essay on clinical features and treatment of cerebral malaria.

#### Q. Write long essay on cerebral malaria-etiopathogenesis, clinical features and management.

**Definition:** Cerebral malaria is defined as diffuse encephalopathy in a patient with falciparum malaria which is not attributable to any other cause.

**Features:** Cerebral malaria manifests as diffuse symmetric encephalopathy.

## Neurological

- **Convulsions:** Usually generalized and often repeated. They occur in both children (50%) and adults (10%) but are more common in children.
- Most common neurological signs in adults are those of a symmetrical upper motor neuron lesion. The abdominal reflexes and cremasteric reflexes are absent.
- Mild neck stiffness may be seen, however, neck rigidity and photophobia and signs of raised intracranial tension are absent. Retinal hemorrhages occur in about 15% of cases, exudates are rare.
- Motor abnormalities like decerebrate rigidity, decorticate rigidity and opisthotonus occur.
- Fixed jaw closure and tooth grinding (bruxism) are common.
- Neuropsychiatric manifestations, cerebellar signs, extrapyramidal syndromes and multiple cranial nerve involvement are common in Indian patients.
- **Residual neurological sequelae:** They develop in about 5% of adults and 10% of children. These include hemiplegia, cerebral palsy, cortical blindness, deafness aphasia and ataxia. They are more frequent in patients with prolonged deep coma, repeated convulsions, those with hypoglycemia and severe anemia.

**Table 4.41:** Criteria for severe and complicated malaria.

<i>Manifestation</i>	<i>Features</i>
<b>World Health Organization criteria from 1990</b>	
1. Cerebral malaria	Unarousable coma not attributable to any other cause, with a Glasgow Coma Scale score $\leq 9$ ; Coma should persist for at least 30 min after a generalized convulsion
2. Severe anemia	Hematocrit $< 15\%$ or hemoglobin $\leq 5$ g/dL the presence of parasite count $> 10000/\mu\text{L}$
3. Renal failure	Urine output $< 400$ mL/24 hours in adults ( $< 12$ mL/kg/24 hours in children) and a serum creatinine $> 265$ $\mu\text{mol/L}$ ( $> 3.0$ mg/dL) despite adequate volume repletion
4. Metabolic (lactic) acidosis	Metabolic acidosis is defined by an arterial blood pH of $< 7.35$ with a plasma bicarbonate concentration of $< 22$ mmol/L; hyperlactatemia is

	defined as a plasma lactate concentration of 2–5 mmol/L and lactic acidosis is characterized by a pH <7.25 and a plasma lactate >5 mmol/L.
5. Pulmonary edema or acute respiratory distress syndrome (ARDS)	Breathlessness, bilateral crackles, and other features of pulmonary edema. The acute lung injury score is calculated on the basis of radiographic densities, severity of hypoxemia, and positive end-expiratory pressure
6. Hypoglycemia	Whole blood glucose concentration of less than 2.2 mmol/L (less than 40 mg/dL)
7. Hypotension and shock (algid malaria)	Systolic blood pressure <50 mm Hg in children 1–5 years or <70 mm Hg in patients ≥5 years; cold and clammy skin or a core-skin temperature difference >10 °C
8. Abnormal bleeding and/or disseminated intravascular coagulation	Spontaneous bleeding from the gums, nose, gastrointestinal tract, retinal hemorrhages and/or laboratory evidence of disseminated intravascular coagulation
9. Repeated generalized convulsions	≥3 generalized seizures within 24 hours
10. Hemoglobinuria	Macroscopic black, brown or red urine; not associated with effects of oxidant drugs or enzyme defects (like G6PD deficiency)

#### **Added World Health Organization criteria from 2000**

11. Impaired consciousness	Various levels of impairment may indicate severe infection although not falling into the definition of cerebral malaria. These patients are generally arousable.
12. Prostration	Extreme weakness, needs support
13. Hyperparasitemia	5% parasitized erythrocytes or >250,000 parasites/μL (in nonimmune individuals)
14. Hyperpyrexia	Core body temperature above 40 °C
15. Jaundice (Hyperbilirubinemia)	Plasma or serum bilirubin >50 μmol/L (3 mg/dL)

#### **Other (Not included in WHO)**

16. Severe thrombocytopenia	Platelet counts less than 10,000/cumm
17. Fluid and electrolyte disturbances	Dehydration, postural hypotension, clinical evidence of hypovolemia
18. Vomiting of oral drugs	Patients with persistent vomiting may have to be admitted for parenteral therapy.
19. Complicating or associated infections	Aspiration bronchopneumonia, septicemia, urinary tract infection, etc.
20. Malarial retinopathy	In children dying with cerebral malaria, malarial

retinopathy was found to be a better indicator of malarial coma. Similar retinopathy in an adult has also been reported

### *Ophthalmological*

- **Eyes** may be divergent and a pout reflex may be elicited by stroking the sides of the mouth. The corneal reflexes are preserved (except in deep coma). Transient abnormalities of eye movement (especially dysconjugate gaze) may be found.
- **Ophthalmoscopy:** Retinal hemorrhages may occur and indicate a poor prognosis. Papilledema is rare.

### *Bad prognostic signs*

- Include prolonged impaired consciousness, respiratory failure, renal failure, jaundice and hypoglycemia.
- The CSF pressure is usually normal. The fluid is clear with less than 10 cells/ $\mu\text{L}$ , CSF lactic acid and protein levels are elevated.
- Cerebral malaria carries a mortality of around 20% in adults and 15% in children. Residual deficits are unusual in adults (<3%). Box 4.15 lists the causes of neurological manifestations in malaria other than hyperparasitemia.

### **Box 4.15:** *Causes of neurological manifestations in malaria other than hyperparasitemia.*

- **High-grade fever**
- **Antimalarial drugs** like chloroquine, quinine, mefloquine and halofantrine.
- **Hypoglycemia**, either due to severe malaria or due to drugs like quinine.
- **Hyponatremia**, most often in the elderly.
- **Severe anemia** and hypoxemia can also cause cerebral dysfunction, particularly in children.

### *Anemia (Box 4.16)*

#### *Renal failure*

- Acute kidney injury is common in severe falciparum malaria and usually occurs in adults. It causes progressive oliguria eventually resulting in anuria. It is accompanied by progressive increase serum creatinine and urea levels. It is usually reversible.
- Caused by renal cortical vasoconstriction and resultant hypoperfusion, sequestration and resultant acute tubular necrosis due to microvascular

obstruction and due to massive intravascular hemolysis in black water fever.

- Dehydration and hypovolemia can lead to renal hypoperfusion, but this is reversible with adequate rehydration.

#### **Box 4.16:** *Causes of anemia in malaria.*

- Hemolysis of
  - infected red cells
  - noninfected red cells (black water fever)
- Dyserythropoiesis
- Splenomegaly causing
  - Erythrocyte sequestration
  - Hemodilution
- Depletion of folate stores
- Hemorrhage secondary to thrombocytopenia/DIC
- Iron deficiency secondary to RBC breakdown

#### *Hypoglycemia*

- Hypoglycemia is an important and common complication of severe falciparum malaria. It is particularly problematic occurs in three groups of patients:
  1. Children with severe disease
  2. Patients treated with quinine or quinidine
  3. Pregnant women (either on admission or following quinine treatment)
- **Mechanism:** In malaria, hypoglycemia develops due to various mechanisms (Box 4.17).

#### **Box 4.17:** *Causes of hypoglycemia in malaria.*

- Failure to hepatic gluconeogenesis
- Increased consumption of glucose by host and malaria parasite.
- Treatment with quinine or quinidine. Both these drugs strongly stimulate pancreas to secrete insulin. This produces hyperinsulinemia resulting in hypoglycemia.

#### *Fluid, electrolyte and acid-base disturbances*

- **Hypovolemia:** Characterized by low jugular venous pressure, postural hypotension, oliguria and high urine specific gravity. This may be associated with signs of dehydration.
- **Acidotic breathing:** It may develop in severely ill patients in shock,

hypoglycemia, hyperparasitemia and renal failure.

- **Lactic acidosis:** It is a common complication and associated with raised lactic acid levels both in blood and CSF.

#### *Noncardiogenic pulmonary edema*

- It is a serious complication of severe falciparum malaria in adults. It carries a high mortality rate (>80%). It can also develop in otherwise uncomplicated vivax malaria, where recovery is usual.
- It may develop several days after antimalarial therapy and at a time when the patient's general condition is improving.
- Noncardiogenic pulmonary edema is associated with hyperparasitemia, renal failure, pregnancy, hypoglycemia and lactic acidosis. It is aggravated by vigorous administration of IV fluid.

#### *Circulatory collapse ('Algid malaria')*

- **Algid malaria** or hypotension due to peripheral circulatory failure may develop suddenly in severe malaria or it may be the presenting feature in some cases of malaria, with a systolic blood pressure less than 80 mm Hg in the supine position [less than 50 mm Hg in children], a cold, clammy, cyanotic skin, constricted peripheral veins and rapid feeble pulse.
- This clinical picture is often associated with a complicating gram-negative septicemia and possible sites of associated infection should be sought in such patients, e.g. lung, urinary tract (especially if there is an indwelling catheter), meninges (meningitis), intravenous injection sites, intravenous lines, etc.
- Circulatory collapse is also observed in patients with pulmonary edema, metabolic acidosis, massive gastrointestinal hemorrhage, dehydration and hypovolemia.
- Blood and urine culture should be done. Soon after collection of the specimen for culture, broad-spectrum antibiotics should be started.

#### *Malarial hemoglobinuria (**Black water fever**)*

- Malaria hemoglobinuria is uncommon, and is usually associated with hyperparasitemia and/or severe disease. It may or may not be accompanied by renal failure.
- Patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency and other erythrocyte enzyme deficiencies may develop vascular hemolysis

and hemoglobinuria when treated with oxidant drugs such as primaquine.

- **Black water fever** typically occurs in nonimmune patients with chronic falciparum malaria, taking antimalarials (especially quinine and primaquine) irregularly. It occurs more commonly in patients with G6PD deficiency.
- The hemolysis can occur so rapidly that the hemoglobin may drop significantly within a few hours and it may recur periodically at intervals of hours or days. Patient presents with head ache, nausea, vomiting and severe pain in the loins and prostration. Fever up to 39.4°C with a rigor is also seen. Urine is dark red to almost black. Box 4.18 lists the chronic complications of malaria.

#### **Box 4.18:** Chronic complications of malaria.

- Tropical splenomegaly syndrome
- Quatran malarial nephropathy
- Burkitt's lymphoma

### ***Investigations and Diagnosis***

#### **Q. Write short essay on laboratory tests in the diagnosis of malaria.**

Malaria should be considered in the differential diagnosis of febrile illness.

#### *Microscopic demonstration of parasite*

- **Peripheral smear examination:** The diagnosis of malaria depends on the demonstration of asexual forms of the parasite in stained peripheral-blood smears. Both thin and thick smears should be examined whenever malaria is suspected. Smears are stained by one of the Romanowsky stains (e.g. Wright's, Field's, Leishman's or Giemsa).
- **Bone marrow aspirate:** Sometimes parasites cannot be detected in peripheral blood smears, even in patient with severe malarial infections. This may be due to partial antimalarials treatment or by sequestration of parasitized cells in deep vascular beds. In these circumstances examination of smears of bone marrow aspirate reveals parasites or malaria pigment.
- **Alternative microscopic methods** have been tried, including faster methods of preparation, dark-field microscopy, and stains like *benzothiocarboxypurine*, *acridine orange* and *Rhodamine-123*.
- **Quantitative buffy coat analysis (QBC):** It is an alternative and probably

more sensitive test than the peripheral smear for detecting the malarial parasite. In this test, the centrifuged buffy coat is stained with a flurochrome (e.g. acridine orange) that ‘lights up’ (microtube concentration methods with acridine orange staining) malarial parasites. The buffy coat smear is viewed under fluorescence microscopy.

### Immunodiagnosis

**Serological techniques:** They can detect malarial antibodies, but these tests are not specific and are not done routinely. The tests include immunofluorescent assay (IFA) and enzyme-linked immunosorbent assay (ELISA).

Table 4.42 shows comparison of rapid diagnostic tests for malaria antigens.

### PCR testing

- Molecular diagnosis by polymerase chain reaction (PCR) amplification of parasite nucleic acid (for parasite messenger RNA or DNA) is more sensitive than microscopy or rapid diagnostic tests.

**Table 4.42:** Comparison of rapid diagnostic tests for malaria antigens.

	<i>PfHRP2 tests</i>	<i>PfHRP2 and PMA test</i>	<i>pLDH test</i>
<b>Target antigen</b>	Histidine rich protein 2 of <i>P. falciparum</i> , water soluble protein expressed on RBC membrane	Pan-specific <i>Plasmodium</i> aldolase, parasite glycolytic enzyme produced by all species and PfHRP2	Parasite lactate dehydrogenase, parasite glycolytic enzyme produced by all species
<b>Capability</b>	Detects <i>P. falciparum</i> only	Can detect all 4 species	Can detect all 4 species
<b>Detection limit</b>	>40–100 parasites/μL	Higher for <i>P. vivax</i> and other non-falciparum species	>100–200 parasites/μL for <i>P. falciparum</i> and <i>P. vivax</i> ; may be higher for <i>P. malariae</i> and <i>P. ovale</i>
<b>Cross-reactivity with autoantibodies</b>	Reported, high (up to 83% with rheumatoid factor)	Not known	Reported low (3.3% with rheumatoid factor)
<b>Indication of viability of parasites</b>	No	No	Positive test indicates presence of viable parasitemia

### Other laboratory findings

- **Blood:**
  - Normochromic normocytic anemia, thrombocytopenia.
  - Total leukocyte count is low to normal, but neutrophil leukocytosis may be observed in severe infections.
- **Acute-phase protein:** ESR (erythrocyte sedimentation rate), plasma viscosity, and levels of C-reactive protein are high.
- **Coagulation study:** In severe infections, prothrombin time and partial thromboplastin time may be prolonged and antithrombin III levels are decreased.
- **Other findings in severe malaria:** In complicated malaria there may be metabolic acidosis and:
  - Low plasma concentrations of glucose, sodium, bicarbonate, calcium, magnesium and albumin.
  - Elevated levels of lactate, BUN, creatinine, muscle and liver enzymes, bilirubin, and gamma globulin.
- **Neuroimaging in cerebral malaria** may show brain swelling, cortical infarcts and hyperintense areas in white matter.

### Q. Write short essay on:

- **Treatment of uncomplicated falciparum malaria**
- **Drugs used in resistant malaria/drug resistant malaria. Drugs for resistant falciparum malaria.**
- **Radical treatment of malaria**
- **Name antimalarial drugs**

### Management/Treatment

Aims of treatment are presented in Table 4.43.

To **counter the threat of resistance of *P. falciparum*** to monotherapies, and to improve treatment outcome, **combinations of antimalarials are now recommended** by WHO for the treatment of falciparum malaria. **Two or more blood schizontocidal drugs** with independent modes of action and thus unrelated biochemical targets in the parasite are used and at present Artemisinin-based Combination Therapy (ACT) is the recommended treatments for uncomplicated falciparum malaria.

- **Artemisinin-based Combination Therapy (ACT)**
- Artemisinin and its derivatives (artesunate, artemether, artemotil, and dihydroartemisinin) **produce rapid clearance of parasitemia** and rapid resolution of symptoms. They reduce parasite numbers by a factor of approximately 10,000 in each asexual cycle, which is more than other current antimalarials (which reduce parasite numbers 100- to 1000-fold per cycle). Artemisinin

and its derivatives are eliminated rapidly.

- When given in combination with rapidly eliminated compounds (tetracyclines, clindamycin), a 7-day course of treatment with an artemisinin compound is required; but when given in combination with slowly eliminated antimalarials, shorter courses of treatment (3 days) are effective.

**Non-artemisinin based combinations (non-aCTs)** include sulfadoxine –pyrimethamine with chloroquine (SP+CQ) or amodiaquine (SP+AQ). However, the prevailing high levels of resistance have compromised the efficacy of these combinations. There is no convincing evidence that SP+CQ provides any additional benefit over SP, so this combination is not recommended.

- The ACT used in the national program in India is artesunate + sulfadoxine + pyrimethamine. It is given as:
  - 200 mg artesunate along with sulfadoxine 1500 mg and pyrimethamine 75 mg on day 1.
  - 200 mg artesunate on days 2 and 3.
- Another option is to use quinine 600 mg salt three times daily for 5 days orally, followed by a single dose of sulfadoxine 1.5 g combined with pyrimethamine 75 mg.
- ACTs can be given in second and third trimester of pregnancy. Recommended treatment in first trimester of pregnancy is quinine.
- If sulfonamide sensitivity is suspected, quinine may be followed by tetracycline 250 m 6 hourly for 7 days.

**Box 4.19:** Chemoprophylaxis of malaria.

- For short-term chemoprophylaxis (less than 6 weeks), doxycycline in a dose of 100 mg daily. It should be started 2 days before travel and continued for 4 weeks after leaving the malarious area.
- For long-term chemoprophylaxis (more than 6 weeks), mefloquine in a dose of 5 mg/kg (up to 250 mg) weekly. It should be administered 2 weeks before, during and 4 weeks after leaving the area.

Chemoprophylaxis of malaria is presented in Box 4.19.

**Table 4.43:** Aims of treatment.

<b>Aims</b>	<b>Causation</b>	<b>Therapy</b>	<b>Drugs</b>
<b>To alleviate symptoms</b>	Symptoms are caused by blood forms of the parasite	Blood schizonticidal drugs	Chloroquine, quinine, artemisinin combinations
<b>To prevent relapses</b>	Relapses are due to hypnozoites of <i>P. vivax/P. ovale</i>	Tissue schizonticidal drugs	Primaquine
<b>To prevent spread</b>	Spread is through the gametocytes	Gametocytocidal drugs	Primaquine for <i>P. falciparum</i> , Chloroquine for all other

- Other drugs for treating chloroquine resistant *P. falciparum* are mefloquine (15 mg/kg followed by 10 mg/kg after 8 hours; generally given as ACT) and halofantrine. Recently, dihydroartemisinin (4 mg/kg/day) + Piperaquine (18 mg/kg/day) combination for three days has been available.

- Summary of treatment of malaria is presented in Table 4.44.

**Radical cure of malaria due to *P. vivax* and *P. ovale*.**

- Primaquine is given at a dose of 15 mg daily for 14 days. It destroys the hypnozoite phase in the liver.

Table 4.45 outlines the treatment of severe malaria.

Management of severe manifestations and complications of falciparum malaria is presented in Table 4.46. Recommendations for treatment of uncomplicated *P. falciparum* malaria in pregnancy is mentioned in Table 4.47.

**Table 4.44: Summary of treatment of malaria.**

<b>Type of infection</b>	<b>Suppressive treatment</b>	<b>Radical treatment</b>
<i>P. vivax</i> and <i>P. ovale</i>	Chloroquine 25 mg of salt/kg over 36–48 hours	Primaquine 0.25 mg/kg for 14 days
<i>P. malariae</i> and <i>P. knowlesi</i>	Chloroquine 25 mg of salt/kg over 36–48 hours	None
<i>P. falciparum</i>	Treatment depends on severity and sensitivity Artesunate + pyrimethamine-sulphadoxine or other ACTs, OR quinine plus tetracycline	Primaquine 0.75 mg/kg in single dose as gametocytocidal
Mixed ( <i>P. vivax</i> + <i>P. falciparum</i> )	ACT as for <i>P. falciparum</i>	Primaquine as for <i>P. vivax</i>

**Table 4.45: Treatment of severe malaria.**

<b>First drug</b>	<b>Follow-on treatment (Full course of any ACT)</b>
Artesunate 2.4 mg/kg body weight (bw) IV or IM on admission; then at 12 h and 24 h, then once a day for at least 24 hours, followed by full course of ACT OR	<ul style="list-style-type: none"> <li>• Artesunate plus sulfadoxine-pyrimethamine</li> <li>• Artesunate plus amodiaquine</li> <li>• Artesunate plus clindamycin or doxycycline</li> </ul>
Artemether 3.2 mg/kg bw IM given on admission then 1.6 mg/kg bw per day for at least 24 hours, followed by full course of ACT	<ul style="list-style-type: none"> <li>• Artemether plus lumefantrine</li> <li>• Dihydroartemisinin+Piperaquine</li> </ul>
Quinine, 20 mg salt/kg bw on admission (iv infusion or divided IM injection), then 10 mg/kg bw every 8 h; infusion rate should not exceed 5 mg salt/kg bw per hour; course for 3 days	Doxycycline 100 mg BID (2.2 mg/kg BID for <45 kg) for 7 days OR clindamycin 20 mg base/kg/day divided in three doses for 7 days in pregnancy

**Table 4.46: Management of severe manifestations and complications of falciparum malaria.**

<b>Manifestation/complication</b>	<b>Immediate management (in addition to antimalarial treatment)</b>
Coma (cerebral malaria)	Maintain airway, place patient on his or her side, exclude other treatable causes of coma (e.g. hypoglycemia, bacterial meningitis); avoid harmful ancillary treatment such as corticosteroids, heparin and adrenaline; intubate if necessary
Hyperpyrexia	Administer tepid sponging, fanning, cooling blanket and antipyretic drugs
Convulsions	Maintain airways; treat promptly with intravenous or rectal diazepam or intramuscular paraldehyde
Hypoglycemia	Check blood glucose, correct hypoglycemia and maintain with glucose-containing infusion
Severe anemia	Transfuse with screened fresh whole blood
Acute pulmonary edema	Over-enthusiastic rehydration should be avoided so as to prevent pulmonary edema. Prop patient up at an angle of 45°, give oxygen, give a diuretic, stop intravenous fluids, intubate and add positive end-expiratory pressure/continuous positive airway pressure in life-threatening hypoxemia
Acute renal failure	Exclude prerenal causes, check fluid balance and urinary sodium; if in established renal failure add hemofiltration or hemodialysis, or if unavailable, peritoneal dialysis. The benefits of diuretics/dopamine in acute renal failure are not proven
Spontaneous bleeding and coagulopathy	Transfuse with screened fresh whole blood (cryoprecipitate, fresh frozen plasma and platelets if available); give vitamin K injection
Metabolic acidosis	Exclude or treat hypoglycemia, hypovolemia and septicemia. If severe add hemofiltration or hemodialysis
Shock	Suspect septicemia, take blood for cultures; give parenteral antimicrobials, correct hemodynamic disturbances
Hyperparasitemia	Treat with artemisinins, intravenously or orally

**Table 4.47:** Recommendations for treatment of uncomplicated *P. falciparum* malaria in pregnancy.

<b>First trimester</b>	Quinine + clindamycin for 7 days. ACT should be used if it is the only effective treatment available
------------------------	--

**Second and third trimesters**

ACT known to be effective in the country/region or artesunate + clindamycin to be given for 7 days or quinine + clindamycin to be given for 7 days

**Q. Write short note on uses of chloroquine (conditions in which chloroquine is used).**

Uses of chloroquine are listed in Box 4.20.

**Box 4.20:** Uses of chloroquine.

- Drug of choice for clinical cure and suppressive prophylaxis of all types of malaria, except that caused by resistant *P. falciparum*
- Extraintestinal Amebiasis
- Rheumatoid arthritis, SLE, chikungunya
- Discoid lupus erythematosus
- Lepra reactions
- Photogenic reactions
- Infectious mononucleosis (symptomatic relief)

### ***Tropical Splenomegaly Syndrome (TSS)***

**Q. Write short essay/note on tropical splenomegaly syndrome (TSS).**

**Tropical splenomegaly syndrome** or big spleen disease, also known as **hyper-reactive malarial splenomegaly** is massive enlargement of the spleen resulting from abnormal immune response to repeated attacks of malaria. It is seen among residents of endemic areas of malaria.

It is one of the chronic complications of malaria.

#### *Etiopathogenesis*

- Chronic or repeated malarial infections produce hypergammaglobulinemia; normocytic normochromic anemia; and massive splenomegaly.
- TSS syndrome is characterized by the production of cytotoxic IgM antibodies to CD8<sup>+</sup> T lymphocytes, antibodies to CD5<sup>+</sup> T lymphocytes, and an increase in the ratio of CD4<sup>+</sup> to CD8<sup>+</sup> T cells. These result in continuous IgM production by B cell and the formation of cryoglobulins (IgM aggregates and immune complexes). This stimulates reticuloendothelial hyperplasia and leads to splenomegaly.

#### *Clinical features*

- Anemia and some degree of pancytopenia are usually found.
- There is increased vulnerability to respiratory and skin infections and many may die due to overwhelming sepsis.
- Physical examination shows massive splenomegaly, hepatomegaly and occasionally low-grade fever.
- The disease generally runs a benign course. Portal hypertension does not develop and the condition is reversible with antimalarial treatment. Some may evolve into malignant lymphoproliferative disorder (e.g. CLL).

### *Diagnosis of TSS*

- **Antimalarial antibodies:** High levels of antimalarial antibodies are found in blood. IgM levels are markedly elevated (up to 20 times).
- There is increase in the serum levels of polyclonal IgM with cryoglobulinemia, reduced C3 and the rheumatoid factor may be positive.
- **Liver biopsy:**
  - Light microscopy of liver shows sinusoidal lymphocytosis and Kupffer cell hyperplasia.
  - **Immunofluorescence microscopy** shows IgM aggregates phagocytosed by RE cells.
- **Peripheral blood:** The peripheral smear shows normocytic normochromic anemia with increased reticulocyte count. Leukopenia and thrombocytopenia may also be seen due to hypersplenism. **Malarial parasites are not found** in the peripheral blood.

### **Treatment of tropical splenomegaly syndrome**

- Chloroquine weekly or proguanil daily have been found to be useful. These drugs may have to be continued for long periods, possibly for life.
- Severe anemia may require blood transfusion.
- Splenectomy may do more harm than good and it may be beneficial in only patients with splenic lymphoma.
- Splenic irradiation or antimetabolic therapy are not beneficial and may be even dangerous.

### **Malaria vaccines**

**Q. Write short note on malarial vaccines.**

#### **Vaccine types**

The candidate malaria vaccines target the different phases of the parasite's life cycle.

- **The pre-erythrocytic vaccines** target sporozoites or schizont infected liver cells and is aimed at preventing infection by stopping the progression of hepatic stage. Even a single sporozoite

escaping vaccine-induced immunity may cause a fully pathogenic blood stage infection, as was found during the clinical trials of the latest antsporozoite RTS, S vaccine.

- **The erythrocytic stage** vaccines are aimed at reducing parasite multiplication and growth in order to protect against clinical disease, particularly severe disease. These vaccines are designed to induce antibody responses against the targets on the asexual blood stage of the parasite such as merozoite surface proteins (such as MSP-1) or those contained in specialized organelles associated with invasion (such as AMA-1). But, the very short duration during which merozoites stay outside the red cells (about 2 minutes), the high degree of polymorphic variability, and the use of alternative invasion pathways by *P. falciparum*.
- **Transmission-blocking vaccines** are aimed at reducing malaria transmission by interrupting the parasite life-cycle in the mosquito by inducing antibodies that prevent either fertilization of the gametes in the mosquito gut or the further development of the zygote into sporozoites. These vaccines do not protect the immunized individual but rather provide herd benefit. **antidisease vaccination**, by preventing the parasite surface protein parasite-derived *Plasmodium falciparum* erythrocyte membrane protein 1 (PfEMP1) from interacting with various vascular endothelial cell-surface receptors, may block the sequestration of parasite-infected erythrocytes and prevent the serious complications such as cerebral malaria or placental malaria.

All these vaccines are in clinical trial stages. RTS, S is the most recently developed recombinant vaccine. It consists of the *P. falciparum* circumsporozoite protein from the pre-erythrocytic stage has been approved to vaccinate children aged 6 weeks to 17 months outside the European Union.

## Leishmaniasis

### Q. Write short note on Leishmaniasis.

Leishmaniasis is a group of diseases caused by unicellular, flagellate, intracellular protozoa of the genus *Leishmania*, which are transmitted by the bite of the **female phlebotomine sandfly**.

### *Clinical Syndromes*

#### *Visceral Leishmaniasis (Kala-azar)*

### Q. Write short note on kala-azar or visceral leishmaniasis.

Visceral leishmaniasis (kala-azar) is a generalized visceral infection caused by the protozoon *Leishmania donovani* complex (comprising *L. donovani*, *L. infantum* and *L. chagasi*).

#### *Epidemiology*

**Mode of transmission:** Sandfly of the Genera Phlebotomus.

- **Endemic:**

- Kala-azar is endemic in several countries. More than 90% of visceral leishmaniasis are found in India, Bangladesh, Southern Sudan, Nepal and Brazil.

– In India, it is endemic in the states of Bihar, West Bengal, Eastern parts of Uttar Pradesh and parts of Odisha.

- **Sporadic** cases have been reported from several other parts of India.

*Life cycle of leishmania (Fig. 4.21)*

*Leishmania* occur in two forms: (1) extracellular, flagellate promastigote form in the sandfly vector and (2) intracellular, nonflagellate amastigote form in humans.

**Incubation period:** Usually 1–6 months, but may be several years.

*Clinical features of kala-azar*

- **Age group:** In India, adults and children are equally affected whereas elsewhere it is mainly seen small children and infants (except in adults with HIV coinfection).
- **Organs involved:** It primarily affects the host's reticuloendothelial system. In visceral leishmaniasis, monocytes and macrophages of the spleen, liver, bone marrow and lymph nodes are primarily affected.
- **Onset:** Great majority of individuals infected remain asymptomatic and onset in others may be abrupt.
- **Fever:** It is the first sign of infection. Few patients present with a low-grade fever, whereas others present with a high-grade, usually accompanied by rigor and chills. The fever is intermittent showing a double rise of temperature in 24 hours ('camel hump fever'). The intensity of fever decreases over time, and patients may be afebrile for intervening periods ranging from weeks to months. This is followed by a relapse of fever which is often less intense.

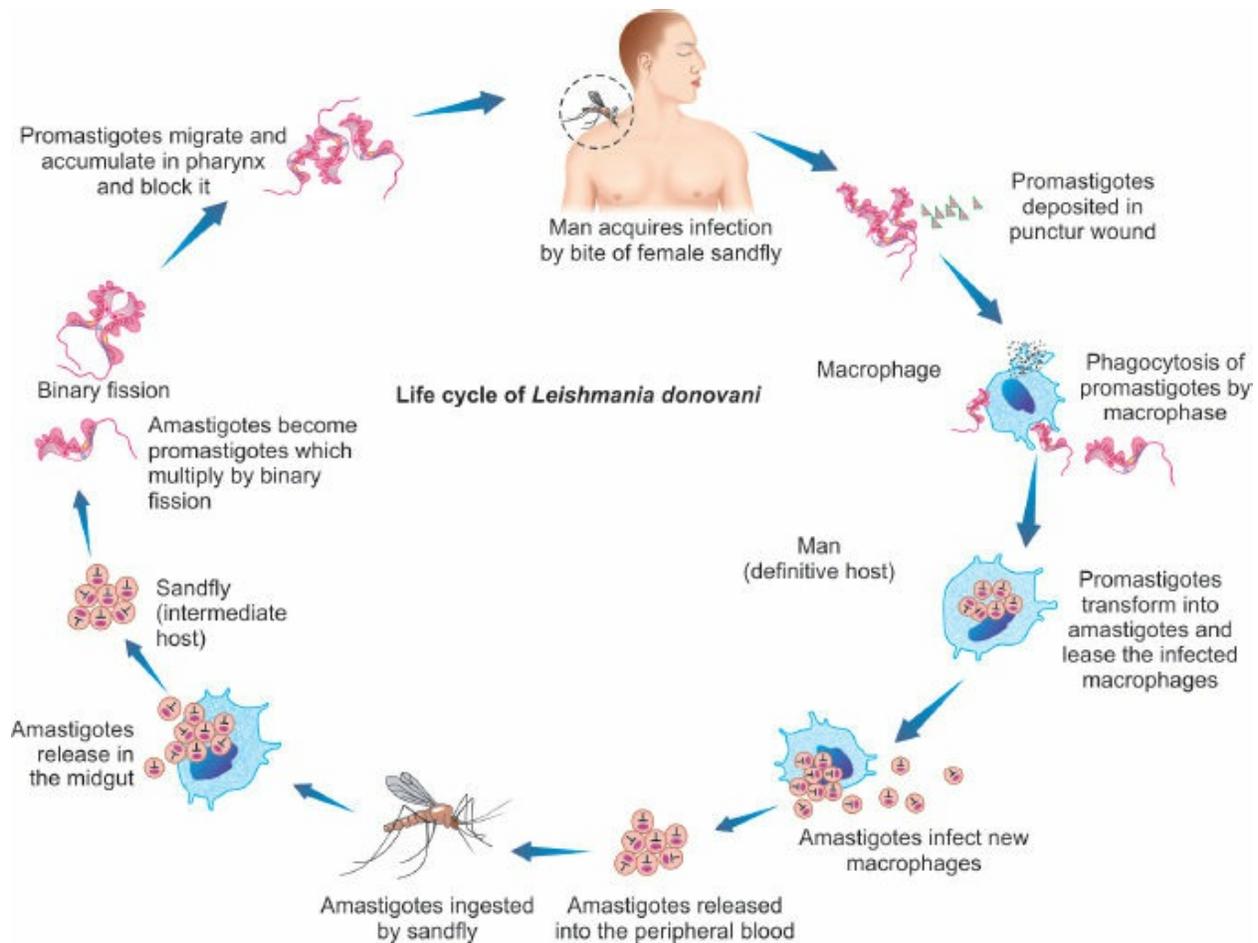

Fig. 4.21: Life cycle of leishmaniasis.

### Physical findings

- **Massive splenomegaly and hepatomegaly:** Splenomegaly develops in the first few weeks and becomes massive as the disease progresses. Moderate hepatomegaly develops later.
- **Lymphadenopathy:** It is common in patients in Africa, the Mediterranean and South America. In India it is more common in patients from West Bengal.
- **Blackish discoloration of the skin:** Disease derived its name; kala-azar is derived from the Hindi word for 'black fever'. Generalized blackish pigmentation with rough skin is prominent over face is an observed in advanced stage of disease and now it is rare.
- **Anemia:** Moderate to severe anemia develops rapidly, and can produce congestive cardiac failure and associated clinical features.
- **Bleeding manifestations:** Thrombocytopenia, often associated with

hepatic dysfunction, may cause bleeding from the retina, gastrointestinal tract and nose.

**Cause of death:** Death usually occurs within a year and is either due to bacterial infection or uncontrolled bleeding.

### *Complications*

- **Hypoalbuminemia:** May develop in advanced stage and may manifest as pedal edema, ascites and anasarca (gross generalized edema and swelling).
- **Immunosuppression:** As the disease advances, severe immunosuppression may lead to secondary infections. These include tuberculosis, pneumonia, malaria, severe amebic or bacillary dysentery, gastroenteritis, herpes zoster and chickenpox. Skin infections (e.g. boils, cellulitis, scabies and cancrum oris) are common.

### *Investigations*

#### Direct evidences

- **Demonstration of amastigotes (Leishman–Donovan bodies):** It can be demonstrated in stained smears of aspirates of bone marrow (50–70% cases), spleen (70–90% cases), liver, lymph nodes or buffy coat of peripheral blood. Demonstration of LD bodies in splenic smears is the most useful for the diagnosis (98% sensitivity); however, there is a risk of serious hemorrhage in inexperienced hands. It is the gold standard for the diagnosis of visceral leishmaniasis (VL).
- **Culture:** The aspirated material can be cultured in the Novy-MacNeal-Nicolle (NNN) medium for the organism.

#### *Indirect evidences*

- **Blood:** Pancytopenia is a common feature (i.e. anemia, granulocytopenia and thrombocytopenia).
- **Biochemical findings:**
  - Low serum albumin (hypoalbuminemia) and **polyclonal hypergammaglobulinemia** (high serum globulin), chiefly IgG followed by IgM in advanced cases.
  - Liver function test: Mildly elevated bilirubin, AST/ALT and alkaline phosphatase may be seen.
- **Serological/immunodiagnostic tests:**
  - These are less invasive and are useful in community surveillance

studies.

- **Leishmanin (Montenegro) skin test:** Intradermal injection of killed culture of promastigotes produces a delayed-type hypersensitivity and is positive only in patients with cured kala-azar.
- **Napier's aldehyde (formal gel) test and Chopra's antimony test:** These are nonspecific test and should not be employed for the diagnosis of VL. They are used for demonstration of increased immunoglobulins.

- **Detection of specific antibody:**

Various test such as complement fixation test, indirect hemagglutination test, indirect fluorescent antibody test and countercurrent immunoglobulins have poor sensitivity and specificity.

- **Antigen detection** by reverse western blotting, dot-enzyme immunoassay (EIA) and latex agglutination test.
- **PCR:** To detect DNA and identify species.

### ***Post-Kala-azar Dermal Leishmaniasis (PKDL)***

**Time of occurrence:** In India, Sudan and other East African countries, 2–50% of patients develop skin lesions due to local parasitic infection concurrent with or after apparent recovery or cure of visceral leishmaniasis.

#### *Clinical features*

**Skin lesions** may be of three types namely: hypopigmented macules, papules or nodules and can occur in varying combinations:

- **Hypopigmented macules:** Earliest lesions and usually found on the trunk and extremities.
- **Erythematous patches:** These have butterfly distribution on the face.
- **Yellowish pink nodules:** They are generally found on the skin and rarely on mucus membrane of tongue and eye.

**Diagnosis:** Demonstration of parasite in the slit smear or by culture of the dermal tissue.

#### **Treatment**

##### **Q. Drugs used to treat kala-azar**

**General considerations:** Blood transfusions to correct severe anemia and treatment of intercurrent bacterial infections with antibiotics.

### ***Pentavalent antimonial compounds***

- Pentavalent antimonial compounds (sodium stibogluconate, meglumine antimoniate) were the first drugs to be used for the treatment of leishmaniasis and still remain the **mainstay of treatment**. The doses are 20 mg/kg either intravenously or intramuscularly for 40 days. However, many patients may fail to respond due to parasitic resistance.
- **Side effects:** Include arthralgias, myalgias, abdominal pain, raised liver enzymes, pancreatitis (in immunosuppressed patients), ECG changes (T wave inversion and reduced amplitude) and rarely death due to cardiotoxicity.
- For PKDL treatment for 3–4 months is necessary.

### ***Amphotericin B***

#### **Q. Write short note on amphotericin B and its side effects.**

Amphotericin B deoxycholate is currently used as a primary drug of choice in Bihar, India. In other parts of the world, it is used as a second line drug when patient is unresponsive to initial antimonial treatment.

- **Dose:** 0.75–1.00 mg/kg given once daily or on alternate days for a total of 15–20 infusion. It has a cure rate of almost 100%.
- **Side effects: Infusion-related side effects** include high fever with chills, thrombophlebitis, diarrhea and vomiting are common. Other side effects include hypokalemia and renal or hepatic toxicity and thrombocytopenia.
- **Lipid formulations of amphotericin b:** Some of above side effects of amphotericin B deoxycholate can be reduced by using lipid- preparations B lipid complex and amphotericin B colloidal dispersion. In India, liposomal amphotericin B is administered at a total dose of 10 or 15 mg/kg, administered in a single dose or as multiple doses over several days. It may be combined with 7–14 days of oral miltefosine.

### ***Miltefosine***

- Miltefosine is an alkyl phospholipid administered orally has shown excellent results. It is the first highly effective, oral drug for treating visceral leishmaniasis.
- **Dose:** 50 mg once a day if weight is <25 kg, and 50 mg twice a day if weight is >25 kg. Duration of treatment is 28 days.
- **Side effects** include vomiting and diarrhea, and occasionally, reversible hepatotoxicity and nephrotoxicity.

### ***Pentamidine***

Pentamidine isethionate was used. Dose of 3–4 mg/kg on alternate days for 5–25 weeks was recommended as a second-line drug to treat antimony resistant cases. However, it is abandoned because of its reduced effectiveness and serious side effects (e.g. hypoglycemia hypotension and induction of diabetes mellitus).

### ***Other drugs***

- Paromomycin (aminosidine): It is antibiotic with antileishmanial action and is highly effective and safe drug. It is given intramuscularly at dose of 11 mg of base/kg daily for 21 days;
- **Azoles: ketoconazole, fluconazole, itraconazole**
  - These oral antifungal agents have variable efficacy in leishmaniasis treatment.

## **Toxoplasmosis**

**Q. Discuss the etiology, clinical manifestations, diagnosis and management of toxoplasmosis.**

Toxoplasmosis is caused by the intracellular protozoan parasite *Toxoplasma gondii*.

### ***Life Cycle of Toxoplasma gondii***

Man is the intermediate host and cat is the definitive host.

### ***Mode of Transmission***

- Humans infection occurs via ingestion of:
  - Oocyst discharged in the feces of infected reservoir animal (cat), contaminated salads, vegetables and water.
  - Raw or undercooked meats containing tissue cysts (bradyzoites). Sheep, pigs and rabbits are the most common meat sources.
- Transplacental infection from mother to fetus may also occur.

### ***Clinical Manifestations***

**Q. Write short note on clinical features of toxoplasmosis.**

*Infection in immunocompetent host*

- **Asymptomatic:** Most acute toxoplasmosis is subclinical and goes unnoticed.
- **Painless lymphadenopathy:** In symptomatic patients, it is the most common presenting feature. It may local or generalized and cervical lymphadenopathy is most common.
- **Other features:**
  - Systemic symptoms are not observed in most patients. If present, these include fever, malaise, fatigue, myalgias, sore throat and headache.
  - Uncommon features are skin rash and confusion.
  - Rarely: Myocarditis, encephalitis, pneumonia, hepatitis, and polymyositis.
- Completely resolution occurs within a few weeks to months.
- **Ocular infection:**
  - Most often ocular involvement (chorioretinitis) observed in congenital

infection

- Examination shows gray white foci of retinal necrosis with adjacent choroiditis, vasculitis, hemorrhage and vitreitis. Anterior uveitis may also be seen.

### *Infection in immunocompromised host*

- In immunocompromised patients, toxoplasmosis is usually due to reactivation of latent infection.
- **Central nervous system:**
  - It is the most common system affected.
  - Manifestations include encephalopathy, meningoencephalitis, seizures, headache and focal neurological deficits.
- Pneumonia and ocular involvement may also occur.

### *Congenital toxoplasmosis*

**Q. Write short note on congenital toxoplasmosis.**

#### *Transmission*

Acute toxoplasmosis is mostly subclinical and develops in 0.3–1% of pregnant women.

#### *Clinical manifestations*

- Congenital toxoplasmosis may be asymptomatic, but can produce serious disease.
- **CNS:** Manifestations include hydrocephalus, microcephaly, encephalitis, convulsions, tremors, paralysis and mental retardation. Cerebrospinal fluid may be xanthochromic with raised protein and mononuclear cells. Skull radiograph may show patches of calcification in the brain.
- **Ophthalmic manifestations:** Microphthalmus, nystagmus, chorioretinitis (common) and blindness.
- Other features: Hepatomegaly, jaundice, thrombocytopenia and purpura may be seen.

#### *Investigations*

- **Blood:** Mild lymphocytosis, raised ESR and mild increase in liver enzymes.

- **Serodiagnosis:** Presence of significant levels of *Toxoplasma* specific IgM antibody indicates acute infection and absence of IgM antibodies virtually rules out acute infection. However, in immunocompromised patients most of the time toxoplasmosis is due to reactivation and there is no rise in IgM antibody. Hence, IgG antibodies are used for presumptive diagnosis.
  - **Sabin–Feldman methylene blue dye test:** A dye test positive with a titer of 1:128 is diagnostic of active toxoplasmosis.
  - **Indirect fluorescent antibody test**
  - **Fluorescent stain for toxoplasma (Goldman’s test):** It is useful for detection of parasites in smears and biopsy specimens.
  - **ELISA test.**
- **PCR for toxoplasma DNA** in ocular secretions and amniotic fluid.
- **Microscopic examination** of smear or biopsy material (from a lymph node or muscle) shows the parasite.
- **Inoculation** of suspected material into laboratory-bred mice, guinea pigs may show characteristic histological changes. These include any of the three infectious stages: tachyzoites in groups, bradyzoites (tissue cysts) or sporozoites within oocyst.
- **Investigations in toxoplasma encephalitis:**
  - **CSF** may be normal or show mild increase in cells and protein
  - **Serum:** IgG antibodies to toxoplasma
  - **Radiological:** CT scan of head may show multiple contrast-enhancing lesions. However, MRI is more sensitive than CT scan in identifying the lesions. Single-photon emission computed tomography (SPECT) helps in differentiating CNS lymphoma from toxoplasmic encephalitis.

### Management

- Acquired uncomplicated toxoplasmosis in an immunocompetent individual is self-limiting and does not require treatment.
- Treatment for severe (especially eye involvement) or progressive disease and for infection in immunocompromised patients:
  - Combination of **sulfadiazine 2–4 g daily (1 g 6 hourly) and pyrimethamine** in a single loading dose 25 mg daily both for 4–6 weeks, along with folinic acid/leucovorin. Steroids are added to the above regime for ocular toxoplasmosis.
  - If the patient is sensitive to sulfonamides, clindamycin or azithromycin can be used.
- **Toxoplasmosis in pregnant women:**
  - If a seronegative women acquires toxoplasmosis during pregnancy (especially during first trimester), or seroconverts during pregnancy, there is a greater risk of transmitting the infection

to fetus giving rise to an infant with congenital toxoplasmosis. Such pregnancies should be terminated.

- The aim of management of pregnant women with toxoplasmosis is to reduce the risk of fetal complications.
- The recommended treatment for a pregnant woman with an established recent infection is **spiramycin** (3 g daily in divided doses) until term. However, whether it has any significant effect on the frequency or severity of fetal damage is not well established. Infected infants should be treated from birth.

## INFECTIONS CAUSED BY HELMINTHS

### CESTODES (TAPEWORMS)

Cestodes (tapeworms) are ribbon-shaped worms which vary from a few millimeters to several meters in length.

#### Life Cycle (Fig. 4.22)

The tapeworm passes its life cycle in two hosts:

- **Definitive host:** Human is the definitive host and harbors the adult worm.
- **Intermediate host:** It may be pig or cattle depending on type of tapeworm and they harbor larval forms.

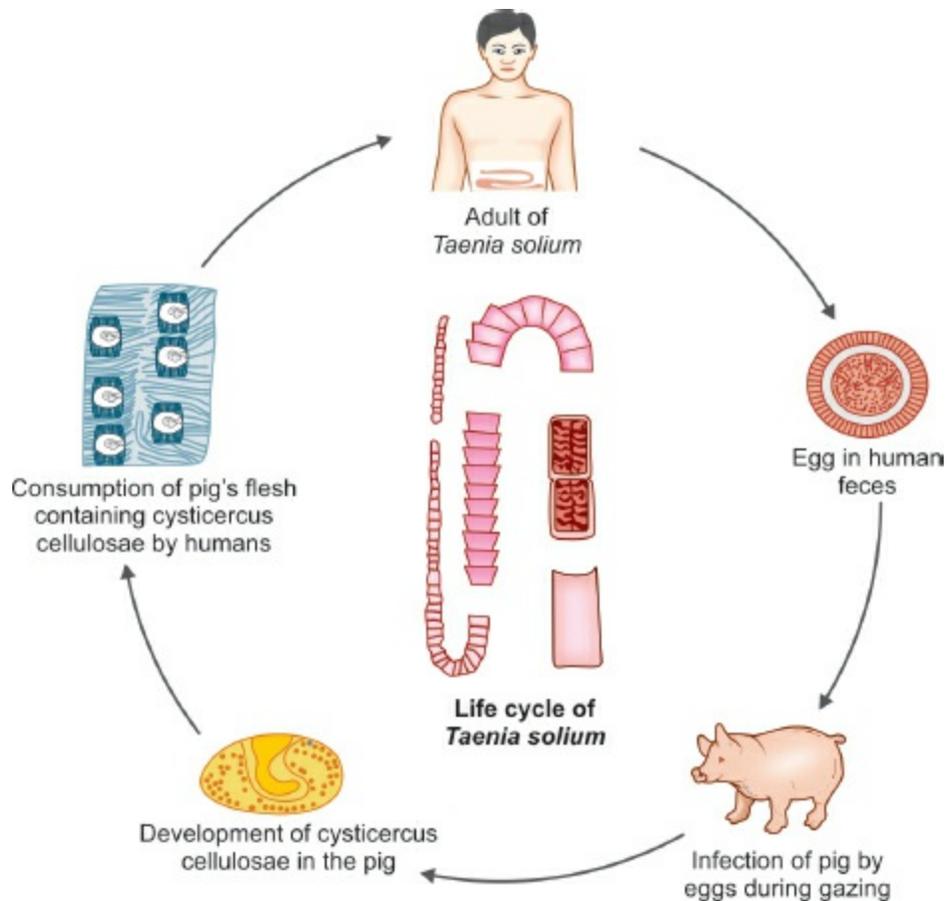

Fig. 4.22: Life cycle of *Taenia solium*.

## Taenia solium

**Q. Write a short note on taeniasis solium and cysticercosis.**

- *Taenia solium*, the pork tapeworm, inhabits the intestinal lumen of humans (only definitive host). Adult worms are found only in human. Pigs are the usual intermediate hosts.

### ***Disease in Humans***

*Taenia solium* causes

- **Intestinal infection:** If a cysticerci present in the undercooked pork is ingested
- **Cysticercosis** (systemic infection from larval migration): If ova present in contaminated food and water are ingested. Feco-oral autoinfection can occur but is rare.

Patients with tapeworms usually do not develop cysticercosis and patients

with cysticercosis do not usually harbor tapeworms.

### *Cysticercosis*

It is the condition in which human tissue is invaded by the larval form of *Taenia solium*.

### *Mode of infection*

- Human cysticercosis results from **ingestion of ova/eggs of *Taenia solium*** which have **contaminated water or vegetable**.
- **Feco-oral autoinfection:** Human harboring adult worm may autoinfect himself either due to unhygienic personal habits.
- **Reversal of peristaltic movements of the intestine** whereby gravid segments are thrown back to the stomach which releases thousands of eggs into the stomach.
- The common sites of cysticerci are subcutaneous tissue, skeletal muscle, brain and eyes.

### *Clinical features*

#### **Q. Write short note on neurocysticercosis.**

**Intestinal infection:** Presence of adult tapeworm in the intestine is usually do not produce symptoms. It is usually discovered when proglottids are found in feces or on underclothing.

**Cysticercosis:** They are usually range from 10 to 1000.

- **Superficially placed cysts:** Those in subcutaneous tissues and muscles cause few or no symptoms. They produce palpable or visible nodule (pea-like ovoid bodies) under the skin or mucosa. Eventually they die and undergo dystrophic calcification. The dead larvae may cause marked tissue response resulting in muscular pain, weakness, fever and eosinophilia.
- **Neurocysticercosis** results from cysts in the brain. Heavy brain infections may present with meningoencephalitis, epilepsy, personality changes, staggering gait, space-occupying lesion, stroke (due to inflammatory changes in the wall of intracranial arteries located in the vicinity of cysticerci) or hydrocephalus. The cerebral signs usually occur after 5–20 years when the larvae die.

### ***Diagnosis***

- **Stool examination:** Eggs and proglottides in stool.
- **Radiological investigations:**
  - **Radiographs** of involved soft tissue (buttocks and thigh) may show calcified cysts (*cigar-shaped/rice grain calcification*) in muscles (Fig. 4.23).

**Fig. 4.23:** X-ray thigh and shows cigar-shaped/rice grain calcification due to calcified cysts of tapeworm in muscles.

- **CT scan** of the brain may show calcified cysticerci, small hypodense lesions (ring or disc-like enhancing lesion) or small hypodense lesions with central bright spot. CT scan is more sensitive than MRI for identifying calcified cysts.
- **MRI scan:** It is better for identifying cystic lesions, enhancement and cysticercosis in the ventricles.
- **Serological test:** Specific enzyme linked immunoelectrodiffusion transfer blot (EITB) using lentil-lectin purified glycoproteins is highly sensitive and specific. IFA and ELISA test are also useful.
- **Histological examination** of the excised subcutaneous nodule or the

lesion will show cysticerci.

**Q. Write short note on:**

- **Drug treatment of tapeworm.**
- **Treatment of neurocysticercosis.**

**Treatment**

***Intestinal infection***

- For the adult worm in the intestine: Niclosamide (2 g as a single dose), praziquantel (5 mg/kg) or albendazole.

***Neurocysticercosis***

- **Albendazole:** 15 mg/kg/day for 2–4 weeks is the drug of choice for parenchymal neurocysticercosis.
- An alternative drug is **praziquantel (PZQ)** in the dose of 50 mg/kg in three divided doses daily for 10 days. Single day course is effective in patients with a single cyst or low cyst burdens, but is less efficacious in those with heavier cyst burdens.
- **Corticosteroids:** Successful treatment is accompanied by increased local inflammation. Hence, **prednisolone** is given in the dose of 10 mg 8 hourly for 14 days, starting 1 day before, during and after the course of anthelmintic (albendazole or PZQ).
- **Antiepileptic drugs** should be administered for epilepsy until the reaction in the brain has subsided.
- **Operative intervention** may be necessary for internal hydrocephalus.

## ***Echinococcus granulosus (Taenia echinococcus) and Hydatid Disease***

**Q. Write short note on hydatid disease.**

### ***Life Cycle of Echinococcus granulosus (Fig. 4.24)***

- **Definitive host:** Dog, wolf, fox and jackal are the definitive host.
- **Intermediate host:** Human, sheep, pig, cattle, goat, etc. are intermediate host.

### ***Hydatid Disease***

Hydatid cyst is the larval stage of *E. granulosus* producing tissue infection of humans or other intermediate hosts (sheep, cattle, camels and other animals from contaminated water).

**Mode of infection:** Human is infected accidentally by ingestion of eggs while handling a dog or drinking contaminated water. Canines (especially dogs) are the definitive hosts for *E. granulosus*.

### ***Clinical features***

- Humans may ingest the eggs while handling a dog or contaminated water. Usually, hydatid cyst is acquired in childhood and diagnosed after a latent period of 5–20 years. It may cause pressure symptoms and vary, depending on the site of the cyst (organ or tissue involved).

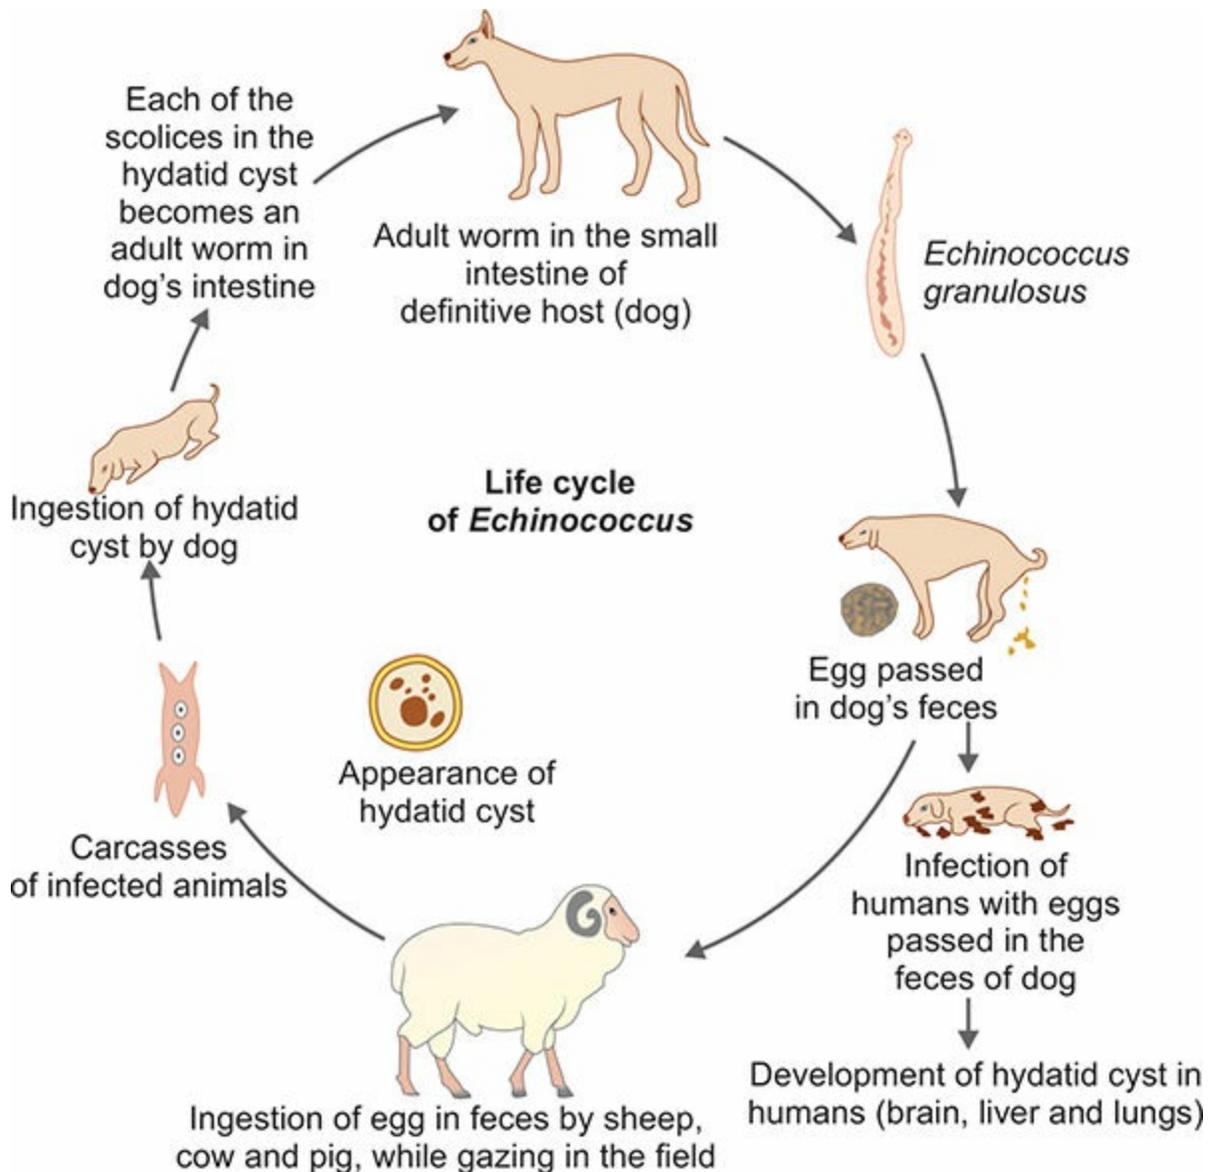

Fig. 4.24: Life cycle of *Echinococcus granulosus*.

- **Liver:** In about 75% of the patients, hydatid disease involves the right lobe of the liver and it contains a single cyst. The lesions in liver often present as palpable masses or abdominal pain.
  - Obstruction of bile duct may produce obstructive jaundice.
  - Intrabiliary extrusion of calcified hepatic cysts can cause recurrent cholecystitis.
- **Rupture of a hydatid cysts:** May occur into the bile duct, peritoneal cavity, lung, pleura or bronchus. It may cause fever, pruritus, urticarial rash or an anaphylactoid reaction which may be fatal.

- **Pulmonary** hydatid cyst may rupture producing cough, chest pain or hemoptysis.
- Hydatid cyst in **central nervous system** may produce epilepsy or blindness.
- Other organs involved: Rarely bone, heart, kidneys, spleen, ovary and thyroid.

Gross appearance of hydatid cyst is shown in Figure 4.25A.

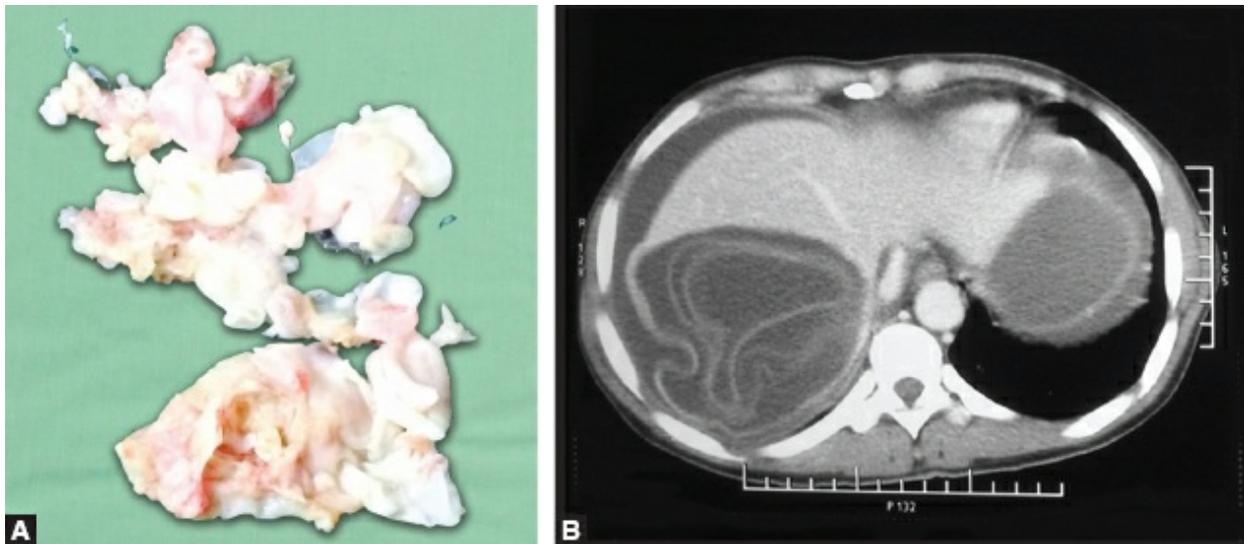

### *Diagnosis*

- **Radiological:**
  - **X-ray:** Routine chest radiographs is helpful in the diagnosis of hydatid cysts of lung. Lung lesions appear as round, irregular masses of uniform density. The ‘meniscus sign’ or ‘crescent sign’ is due to the presence of air between the pericyst and the laminated membrane. The ‘water lily sign’ is due to an endocyst floating in a partially fluid-filled cyst. Occasionally, a chest X-ray may show smooth rim of calcified hepatic cyst.
  - **CT scan (Fig. 4.25B), ultrasonography and MRI** can identify the hydatid cysts by showing scolices and daughter cysts.
- **Casoni’s skin test** is performed by intradermal injection of 0.2 mL of fresh sterile hydatid fluid. Positive test produces immediate hypersensitivity reaction (not routinely available).
- **Serological test:**
  - Precipitin reaction, complement fixation, immunofluorescent tests and ELISA are positive in 70–90% of patients.
  - IHAT, ELISA using specific echinococcal antigens.

### **Q. Write short note on medical management of hydatid disease.**

#### **Management/treatment**

- Surgical excision of the cysts wherever possible is the treatment of choice. Great care is needed to avoid spillage of fluid and cavities are sterilized with 0.5% silver nitrate or 2.7% sodium chloride.
- In inoperable cases, ‘high-dose’ albendazole (7.5 mg/kg/twice daily or 400 mg twice daily) is given for 1–3 months. In selected cases, the drug can combined with PAIR (percutaneous puncture, aspiration, injection of scolicidal agent and reaspiration).
- Praziquantel (20 mg/kg twice daily for 14 days) kills protoscolices and useful perioperatively.

**Figs. 4.25A and B:** (A) Gross appearance of hydatid cyst; (B) Hydatid cyst on CT abdomen.

## ***Enterobius vermicularis* (Threadworm/Pinworm)**

**Q. Write a short note on enterobiasis, pinworm infection and threadworm infection.**

Enterobiasis is an intestinal infection of humans caused by *Enterobius vermicularis* (threadworm).

### ***Mode of Infection***

Humans are usually infected by the ingestion of eggs by direct transfer of eggs from the anus to the mouth by way of contaminated fingers or through contaminated food or water. Retroinfection occurs when the eggs hatch in the perianal region and the larvae migrate back into the bowel lumen.

### ***Clinical Features***

**Q. Write a short note on clinical features of *Enterobius vermicularis*.**

- **Perianal itching (Pruritus ani):** It is the most common symptom, especially at night. This is due to the gravid female worm which migrates to anal region at night and lays ova around perianal region causing intense itching at night. The ova are carried to the mouth on the fingers and so reinfection or human-to-human infection is common (autoinfection). The adult worms may be seen moving on the buttocks or in the stool.
- **In females:** Migration of adult worm into the female genitalia. It may

result in vaginal discharge, salpingitis and endometritis.

- **Other symptoms** include irritability, insomnia and enuresis.

## ***Investigations and Diagnoses***

**Q. Write a short note on laboratory features of pinworm infestations.**

- **Direct visualizing the worms** in the perineal and perianal region.
- **Stool examination** for eggs may be positive in only 5–10% cases.
  - **Cellophane tape test:** This test is performed by touching the adhesive surface of cellophane tape to the perianal area of skin several times in the morning and removing. It is then examined for eggs on a glass slide under the microscope. Sensitivity of test is about 90%.

### **Treatment/Management**

- **Pyrantel pamoate** given in a single oral dose of 11 mg/kg is the treatment of choice.
- **Other drugs:** A single oral dose of **mebendazole** (100 mg), **albendazole** (400 mg) or piperazine (4 g).
- **Recurring infections:** If infection constantly recurs in a family, each family member should be given mebendazole 100 mg twice daily for 3 days. This should be repeated after 2 weeks (for also to control autoreinfection). During this period all night clothes and bed linens are laundered. Finger nails must be trimmed and hands are washed before meals.

## ***Ascaris lumbricoides (Roundworm)***

**Q. Write short note on ascariasis or roundworm infection.**

Ascariasis is an infection of humans caused by nematode *Ascaris lumbricoides*.

### ***Clinical Features***

**Q. Write short note on complications of roundworm infestations.**

- Infection is usually asymptomatic.
- Heavy infections are associated with nausea, vomiting, abdominal discomfort, anorexia and malnutrition (fat, protein, carbohydrate and vitamins) especially in children. However, serious morbidity and mortality are rare in ascariasis.
- The adult worm may be vomited or passed in the stool.
- **Mechanical effects:** The large size of the adult worm and its tendency to

aggregate can form bolus of adult worms. It may produce volvulus, intussusception or obstruction of the small intestine (most common in the terminal ileum), hemorrhagic infarction and perforation.

- **Ectopic Ascariasis:**

- They may occasionally migrate and invade the appendix (causing acute appendicitis), or the bile duct (causing biliary obstruction, suppurative cholangitis and liver abscess) and pancreatic ducts (pancreatitis).
- **Pulmonary:** Larval migration through the lungs may produce **pulmonary eosinophilia**, ascari bronchopneumonia (characterized by fever, cough, dyspnea, wheeze, eosinophilic leukocytosis and migratory pulmonary infiltrates), eosinophilic granulomas, bronchial asthma and urticaria.

### ***Investigations and Diagnoses***

- Stool examination: Microscopically shows typical ova in the feces and occasionally adult worms are expelled from the mouth or the anus.
- Radiographic study: barium examination may demonstrate the worms.
- Blood shows eosinophilia.

#### **Management/Treatment**

- **Intestinal ascariasis:** A single dose of albendazole (400 mg), pyrantel pamoate (11 mg/kg; maximum 1 g), ivermectin (150–200 µg/ kg) or mebendazole (100 mg twice daily for 3 days). The older drug, piperazine citrate is highly effective and less expensive, but slightly more toxic.
- **Obstruction** due to ascariasis adult worms should be treated with nasogastric suction, piperazine citrate and intravenous fluids. Very rarely, surgical or endoscopic intervention may be needed for intestinal or biliary obstruction.
- **Ascaris bronchopneumonia** is treated symptomatically.

### **Trichuris trichiura (Whipworm)**

**Q. Write a short note on trichuriasis/whipworm infection.**

Trichuriasis is an intestinal infection of humans caused by *Trichuris trichiura* (whipworm).

#### ***Clinical Features***

- Infection is usually asymptomatic, but mucosal damage at the attachment of worm in the intestine can produce petechiae. This may cause loss of 0.005 mL blood/worm/day by the patient and cause anemia.

- Occasionally intense infections in children may cause severe mucosal damage leading to colonic ulceration, persistent diarrhea/dysentery, growth retardation or rectal prolapse.

**Treatment:** Mebendazole in the dose of 100 mg twice daily for 3 days or albendazole 400 mg once daily for 3 days in the treatment of choice. Heavy infections may need repetitions of dose.

## Ancylostomiasis (Hookworm)

**Q. Discuss the etiopathogenesis, clinical features, and management and prevention of hookworm disease.**

- Ancylostomiasis is a symptomatic infection caused by parasitization with human hookworms *Ancylostoma duodenale* or *Necator americanus*.
- Hookworm infection is one of the major causes of **anemia** in the tropics and subtropics.
- *Ancylostoma duodenale* or old-world hookworm is found in East Asia, Africa, China, Japan, India and the Pacific Islands. *Necator americanus* or new-world hookworm is found in South and Central America and the Caribbean.

### ***Mode of Infection***

It occurs through skin by filariform larvae when human walks bare-foot on the focally contaminated soil.

### ***Clinical Features***

- **Lesion in skin: Allergic dermatitis/itching dermatitis** ('ground itch dermatitis') develops at the site of entry of the infective filariform larvae. The lesions are usually on the feet, particularly between the toes.
- **Pulmonary manifestations:** The passage of larvae through the lungs in a heavy infection produces cough with blood-stained sputum, fever. There may be bronchitis, patchy pulmonary consolidation/bronchopneumonia and eosinophilia.
- **Gastrointestinal manifestations:** Light infections (especially in well-nourished individuals) are often asymptomatic. When the worms have reached the small intestine, heavier worm loads may produce epigastric pain, nausea, and vomiting resembling peptic ulcer disease. Other symptoms include abdominal distension, pica, and small frequent loose

stools.

- **Pathological effects:** Chronic heavy infection, particularly on a background of malnourishment, may cause:
  - **Iron deficiency anemia** due to chronic intestinal blood loss.
  - **Hypoproteinemia/hypoalbuminemia**
  - **Retarded physical, mental and sexual development** may occur in older children with heavy infection in children.

### ***Investigations and Diagnoses***

- **Stool examination:**
  - **Microscopic examination of stool shows** the characteristic **eggs/ovum**. The eggs of both *Ancylostoma duodenale* and *Necator americanus* are 60–70 µm in length and bounded by an ovoid transparent hyaline membrane.
  - **Occult blood:** The stools rarely show gross blood, but tests for occult blood are **usually positive**.
- **Blood:**
  - **Peripheral blood smear:** Characteristically shows **microcytic hypochromic anemia**. There may be **eosinophilia** (as high as 70–80%) in some cases.
  - **Hemoglobin level is usually low.**
- **Hypoalbuminemia** is a common in severe disease.

**Q. Write short essay/note on:**

- **Treatment of ancylostomiasis**
- **Mention the drugs used in ancylostoma infestation.**

#### **Treatment/Management**

- **Drugs:** A single dose of albendazole in the dose of 400 mg is the treatment of choice. Other drugs include mebendazole (100 mg twice daily for 3 days), and pyrantel pamoate (single oral dose of 11 mg/kg). Eradication of infestation should be confirmed by follow-up stool examination 2 weeks after discontinuation of treatment.
- Improvement of nutrition with a high-protein diet.
- **Anemia:** Mild anemia usually responds to oral iron therapy. Severe anemia is often associated with anasarca, and heart failure. This should be treated carefully if required with blood transfusions.

## Cutaneous Larva Migrans (Creeping Eruption)

### Q. Write short note on cutaneous larva migrans (creeping eruption).

- **Definition:** Cutaneous larva migrans (CLM) is a creeping eruptions in the skin caused by the filariform larvae which aimlessly wander through the skin for weeks or months producing a reddish itch papule along the path of travel of the larvae (termed 'larva migrans').
- **Cause:** Cutaneous larva migrans is particularly observed with non-human hookworms namely *Ancylostoma braziliense* and *A. caninum*.
  - ***Strongyloides stercoralis*** may produce creeping eruptions and its filariform larvae moves rapidly in short line; hence it is termed **larva currens** (reflecting fast movement of strongyloides larva) (Fig. 4.26).
- **Sites affected:** The main sites affected in cutaneous larva migrans are the dorsum and sole of the feet, buttocks, pelvic waist, legs and shoulders. Infestation is usually self-limited. It can persist for a few days to months, but rarely for years.
- **Loeffler's syndrome** (transient migratory pulmonary infiltrates, peripheral blood eosinophilia and sputum eosinophilia) is found in many cases of cutaneous larva migrans.

Fig. 4.26: Cutaneous larva migrans.

### Clinical Features

There are usually no systemic symptoms and diagnosis is purely made on clinical grounds. Skin shows multiple, clearly defined, intensely pruritic, linear and serpiginous tracts.

### Treatment

- **Ivermectin:** It is the drug of choice and given as a single dose in the dose of 150–200 µg/kg.
- Alternative drug is **albendazole** (200 mg twice a day for 5–7 days).
- Antihistamines may be given for intense itching.

## Strongyloidiasis

### Q. Discuss clinical features, diagnosis and treatment of strongyloidiasis.

- Strongyloidiasis is an intestinal infection of humans caused by *Strongyloides stercoralis*.
- The adult worm of *Strongyloides stercoralis* is small and measures 2 mm in length. It is found in many parts of the tropics and subtropics. It lives in the small intestine namely upper part of jejunum.

### Clinical Features

- **Skin lesions:** Larval migration through skin may produce itchy rashes at the site of entry. Autoinfection may produce migratory linear weal around the buttocks and lower abdomen (cutaneous larva currens). The classic triad of symptoms is (i) abdominal pain, (ii) diarrhea and (iii) urticaria.
- **Pulmonary lesions:** Larval migration through lungs may produce cough, dyspnea, hemoptysis and bronchospasm.
- **Intestinal lesions:** Adult worms in the intestine may cause abdominal pain, bloating diarrhea, steatorrhea (malabsorption) and weight loss. In heavy infections damage to the small intestinal mucosa can cause even perforation.
- **Systemic infection:** Systemic strongyloidiasis (the *Strongyloides* hyperinfection syndrome), with dissemination of larvae throughout the body. It may occur in immunocompromised states (e.g. HIV infection and corticosteroid therapy). This may produce diarrhea, severe, generalized abdominal pain, abdominal distension, pneumonia, meningoencephalitis shock and death. Gram-negative sepsis may develop.

### Diagnosis

- Stool examination: Motile larvae (at least three samples) may be observed on microscopic examination of stool, especially after a period of incubation. Larvae may also be cultured from stool.

- Blood: Eosinophilia may be found in some patients.
- Duodenal/jejunal aspirate may show larvae.
- Serological tests: ELISA for antibody to *S. stercoralis*.
- In patients with disseminated infection: Stool examination, ELISA, and sputum and blood examination for larvae.

**Q. Write short note on management of strongyloidiasis.**

**Treatment**

- **Ivermectin** (200 µg/kg/day) for 2 days is the drug of choice.
- **albendazole**: It is an alternative drug but is less effective drug. It is given orally at a dose of 400 mg twice daily for 7 days.
- **Disseminated systemic infections**: Both ivermectin and albendazole should be given and may be continued for 7 days or till the parasites are cleared.

## Filariasis

**Q. Discuss the clinical features, diagnosis and treatment of filariasis.**

Conditions included under filariasis are listed in Box 4.21.

**Box 4.21: Conditions included under filariasis.**

- Lymphatic filariasis: Caused by *Wuchereria bancrofti* and *Brugia malayi*.
- Onchocerciasis (river blindness): Caused by *Onchocerca volvulus*
- Loiasis: Caused by *Loa loa*

## Lymphatic Filariasis

**Q. Write short essay on lymphatic filariasis and bancroftian filariasis and their clinical manifestations and management.**

Clinical outcome of lymphatic filariasis may range from subclinical infection to hydrocele and elephantiasis. Life cycle of filariasis is presented in Figure 4.27.

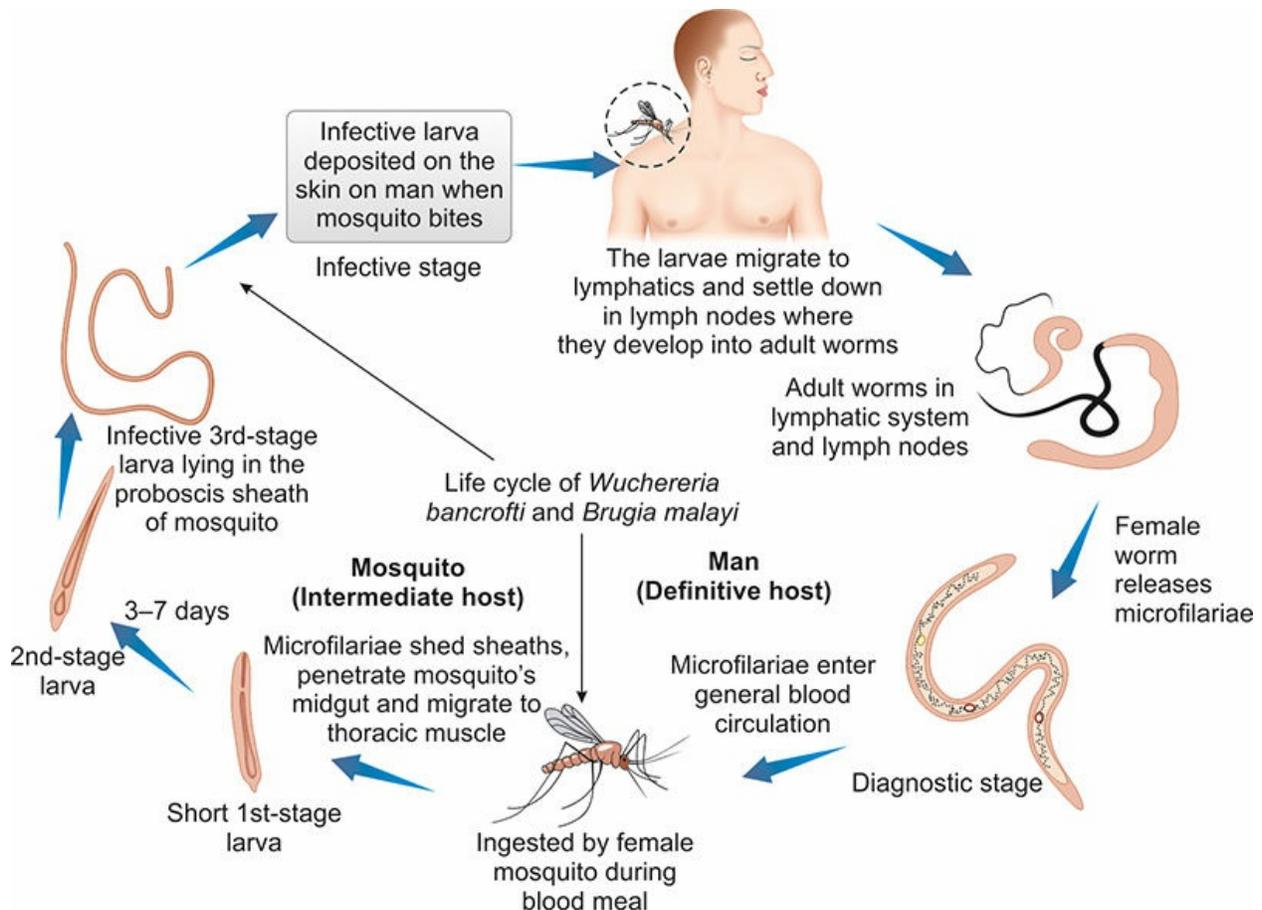

Fig. 4.27: Life cycle of filariasis.

## Clinical Features

### Q. Write short essay on clinical features of filariasis.

- **Acute filarial lymphangitis:** It presents with fever, with chills and sweats, headache and muscle pain. On examination there will be **pain, tenderness and erythema along the course of inflamed lymphatic vessels**. The whole episode may last for few days, but it may recur several times in a year. Temporary edema becomes more persistent and regional lymph nodes (e.g. inguinal) enlarged painful and tender. Inflammation of the **spermatic cord (funiculitis), epididymis (epididymitis) and testis (orchitis)** is common.
- **Chronic stage of the disease:** It is characterized by development of permanent lymphedema (**'elephantiasis'**) of legs (Fig. 4.28), scrotal edema, **chylous ascites, chylous pleural effusion and chyluria**. Progressive enlargement of lymphedema may produce coarsening,

corrugation, fissuring and bacterial infection of the skin and subcutaneous tissue. This results in irreversible 'elephantiasis'. The scrotum may become very large in size because of hydrocele. Chyluria and chylous effusions appear as milky and opalescent which on standing shows fat globules on the top of chylous fluid.

- **Tropical pulmonary eosinophilia (refer pages 380-2).**

**Fig. 4.28:** Lymphatic filariasis.

### ***Investigations (Laboratory Findings) and Diagnoses***

**Q. Write short essay on laboratory findings in filariasis.**

- In the early stages of lymphangitis diagnosis can be made on clinical grounds, and peripheral blood eosinophilia. Microfilariae are not seen in the peripheral blood during early infestation.
- **Peripheral blood:**
  - **Eosinophilia:** Host immune response to the parasite produces massive eosinophilia.
  - **Demonstration of microfilariae:** In the peripheral blood at night.
- **Demonstration of microfilariae in other fluids:** Microfilariae can be demonstrated in the hydrocele fluid and may occasionally show an adult

worm.

- **Diethylcarbamazine (DEC) provocation test:** In this test, administration of 100 mg DEC usually produces positive blood specimens within 30–60 minutes.
- **Radiology:** Calcified filariae may be demonstrable by radiography.
- **Serological tests:**
  - **Antigen detection and antibody detection in the blood:** By ELISA or immunochromatic method.
- **PCR** for DNA detection.
- **Radionuclide lymphoscintigraphy:** It is used to detect widespread lymphatic abnormalities.
- **Tropical pulmonary eosinophilia:** Serology is strongly positive and IgE levels are markedly raised but circulating microfilariae are not found. The chest X-ray shows miliary changes or mottled opacities. Lung function tests show a restrictive picture.

#### Treatment

- **Aim of treatment:** Reversing and halting the disease progression.
- **Diethylcarbamazine (DEC)** in the dose of 6 mg/kg in three divided doses for 12–21 days kills both microfilariae and adult worms.
  - **Adverse effects:** Due to the host response to dying microfilariae. The intensity of reaction directly proportional to the microfilarial load. The main symptoms include fever, headache, nausea, vomiting, arthralgia and prostration. They usually develop within 24–36 hours of the first dose of DEC. Antihistamines or corticosteroids may be needed to control these allergic reactions.
- **Ivermectin** kills only microfilariae, but not the adult worms.
- Combined albendazole (400 mg) and ivermectin (200 µg/kg) in a single dose, with or without DEC (300 mg), is also highly effective.
- **Doxycycline 200 mg per day for 4 weeks** plus ivermectin as a single dose (200 µg/kg provides additional benefit by eliminating the bacteria. This interrupts the parasite embryogenesis.
- **Surgery** may be of useful in the treatment established elephantiasis.

#### Chronic lymphatic pathology

- **Prevention of secondary infection:** Advised to take meticulous care of skin in lymphedematous limbs to prevent secondary bacterial and fungal infections.
- **Control of lymphedema:** Tight bandaging, massage and bed rest with elevation of the affected limb to control the lymphedema.
- **Prevention of further damage:** Prompt diagnosis and antibiotic therapy of bacterial cellulitis to prevent further lymphatic damage and worsening of existing elephantiasis.
- **Surgery:** Plastic surgery may be required in established elephantiasis. Hydroceles and chyluria can be repaired by surgery.

# ECTOPARASITES

Ectoparasites are parasites that live on the surface of its host.

## Scabies

**Q. Write short essay on scabies.**

Scabies is an intensely itchy rash caused by the ectoparasitic, **mite**, *Sarcoptes scabiei* var *hominis*.

**Age:** It is most common in **children and young adults** but can occur at any age group.

### *Mode of Transmission*

- **Person to person contact:** Scabies is a highly contagious. Newly fertilized female mites are transmitted from person to person by prolonged close/intimate personal contact (e.g. within households or institutions) with the skin, and by sexual contact. This transmission is facilitated by social crowding, poor hygiene, and multiple sexual partners. In the absence of host contact, the mites usually die within a day or so. About 15–20 minutes of close contact with an infected individual is necessary for transfer of the mites from one individual to another.
- **Through contaminated clothes:** Transfer through clothes and bedding contaminated by infested patient immediately beforehand.

### *Clinical Features*

**Q. Write short essay on clinical features of scabies.**

- Scabies clinically present with itchy red papules (or occasionally vesicles and pustules). Itching/pruritus are worse at night.
- **Distribution of lesions:** Often suggests the diagnosis. Skin lesions can occur anywhere but rare on the face and scalp, except in infants. Sites of predilection are (i) between the web spaces of the fingers (Fig. 4.29A) and toes, (ii) on the palms and soles (more commonly in small children), (iii) around the wrists and axillae, on the male genitalia (Fig. 4.29B), and around the nipples and umbilicus. **Circle of Hebra** is an imaginary circle intersecting sites of predilection and include areolae, axillae, elbow flexures, wrists, finger webs, umbilicus, lower abdomen, genitalia.

- **Pruritus/itching** is a prominent feature and usually intense and worse (most severe) at night and after a hot shower. The itching develops a few days after infestation. It may develop within a few hours if the mite is infested for second time. It develops in the trunk and limbs and usually not affect the scalp.
- **Generalized rash** of scabies appears as tiny red intensely itchy bumps on the limbs and trunk. It is due to an allergic reaction to the mites and their products. It may develop several weeks to develop after initial infestation.

**Figs. 4.29A and B:** (A) Scabies involving the web spaces of the fingers; (B) Genital region of male.

- **Nodules:** Presence of itchy lumps or nodules in the armpits and groins or along the shaft of the penis is highly suggestive of scabies. Nodules may persist for several weeks or longer even after the successful eradication of living mite.
- **Acropustulosis:** Blisters and pustules on the palms and soles of infants with scabies.

**Pathognomonic sign:** It is the presence of **linear or curved skin burrows** in which the mites live. However, these are not always seen. Burrows are seen as dark wavy lines in the epidermis and measure up to 15 mm. Typical burrows may be only few in number. Hence, they are often missed if the skin has been scratched or become secondarily infected or if there is eczema. Microscopic examination of the contents of a burrow may show many mites, eggs or mite feces (scybala).

**Q. Write short note on systemic complications of scabies.**

**Complication:** Excoriations and secondary bacterial infection may develop

in the skin rash. Secondary infection of lesions of scabies due to nephritogenic streptococci may complicate the rash leading to poststreptococcal glomerulonephritis.

## ***Diagnosis***

### **Q. Write short essay on Norwegian or crusted scabies.**

- **Clinical grounds:** Scabies should be considered on the basis of clinical presentation and history. Diagnosis can be made in patients with itching and symmetrical skin lesions in characteristic distribution/locations. It may be obvious if there is a history of household/close contact with an affected patient.
- **Confirmation of scabies:** It is by **identifying the scabietic burrow** and **visualizing the mite**. Burrows should be unroofed with a sterile needle or scalpel blade. The skin scrapings of a lesion should be examined microscopically (by a potassium hydroxide preparation) for the mite and/or its eggs and its fecal pellets. Microscopic examination of clear adhesive tape lifted from lesions and skin biopsy also may be useful for diagnosis.

Disorders predisposing to crusted scabies are shown in Table 4.48.

## ***Crusted or Norwegian Scabies***

### **Q. Write short note on diagnosis of scabies.**

- Crusted scabies or Norwegian scabies is clinical variant of scabies characterized by hyperinfestation (huge numbers) of *Sarcoptes scabiei* mites in the skin.
- It is named Norwegian scabies because of its initial description in Norwegian patients with leprosy.
- **Predisposing conditions:** Patients are highly infectious. The number of mites rapidly increases (hyperinfestation) due to impaired immune response, lack of pruritus or patient's with neurological disorders with physical inability to scratch. Disorders predisposing to crusted scabies are listed in Table 4.48. It may be associated with HLA-A11. Transmission through fomites can occur because mites survive on the sloughed skin in environment.

- **Clinical features:** Patient presents with marked thickening and crusting of the skin (hyperkeratotic crusted lesions) particularly on the hands. However, entire body including the face and scalp is often involved. Nails often show hyperkeratosis.

**Table 4.48:** Disorders predisposing to crusted scabies.

<b>Disorders with defective T-cell response:</b> AIDS, lymphoma, organ transplantation, T-cell leukemia	<b>Neurological disorders:</b> Parkinson's disease, tabes dorsalis, syringomyelia
<b>Physical debilities:</b> Critical illness, kwashiorkor	<b>Mental debilitation:</b> Down's syndrome, mental retardation
<b>Reduced sensation:</b> Leprosy	<b>Metabolic disorder:</b> Diabetes mellitus

**Q. Write short essay on management of scabies/drugs used to treat scabies.**

**Treatment**

**Principles of scabies treatment**

- Topical treatment of the patient and all asymptomatic close contacts (family members/physical contacts) should be done simultaneously to ensure eradication.
- Include a scabicide and a keratolytic in the treatment.
- To avoid reinfection, washing or cleaning of recently worn clothes (including underclothing) and bed linen (preferably at 60°C) is recommended.

**Topical treatment**

- **Areas of application:** Scabicides are applied thinly and thoroughly to all over the skin below the neck (including the genitalia, palms and soles, and under the nails). Reapply topical scabicide to the hands if patient washed it during the treatment period.
- **Duration of treatment:** Usually effectively treated scabies infestations become noninfectious within a day. However, even after successful treatment, pruritus/itching and rash may remain even up to 4 weeks. Unnecessary retreatment may cause contact dermatitis.
- **Repetition of application:** Topical application should be repeated after one week.

**Topical scabicide**

These include (i) precipitated sulfur 2–10% in petrolatum, (ii) benzyl benzoate 10–25%, (iii) crotamiton 10%, (iv) Lindane (gamma benzene hexachloride) 1%, (v) permethrin 5%, and (vi) malathion 0.5%.

**Oral therapy**

*Ivermectin*

- **Dose:**
  - Single oral dose 200 µg/kg in otherwise healthy individuals and side effects are rare.
  - Two doses of oral ivermectin (200 µg/kg, as 2 doses 2 weeks apart) is easy to use and as effective as topical therapy. Two doses are indicated in Crusted scabies or Norwegian scabies. The toxic effects with two doses are insignificant.

Oral antihistamines can alleviate the hypersensitivity response.

## Lice Infection

### Q. Write a short essay/note on pediculosis.

Lice are blood-sucking ectoparasites and can infest human in three ways:

#### 1. Head lice (*Pediculus capitis*)

- Infestation with the head louse, *Pediculus humanus capitis*, is common worldwide.
- **Age and gender:** Predominantly affects children and more common in females.
- **Spread:**
  - It is highly contagious and spread by direct head-to-head contact and associated with overcrowding.
  - It may be indirectly spread through hats, clothes or pillow covers.
- **Clinical presentation:** Head lice usually presents with scalp itch that leads to scratching, scalp excoriations, secondary infection (important cause of impetigo) and cervical lymphadenopathy. Itching may produce sleep disturbances and difficulties in concentration and the affected children may perform poorly in school.
- **Diagnosis:**
  - Confirmed by identifying the living louse or nymph or empty egg cases ('nits' look like whitish shells stuck to the hair shaft on the scalp and are difficult to dislodge).

#### Treatment

- Apply **malathion or permethrin or carbaryl or phenothrin in lotion or aqueous formulations**, twice at an interval of 7–10 days (with a contact time of 12 hours). If treatment with one fails, a different insecticide is used for the next course. Rotational treatments within a community can avoid resistance. Treatment is usually repeated after 7 days.
- Regular 'wet-combing' (physical removal of live lice by regular combing of conditioned wet hair, metal nit combs may help remove the eggs) is less effective than pharmacological applications.
- Apply vaseline to eyelashes/brows twice daily for at least a fortnight.
- **Resistant cases:** Use oral ivermectin (400 µg/kg as 2 doses 1 week apart).
- Treatment of secondary bacterial infection if present.

#### 2. Body lice (*Pediculus corporis*)

- Body lice are ectoparasites similar to head lice but they live on clothing (e.g. seams), and feed on the skin.

- **Predisposing factors** include poor hygiene, poverty, neglect and overcrowded conditions. It is rare in developed countries (except in homeless and vagrants).
- **Spread:** By direct contact or sharing infested clothing. The lice and eggs are commonly found on the clothing but are rarely observed on the skin of the patient.
- **Clinical presentation:** It presents with itch, excoriations and secondary infection. Sometimes, there may be post-inflammatory hyperpigmentation of the skin.

**Treatment:** By malathion or permethrin. Dry cleaning and high-temperature washing or insecticide treatment for the clothes is helpful.

### 3. Pubic lice (Crab lice, Phthiriasis pubis)

- Pubic louse (*Phthirus pubis*) is a bloodsucking insect that attaches tightly to the pubic hair.
- **Mode of transmission:** Usually, it is sexually acquired (direct contact) and transferred only by close bodily contact. The lice lay its eggs (nits) at hair bases and usually hatch within a week.
- **Clinical presentation:** It may be asymptomatic or presents with severe itching, especially at night. Usually infests public hair and occasionally other hairy areas (eyebrows, eyelashes and the beard). Lice can be seen near the base of the hair with eggs.

**Treatment:** Similar to head lice and the treatment of choice is malathion or carbaryl in an aqueous base. They are applied on two occasions to the whole body, because it can also infest body hair. All sexual contacts (patient's partner) should also be treated. Patient should be screened for other sexually transmitted diseases. Infestation of the eyelashes and eyebrows is treated with application of white soft paraffin 3 times daily for 1–2 weeks.

## SEXUALLY TRANSMITTED INFECTIONS

STD (Sexually Transmitted Disease) are a group of communicable diseases that are transmitted predominantly by sexual contact and caused by a wide range of bacterial, viral, protozoal and fungal agents and ectoparasites (Table 4.49).

### Gonorrhoea

**Q. Write short note on gonorrhoea/acute gonococcal urethritis.**

**Definition:** Gonorrhoea is a sexually transmitted infection (STI) due to the gram-negative diplococcus, *Neisseria gonorrhoea*. It commonly infects columnar epithelium in the lower genital tract (cervicitis, urethritis), rectum (proctitis), and eye (conjunctivitis).

**Mode of transmission:** Genital-genital, genital-anorectal, or oro-genital or oro-anal contact or from mother-to-child transmission during delivery.

**Incubation period:** Usually 2–10 days following exposure.

### **Clinical Features**

- **Gonococcal infections in men: Acute urethritis** is the most common clinical manifestation and presents with urethral discharge and dysuria usually without urinary frequency or urgency. On examination, urethra shows mucopurulent discharge that may be accompanied by erythema of the urethral meatus.
- **Gonococcal infections in women:** Gonococcal cervicitis and vaginitis present with symptoms related to endocervical and urethral infection and include scant vaginal discharge and dysuria. Gonococci may infect the urethra, paraurethral glands/ducts, and Bartholin's glands/ducts. It may be asymptomatic in up to 80% of women.

**Table 4.49: Sexually transmitted infections.**

<b>Bacterial agents</b> <ul style="list-style-type: none"><li>• <i>Neisseria gonorrhoea</i></li><li>• <i>Chlamydia trachomatis</i></li><li>• <i>Haemophilus ducreyi</i></li><li>• <i>Mycoplasma hominis</i></li><li>• <i>Ureaplasma urealyticum</i></li><li>• <i>Calymmatobacterium granulomatis</i></li><li>• <i>Shigella spp.</i></li><li>• Group B <i>Streptococcus</i></li><li>• Bacterial vaginitis associated organisms</li></ul>	<b>Viral agents</b> <ul style="list-style-type: none"><li>• Human (alpha) herpesvirus</li><li>• Human (beta) herpesvirus</li><li>• Hepatitis B virus</li><li>• Human papillomavirus</li><li>• Molluscum contagiosum virus.</li><li>• Human immunodeficiency virus</li></ul>
<b>Protozoal agents</b> <ul style="list-style-type: none"><li>• <i>Entamoeba histolytica</i></li><li>• <i>Giardia lamblia</i></li><li>• <i>Trichomonas vaginalis</i></li></ul>	<b>Fungal agents</b> <p><i>Candida albicans</i></p> <b>Ectoparasites</b> <ul style="list-style-type: none"><li>• <i>Phthirus pubis</i></li></ul>

- **Anorectal and pharyngeal gonorrhoea** are usually asymptomatic.
- **Ocular gonorrhoea:** Gonococcal conjunctivitis is uncommon. It may present with purulent discharge from the eye(s), inflammation of the conjunctivae and edema of the eyelids, pain and photophobia. Gonococcal ophthalmia neonatorum also presents with purulent conjunctivitis and edema of the eyelids. Conjunctivitis must be treated early to prevent corneal damage.
- **Disseminated gonococcal infection (DGI):** Dissemination can result in gonococcal bacteremia and is rare and develops in women with asymptomatic genital infection. Symptoms include arthritis of one or more joints (asymmetric and migratory), pustular skin lesions, fever and tenosynovitis. Gonococcal endocarditis or meningitis may rarely occur.
- **Acute perihepatitis (Fitz-Hugh-Curitis syndrome)** is a rare complication of PID, and is thought to occur through direct extension of *N. gonorrhoeae* from fallopian tube to liver capsule and peritoneum along the paracolic gutters. Patients present with sharp, pleuritic right upper quadrant pain.

## Diagnosis

### **Q. Write short note on gonorrhoea diagnosis and treatment.**

- **Gram's staining and culture** of urethral exudates, genital, rectal, pharyngeal or ocular secretions show gram-negative intracellular monococci and diplococci.
- **Sterile pyuria:** Urine may show polymorphonuclear leukocytes with a negative urine culture report.
- **Nucleic acid probe tests:** Nucleic acid amplification tests (NAATs) is more sensitive than culture. They can be performed on urine samples, swabs from endocervix, urethra, rectum and pharynx.
- Direct antigen detection by fluorescein-conjugated monoclonal antibodies and direct fluorescence microscopy.
- Enzyme-linked immunoassays for the detection of gonococcal antigen.
- Blood cultures in disseminated disease.

**Complications:** If untreated infections can develop following complications:

- **In females:** Causes pelvic inflammatory disease PID (pelvic inflammatory

disease). Local complications such as endometritis, salpingitis, tubo-ovarian abscess, Bartholin's abscess, peritonitis, and perihepatitis.

- **In male patients:** Periurethritis, epididymitis, epididymo-orchitis and prostatitis.
- **Newborns:** Ophthalmia neonatorum in newborns.

#### Box 4.22: Treatment of gonorrhoea.

- One of the following regimens is recommended at present:
  - Cefixime 400 mg orally (single dose)
  - Ceftriaxone 250 mg intramuscularly (single dose)
  - Spectinomycin 2 g intramuscularly (single dose)
- If quinolone and azithromycin resistance is not a problem:
  - Ciprofloxacin 500 mg orally (single dose)
  - Ofloxacin 400 mg orally (single dose)
  - Levofloxacin 250 mg orally (single dose)
  - Azithromycin 2 g orally (single dose)
- For epididymo-orchitis doxycycline 100 mg twice daily for 14 days along with one dose of ceftriaxone or ciprofloxacin.

#### Q. Write short note on:

- **Management of urethral discharge in males**
- **Treatment of gonorrhoea in adults.**

Treatment of gonorrhoea (Box 4.22).

## Nongonococcal Urethritis

### Etiology (Table 4.50)

#### Signs and symptoms

Symptoms and signs of gonococcal urethritis and non-gonococcal urethritis are similar but differ significantly in severity.

**Table 4.50: Causes of nongonococcal urethritis.**

<i>Chlamydia trachomatis</i> (15–40%)	<i>Mycoplasma genitalium</i> (15–25%)
Others (20–50%) <ul style="list-style-type: none"> <li>• <i>Trichomonas vaginalis</i></li> <li>• <i>Ureaplasma urealiticum</i></li> <li>• Herpes simplex virus (in absence of skin</li> </ul>	<i>Miscellaneous</i> In association with urinary tract infection, bacterial prostatitis, urethral stricture, phimosis, secondary to instrumentation of the urethra, congenital abnormalities, chemical irritation,

lesions)

- Adenovirus
- Hemophilus

tumors

## Diagnosis

- **Gram staining of discharge or sediment** of first voided urine: (symptomatic/asymptomatic)
- Direct fluorescence assay
- Enzyme immunoassay
- Hybridization assay
- Nucleic acid amplification tests.

### **Q. Write short note on drugs used in nongonococcal urethritis.**

#### Treatment

- STD treatment guidelines from the CDC 2010 and the WHO recommends
  - **Doxycycline 100 mg twice daily** for 7 days. **OR**
  - **azithromycin 1 g orally**

#### Alternatives

- Erythromycin base 500 mg four times for 7 days, OR
- Ofloxacin 300 mg twice daily for 7 days, OR
- Levofloxacin 500 mg once daily for 7 days

#### General Features

- All sex partners in last 60 days should be evaluated and treated.
- Sexual abstinence till completion of treatment.
- Patients should be reviewed 2–3 weeks after treatment to confirm resolution of symptoms and treatment of sexual contacts.
- Should be checked for other STIs including syphilis and HIV. Results of tests checked during review.

## Chancroid

### **Q. Write short essay/note on clinical features and treatment of chancroid.**

- Chancroid or soft chancre is an acute sexually transmitted infection caused by *Haemophilus ducreyi*. It is characterized by painful genital ulcerations and inguinal adenitis.
- The genital ulceration in chancroid increases the efficiency of transmission and the degree of susceptibility to HIV in infection.

- Coinfection with *Treponema pallidum* and herpes simplex is observed in 10% of cases.

## **Clinical Features**

### **Q. Write short note on bubo.**

- Incubation period: Usually 3–10 days.
- Infection is acquired due to a break in the epithelium during sexual contact with an infected individual.
- **Lesion in the external genitalia:**
  - **Sites of lesions:** Prepuce and frenulum in men and vaginal entrance and the perineum. At the site of inoculation (the external genitalia), an initial erythematous papule appears which then breaks down within 2–3 days into a classic chancroidal ulcer.
  - **Characteristics of ulcer:** This chancroid ulcer is superficial, circumscribed and painful. Ulcers have ragged and undermined edges, and necrotic base, bleeds easily and generally not indurated. Ulcer may be single. If multiple, they may merge to form giant serpiginous ulcer.
- **Lymphadenopathy:** About 50% of patients develop enlarged, painful, tender inguinal lymph nodes (usually unilateral). The involved nodes become matted and progress to form large unilocular buboes which suppurate.

## **Diagnosis**

### **Q. Write short note on chancroid diagnosis and treatment.**

#### **Treatment of chancroid (Box 4.23)**

Sex partners of chancroid patients should be examined and treated, if they had sexual contact with the patient during the 10 days preceding the patient's onset of symptoms. This is regardless of whether they have symptoms of the disease or not.

#### **Box 4.23: Treatment options for chancroid.**

- Azithromycin, 1 g orally, as a single dose, OR
- Ceftriaxone, 250 mg by intramuscular injection as a single dose, OR
- Ciprofloxacin, 500 mg orally, twice daily for 3 days, OR
- Erythromycin base, 500 mg orally 4 times daily for 7 days

- It is based on the microscopic identification and culture isolation of *Hemophilus ducreyi* in scrapings from ulcer or pus from bubo.
- Polymerase chain reaction (PCR) technique not commercially available.
- Detection of antibody to *H. ducreyi* using EIA may be useful.

## CHLAMYDIAL INFECTIONS

**Q. Write a short note on chlamydial infections.**

Chlamydial infections may be asymptomatic or cause:

- **In male:** Urethritis, epididymitis, prostatitis. Untreated infection can cause infertility and reactive arthritis.
- **In female:** Cervicitis and salpingitis. Most of the infected females are asymptomatic and are likely to develop complications such as PID, infertility or ectopic pregnancy.

## Lymphogranuloma Venereum (LGV)

**Q. Write a short note on lymphogranuloma venereum (LGV).**

It is a sexually transmitted disease caused *Chlamydia trachomatis* (types LGV 1, 2 and 3).

### *Clinical Features*

- **Incubation period:** 3–30 days.
- **Stages:** Three characteristic stages:
  1. **Primary genital lesion:** LGV starts as an asymptomatic small painless papule at the site of inoculation (external genitalia) and tends to ulcerate.
  2. **Regional lymphadenopathy:** A few days to weeks, the ulcers heal and regional lymphadenopathy (usually unilateral develops). The lymph nodes are initially discrete painful and fixed and the overlying skin appears dusky and erythematous.
  3. **Buboes:** Later in the course, the lymph nodes may become matted, fluctuant (buboes) and rupture. The overlying skin becomes thinned, inflamed, and fixed. Finally, multiple draining fistulae may occur. Extensive enlargement of inguinal lymph nodes above and below the inguinal ligament ('groove sign') can develop.

- **Other feature:**
  - Acute LGV can also cause proctitis with perirectal abscesses, which may resemble anorectal Crohn's disease.
  - **Chronic phase:** Chronic infection may produce extensive scarring and abscess and sinus formation. The destruction of local lymph nodes can produce lymphedema of the genitalia.
  - **Constitutional symptoms:** These include fever, chills, headache, anorexia, meningismus, myalgias and arthralgias.

## Diagnosis

- **Detection of nucleic acid (DNA):** Direct immunofluorescent antibody, and nucleic acid amplification tests are positive which should be confirmed by real time PCR for LGV specific DNA.
- **Isolation of the LGV (L1–3 serotypes) strain of Chlamydia:** Tissue culture from swab obtained from ulcer aspirated bubo pus, rectum, urethra, endocervix or from other infected tissue is the most specific test; however, sensitivity is only 75–85%.
- **Serological tests:** Microimmunofluorescence (micro IF) test, complement fixation test (CF) to detect antibodies.
- Frei skin test is not useful.

### Treatment (Box 4.24)

- Early treatment is necessary to prevent the chronic phase.
- Fluctuant buboes should be aspirated with a syringe and needle.
- Surgical drainage or reconstructive surgery may be sometimes needed.

### Box 4.24: Treatment options for lymphogranuloma venereum.

- Doxycycline, 100 mg orally, twice daily for 14 days, OR
- Erythromycin, 500 mg orally, 4 times daily for 14 days, OR
- Tetracycline, 500 mg orally, 4 times daily for 14 days

## GRANULOMA INGUINALE (DONOVANOSIS)

### **Q.** Write short note on granuloma inguinale (donovanosis).

Granuloma inguinale is a genital ulcerative disease caused due to intracellular gram-negative bacterium *Klebsiella granulomatis* formerly known as

calymmatobacterium granulomatis (Donovan bodies).

**Incubation period:** 3–40 days.

## Clinical Features (Genital Lesions)

### Treatment (box 4.25)

- Treatment will prevent the progression of lesions. Treatment should be continued until all lesions have completely epithelialized.
- Treatment with antibiotics is needed for at least 3 weeks. Effective regimens are presented in Box 4.25.

### Box 4.25: Treatment options for granuloma inguinale.

- Azithromycin, 1 g orally on the first day, then 500 mg orally, once a day, OR
  - Doxycycline, 100 mg orally, twice daily, OR
  - Erythromycin, 500 mg orally, 4 times daily, OR
  - Tetracycline, 500 mg orally, 4 times daily, OR
  - Trimethoprim 80 mg/sulfamethoxazole 400 mg, 2 tablets orally, twice daily
- Painless, progressive ulcerative lesions without regional lymphadenopathy.
  - Genital lesions are highly vascular produces ‘beefy red appearance’ and bleeds easily on touch. However, it can also produce hypertrophic granulomatous, necrotic or sclerotic lesions.

**Diagnosis:** Microscopy examination of material from the lesion (tissue crush preparation or biopsy) shows dark staining intracellular bipolar-staining Donovan bodies. The causative organism is difficult to culture.

## SYPHILIS

Syphilis (lues) is a **chronic**, systemic infection **caused by spirochete** *Treponema pallidum* is usually **sexually transmitted**. Spirochetes are gram-negative, slender corkscrew-shaped.

### Source of Infection

Contact with an open infectious lesion of **primary or secondary syphilis**. Lesions in the mucous membranes or skin of the genital organs, rectum, mouth, fingers, or nipples. These lesions include chancre, mucous patch, skin rash or condylomata lata.

### Mode of Transmission

- **Sexual contact:** It is the usual mode of spread.
- **Transplacental transmission:** From mother with active disease to the fetus (during pregnancy) → congenital syphilis.
- **Blood transfusion**
- **Direct contact** with the open lesion is rare mode of transmission.

Transmission from a mother to her fetus, and rarely by blood transfusion is possible for several years following infection.

- *Treponema pallidum* can penetrate intact mucous membranes or abraded skin rapidly and gain entry into the lymphatics and bloodstream and produce systemic infection.

## Classification (Table 4.51 and Fig. 4.30)

### Acquired Syphilis

#### Primary syphilis

**Primary chancre:** It is the classical lesion of primary syphilis.

- **Location:** The primary chancre develop at the site of inoculation
  - **In males: Penis or scrotum** in males (in heterosexual) and in homosexual males, it may occur in the anal canal, rectum fingers, or within the mouth
  - **In females: Cervix, vulva and vaginal wall.**
- Primary chancre (Fig. 4.31) is single, firm, **non-tender (painless)**, slightly raised, **red papule** (chancre) up to several centimeters in diameter. It rapidly becomes eroded to create a clean-based shallow ulcer. Because of the induration surrounding the ulcer, it is designated as **hard chancre**.

**Table 4.51:** Classification of syphilis.

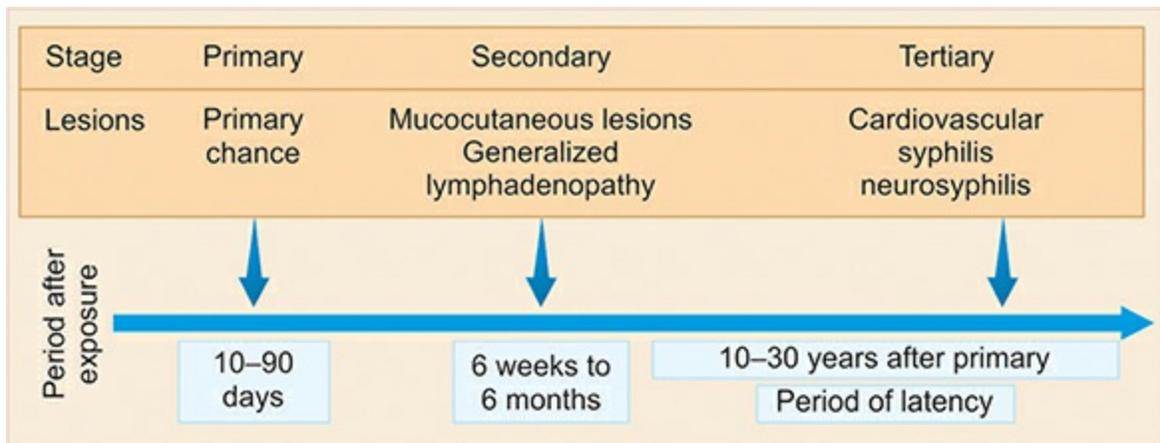

Acquired syphilis	Congenital syphilis
A. Primary syphilis B. Secondary syphilis C. Latent syphilis D. Late syphilis (tertiary) <ul style="list-style-type: none"> <li>• Late latent</li> <li>• Benign tertiary</li> <li>• Quaternary syphilis (cardiovascular and neurosyphilis)</li> </ul>	<ul style="list-style-type: none"> <li>• Intrauterine death and perinatal death.</li> <li>• Early (infantile)</li> <li>• Late (tardive)</li> </ul>

**Regional lymphadenitis:** Usually accompanies the primary chancre within 1 week of the onset of the lesion.

- The lymph nodes are firm, rubbery, mobile, nonsuppurative, painless and non-tender.
- Chancres on external genital and anus produce bilateral inguinal lymphadenopathy, where as those on cervix and vagina cause iliac or perirectal lymphadenopathy.

**Fate:** Even without therapy, the primary chancre heals within 4–6 weeks, but the lymphadenopathy may persist for months.

- Primary syphilis in HIV positive patients is often asymptomatic and they frequently present with secondary or latent syphilis.

**Fig. 4.30:** Course of syphilis (if untreated).

**Fig. 4.31:** Primary chancre in primary acquired syphilis.

## ***Secondary syphilis***

### **Q. Write short essay/note on:**

- **Secondary syphilis**
- **Condylomata lata, mucous patches and snail track ulcers.**

Secondary syphilis develops 4 to 10 weeks after the primary chancre in approximately 75% of untreated patients. Its manifestations are due to systemic spread and proliferation of the spirochetes within the skin and mucocutaneous tissues. It starts with symptoms of generalized infection such as malaise, sore throat, headache, low-grade fever and arthralgia.

### *Lesions*

**Mucocutaneous lesions:** These are painless, superficial lesions and contain spirochetes and are infectious.

- **Skin rashes (75%):** They begin as **discrete red-brown macules** less than 5 mm in diameter. They are generalized symmetrical and non-irritable but more frequent on the trunk and proximal limbs. These macular lesions may progress to a scaly/pustular/annular or necrotic ulcers which

frequently involve the palms (Fig. 4.32A), and soles. The lesions which are initial red, changing to a 'gun-metal' gray as they resolve.

- **Condylomata lata (10%)** (Fig. 4.32B): These are **broad-based**, moist, pink or gray-white, **elevated plaques** (papules coalescing to plaques), highly infectious containing numerous spirochetes. They are seen in moist, warm, intertriginous areas of the skin, such as the **anogenital region (perineum, vulva, and scrotum)**, inner thighs, and axillae.
- **Mucosal lesions (30%)**: Usually occurs in the mucous membranes of **oral cavity (lip, oral mucosa, tongue, palate, and pharynx) or vulva, vagina or glans penis as silvery-gray superficial mucosal erosions**. They are surrounded by a red serpiginous periphery and are usually painless. Rarely, they may coalesce to produce characteristic 'snail track' ulcers in the mouth.
- These lesions contain numerous *T. pallidum* and are the **highly infectious**. **Microscopy**: Similar to primary chancre, i.e. infiltration by plasma cells and endarteritis obliterans.

**Figs. 4.32A and B:** (A) Symmetrical skin rashes of secondary syphilis on palm; (B) Condyloma lata.

**Generalized painless lymphadenopathy:** Generalized, firm non-tender lymphadenopathy (shotty) occurs in about 50% of patients. They involve especially **epitrochlear nodes** and show plenty of spirochetes. Mild fever, malaise, and weight loss are common in secondary syphilis, which may last for several weeks. The lesions subside even without treatment.

**Less common manifestations** include meningitis, cranial nerve palsies, anterior or posterior uveitis, hepatitis, gastritis, glomerulonephritis (proteinuria, nephrotic syndrome or hemorrhagic glomerulonephritis) or arthritis and periostitis.

### *Latent syphilis*

Without treatment, the clinical manifestations of secondary syphilis will

resolve over 3–12 weeks. In an untreated (about 30%) patient during this phase, there is no evidence of clinical disease but shows the presence of positive syphilis serology or the diagnostic cerebrospinal fluid (CSF) abnormalities of neurosyphilis. This is known as latent syphilis and is divided into:

- Early latency (within 1 year of infection): During this period syphilis may be transmitted sexually.
- Late latency (begins at 1 year of infection): During this, the patient is no longer sexually infectious. Pregnant women with latent syphilis may infect the fetus in utero.

### *Late (tertiary) syphilis*

#### 1. **Late latent syphilis**

- This phase may persist for many years or for life.
- No symptoms or signs of syphilis.
- More than 60% of patients suffer little or no ill health even without treatment.

#### 2. **Benign tertiary (gummatous) syphilis**

- It is called benign because of its response to therapy rather than its clinical manifestations.
- It may develop after 3 to 10 years after initial infection.
- Structures involved: Skin (frequently at sites of trauma as nodules or ulcers), mucous membranes (mouth, pharynx, larynx or nasal septum appear as punched-out ulcers), bone (e.g. skull, tibia, fibula and clavicle) muscle or viscera (e.g. liver-hepar lobatum, spleen).
- Characteristic feature: It is a chronic granulomatous (sometimes ulcerating) lesion called a gumma, which may be single or multiple.
- Consequences: Healing with scar formation may damage the function of the structure involved.

#### 3. **Quaternary syphilis:** Neurosyphilis and cardiovascular syphilis may coexist and sometimes called as quaternary syphilis.

### **Q. Write short note on cardiovascular syphilis.**

- **Cardiovascular syphilis**
  - May present many years after initial infection.

- Most **frequently involves the aorta** (the ascending aorta aortic valve and/or the coronary ostia, the aortic arch) and known as syphilitic aortitis.
- Clinical features include angina, features of aortic incompetence and aortic aneurysm.
- **Neurosyphilis** (discussed on pages 976-7).

## ***Congenital Syphilis (Box 4.26)***

### **Box 4.26:** *Stigmata of congenital syphilis.*

- Hutchinson's incisors (anterior-posterior thickening with notch on narrowed cutting edge)
- Mulberry molars (imperfectly formed cusps/deficient dental enamel)
- High arched palate
- Maxillary hypoplasia
- Saddle nose
- Rhagades (radiating scars around mouth, nose and anus following rash)
- Salt and pepper scars on retina (from choroiditis)
- Corneal scars (from interstitial keratitis)
- Sabre tibia (from periostitis)
- Bossing of frontal and parietal bones (healed periosteal nodes)

### **Q. Write short note on congenial syphilis.**

- **Transplacental transmission:** *T. pallidum* can cross placenta and spread it infected **mother to the fetus** (during pregnancy).
- Transmission occurs, when **mother is suffering from primary or secondary syphilis** (when the spirochetes are abundant. Because of routine serologic testing for syphilis is done in all pregnancies) congenital syphilis is rare.

**Manifestations:** Can be divided into:

1. **Intrauterine death and perinatal death.**
2. **Early (infantile) congenital syphilis:** It manifests within the **first 2 years of life** and often manifested by **nasal discharge** (rhinitis) and congestion (**snuffles**). They resemble features of secondary syphilis.
  - A **desquamating or bullous eruption/rash** can lead to epidermal sloughing of the skin, mainly in the hands, feet, around the mouth and anus. Also may show condyloma lata.

- **Skeletal abnormalities: Syphilitic osteochondritis** (inflammation of bone and cartilage is more distinctive in the nose → produces characteristic **saddle nose deformity**); **syphilitic periostitis** (involves the tibia and leads to anterior bowing, or **saber shin**).
  - Others organs involved **liver** (diffuse fibrosis) and **lungs** (airless-**pneumonia alba**).
3. **Late (tardive) congenital syphilis:**
- Manifests **2 years after birth**, and about 50% of untreated children with neonatal syphilis will develop late manifestations and take the form of ‘stigmata’ relating to early damage to developing structures, particularly teeth and long bones.
  - Distinctive manifestation in **Hutchinson’s triad** is: (1) **interstitial keratitis, Hutchinson’s teeth** and (2) **eighth-nerve deafness**. Other features include Clutton’s joints, neurosyphilis, gummatous periostitis, destruction of palate and nasal septum. Cardiovascular involvement is rare. Stigmata of congenital syphilis are listed in Box 4.26.

## Laboratory Diagnosis

**Q. Write short note/essay on:**

- **Tests for diagnosis of syphilis**
- **Serological tests for syphilis**
- **VDRL test.**

### *Demonstration of Treponema pallidum*

- **Dark-field microcopy:** Most sensitive and specific method is identification in serum collected from primary chancres, or from moist or eroded mucous lesions in secondary syphilis by dark-field microscopy. It shows drifting rotary motion (corkscrew) of *Treponema pallidum*. Patients with either primary or secondary disease are highly infectious.
- Direct fluorescent antibody *T. pallidum* (DFA-TP) test: In fixed smears from the chancre is important for diagnosis in primary syphilis.
- Microscopic demonstration of *Treponema pallidum* in tissues stained by appropriate stains and PCR are also useful.

### *Serological Tests*

- **Non-treponemal antibody (nonspecific) tests:** These tests measure antibody to cardiolipin, a phospholipid present in both host tissues and *T. pallidum*.

These test include:

- **Venereal Diseases Research Laboratory (VDRL) test**
- Rapid plasma reagin (RPR) test
- **Treponemal (specific) antibody tests:** They measure antibodies, which react with *T. pallidum*.

*Significance*

- Used for confirmation. They are highly specific for treponemal disease. However, do not differentiate between syphilis and other treponemal infection (e.g. as yaws).
- Most of the patients, these tests usually remain positive for life, regardless of treatment or disease activity. However, 15–25% of patients treated in primary stage become nonreactive after 2–3 years.
- Various tests include:
  - ◆ Treponemal antigen-based enzyme immunoassay (EIA) for IgG and IgM
  - ◆ *T. pallidum* hemagglutination assay (TPHA)
  - ◆ *T. pallidum* particle agglutination assay (TPPA)
  - ◆ Fluorescent treponemal antibody absorption (FTA-ABS) test.

**Examination of CSF:** In benign tertiary and cardiovascular syphilis, CSF should be examined because of coexistence of asymptomatic neurological disease. CSF should be examined in neurosyphilis and in both early and late congenital syphilis.

**Other tests:** Chest X-ray, electrocardiogram (ECG) and echocardiogram are necessary in cardiovascular syphilis. Biopsy may be necessary to diagnose gumma.

#### Management (Table 4.52)

- Patients allergic to penicillin: In primary, secondary and early latent syphilis, these patients should be given tetracycline or doxycycline for 2 weeks and in late latent syphilis it should be given for 4 weeks.
- **Ceftriaxone:** It may be given in the dose of 1 g once a day for 10–14 days.
- **Azithromycin:** Single dose of 2 g is also effective except in homosexual men and during pregnancy.

- **Response to treatment** is considered as satisfactory, if there is a four-fold decrease in non-treponemal titers at 3 to 6 months in all stages of syphilis.
- **Neurosyphilis:** It should be followed up with lumbar puncture and evaluation of CSF every 6 months until the cell count is normal. If after 6 months the cell count is not decreased, retreatment should be given.

**Treatment reactions**

- **Anaphylaxis:** Penicillin is a common cause.
- **Jarisch-Herxheimer reaction:**
  - Treatment of syphilitic patients having a high bacterial load, by antibiotics can cause a massive release of endotoxins, and cytokine causing Jarisch-Herxheimer reaction.
  - Jarisch-Herxheimer reaction is an acute febrile reaction that follows after (about 8 hours after the first injection) any therapy for syphilis. It is characterized by headache, myalgia, malaise, mild fever, rigors, and other symptoms that usually resolve within the first 24 hours.
  - It is common in early syphilis and rare in late syphilis.

**Table 4.52: Management of syphilis.**

<i>Stage of syphilis</i>	<i>Drug</i>	<i>Regimen</i>
Primary	Procaine penicillin	6,00,000 units IM/day for 12 days
	Oxytetracycline	500 mg orally four times/day for 15 days
	Doxycycline	100 mg orally two times/day for 15 days
	Benzathine penicillin	2.4 mega (million) units IM single dose (1.2 million units in each buttock)
Secondary	Procaine penicillin	6,00,000 units IM once daily for 15 days
	Benzathine penicillin	2.4 million units IM single dose
Early latent	Benzathine penicillin	2.4 million units IM single dose
Late latent/tertiary and cardiovascular syphilis	Benzathine penicillin	2.4 million units IM weekly for 3 weeks
Neurosyphilis	Crystalline penicillin	18–24 million units/day for 10–14 days
	Procaine penicillin PLUS probenecid	2.4 million units/day IM for 10–14 day + 500 mg QID for 10–14 day

- It may induce fetal distress or premature labor in pregnancy. This concern should not prevent or delay therapy. It may be severe and worsen the clinical manifestations in cardiovascular or neurosyphilis.
- Penicillin should not be withheld because of the Jarisch–Herxheimer reaction. Because it is not a dose-dependent and there is no point in giving a smaller dose.
- Prednisolone 10–20 mg orally three times daily for 3 days given for 24 hours prior to therapy

may prevent the reaction.

## Approach to a Case of Genital Ulcer (Genital Ulcer Disease/GUD)

**Definition:** Genital ulcer is defined as ulcerative, erosive, pustular or vesicular lesions on the genitalia with or without lymphadenopathy.

### Etiology (Table 4.53)

**Table 4.53: Causes of genital ulcer disease.**

STD-related etiologies and organisms	
Genital herpes	<i>Herpes simplex virus type 1 and type 2</i>
Primary syphilis	<i>Treponema pallidum var. pallidum</i>
Chancroid	<i>Hemophilus ducreyi</i>
Lymphogranuloma venereum (LGV)	<i>Chlamydia trachomatis serovars L1-L3</i>
Granuloma inguinale (Donovanosis)	<i>Calymmatobacterium granulomatis now called Klebsiella granulomatis</i>
Non-STD-related etiologies	
Non-STD infectious	Candida, CMV, EBV, Mycobacteria, <i>Staphylococcus</i>
Noninfectious	Behcets, Reiters, cancer, trauma, aphthous, fixed drug eruptions
<b>No etiological agent is found in 20 to 50% of Genital Ulcer Disease (GUD)</b>	

Features and differential diagnosis of genital ulcer disease is presented in and Table 4.54.

**Table 4.54: Differential diagnosis of a few genital ulcer diseases.**

Characteristic	Syphilis	Herpes (Fig. 4.33)	Chancroid	LGV	Donovanosis
Primary lesion	Papule	Vesicle	Pustule	Papule, vesicle, pustule	Papule
Number of lesions	Usually 1	Multiple	Multiple	Single	Variable
Diameter	5–15 mm	1–2 mm	Variable	2–10 mm	Variable
Edges	Sharply demarcated elevated	Erythematous, polycyclic	Undermined, ragged	Elevated, round or oval	Elevated, irregular

Depth	Superficial or deep	Superficial	Excavated	Superficial or deep	Elevated
Base	Smooth, non-purulent covered with serous exudate	Erythematous	Purulent, dirty gray base	Variable	Red velvety, bleeds easily
Induration	Button hole	None	Not indurated	Not indurated	Not indurated
Pain	Absent	Present	Present	Absent	Absent
Lymph nodes	Bilateral non-tender, firm, lead shot, nonsuppurative	Bilateral tender, firm, nonsuppurative	Unilateral, tender, suppurative, unilocular	Unilateral, tender, suppurative, multilocular	None. Pseudobubo seen

## NOSOCOMIAL INFECTIONS (HOSPITAL INFECTIONS)

### Introduction

**Q. Write short essay/answer on nosocomial infections.**

**Nosocomial infection** is the term derived from two Greek words ‘nosos’ (disease) and ‘komeion’ (to take care of).

**Definition:** In its broad meaning, nosocomial infection is defined as any **infection or disease that any individual suffers from the invasion of pathogens in hospital.**

Requisites for using the term nosocomial infections are:

- Manifestation of the symptoms, **first appear 48 hours or more after hospital admission or within 30 days after discharge** from hospital.
- Any infection or disease which does not exist or is not in incubation period when the clients are hospitalized. They are the result of treatment in a hospital or a healthcare service unit, but secondary to the patient’s original condition
- Infection is caused by the invasion of disease-producing microorganisms acquired in hospital.

**Fig. 4.33:** Herpetic penile ulcer.

## **Health Care-Associated Infection (HAI)**

An infection that develops in a patient who is cared for in any setting where health care is delivered (e.g. acute care hospital, chronic care facility, ambulatory clinic, dialysis center, surgicenter, home).

## **Classification of Nosocomial Infection**

**According to the site of infections**, nosocomial infection has the possibility to occur in every system and every site.

**According to the source of the pathogens**, nosocomial infections can be classified into:

- **Reactivation of latent infection:** TB, herpes viruses.
- **Endogenous infections (autogenous infections):** From normal commensals of the skin, respiratory, GI, GU tract are common. It can occur when part of the individual's flora becomes altered and results in an overgrowth of microorganism. When sufficient numbers of microorganisms normally found in one body cavity or lining are

transferred to another body site, an endogenous infection develops. For example, transmission of enterococci, normally found in fecal material, from hands to the skin is a cause of wound infections.

- **Exogenous infections (cross infections):** They are due to the invasion of causative microorganisms from the source other than the individual's themselves, such as from hospital personnel, the other individuals, various objects and hospital environment.
  - **Inanimate environment:** *Aspergillus* from hospital construction, *Legionella* from contaminated water.
  - **Animate environment:** Hospital staff, visitors, other patients and cross transmission is common.

## Factors Predisposing to Hospital Infection

1. Pre-existing condition
2. Need for invasive devices
3. Effect of surgery (skin wound, tissue trauma, opening colonized viscus, immobilization, implants of foreign material (joint prostheses, arterial graft)
4. Effect of antibiotic treatment (colonization by resistant bacteria and fungi)
5. Effect of immunosuppressive treatment (corticosteroids, cancer chemotherapy, radiotherapy, transplant immunosuppression)
5. Exposure to health care workers and other patients, who may transmit pathogens
7. Exposure to pathogens in the hospital environment.

**Epidemiology:** It develops in ~10% of patients admitted to hospital

**Etiology:** *Staphylococcus aureus*, enterobacteria, *Pseudomonas aeruginosa*, *Acinetobacter* spp., coagulase-negative *Staphylococci*, *Enterococci* and *Candida* are the most frequent pathogens.

## Mechanisms of Transmission

- **Contact:** Direct (person-person), indirect (transmission through an intermediate object-contaminated instruments)
- **Airborne:** Organisms that have a true airborne phase as pattern of dissemination (TB, Varicella)
- **Common-vehicle:** Common animate vehicle as agent of transmission (ingested food or water, blood products, IV fluids)

- **Droplet:** Brief passage through the air when the source and patient are in close proximity
- **Arthropod borne.**

## Main Groups of Nosocomial Infection (Box 4.27)

**Q.** Write short essay/answer on common types of nosocomial infections.

### ***Intravascular Catheter-Related Infections***

- Localized: Peripheral thrombophlebitis, absces
- Systemic: Bacteremia, sepsis, endocarditis, metastatic infection.

**Microbiology:** Coagulase-negative staphylococci (*S. epidermidis*), *S. aureus*, *Candida* spp., *Enterococcus* spp., gram-negative rods.

### **Clinical features:**

- Local signs of inflammation at the site of entry: Redness, tenderness, swelling, slight purulent exudate—prominent in peripheral lines, less in central lines.
- Systemic signs: Fever, rigors and no other source of fever.
- Clinical improvement after catheter removal.
- Elevated inflammatory markers, typical pathogens in blood culture.

### **Box 4.27:** *Main groups of nosocomial infections.*

- Catheter-related infections
- Pneumonia
- Respiratory tract infections other than pneumonia
- Surgical site infections
- Urinary tract infections
- Gastrointestinal infections
- Central nervous system infections

### **Management of catheter/line-related sepsis**

- Two blood cultures, one from catheter, one from peripheral to differentiate colonization vs catheter related bacteremia.
- Catheter removal, culture of the tip – semiquantitative > 15 CFU = infection (insertion of a new catheter not immediately).
- Antibiotics, if symptoms did not resolve after removal, guided by culture results.
- Long-time catheters (Broviac, Hickman) – catheter treatment, antibiotic locks.

### ***Prevention and control***

- Choice of catheter and insertion site.
- Aseptic and atraumatic insertion (skin disinfection, barrier precautions), fixation to the skin.
- TPN-total parenteral nutrition (all-in-one bags) prepared in the pharmacy under sterile precautions.
- Minimize opening of the IV set for additive drugs, every opening strictly aseptic.
- Maintaining adequate hygiene and dressing of the insertion site and regular review of insertion site.
- Replacing giving set and catheter at appropriate intervals.
  - Giving set every 72 hours, if lipid emulsions or blood products—24 hours.
  - Catheter—peripheral 48 h, central 7 days, tunneled line much longer.
  - Removal of catheter if not longer necessary.

## ***Hospital-Acquired, Nosocomial Pneumonia (discussed in Chapter 6 on pages 326-36)***

### **Prevention**

- Pulmonary toilet
- Change position second hourly: Elevate head to 30–45°
- Deep breathing, incentive spirometry
- Frequent suctioning
- Bronchoscopy to remove mucous plugging

## ***Other Respiratory Tract Infections***

Tracheobronchitis, sinusitis—frequent in mechanically ventilated patients risk factor for development nosocomial pneumonia and sepsis.

## ***Urinary Tract Infections (UTI)—Urinary Catheter-Related Infections***

### **Source of uropathogens**

- **Endogenous:** Most common
  - Catheter insertion
  - Retrograde movement up the urethra (70–80%)
  - Patient’s own enteric flora (*E. coli*)
- **Exogenous**
  - Cross contamination of drainage systems
  - May cause clusters of UTI’s.

**Etiology:** Gram-negatives (*E. coli*, *Klebsiella pn.*, *Pseudomonas*, *Proteus* spp.), enterococci, *Candida* spp.

**Risk factors:** Length of catheterization (5%/day), opened drainage system, diabetes, female sex, age above 50 years.

Colonization is often asymptomatic, but there is a risk of ascending infection—pyelonephritis, bacteremia, sepsis.

**Diagnosis:**

- Pyuria: >5 leukocytes per high-power field
- Urine culture: Significant bacteriuria  $\geq 10^5$  CFU/mL.

**Treatment**

- Catheter removal or change
- Antibiotics in symptomatic UTI

**Prevention**

- Avoid catheter when possible and discontinue ASAP—**MOST IMPORTANT**
- Aseptic insertion by trained health care workers
- Maintain closed system of drainage
- Ensure dependent drainage
- Minimize manipulation of the system
- Silver coated catheters
- Maintenance of good patient hygiene
- Replacing catheter at appropriate intervals
- ICU-bacteriological screening—urine culture at appropriate intervals.

## ***Surgical Site Infections (SSI)***

Infections in the site of surgery and related bacteremias.

**CDC classification:**

- **Superficial SSI:** Skin and subcutaneous tissue involved
- **Deep SSI:** Deep soft tissue, fascia, muscles
- **Organ SSI:** Organs, cavities.

**Microbiology:** *S. aureus*, coagulase-negative staphylococci, enterococci, *E. coli*, *Pseudomonas*, *Enterobacter*.

**Antibiotic prophylaxis**

Antibiotics: Bactericidal, effective against considered pathogens, with respect to local resistance, not beta-lactamases inducers. Short course of prophylaxis—first dose IV at induction of anesthesia, second dose if surgery > 3 hours.

**Prevention of SSI**

- **Preoperative:**
  - Minimizing the preoperative hospital stay

- Cutting better than shaving of surgical site
- Antibiotic prophylaxis, if indicated
- Surgical team clothing and washing
- Skin decolonization
- Chlorhexidine
- Intranasal Mupirocin for *S. aureus* carriers
- **Intraoperative:**
  - Regardful (tissue-saving) operation technique
  - Bleeding control
  - Excision of foreign bodies and devitalized tissue
  - Isolation of incised bowel
  - Minimizing of surgical staff and their movement
- **Postoperative:** Aseptic care of the site, sterile covering

## ***Gastrointestinal Infections***

### **Antibiotic-associated colitis**

Precipitated by previous antibiotic treatment, mainly lincosamides, ampicillin, cephalosporins.

***Clostridium difficile*** toxin A (enterotoxin), toxin B (cytotoxin)

**Transmission** via spores may cause hospital epidemics.

- **Postantibiotic diarrhea, simple colitis**
- **Pseudomembranous colitis**
- **Toxic megacolon**

### **Diagnosis:**

- **Clinical:** Diarrhea, fever, abdominal pains, vomiting, related to antibiotic treatment.
- **Laboratory:** *Cl.difficile* toxin detection—ELISA, antigen detection—latex agglutination (stool culture on selective agar, cytotoxicity test on tissue culture = gold standard, rarely available).
- **Colonoscopy:** Typical morphology with pseudomembranes, typical histology in biopsy specimens.

### **Treatment**

- Stop precipitating antibiotic
- Rehydration, diet
- Antibiotic: per oral. metronidazol 3–4 × 500 mg p.o. or vancomycin 4 × 125–250 mg treat at least 7 days
- Probiotic drugs, colestipol, rifaximin have been tried

- Toxic megacolon—colectomy

## ***Central Nervous System Infections***

- CSF shunt-related, rare occurrence, mostly *Staph. aureus* and *Pseudomonas*, often serious course (nosocomial ventriculitis) and high mortality.

## **Strategies to Reduce Nosocomial Infection**

**Q. Write short essay/answer on measures to minimize nosocomial infection.**

- Modify host: Risk factors such as age, underlying disease are difficult to change.
- Reduce patient exposure to pathogens.
- Reduce the number and virulence of nosocomial pathogens.

## ***Exposure Reduction***

- Use of aseptic technique during patient care.
- Regular handwashing.
- Proper isolation of patients known or suspected of harboring infectious diseases.

**Handwashing frequently is the single most important measure to prevent nosocomial infections.**

## **SEPSIS**

**Q. Discuss management of a patient with septic shock.**

**Q. Write short note on sepsis/SIRS/ MODS/Septic shock.**

### **Systemic inflammatory response syndrome(SIRS)**

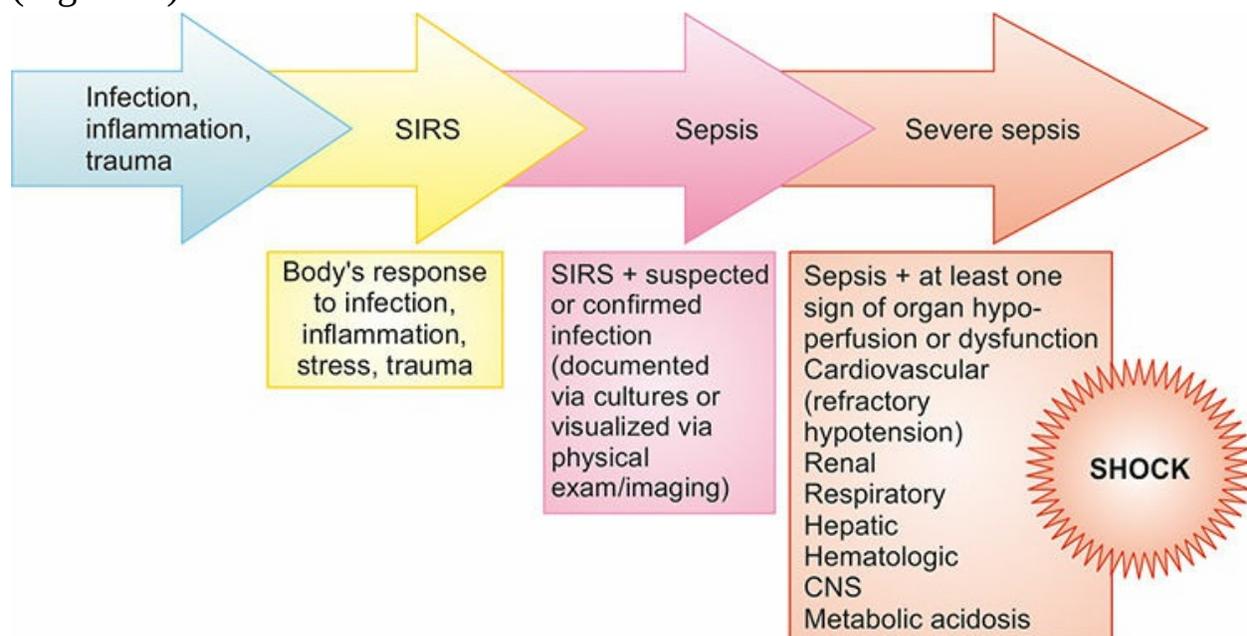

- SIRS is the body's response to a clinical insult (e.g. infection, inflammation, stress, trauma, burns)
- Must have at least 2 of the following:
  - Temperature  $>38.5^{\circ}\text{C}$  or  $<36^{\circ}\text{C}$
  - Heart rate  $>90$  beats/min
  - Respiratory rate  $>20$  breaths/min or  $\text{PaCO}_2 < 32$  mm Hg
  - WBC  $>12,000$  cells/ $\text{mm}^3$ ,  $<4000$  cells/ $\text{mm}^3$ , or  $>10\%$  immature (band) forms.

**Sepsis:** SIRS + suspected or confirmed infection (documented via cultures or visualized via physical exam/imaging). Latest definition of sepsis-*Sepsis is defined as life threatening organ dysfunction caused by the dysregulated host response to infection.* (Sepsis = suspected infection PLUS q SOFA = 2) q SOFA- 3 criteria:Hypotension-systolic BP <100 mm Hg, altered mental status-GCS <13, respiratory rate >22.

**Severe sepsis:** Sepsis + at least one sign of organ hypoperfusion or dysfunction (this category is removed as per 2016 guidelines).

- **Septic shock:** Severe sepsis plus one of the following conditions:
  - MAP <60 mm Hg (<80 mm Hg if previous hypertension) after adequate fluid resuscitation.
  - Need for pressors to maintain BP after fluid resuscitation.
  - Adequate fluid resuscitation = 40–60 mL/kg saline solution (NS 5L-10L).
  - Lactate >2 mmol/L.
- **Multiple organ dysfunction syndrome (MODS)**
  - Altered organ function in an acutely ill patient.
  - Homeostasis cannot be maintained without intervention.

A continuum of severity describing the host systemic inflammatory response (Fig. 4.34).

**Fig. 4.34:** Continuum of severity of sepsis.

(SIRS: systemic inflammatory response syndrome; CNS: central nervous system)

## Etiology of Sepsis

Septic shock may be caused by **gram-positive** (most common) or **gram-negative bacteria, fungi**, and, very rarely, protozoa or Rickettsiae. The common gram-positive bacteria include *Staphylococcus aureus*, **enterococci**, *Streptococcus pneumoniae*, and gram-negative bacilli which are resistant to usual antibiotics.

Risk factors for sepsis are listed in Table 4.55.

Pathogenesis of septic shock is illustrated in Figure 4.35.

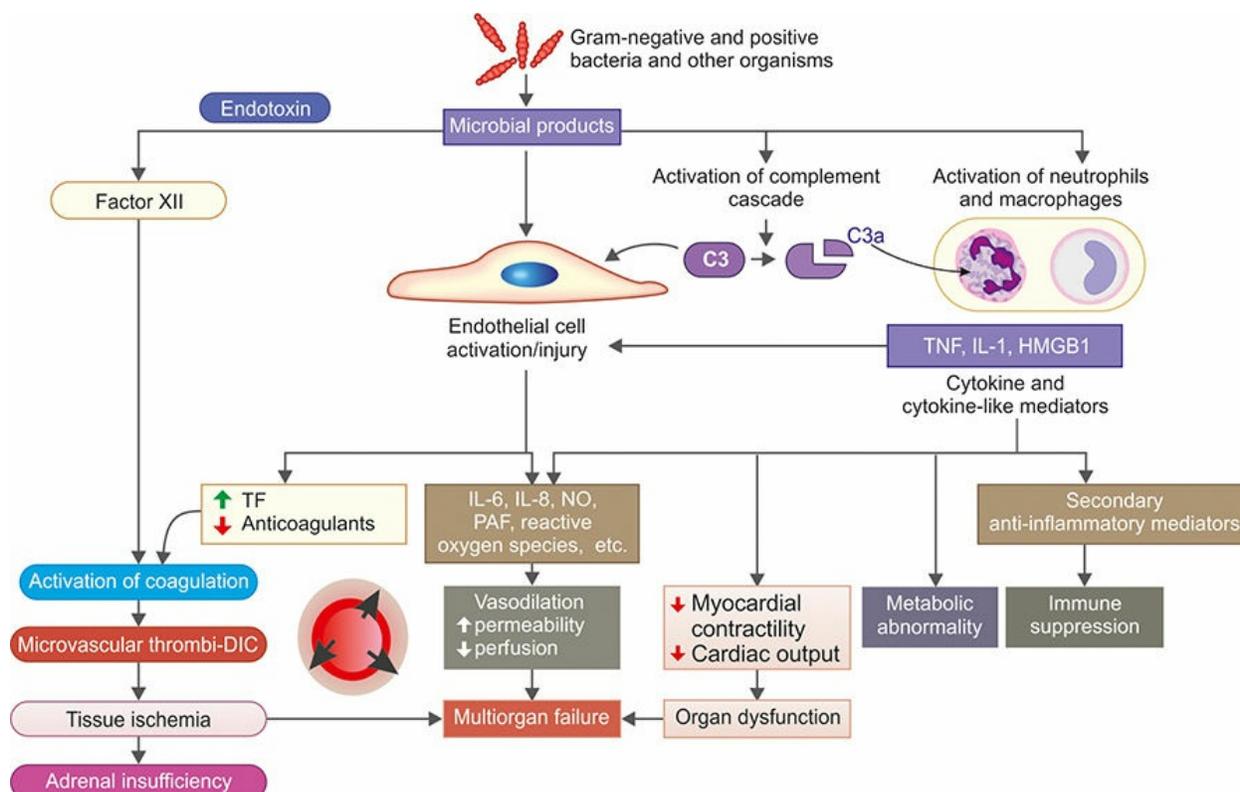

### Management of Sepsis

#### *Surviving sepsis campaign*

- Step 1: Identify sepsis
- Step 2: Categorize sepsis
- Step 3: Initiate treatment

**Table 4.55: Risk factors for sepsis.**

Genetic polymorphism <ul style="list-style-type: none"> <li>• Cytokine responses</li> <li>• Coagulation</li> <li>• Mannose binding proteins</li> </ul>	Intrinsic factors <ul style="list-style-type: none"> <li>• Age</li> <li>• Nutrition</li> <li>• Comorbidities</li> <li>• Vaccination</li> <li>• Immunosuppression</li> </ul>
Procedures <ul style="list-style-type: none"> <li>• Urinary catheters</li> <li>• Intravenous cannula</li> <li>• Wound dressings</li> </ul>	Community factors <ul style="list-style-type: none"> <li>• Contacts</li> <li>• Disease outbreaks</li> <li>• Specific exposure</li> </ul>
Surgery <ul style="list-style-type: none"> <li>• Wounds</li> <li>• Emergency versus elective</li> <li>• Dirty versus clean</li> <li>• Prosthetic material</li> </ul>	Hospital factors <ul style="list-style-type: none"> <li>• Duration of stay in hospital</li> <li>• Where in hospital (e.g. intensive care unit)</li> <li>• Outbreaks</li> <li>• Local antimicrobial resistance rates</li> </ul>

**Fig. 4.35:** Pathogenesis of septic shock. Microbial products initiate endothelial cell activation/injury activates endothelial cells, complement activation, activation of neutrophils and macrophages, factor XII. These initiating events lead to end-stage multiorgan failure. (DIC: disseminated intravascular coagulation; HMGB1: high mobility group box 1 protein; NO: nitric oxide; PAF: platelet activating factor; TF: tissue factor)

Identifying acute organ dysfunction as a marker of severe sepsis is presented in Table 4.56. Box 4.28 lists the principles of sepsis management.

**Box 4.28:** Principles of sepsis management.

- **Recognize sepsis early** and determine **severity**.
  - Organ dysfunction is determined by SOFA (Sequential Organ Failure Assessment Score) which include  $\text{paO}_2$ , bilirubin, creatinine and platelet count.
  - **Early antibiotics** are critical to resolution of shock.
  - **Resuscitate** severe sepsis and septic shock as soon as possible.
  - **Early goal directed therapy**
- 
- **Initial resuscitation:** Volume resuscitation with normal saline 30 mL/kg over first 30 min → if mean arterial pressure >70 mm Hg start inotropes (discussed later).
  - **Diagnosis**
    - **Blood culture:** Before the initiation of antimicrobial therapy, at least two blood cultures should be obtained: (1) at least one drawn percutaneously and (2) at least one drawn through each vascular access device if inserted longer than 48 hours.
    - **Other cultures** such as urine, cerebrospinal fluid, wounds, respiratory secretions or other body

fluids should be obtained as per the clinical situation.

- **Other diagnostic studies** such as imaging and sampling should be performed promptly to determine the source and causative organism of the infection.

- **Antibiotic therapy**

- **Start intravenous antibiotic therapy** within the **first hour** of recognition of severe sepsis after obtaining appropriate cultures.
- Empirical choice of antimicrobials should include one or more drugs with activity against likely pathogens, both bacterial or fungal
  - ◆ Penetrate presumed source of infection
  - ◆ Guided by susceptibility patterns in the community and hospital
  - ◆ Continue broad spectrum therapy until the causative organism and its susceptibilities are defined

- **Source control:** Evaluate patients for focus of infection amenable to source control measures (Table 4.57)

- **Fluid therapy**

- Crystalloids: **always use first!**
- **Table 4.56:** Identifying acute organ dysfunction as a marker of severe sepsis.

**Table 4.56:** Identifying acute organ dysfunction as a marker of severe sepsis.

<b>qSOFA-Quick SOFA</b>	
Respiratory rate >22/min, altered mentation, SBP<100 mm Hg	Any two positive-poor prognosis

- **Vasopressors**

- Initiate vasopressor therapy if appropriate fluid challenge fails to restore adequate blood pressure and organ perfusion.
- Either norepinephrine or dopamines are first line agents to correct hypotension in septic shock.
  - ◆ **Norepinephrine** is more potent and may be more effective than dopamine at reversing hypotension in septic shock patients.
  - ◆ Dopamine may be particularly useful in patients with compromised systolic function but causes more tachycardia and may be more arrhythmogenic.

- **Inotropic Therapy**

- In **patients with low cardiac output** despite of adequate fluid resuscitation, **dobutamine** can be used to increase cardiac output.
- Should be combined with vasopressor therapy in the presence of hypotension.

- **Steroids**

- In patients with septic shock who require vasopressor therapy to maintain blood pressure intravenous corticosteroids are recommended.
- Administer intravenous hydrocortisone 200–300 mg/day for 7 days in three or four divided doses or by continuous infusion.

- **Recombinant Human activated Protein C (rhaPC) [drotrecogin alfa (activated)]:** It is recommended in patients at a high risk of death

- APACHE II (Acute Physiology and Chronic Health Evaluation II) score  $\geq 25$ , or
- Sepsis-induced multiple organ failure, or
- Septic shock, or
- Sepsis induced acute respiratory distress syndrome

Patients should have no absolute or relative contraindication related to bleeding risk that outweighs the potential benefit of rhAPC.

- **Blood product administration:** Red blood transfusion should be given only when hemoglobin decreases to  $<7$  g/dL. Target hemoglobin of 7–9 g/dL.

- **Mechanical ventilation**

- Sepsis-induced acute lung injury (ALI)/ARDS (adult respiratory distress syndrome).
- High tidal volumes,  $>6$  mL/kg, coupled with high plateau pressures,  $>30$  cm H<sub>2</sub>O, should be avoided. A minimum amount of positive end expiratory pressure should be set to prevent lung collapse at end-expiration.

- **Sedation, analgesia, and neuromuscular blockade in sepsis**

- The use of protocols and daily interruption/lightening of continuous sedative infusion have shown to reduce the duration of mechanical ventilation and length of stay.

- **Glucose control:** Following initial stabilization of patients with severe sepsis, blood glucose to <150 mg/dL. Glycemic control strategy must include a nutrition protocol with the preferential use of the enteral route.
- **Renal replacement:** Continuous veno-venous hemofiltration and intermittent hemodialysis are considered equivalent in acute renal failure. Continuous hemofiltration offers easier management of fluid balance in hemodynamically unstable septic patients.
- **Bicarbonate therapy:** Bicarbonate is not recommended for improving hemodynamics or reducing vasopressor requirements or for the treatment of hypoperfusion induced lactic acidemia with pH >7.15.
- **Deep vein thrombosis prophylaxis:** DVT prophylaxis with either low-dose unfractionated heparin or low molecular weight heparin should be used in severe sepsis patients.
- **Stress ulcer prophylaxis:** Stress ulcer prophylaxis should be given to all patients with severe sepsis. H2 receptor blockers are more efficacious than sucralfate and are the preferred agents. Proton pump inhibitors compared to H2 blockers have not been assessed.

**Early goal directed therapy (EGDT) (Table 4.58).**

**Q. Write short note on EGDT (early goal directed therapy).**

**Table 4.58: Early goal directed therapy (EGDT).**

<i>6-hour severe sepsis/septic shock bundle</i>	<i>24-hour severe sepsis and septic shock bundle</i>
<ul style="list-style-type: none"> <li>• <b>Early detection:</b> Obtain serum lactate level.</li> <li>• <b>Early blood culture/antibiotics:</b> Within 3 hours of presentation.</li> <li>• <b>Hypotension (SBP &lt;90, MAP &lt;65) or lactate &gt;4 mmol/Initial fluid bolus 20–40 mL of crystalloid (or colloid equivalent) per kg of body weight.</b></li> <li>• <b>Vasopressors:</b> <ul style="list-style-type: none"> <li>– Hypotension not responding to fluid</li> <li>– Titrate to MAP &gt;65 mm Hg.</li> </ul> </li> <li>• <b>Septic shock or lactate &gt;4 mmol/L:</b> <ul style="list-style-type: none"> <li>– CVP and ScvO<sub>2</sub> measured.</li> <li>– CVP maintained &gt;8 mm Hg.</li> <li>– MAP maintain &gt;65 mm Hg.</li> </ul> </li> <li>• <b>PRBCs (packed RBCs) if hematocrit &lt;30%.</b></li> <li>• <b>Inotropes.</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>Glucose control:</b> Maintained on average &lt;150 mg/dL</li> <li>• <b>Drotrecogin alfa (activated):</b> Administered in accordance with clinical situation</li> <li>• <b>Steroids:</b> For septic shock requiring continued use of vasopressors for equal to or greater than 6 hours.</li> <li>• <b>Lung protective strategy:</b> Maintain plateau pressures &lt;30 cm H<sub>2</sub>O for mechanically ventilated patients</li> <li>• <b>DVT prophylaxis</b></li> <li>• <b>Early enteral nutrition</b></li> <li>• <b>Stress ulcer prophylaxis</b></li> </ul>

## ANTI-INFECTIVE THERAPY

### Antimicrobial Combination Therapy

**Limit combination therapy to special situations**

- **Synergistic killing**, e.g.  $\beta$ -lactam plus aminoglycoside for endocarditis
- **Mixed infections or severe infections of unknown cause**, e.g. limb infections in diabetic patients
- **To prevent the emergence of resistance**, e.g. *M. tuberculosis*
- Initial empiric therapy

## Multidrug Therapy

Tuberculosis, infective endocarditis, malaria, HIV, leprosy.

## Antibiotic Chemoprophylaxis

- **Infective endocarditis:** Amoxicillin + Gentamicin
- **Splenectomy:** Penicillin
- **Rheumatic fever:** Penicillin
- **Tuberculosis:** INH
- **Meningitis:** Meningococcal and *H. influenzae*: Rifampicin

## Beta-lactam Antibiotics

**Q. Write a short essay/note on  $\beta$ -lactam antibiotics.**

**Q. Mention four  $\beta$ -lactam antibiotics with dosage.**

**Q. Mention Cephalosporins and name drugs belonging to third generations.**

These antibiotics have a  $\beta$ -lactam ring structure and their bactericidal (lysis of bacteria) action is due to their inhibition enzymes involved in cell wall formation in the bacteria (penicillin binding proteins, PBP).

**Types of beta-lactam antibiotics (Flowchart 4.3)**

**Adverse effects of beta-lactam antibiotics (Box 4.29)**

## Drug Resistance

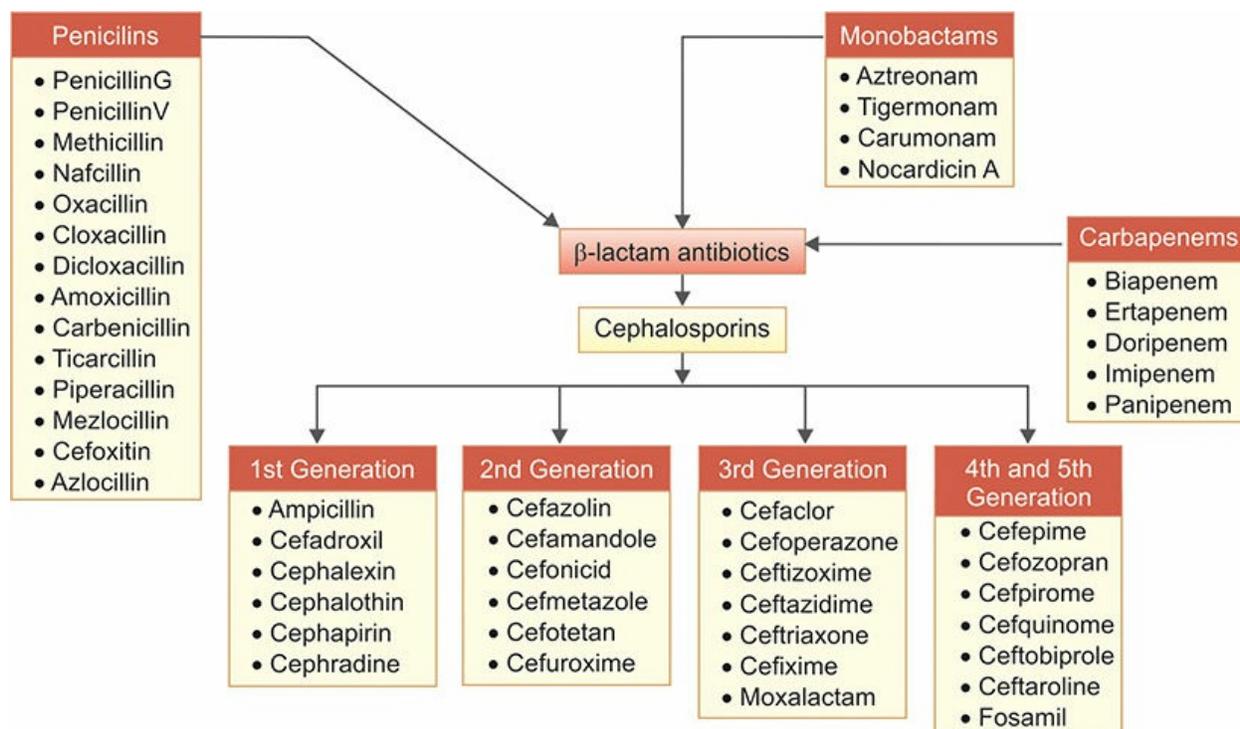

Antibiotic resistance is a challenging and growing problem. The most important mechanism of drug resistance is destruction of drugs by beta-lactamase enzymes.

**Box 4.29:** Adverse effects of beta-lactam antibiotics.

- Generalized allergy to penicillin

- Gastrointestinal upset and diarrhea
- Mild reversible hepatitis
- Leucopenia, thrombocytopenia and coagulation deficiencies, and interstitial nephritis and potentiation of aminoglycoside-mediated renal damage
- Thrombophlebitis with parenteral  $\beta$ -lactams.

**Flowchart 4.3:** Classification of beta-lactam antibiotics.

## $\beta$ -Lactamases

**Q.** Write a short essay/note on  $\beta$ -lactamases.

- Beta-lactam antibiotics have a  $\beta$ -lactam ring structure. They exert a bactericidal action by inhibiting enzymes involved in cell wall synthesis (penicillin binding proteins, PBP).
- $\beta$ -lactamases are bacterial enzymes produced by many gram-positive and gram-negative bacteria. These enzymes can inactivate  $\beta$ -lactam antibiotics by hydrolysis of  $\beta$ -lactam ring structure and results in inactive compounds. Production of  $\beta$ -lactamases by these bacteria is the most important factor that contributes to  $\beta$ -lactam antibiotic resistance.
- Many serine-active  $\beta$ -lactamase inhibitors (e.g. clavulanic acid, sulbactam and tazobactam) in combination with  $\beta$ -lactam antibiotics are used to reduce drug resistance by bacteria containing  $\beta$ -lactamases.

## Extended-Spectrum $\beta$ -Lactamases (ESBL)

Several isolates of *Enterobacteriaceae* and *Pseudomonas* have been identified which produce newer  $\beta$ -lactamases. These enzymes include (1) plasmid-mediated cephamycinases, (2) extended-spectrum  $\beta$ -lactamases (ESBLs), and (3) carbapenem-hydrolyzing enzymes or carbapenemases.

### Major sources of $\beta$ -lactamases (Table 4.59)

- Most commonly  $\beta$ -lactamases are produced by *Klebsiella* spp., *Escherichia coli* but can occur in other GNB (gram-negative bacilli), including *Enterobacter*, *Proteus*, *Salmonella*, and *Citrobacter* spp., *Morganella amorganii*, *Shigella dysenteriae*, *Serratia marcescens*, *Pseudomonas aeruginosa*, and *Burkholderia cepacia*.
- Mutant, plasmid-mediated  $\beta$ -lactamases enzymes are derived from amino acid substitutions in native  $\beta$ -lactamases (particularly TEM-1, TEM-2, and SHV-1)

Typically associated with multidrug resistance (fluoroquinolones, co-trimoxazole, aminoglycosides).

**Table 4.59:** Major sources of  $\beta$ -lactamases.

Types of $\beta$ -lactamases	Major sources
TEM, SHV	<i>Escherichia coli</i> , <i>Klebsiella pneumoniae</i>
Cefotaxime hydrolyzing (CTX-M)	<i>Salmonella typhimurium</i> , <i>E. coli</i> , <i>K. pneumoniae</i>
Oxacillin hydrolyzing (OXA)	<i>Pseudomonas aeruginosa</i>
PER-1	<i>P. aeruginosa</i> , <i>A. baumannii</i> , <i>S. typhimurium</i>
PER-2	<i>Salmonella typhimurium</i>
VEB-1	<i>E. coli</i> , <i>P. aeruginosa</i>

### Actions

- $\beta$ -lactamases are able to hydrolyze all penicillins, cephalosporins (except cephamycins), and monobactams. These are associated with **multidrug resistance** (fluoroquinolones, co-trimoxazole, aminoglycosides).
- The ESBLs are a group of enzymes capable of hydrolyzing and cause resistance to the oxyimino-cephalosporins (cefotaxime, ceftazidime, ceftriaxone, cefuroxime and cefepime) and monobactams (aztreonam), but not the cephamycins (cefoxitin, cefotetan) or carbapenems (imipenem,

meropenem, doripenem and ertapenem).

**Risk factors:** Predisposing to infection or colonization with ESBL-producing pathogens are presented in Table 4.60.

**Treatment recommendations for infections with ESBL producers (Table 4.61).**

## Carbapenem-Resistant Enterobacteriaceae

### *KPC (Klebsiella pneumoniae Carbapenemase)*

Clonal outbreaks in New York, Israel, Greece, Colombia, Brazil, China, Canada (Montreal)

**Q. Write a short essay/note on New Delhi Metallo- $\beta$ -lactamase (NDM-1).**

### *NDM-1 (New Delhi metallo- $\beta$ -lactamase)*

- It is a novel metallo- $\beta$ -lactamase (MBL) coded by a novel gene bla (NDM-1) in *Enterobacteriaceae*.

#### Table 4.60: Risk factors predisposing to infection or colonization with ESBL-producing pathogens.

1. Critically ill patients/severely debilitated individuals
  - Prolonged stay in hospital or ICU unit
  - Invasive procedures: e.g. indwelling catheter, central venous catheter, tracheostomy, endotracheal or nasogastric tube
  - Stay in long-term care facility
  - Decubitus ulcer
  - Total dependence on health care workers
2. Prior antibiotic use in last 3 months
  - Exposure to 2nd, 3rd cephalosporins, aztreonam, penicillin, and quinolones
  - Delay in appropriate antibiotic therapy

#### Table 4.61: Treatment recommendations for infections with ESBL producers.

1. **No treatment needed** for colonization with ESBL producers
2. **Imipenem or meropenem**
  - Bloodstream infection
  - Ventilator-associated pneumonia

- Any producers that appear to have reduced susceptibility to ertapenem
3. **Ertapenem or doripenem**
    - Complicated infections of urinary tract
    - Diabetic foot infections
    - Intra-abdominal infections
  4. **Quinolones:** Infections in patients with risk for allergy to carbapenems, if isolates are susceptible
  5. **Nitrofurantoin or fosfomycin:** Uncomplicated infection of lower urinary tract
  6. **Tigecycline, colistin, or polymyxin B**
    - Isolates resistant to all other antibiotic options
    - Patients allergic to  $\beta$ -lactams
- First it was reported in a Swedish male diabetic, who returned to Sweden after having treatment for gluteal abscess in December 2007 at a hospital in New Delhi. Since the immediate previous treatment was in New Delhi it was named as NDM-1.
  - Subsequently, *Enterobacteriaceae* family containing this genetic element was detected in various regions of India, Pakistan, Bangladesh, Britain and many other countries.
  - MBL (metallo- $\beta$ -lactamase) enzymes mediate resistance to almost  $\beta$ -lactam agents (except monobactams, e.g. aztreonam) including carbapenems.
  - Organism carrying this gene has multidrug resistance and are susceptible only to tigecycline and colistin.

## MISCELLANEOUS

### Amikacin

#### **Q. Write short note on amikacin.**

- It is a **semisynthetic derivative of kanamycin** and has pharmacokinetics, dose and toxicity.
- Outstanding feature: Amikacin has the **wide spectrum of activity and effective against many organisms that are resistant to other aminoglycosides**. However, it is effective in relatively higher dose against *Pseudomonas*, *Proteus*, and *Staphylococci*.
- **Indications:** The range of conditions in which amikacin can be used is as same as for gentamicin. It is **reserved for hospital acquired gram-negative bacterial infections where gentamicin/tobramycin resistance**

is **high**. It is effective against tuberculosis, but rarely used for its treatment.

- **Toxicity:** It causes more hearing loss than vestibular disturbance, nephrotoxicity, neurotoxicity.
- **Dose:** 15 mg/kg/day in 1–3 doses; urinary tract infections 7.5 mg/kg/day. Best given as single daily infusion (minimizes the toxicity).

## Indications of Doxycycline

**Q. Write short note on indications of doxycycline.**

Doxycycline is a tetracycline antibiotic. It is indicated for many different bacterial infections, such as acne, urinary tract infections, intestinal infections, eye infections, gonorrhoea, chlamydia, etc.

## Cephalosporins

**Q. Write short note on cephalosporins.**

Cephalosporins are group of semisynthetic antibiotics derived from cephalosporin-C obtained from a fungus *Cephalosporium*. They are chemically related to penicillins.

- First generation cephalosporins: Cephalexin, cephadrine, cefadroxil
- Second generation cephalosporins: Cefuroxime, cefuroxime axetil, Cefaclor
- Third generation cephalosporins: Cefotaxime, ceftizoxime, ceftriaxone, ceftazidime, cefoperazone, cefixime, cefpodoxime, cefdinir, ceftibuten, ceftamet pivoxil
- Fourth generation cephalosporins: Cefepime, cefpirome.

## Side Effects of Tetracycline, Chloramphenicol, Quinolones (Table 4.62)

**Table 4.62:** Side effects of tetracycline, chloramphenicol, quinolones, lithium.

Drug	Side effects
Tetracycline	<ul style="list-style-type: none"><li>• <i>Dose related:</i> Epigastric pain, nausea, vomiting, diarrhea, fatty liver, renal damage, phototoxicity, brown discoloration of teeth, antianabolic effect, increased intracranial</li></ul>

	pressure, vestibular toxicity <ul style="list-style-type: none"> <li>• Hypersensitivity</li> <li>• Superinfection</li> </ul>
Chloramphenicol	Bone marrow depression, hypersensitivity reactions, nausea, vomiting, diarrhea, superinfection, gray baby syndrome
Quinolones/fluoroquinolones	<ul style="list-style-type: none"> <li>• <i>GIT</i>: Nausea, anorexia, vomiting, bad taste</li> <li>• <i>CNS</i>: Dizziness, headache, restlessness, anxiety, insomnia, tremor</li> <li>• <i>Skin</i>: Hypersensitivity, rash, pruritus</li> <li>• Tendonitis and tendon rupture</li> </ul>

**Q. Write short note on side effects of tetracycline, chloramphenicol, quinolones.**

## Side Effects of Sulfonamides (Box 4.30)

**Box 4.30:** *Side effects of sulfonamides.*

- Nausea, vomiting and epigastric pain
- Crystalluria
- Hypersensitivity reactions
- Hepatitis
- Contact sensitization with topical use
- Hemolysis in persons with G6PD deficiency
- Precipitation of kernicterus in premature newborn

**Q. Write short note on side effects of sulfonamides.**

## Classification of Antifungal Drugs (Table 4.63)

**Q. Write short note on antifungal drugs.**

### ***Ketoconazole***

**Q. Write short note on ketoconazole.**

Ketoconazole is antifungal drug belonging to the azole group. It inhibits enzymes involved in steroid hormone biosynthesis and prevents the growth of the fungus. Ketoconazole is available for oral administration (causes severe hepatitis and it has been discontinued in many countries) and for topical application (e.g. for the treatment of tinea, cutaneous candidiasis).

## Antiviral Agents (Table 4.64)

## Ivermectin

### Q. Write short note on ivermectin.

It is an extremely potent semisynthetic derivative of the antinematodal principle obtained from *Streptomyces avermitilis*.

### Indications

- Drug of choice for single dose treatment of onchocerciasis and strongyloidiasis.
- Bancroftian and brugian filaria
- Cutaneous larva migrans and ascariasis.
- Scabies and head lice.

## Indications for Intravenous Gamma Globulin (Box 4.31)

### Q. Write short note on indications for intravenous gamma globulin.

**Table 4.63:** Classification of antifungal drugs.

Type of drug	Examples
1. <b>Antibiotic</b> <ul style="list-style-type: none"><li>• Polyenes</li><li>• Heterocyclic bezofuran</li></ul>	<ul style="list-style-type: none"><li>• Amphotericin B (AMB), nystatin, hamycin, natamycin</li><li>• Griseofulvin</li></ul>
2. <b>Antimetabolite</b>	<ul style="list-style-type: none"><li>• Flucytosine</li></ul>
3. <b>Azoles</b> <ul style="list-style-type: none"><li>• Imidazoles (topical)</li><li>• Triazoles (systemic)</li></ul>	<ul style="list-style-type: none"><li>• Clotrimazole, econazole, miconazole, oxiconazole (systemic, ketoconazole)</li><li>• Fluconazole, itraconazole, voriconazole</li></ul>
4. <b>Echinocandin: Impairs b 1,3 glucan synthesis</b>	<ul style="list-style-type: none"><li>• Caspofungin, micafungin ,anidulafungin</li></ul>
5. <b>Other topical agents</b>	<ul style="list-style-type: none"><li>• Tolnaftate, undecyleni acid, benzoic acid, quiniodochlor, ciclopirox olamine, butenafine, sodium thiosulfate</li></ul>
6. <b>Allylamine</b>	<ul style="list-style-type: none"><li>• Terbinafine</li></ul>

**Table 4.64:** Antiviral agents.

Category	Drugs

Anti-influenza agents	Amantadine, Oseltamir, Permivir, Rimantadine, Zanamivir
Antiherpes virus agents	Aciclovir, Cidofovir, Docosanol, Famciclovir, Foscarnet, Fomivirsen, Ganciclovir, Idoxuridine, Penciclovir, Trifluridine, Tromantadine, Valaciclovir, Valganciclovir, Vidarabine
Antiretroviral agents	<b>NRTIs:</b> Zidovudine, Didanosine, Stavudine, Zalcitabine, Lamivudine, Abacavir, Tenofovir <b>NNRTIs:</b> Nevirapine, Efavirenz, Delaviridine <b>PIs:</b> Saquinavir, Indinavir, Atazanavir, Ritonavir, Nefinavir, Amprenavir, Lopinavir, Tipranavir <b>New ART:</b> Maraviroc, Enfluvitide
Other antiviral agents	Fomivirsen, Enfuvirtide, Iniquimod, Interferon, Ribavirin, Viramidine

### **Box 4.31:** *Indications for intravenous gammaglobulin.*

#### **Transplantation**

- Allogeneic bone marrow transplantation
- Kidney transplantation with a high antibody recipient or with an ABO incompatible donor
- Hematopoietic stem cell transplantation in patients older than 20 years

#### **Immunodeficiency**

- Common variable immunodeficiency (CVID)
- Primary immunodeficiency disorders associated with defects in humoral immunity.

#### **Others**

- Chronic inflammatory demyelinating polyneuropathy (CIDP)
- Chronic lymphocytic leukemia
- Immune-mediated thrombocytopenia
- Kawasaki disease
- Pediatric HIV type 1 infection

### **Box 4.32:** Mnemonic: *Very Sick Person Must Take Double Eggs.*

Varicella (Chicken pox): 1st day (rash is often 1st sign in children)

Scarlet fever: 2nd day

Pox (Small pox): 3rd day

Measles (Rubeola or 14 day measles): 4th day (Remember: Koplik spots appear in pre-eruptive phase on 2nd day of fever)

Typhus: 5th day

Dengue: 6th day

Enteric fever: 7th day

## ***Commonly Used Immunoglobulins***

- Human immunoglobulins:
  - Human normal immunoglobulins: Hepatitis A, measles, rabies, tetanus, mumps.
  - Human specific immunoglobulins: Hepatitis B, varicella, diphtheria.
- Non-human (antisera): Bacterial (e.g. diphtheria, tetanus, gas gangrene, botulism), viral (e.g. rabies)

## Infections Associated with Skin Rash (Table 4.65 and Box 4.32)

**Q. Write short note on infections associated with skin rash.**

**Table 4.65: Infections associated with skin rash.**

**Macular/maculopapular:** Measles, rubella, enterovirus, Epstein–Barr virus, cytomegalovirus, human immunodeficiency virus (HIV), dengue, typhoid, secondary syphilis, Rickettsiae spotted fevers

**Erythematous:** Scarlet fever, Lyme disease, Toxic shock syndrome (Staphylococcus, Streptococcus), Human parvovirus B19

**Vesicular:** Chickenpox (varicella zoster virus), Shingles (varicella zoster virus), herpes simplex virus

**Petechial/hemorrhagic:** Meningococcal septicemia, any septicemia with disseminated intravascular coagulation (DIC), Rickettsiae and viruses (Flavivirus, Bunyavirus, Arenavirus, Filovirus)

**Urticarial:** *Strongyloides*, *Schistosoma*, Cutaneous larva migrans

**Others:** Tick typhus (eschar), primary syphilis (chancre), anthrax (ulcerating papule), ulcers associated with other STD's

# **HIV Infection and AIDS**

# CHAPTER

# 5

## INTRODUCTION

**Q. Discuss the etiology/epidemiology, mode of transmission, clinical features, stages, laboratory diagnosis and management of HIV-acquired immunodeficiency syndrome (AIDS).**

- More than 36.7 million individuals worldwide are seropositive for human immunodeficiency virus (HIV).
- India has the third largest HIV epidemic in the world. In 2016, HIV prevalence in India was an estimated 0.3%.
- Overall, India's HIV epidemic is slowing down, with a 32% decline in new HIV infections (80,000 in 2016), and a 54% decline in AIDS-related deaths between 2007 and 2015.

### Characteristic Features of HIV

- Acquired immunodeficiency syndrome (AIDS) is caused by the **retrovirus human immunodeficiency virus** (HIV). HIV is a single-stranded RNA human retrovirus and possesses the RNA-dependent DNA polymerase (reverse transcriptase (RT) enzyme).
- Discovered independently by *Dr Luc Montagnier, Dr Anthony Gallo and Dr Jay Levy* in 1983–84.
- The virus causes infection and depletion of CD4+ T lymphocytes.
- Severe immunosuppression → leads to opportunistic infections, secondary neoplasms, and neurologic manifestations.
- **AIDS:** It is defined as clinical diagnosis of any stage 4 condition (defined below) or CD4 cell count <200 cells/μL with confirmed HIV infection or a CD4+ T-cell percentage less than 15% of total lymphocytes.
- Former names of the virus include: Human T-cell lymphotropic virus (HTLV-III), lymphadenopathy associated virus (LAV), AIDS-associated

retrovirus (ARV).

## ETIOLOGY

**Q.** Write short essay/note on etiology of HIV-AIDS.

### Properties of HIV

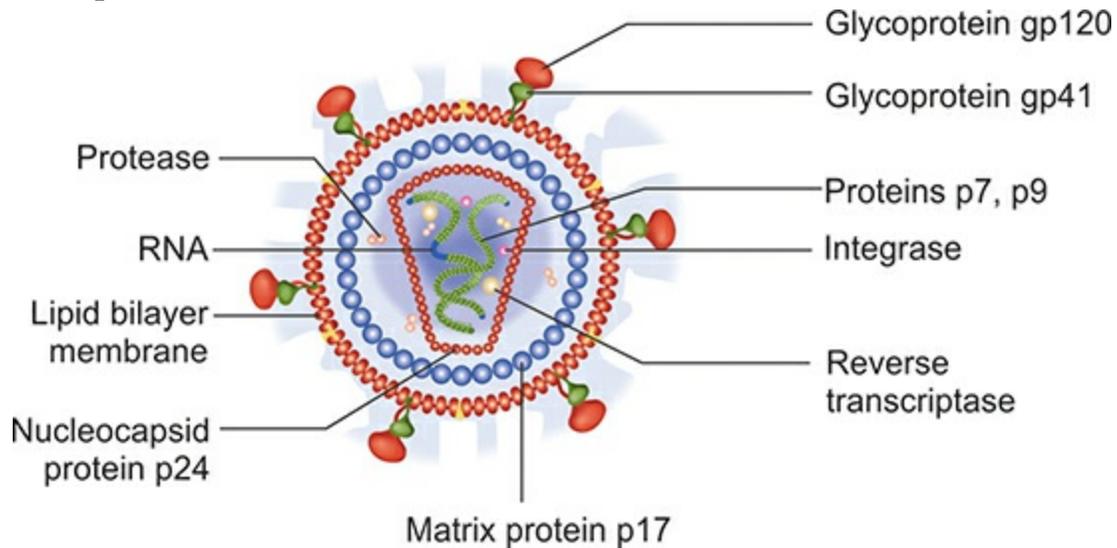

AIDS is caused by HIV, which is a nontransforming human retrovirus belonging to the lentivirus family. Retroviruses are RNA viruses having an enzyme called **reverse transcriptase**, which **prepares a DNA copy of the RNA genome of the virus in host cell**.

**Genetic forms:** HIV occurs in two genetically different but related main forms—**HIV-1 and HIV-2**.

- **HIV-1** is most common in the United States, Europe, and Central Africa. HIV-1 comprises several subtypes with different geographic distribution. Four major groups of HIV-1 are:
  1. **Group M** (*‘major’*, 98% of infections worldwide): Group M *subtypes* exhibit a high degree of diversity and consists of 9 subtypes: A–D, F–H, J and K (subtypes E and I were subsequently shown to be recombinants of other subtypes).
    - ◆ Subtype C (Africa and India accounts for half of the strains and more readily transmitted).
    - ◆ Subtype B predominates in Western Europe, North Americas and Australia.
    - ◆ Subtypes A and D are associated with slower and faster disease progression respectively.
  2. **Group O** (*‘outlier’*) *subtypes* are highly divergent from group M and are largely confined to small numbers centred on Cameroon.
  3. **Group N** (*new-‘non-major and non-outlier’*) is mostly restricted to West Central Africa (e.g. Gabon).
  4. **Group P** related to gorilla strains of SIV (simian immunodeficiency virus) has been identified from a patient from Cameroon.
- **HIV-2 is common** in West Africa and India.

### Structure of HIV (Fig. 5.1)

- HIV-1 is **spherical enveloped** ribonucleic acid (RNA) retrovirus from the *Lentivirus* family. It is about 90–120 nm in diameter.
- Each mature virion consists of electron-dense, cone-shaped core surrounded by nucleocapsid cell which is covered by lipoprotein envelope/membrane.

**Fig. 5.1:** Diagrammatic representation of structure of the human immune deficiency virus (HIV)-1 virion.

### ***Viral Core***

- **Major capsid protein p24:** This viral antigen and the antibodies against this are **used for the diagnosis of HIV infection** in enzyme-linked immunosorbent assay (ELISA).
- **Nucleocapsid protein p7/p9.**
- Two identical copies of **single stranded RNA genome**. The inner cone-shaped protein core (p24) houses two copies of the single-stranded RNA genome and viral enzymes (mentioned below).
- **Three viral enzymes: (1) protease, (2) reverse transcriptase** (RNA-dependent DNA polymerase), and **(3) integrase**. When the virus infects a cell, the retroviral RNA is not translated; instead it is transcribed by reverse transcriptase into DNA. The DNA form of the retroviral genome is called a provirus which can be integrated into the chromosome of host cell.

### ***Nucleocapsid***

The viral core is surrounded by a matrix **protein p24 and p17**, which lies underneath the lipid envelope of the virion.

### **Lipid Envelope**

The virus contains a lipoprotein envelope/membrane, which consists of lipid derived from the host cell and two viral glycoproteins. These glycoproteins are: **(1) gp120** which project as numerous external (on the surface) knob-like spikes, and **(2) gp41** anchoring transmembrane pedicle. These glycoproteins are essential for HIV infection of cells.

### **HIV Genome**

It contains two main groups of genes and their products act as antigens.

1. **Standard genes:** HIV-1 RNA genome contains **three** characteristic standard retroviral genes, which are typical of retroviruses. These include: **gag** (encodes the structural proteins of the core, including p24), **pol** (codes for the enzymes crucial for viral replication, i.e. reverse transcriptase, integrase and protease) and **env** (codes for envelope glycoproteins gp120 and gp41). Initially, the protein products of the **gag** and **pol** genes are translated into large precursor proteins and are later cleaved by the viral enzyme protease to form → mature proteins.
2. **Six regulatory/accessory genes:** HIV contains accessory genes, e.g. **tat, rev, vif, nef, vpr, and vpu**. They regulate the synthesis and assembly of infectious viral particles and the **pathogenicity of the virus**.

### **Modes/Routes of Transmission**

**Q. Write short essay/note on modes of transmission of HIV infection and high-risk groups.**

Transmission of HIV occurs when there is an exchange of blood or body fluids containing the virus or virus-infected cells. Exposure route and percentage of transmission of HIV is presented in Table 5.1. **High viral load is one of the high-risk factor** common to all mode of transmission.

**Table 5.1: Exposure route and percentage of transmission of HIV.**

<i>Exposure route</i>	<i>HIV transmission</i>
Blood transfusion	90–95%
Perinatal	20–40%

<i>Sexual intercourse:</i>	0.1 to 1%
• Vaginal	0.05–0.1%
• Anal	0.065–0.82%
• Oral	0.005–0.01%
Injecting drugs use	0.63–2.14%
Needle stick exposure	0.13%
Mucous membrane splash to eye, oronasal	0.09%

The three major routes of transmission are:

1. **Sexual transmission:** It is the **main route of infection** in more than 75% of cases of HIV. **Risk** of sexual transmission of HIV is increased when there is **coexisting sexually transmitted diseases, especially those associated with genital ulceration** (e.g. syphilis, chancroid, and herpes). Other risk factors include **vaginal/rectal laceration, menstruation and uncircumcised male partner**.

**Homosexual or bisexual men or heterosexual contacts:** It may be male-to-male, or male-to-female or female-to-male transmission. *Worldwide, the major route of transmission is heterosexual.*

**HIV is present in genital fluids** such as vaginal secretions and cervical cells (in women) and semen (in men). The risk of contracting HIV after exposure to infected body fluid is dependent on the integrity of the exposed site, the type and volume of fluid, and the level of viremia in the source person. Risk of HIV acquisition is decreased with circumcision in heterosexual men.

**Parenteral transmission:**

- i. **Intravenous drug abusers:** Transmission occurs by **sharing of needles, and syringes contaminated** with HIV-containing blood.
- ii. **Hemophiliacs:** Mainly those who received large amounts factor VIII and factor IX concentrates before 1985. Now increasing use of recombinant-clotting factors have eliminated this mode of transmission.
- iii. **Transfusion of blood or blood components:** Recipients of blood transfusion of **HIV-infected whole blood or components** (e.g. platelets, plasma) was one of the modes of transmission. Screening of donor blood and plasma for antibody to HIV has reduced the risk of this mode of transmission. However, since a recently infected

individual may be antibody-negative (seronegative), there is a small risk of acquiring AIDS through transfusion of blood.

- iv. Splash of body fluids on mucosa (e.g. nose, mouth and eyes)
- v. Organs from HIV-infected donors can also transmit AIDS.

2. **Perinatal transmission (mother-to-infant transmission):** Major mode of transmission of AIDS in children. Transmission of infection can occur by three routes:

- i. **In utero vertical transmission from mother to fetus:** It is transmitted by transplacental spread. It can occur in two ways: (1) direct inoculation of virus or infected cells into the blood vessels at the site of breach caused by trauma; and (2) by uptake into the mucosal dendritic cells (DCs).
- ii. **Perinatal/peripartum spread:** During normal vaginal delivery or child birth (intrapartum) **through an infected birth canal** and in the immediate period (peripartum). High-risk group includes **older gestational age and prolonged rupture of membranes**.
- iii. **After birth through breastfeeding:** It is transmitted by ingestion of breast milk or from the genital secretions.

**Transmission of HIV infection to healthcare workers:** There is an **extremely small risk** of transmission to healthcare professional, after accidental needle-stick injury or exposure of nonintact skin to infected blood.

### **Routes by which HIV is not transmitted (Box 5.1)**

**Box 5.1:** Routes by which HIV is not transmitted.

- Close personal contact (including kissing, hugging)
- Sharing of utensils and insect bites
- Household contact
- Contact at school, swimming pool, etc.

## **PATHOGENESIS OF HIV INFECTION AND AIDS**

- The interaction between HIV and the host immune system is the basis of the pathogenesis of HIV disease. From the site of initial mucosal exposure, virus enters the blood or tissues of an individual. HIV is

transported by **dendritic cells** from mucosal surfaces to regional lymph nodes where it establishes a permanent infection. This is followed by viremia and dissemination to lymphoid organs, which are the main sites of viral replication.

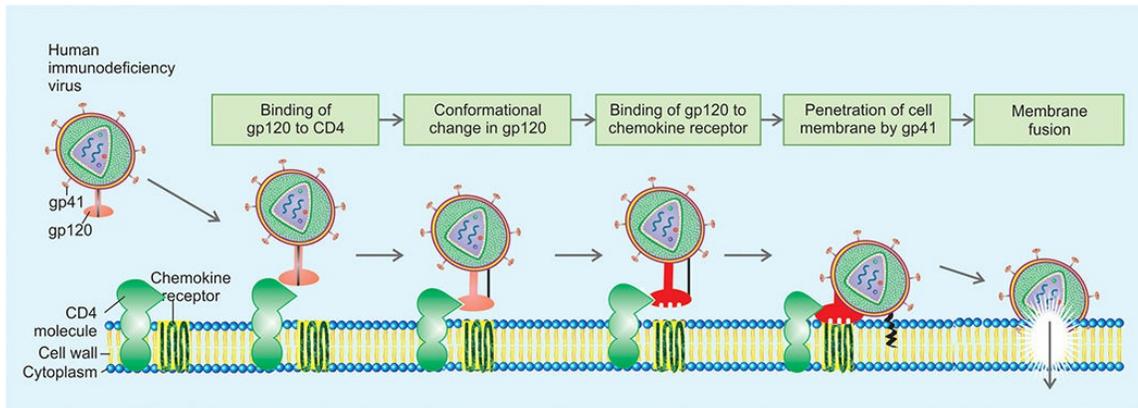

- **Major targets:** Two major targets of HIV infection are the **immune system** and the **nervous system**.

## Life Cycle of HIV

Life cycle of HIV consists of four main steps namely: (1) infection of cells by HIV, (2) integration of the provirus into the host cell genome, (3) activation of viral replication, and (4) production and release of infectious virus (Fig. 5.2).

### 1. Infection of Cells by HIV:

- **Cell tropism:** HIV can infect many tissues, but it has **selective affinity** for host cells **bearing the CD4 molecule receptor**. The cells with such receptors include **CD4+ T-cells** (T-helper lymphocytes) which are present in the **mucosal lymphoid tissue** (largest reservoir of T-cells and where majority of memory cells are lodged) and other CD4+ cells such as **monocytes/macrophages, dendritic cells** and microglial cells in the central nervous system. The HIV envelope contains two glycoproteins, surface gp120 noncovalently attached to a transmembrane protein, gp41.
- **Gp120 of HIV binding to CD4 molecule receptor** on the host cell is the first step in HIV infection. Binding alone is not enough for infection and requires participation of a coreceptor molecule.
- **Conformational change:** Binding to CD4 leads to a conformational change in the HIV, that results in the formation of a new recognition site on gp120 for the **coreceptors CCR5 or CXCR4**. Inhibition of this binding will inhibit viral replication. T-cell tropic HIV strains mainly use CXCR4 as a coreceptor and are called **X4 strains**, whereas 223macrophage-tropic strains, responsible for host-to-host transmission, use CCR5 as a coreceptor and are referred to as **R5 strains**. *Individuals homozygous for mutations within CCR5 gene are resistant to infection by HIV1.*

**Fig. 5.2:** Various molecular steps involved in the life cycle of HIV.

- **Gp120 binding to chemokine receptor:** New recognition site on gp120 of HIV binds to **chemokine receptors**, i.e. CCR5 and CXCR4.
  - **Penetration of host cell membrane by gp41:** Binding of gp120 to the chemokine coreceptors leads to **conformational changes** in gp41.
  - **Membrane fusion:** The conformational change in gp41 allows HIV to penetrate the cell membrane of the target cells (e.g. CD4<sup>+</sup> T-cells or macrophages), leading to fusion of the virus with the host cell.
  - **Entry of viral genome into cytoplasm of host cell:** Once internalized, the virus core containing the HIV genome enters the cytoplasm of the host cell.
2. **Integration of the proviral DNA into the genome of the host cell**
- After the internalization of the virus core, reverse transcriptase enzyme initiates copying of the viral RNA into double-stranded DNA → leading to the **synthesis of double-stranded complementary DNA (cDNA/proviral DNA)**.
- **Episomal form:** In quiescent T-cells, HIV cDNA may remain as a linear episomal form in the cytoplasm of infected cell.
  - **Integration of cDNA:** In dividing T-cells, HIV **cDNA enters the nucleus**, and **becomes integrated into the genome** of the host cell utilizing the enzyme viral integrase. The provirus can then remain latent or be active generation of new virions.
3. **Viral replication:** After the integration of proviral DNA, it can either be latent or productive infection.
- **Latent infection:** During this, the **provirus remains silent** for months or years.

- **Productive infection:** In this, the **proviral DNA is transcribed** → leading to **viral replication** → formation of **complete viral particles**.
4. **Production and release of infectious virus:** The complete **virus particle** formed, **buds from the cell membrane** and **release new infectious virus**. This productive infection when extensive, leads to death of infected host cells. **HIV causes death of CD4+ cells** resulting in **significant depletion of CD4+ T-cells**.

The virus infection remains latent for long periods in lymphoid tissues. Active viral replication is associated with more infection of cells and progression to AIDS.

**Dissemination:** Virus disseminates to other target cells. This occurs either by fusion of an infected cell with an uninfected one or by the budding of virions from the membrane of the infected cell.

## HIV Clinical Staging and Classification (Table 5.2)

**Q. Write short essay/note on clinical staging and classification of HIV.**

Different steps involved in HIV infection are: Viral transmission → acute retroviral syndrome (2–3 weeks) → seroconversion (2–4 weeks) → asymptomatic chronic HIV infection (8 years average) → symptomatic HIV infection/AIDS (1.3 years average).

Clinical staging of patients should be done at the initial medical examination. Two clinical staging systems namely World Health Organization (WHO) and Centers for Disease Control (CDC) (Table 5.3) are being used. In both systems, patients are staged according to the most severe manifestation. CDC classifies the patients into categories based on CD4 count and symptoms.

**Table 5.2: WHO clinical staging classification of HIV infection.**

<i>WHO clinical staging of HIV infection</i>	
<b>Primary HIV Infection</b> <ul style="list-style-type: none"> <li>• Asymptomatic</li> <li>• Acute retroviral syndrome</li> </ul>	<b>Clinical stage 4</b> <ul style="list-style-type: none"> <li>• Candidiasis of esophagus, trachea, bronchi or lungs</li> <li>• Cryptococcosis—extrapulmonary</li> <li>• Cytomegalovirus disease (outside liver, spleen and nodes)</li> <li>• HIV encephalopathy</li> </ul>
<b>Clinical Stage I</b> <ul style="list-style-type: none"> <li>• Asymptomatic</li> <li>• Persistent generalized lymphadenopathy</li> </ul>	

### Clinical Stage 2

- Unexplained moderate weight loss (<10% of body weight)
- Recurrent upper respiratory tract infections (sinusitis, tonsillitis, otitis media, pharyngitis)
- Herpes zoster
- Angular cheilitis
- Recurrent oral ulceration
- Papular pruritic eruptions
- Seborrheic dermatitis
- Fungal nail infections

### Clinical Stage 3

- Unexplained severe weight loss (>10% of body weight)
- Unexplained chronic diarrhea for longer than one month
- Unexplained persistent fever (above 37.5°C for >1 month)
- Persistent oral candidiasis
- Oral hairy leukoplakia
- Pulmonary tuberculosis
- Severe bacterial infections
- Acute necrotizing ulcerative stomatitis, gingivitis or periodontitis
- Unexplained anemia (<8 g/dL), neutropenia (<500/ $\mu$ L) or HIV associated immune thrombocytopenia (<50,000/ $\mu$ L)

- Isosporiasis, chronic (>1 month)
- Lymphoma (cerebral or B-cell non-Hodgkin's)
- Mycosis-disseminated endemic (coccidioidomycosis or histoplasmosis)
- *Pneumocystis pneumonia*
- Progressive multifocal leukoencephalopathy
- Tuberculosis—extrapulmonary (*CDC includes pulmonary*)
- Symptomatic HIV-associated nephropathy
- Symptomatic HIV-associated cardiomyopathy
- Cervical carcinoma—invasive
- Cryptosporidiosis, chronic (>1 month)
- Herpes simplex chronic (>1 month) ulcers or visceral
- HIV wasting syndrome
- Kaposi's sarcoma
- Mycobacterial infection, non-tuberculous, extrapulmonary or disseminated
- Pneumonia, recurrent bacterial
- Toxoplasmosis—cerebral
- Septicemia, recurrent (including non-typhoidal *Salmonella*) (*CDC only includes Salmonella*)
- Leishmaniasis, atypical disseminated

## NATURAL HISTORY OF HIV INFECTION (FIGS. 5.3 AND 5.4)

Virus usually enters the body through mucosal epithelia and clinical course can be divided into three main phases:

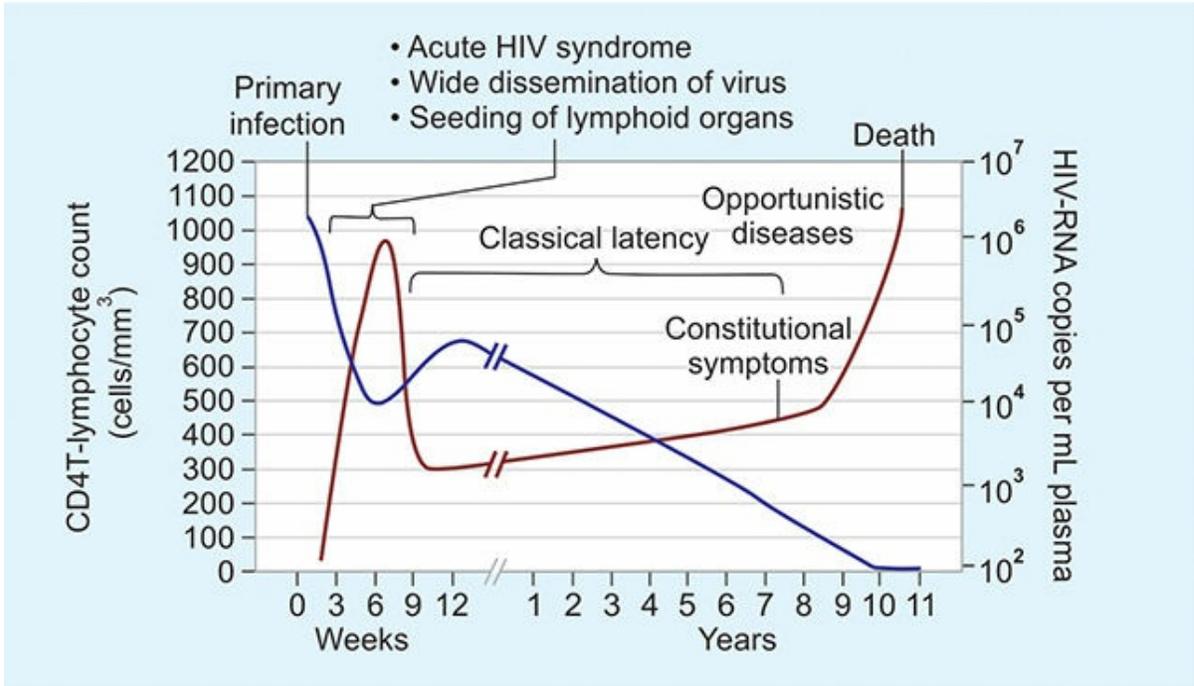

### 1. Early Acute Phase

- **Primary HIV infection (PHI)** refers to the first 6 month period following acquisition of HIV. Fiebig stages of early HIV infection can be used to detect early HIV infection (Table 5.4). HIV infection starts as an acute infection, usually **self-limited nonspecific illness**. During this period, uncontrolled viral replication occurs and results in high levels of HIV circulating in the plasma (**viremia**) and genital tract. At this period, patient

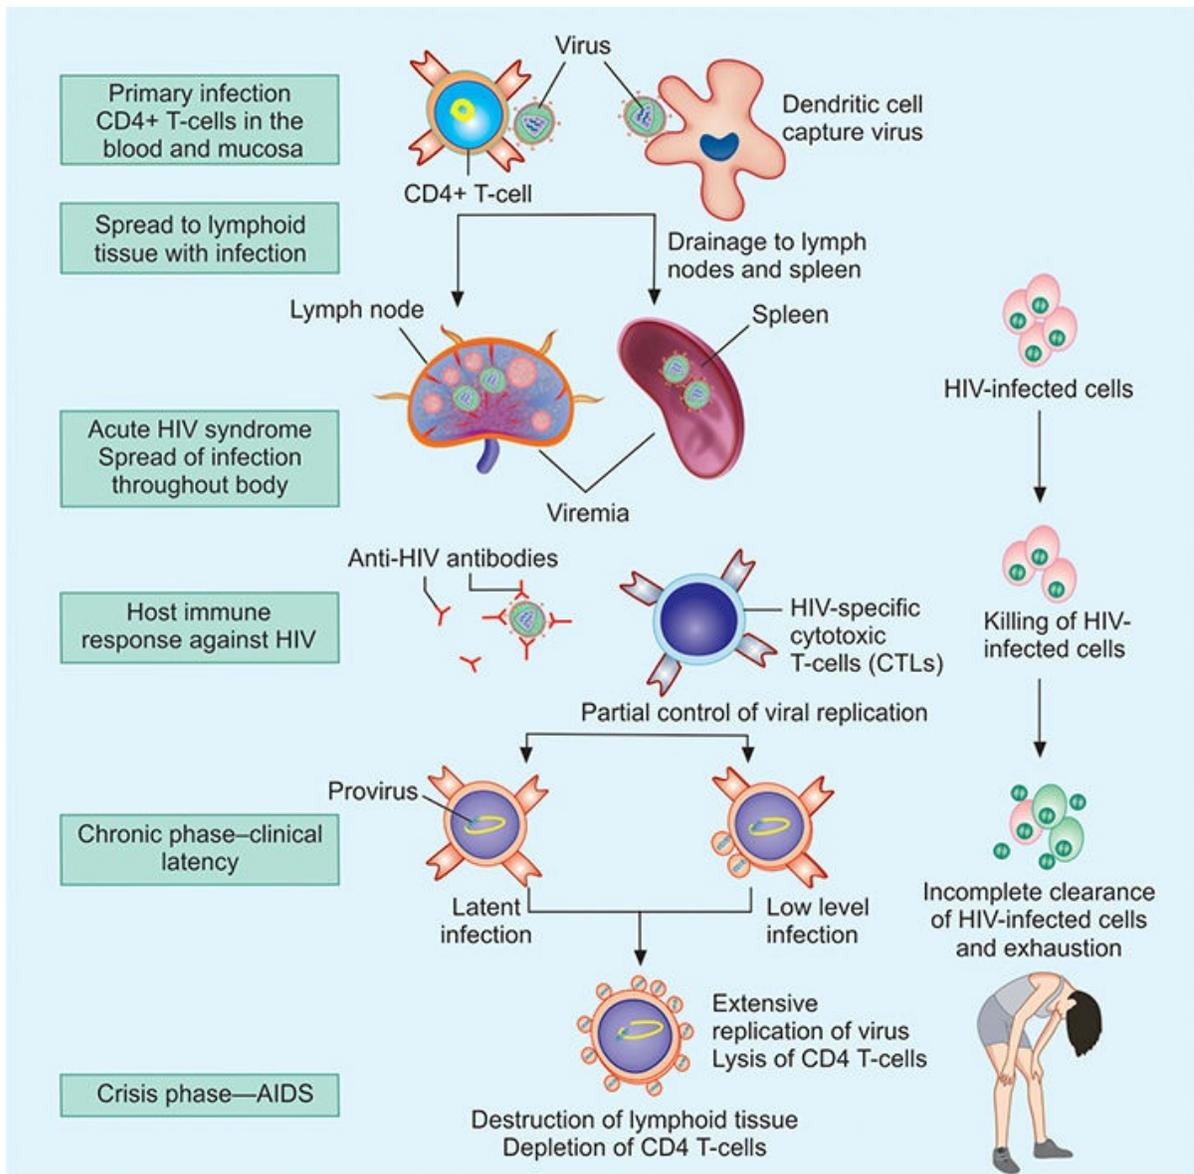

is highly infectious. The 2–4 weeks immediately following infection may be silent both clinically and serologically. It may be followed by **acute HIV syndrome** (nonspecific signs and symptoms similar to many viral diseases). These symptoms include **sore throat, mucosal ulcers, arthralgia, myalgias, fever, weight loss, lethargy, lymphadenopathy, and fatigue**. Other features, such as transient faint pink maculopapular rash, diarrhea and vomiting may also occur. Neurological symptoms are common, including myelopathy, neuropathy, headache, and photophobia. The illness lasts up to 3 weeks and followed by complete recovery.

**Table 5.3: Centers for Disease Control (CDC)—case definition for HIV infection among adolescents and adults.**

<i>Stage</i>	<i>CD4 count</i>	<i>CD4 %*</i>	<i>Clinical evidence</i>
Stage 0	Early HIV infection		
Stage 1	≥500 cells/mm <sup>3</sup>	26	No AIDS-defining condition
Stage 2	200-499 cells/mm <sup>3</sup>	14-25	No AIDS-defining condition
Stage 3	<200 cells/mm <sup>3</sup>	<14	or documentation of AIDS-defining condition
Stage unknown	No data	No data	No information on presence of AIDS-defining conditions

**Fig. 5.3:** HIV disease progression—clinical latency.

**Fig. 5.4:** Pathogenesis of HIV infection. HIV infects CD4+ T-cells and dendritic cells, and spreads to lymph nodes. Viral replication in lymphoid node leads to viremia and widespread seeding of lymphoid tissue. The viremia is controlled by the host immune response, and the disease enters a phase of clinical latency. During this phase, viral replication in both T-cells and macrophages continues. Ultimately, there is progressive decrease of CD4+ cells and patient develops clinical symptoms of full-blown AIDS entering the crisis phase.

**Table 5.4:** Fiebig stages of early HIV infection.

<i>Fiebig stage</i>	<i>Cumulative duration (days)</i>	<i>HIV-RNA</i>	<i>p24 antigen</i>	<i>Immunoassay</i>	<i>Western blot</i>

1	5	+	-	-	-
2	10	+	+	-	-
3	14	+	+	+	-
4	19	+	+/-	+	Indeterminate
5	88	+	+/-	+	+ (p31 band negative)
6	Open-ended	+	+/-	+	+ (p31 band positive)

## 2. Middle Chronic Phase (Clinical Latency Period)

- **Minimal/no symptoms:** This phase is characterized by dissemination of virus, viremia, continuous viral replication in the lymph nodes and spleen and development of immune response by host. The host immune response can handle most infections with opportunistic microbes with no or minimal clinical symptoms. It may have few or no clinical manifestations. The symptoms may be due to **minor opportunistic infections**, such as oral candidiasis (thrush), vaginal candidiasis, herpes zoster, and perhaps mycobacterial tuberculosis.
- **Persistent generalized lymphadenopathy (PGL):** A subgroup of patients may develop persistent generalized lymphadenopathy (PGL). *PGL is defined as lymphadenopathy (>1 cm) at 2 or more extralingual sites for more than 3 months in the absence of causes other than HIV infection.* Biopsy reveals non-specific lymphoid hyperplasia. The lymph nodes are usually symmetrical, firm, mobile and nontender. Nodes may disappear as the disease progresses.
- **Progressive decrease of CD4+ T-cells:** There is **continuous destruction of CD4+ T-cells in the lymphoid tissue** accompanied by steady **decrease in their number in the peripheral blood**. During the early course of disease, the loss of CD4+ T-cells can be replaced by new T-cells. However, over a period of years, the continuous cycle of viral infection and death of T-cells → leads to steady decrease in the number of CD4+ T-cells both in the lymphoid tissue and in circulation. **Direct killing of T-cells by the virus** is the major **mechanism of T-cell depletion**.
- **Inversion of CD4+/CD8+ ratio:** Normal CD4+/CD8+ ratio is 2:1. Loss of CD4+ cells in AIDS patient leads to inversion of ratio of **0.5 or less**.
- **HIV Infection of non-T-cells:** HIV can infect non-T-cells such as macrophages and dendritic cells (**mucosal and follicular**).

## ***Abnormalities of B-cell Function***

- Polyclonal activation of B-cells → hypergammaglobulinemia → circulating immune complexes.
- Impaired humoral immunity → disseminated infections caused by capsulated bacteria, such as *S. pneumoniae* and *H. influenzae*.

## **3. Final Crisis Phase/AIDS and Advanced HIV Infection**

It is final phase of HIV with progression to **AIDS**. Within an average of 7–8 years, the patients present with **fever, weight loss, diarrhea, generalized lymphadenopathy, multiple opportunistic infections, neurologic disease, and secondary neoplasms**. Most of untreated (but not all) patients with HIV infection progress to AIDS after a chronic phase lasting from 7 to 10 years. AIDS is defined as a CD4 cell count <200 cells/μL or the presence of any AIDS-defining condition (Box 5.2) regardless of the CD4 cell count.

## **Patterns of HIV Progression**

- **Typical progressors** have a drop of 35–50 CD4 cells/year.
- **Rapid progressors** (‘CD4 crash’) have a drop of 50 CD4 cells per month after seroconversion. In these patients, the middle, chronic phase is shortened to 2 to 3 years after primary infection, and they **rapidly progress to AIDS**.
- **Slow progressors** have a CD4 decline that is very slow compared to the typical progressors.
- **Long-term non-progressors** have CD4 counts that are stable at a baseline for many years. It is defined as untreated patients who are asymptomatic for 10 years or more, with stable CD4+ T-cell counts and low levels of plasma viremia.
- **Elite controllers** are HIV-infected individuals who have no evidence of viremia, as measured by standard assays (either <50 or <75 copies/mL) and maintain high CD4 cell counts for prolonged periods.

**BOX 5.2:** AIDS-defining conditions (CDC).

- Bacterial infections, multiple or recurrent
- Candidiasis of bronchi, trachea, or lungs
- Candidiasis of esophagus
- Cervical cancer, invasive
- Coccidioidomycosis, disseminated or extrapulmonary
- Cryptococcosis, extrapulmonary

- Cryptosporidiosis, chronic intestinal (>1 month's duration)
- Cytomegalovirus disease (other than liver, spleen, or nodes), onset at age >1 month
- Cytomegalovirus retinitis (with loss of vision)
- Encephalopathy, HIV related
- Herpes simplex: chronic ulcers (>1 month's duration) or bronchitis, pneumonitis, or esophagitis (onset at age >1 month)
- Histoplasmosis, disseminated or extrapulmonary
- Isosporiasis, chronic intestinal (>1 month's duration)
- Kaposi's sarcoma
- Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex
- Lymphoma, Burkitt (or equivalent term)
- Lymphoma, immunoblastic (or equivalent term)
- Lymphoma, primary, of brain
- *Mycobacterium avium* complex or *Mycobacterium kansasii*, disseminated, or extrapulmonary
- *Mycobacterium tuberculosis* of any site, pulmonary, disseminated or extrapulmonary
- *Mycobacterium*, other species or unidentified species, disseminated or extrapulmonary
- *Pneumocystis jirovecii* pneumonia
- Pneumonia, recurrent
- Progressive multifocal leukoencephalopathy
- *Salmonella* septicemia, recurrent
- Toxoplasmosis of brain, onset at age >1 month
- Wasting syndrome attributed to HIV

## IMPORTANT INFECTIONS AND PRESENTING PROBLEMS IN AIDS (Box 5.2)

**Q. List of important/opportunistic infections in AIDS.**

**Q. Write short essay/note on AIDS-defining diseases and opportunistic infections in HIV.**

**Q. HIV-opportunistic fungal infections and their prophylaxis.**

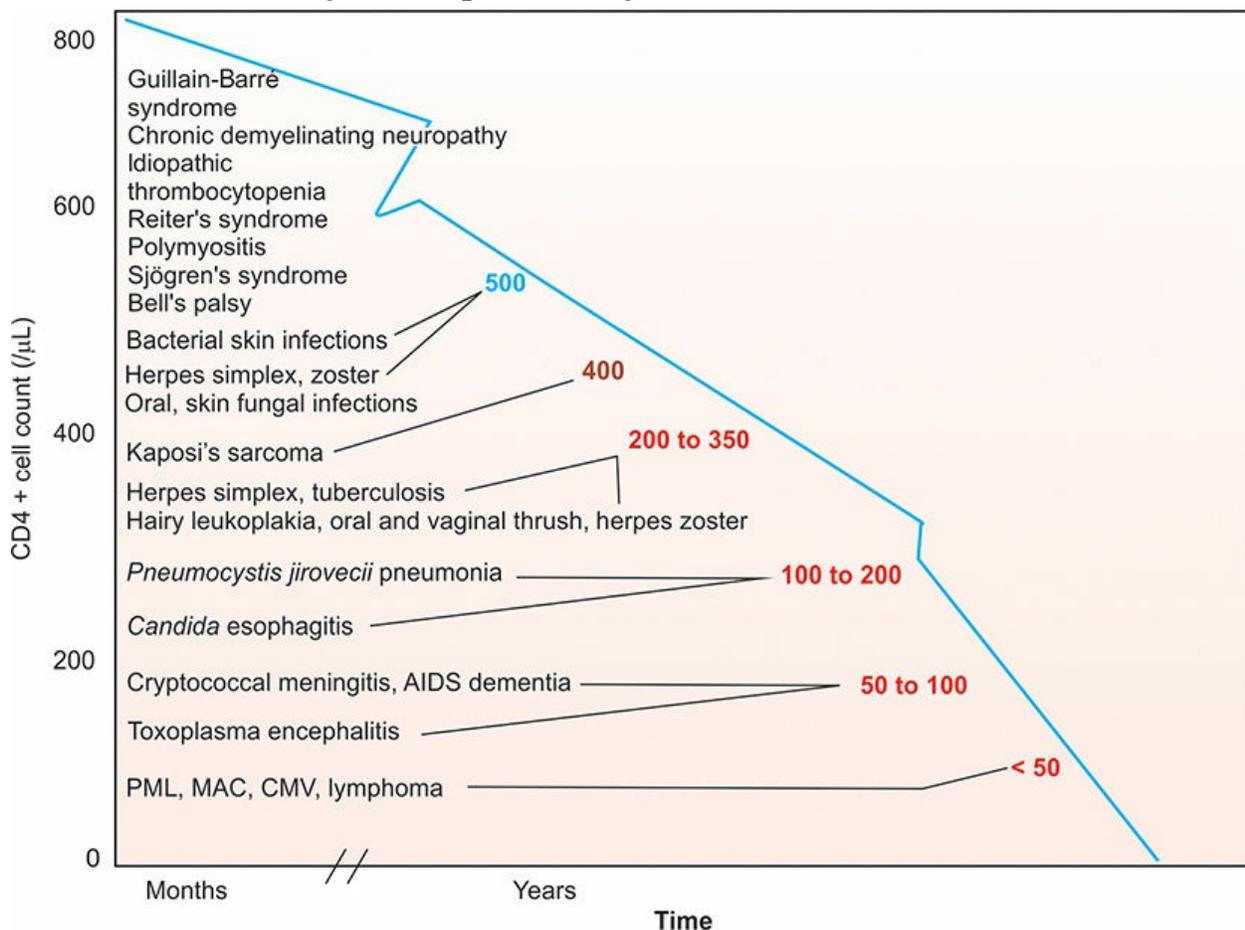

Relation between CD4+ cell count and common illness in HIV patients is presented in Figure 5.5.

### Respiratory System

**Q. Write short essay/note on upper/lower respiratory tract infections and pulmonary complications in AIDS.**

## Acute Bronchitis and Sinusitis

- They are prevalent during all stages of HIV infection. Sinusitis presents as fever, nasal congestion, and headache. The maxillary sinuses are most commonly involved and others frequently involved are ethmoid, sphenoid, and frontal sinuses.
- **Microorganisms:** Infection is usually due to encapsulated organisms such as *H. influenzae* and *Streptococcus pneumoniae*. Patients with low CD4+ T-cell counts may develop mucormycosis infections of the sinuses.

**Fig. 5.5:** Relation between CD4+ cell count and common illness in HIV patients.

(PML: progressive multifocal leukoencephalopathy; MAC: *Mycobacterium avium* complex; CMV: cytomegalovirus infection)

## Pneumonia

- It is the most common manifestation of pulmonary disease in patients with AIDS. It occurs as consequence of altered B-cell function and/or defects in neutrophil function secondary to HIV disease.
- **Microorganism:** Most cases of bacterial pneumonia are due to

*Streptococcus pneumoniae* and *H. influenzae*. Other agents frequently involved include *S. aureus* and *P. aeruginosa*.

### ***Pulmonary Tuberculosis***

- Discussed later on pages 239-40.

### ***Pneumocystis jirovecii* Infection**

**Q. Write short essay/note on pneumocystis jirovecii pneumonia (PJP), its treatment and prophylaxis.**

- *Pneumocystis jirovecii* pneumonia (previously known as *pneumocystis carinii*) is officially classified as a fungal pneumonia. PJP does not respond to antifungal treatment.
- Single most common cause of pneumonia in patients with HIV and responsible for about 25% of cases of pneumonia in patients with HIV infection.
- **Life cycle of *pneumocystis jirovecii***: It consists of three stages namely cysts, trophozoites (outside cyst) and sporozoites (inside cyst).

#### *Clinical features*

- Key presenting feature of PCP (*Pneumocystis* pneumonia) is **progressive dyspnea**. Fever and dry (non-productive) **cough** or productive cough with only scant amounts of white sputum are common.
- They may complain of a characteristic sharp or burning, retrosternal chest pain which is worse on inspiration. Acute onset is uncommon.
- Physical examination reveals **crepitations** and features of consolidation are unusual. **Exercise oximetry**, i.e. demonstrating fall in oxygen saturation after exercise is quite classical.
- Extrapulmonary sites may be involved by *Pneumocystis jirovecii* (e.g. skin, meninges, brain, eyes, heart, liver, spleen and kidneys).

#### *Diagnosis*

- **Chest X-ray**: Bilateral interstitial infiltrate spreading out from the hilar regions (Fig. 5.6). Pneumatocoles may occur and may rupture, resulting in a pneumothorax.
- **High-resolution CT scan**: More sensitive than chest X-ray and usually shows typical '**groundglass**' **interstitial infiltrates**.

- **Arterial blood gas:** Hypoxemia with an increased alveolar-arterial oxygen gradient and respiratory alkalosis.
  - **Mild cases:** Room air arterial oxygen ( $pO_2$ )  $>70$  mm Hg or alveolar-arterial  $O_2$  difference  $<35$  mm Hg.
  - **Moderate-to-severe cases:**  $pO_2 <70$  mm Hg or alveolar-arterial)  $O_2$  difference  $>35$  mm Hg.
- **Serum LDH:** Elevated
- **Pulmonary functions:** Restrictive pattern with reduced diffusion capacity.
- **Diagnosis:** It is made by examination of induced (hypertonic saline nebulization) sputum stained with silver stains, PCR or immunofluorescence of bronchoalveolar lavage or transbronchial biopsy.
  - **Methenamine silver stains the cyst wall** while **Giemsa stains the wall** of the trophozoites and sporozoites. Trophozoites are in plenty in the lungs.

**Fig. 5.6:** Chest X-ray of *Pneumocystis pneumonia* showing bilateral perihilar infiltrates

### Management (Table 5.5)

#### *Prophylaxis*

Primary prophylaxis is indicated in patients with CD4 cell count  $<200/mm^3$  or if there is a history of oropharyngeal candidiasis. Secondary prophylaxis is indicated in all patients who have recovered from PCP.

- **Alternative treatments** for mild-to-moderate PCP include dapsone/trimethoprim, clindamycin/primaquine, and atovaquone. IV pentamidine is the treatment of choice for severe disease in the patient unable to tolerate TMP/SMX. **Adjunctive steroids** needed if the patient is

hypoxic.

- Trimethoprim 160 mg + sulphamethoxazole 800 mg/day, i.e. one single-strength tablet daily (TMP-SMX at a dose of one double-strength tablet daily confers cross-protection against toxoplasmosis also) OR
- Aerosolized pentamidine 300 mg once a month OR
- Dapsone 50 mg BID.
- Others include atovaquone, dapsone plus pyrimethamine plus leucovorin

**Table 5.5: Treatment options for *Pneumocystis jirovecii* infection.**

<b>Mild cases</b>	<b>Moderate-to-severe cases (<math>PaO_2 &lt; 70</math> mm Hg)</b>
Trimethoprim 5 mg/kg 6 hourly + sulphamethoxazole 25 mg/kg 6 hourly orally <b>OR</b>	Trimethoprim 5 mg/kg 6 hourly + sulphamethoxazole 25 mg/kg 6 hourly IV <b>OR</b>
Trimethoprim 5 mg/kg 6 hourly + dapsone 2 mg/day <b>OR</b>	Pentamidine 4 mg/kg/day IV <b>OR</b>
Pentamidine 4 mg/kg/day IV <b>OR</b>	Clindamycin (600 mg qid) + primaquine (30 mg od)
Atovaquone 750 mg BID	In all cases, add prednisolone 40 mg BID for 5 days, then 40 mg/day for 5 days and then 20 mg/day for 11 days.

### ***Atypical Mycobacterial Infections***

- **Atypical mycobacterial infections** are also seen with an increased frequency in patients with HIV infection. ***Mycobacterium avium* complex (MAC)** infection is a **late complication of HIV infection**, occurring predominantly in patients **with CD4+ T-cell counts of  $< 50/\mu\text{L}$** .
- The most common atypical mycobacterial infection is with *M. avium* or *M. intracellulare* species—the *Mycobacterium avium* complex (MAC).
- Prior infection with *M. tuberculosis* **decreases** the risk of MAC infection.

#### *Mode of infection of MAC*

- MAC infections arise from organisms that are ubiquitous in the environment, including both soil and water.
- Person-to-person transmission
- **Portals of entry:** Respiratory and GI tract.

#### *Clinical features*

- Common presentation is **disseminated disease with fever, weight loss, and night sweats, abdominal pain, diarrhea, massive splenomegaly**

### **and lymphadenopathy.**

- Bilateral, lower lobe infiltrate suggestive of miliary spread. Alveolar or nodular infiltrates and hilar and/or mediastinal adenopathy can also occur.
- Anemia and elevated liver alkaline phosphatase are common.

#### **Treatment**

Azithromycin (600 mg daily) or clarithromycin (500 mg twice daily)+/- ethambutol (15 mg/kg PO once daily)/rifabutin for minimum 12 months.

**Chemoprophylaxis** against disseminated MAC disease is needed if CD4+ count are  $<50/\mu\text{L}$ . Preferred prophylactic agents include azithromycin (1200 mg once weekly) or daily clarithromycin (500 mg twice daily).

### ***Other Respiratory Infections***

***Rhodococcus equi*** is a gram-positive, pleomorphic, acid-fast non-spore forming bacillus that can cause pulmonary and disseminated infection in HIV-infected patients.

- Fever and cough with expectoration are the common presenting complaints.
- X-ray shows cavitory lesions and consolidation.

***Coccidioides immitis*** is a mould that is endemic in the southwest United States.

- It can cause a reactivation pulmonary syndrome in patients with HIV infection.
- Most patients have CD4+ T-cell counts  $< 250/\mu\text{L}$ .
- Patients present with fever, weight loss, cough, and extensive, diffuse reticulonodular infiltrates on chest X-ray.
- Nodules, cavities, pleural effusions, and hilar adenopathy are also seen.

**Invasive aspergillosis** is not an AIDS-defining illness and is generally not seen in patients with AIDS in the absence of neutropenia or administration of glucocorticoids.

- Presents as pseudomembranous tracheobronchitis.

Primary pulmonary infection of the lung may be seen with **histoplasmosis**.

**Idiopathic interstitial pneumonia** is a benign infiltrate of the lung and is due to the polyclonal activation of lymphocytes is common.

### **Gastrointestinal Disease**

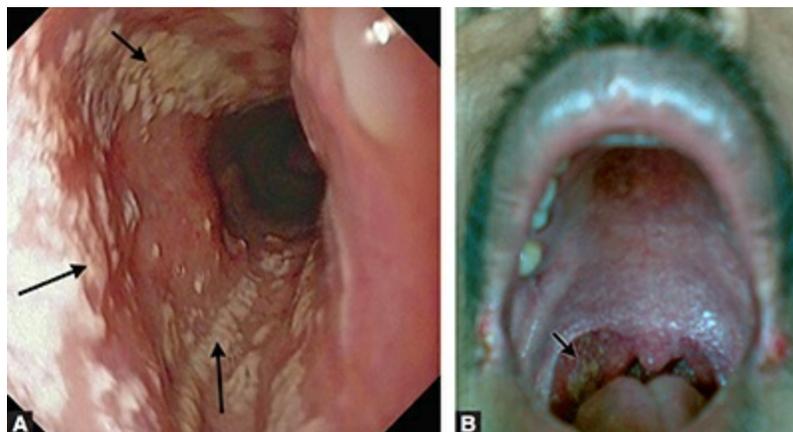

**Q. Write short essay/note on gastrointestinal manifestations of AIDS.**

### ***Esophageal Diseases***

- Esophagitis develops in as many as 90% of the patients with AIDS. It is usually due to *Candida*, CMV and *Herpes simplex* virus.
- Esophageal candidiasis (Fig. 5.7A) is the most common cause of pain on swallowing (odynophagia), dysphagia and regurgitation in HIV patients. Systemic azole therapy (e.g. fluconazole 200 mg daily for 14 days) is usually curative.

### ***Diarrhea***

- Chronic diarrhea is a very common in patients with advanced HIV and is a major cause of wasting. The presentation and etiology (Table 5.6) of acute diarrhea are similar to in HIV-uninfected patients.

**Figs. 5.7A and B:** (A) Esophageal candidiasis; (B) Oral candidiasis in patient with AIDS.

#### **Treatment**

- Protozoal, CMV and mycobacterial infections usually produce protracted diarrhea, and fluid and electrolyte imbalance. **Nitazoxanide** is the treatment of choice for *Cryptosporidium* infection. **Co-trimoxazole** (TMP-SMX) is drug of choice for treatment of *isosporiasis*.
- **ART** is indicated in **all patients with opportunistic infections** because immune restoration often leads to eradication of infections.

**Table 5.6: Cause of diarrhea in HIV patients.**

<b><i>Infections</i></b>	<b><i>HIV related</i></b>
<b>Bacterial:</b> <i>Salmonella</i> , <i>Shigella</i> , <i>Campylobacter</i> , <i>Escherichia coli</i> <i>Clostridium difficile</i>	HIV invading gut epithelium (AIDS enteropathy)
<b>Fungal:</b> Histoplasmosis, Coccidioidomycosis	<b>GI malignancies</b>

and Penicilliosis

**Protozoa:** *Cryptosporidia*, *Microsporidia*,  
*Isospora belli*, *Giardia*, *Entameba histolytica*  
*Enterocytozoon bienewisi*  
*Septata intestinalis*

**Viral:** Cytomegalovirus (CMV), herpes,  
adenovirus, astrovirus, Calicivirida

***Mycobacterium avium complex*, *Mycobacterium tuberculosis***

- Lymphoma
- Kaposi's sarcoma

## Mucocutaneous Diseases (Figs. 5.8A to F)

### **Q. Write short note on mucocutaneous/oral lesions in AIDS.**

- Mucocutaneous manifestations are extremely common in HIV. These include warts (Fig. 5.8A), molluscum contagiosum (Fig. 5.8B), herpes simplex (Fig. 5.8C and D), herpes varicella zoster (Figs. 5.8E), bacillary angiomatosis (caused by *Bartonella* infection), oral candidiasis (Fig. 5.7B), anogenital warts and Kaposi's sarcoma (Fig. 5.8F).

## Neurological Disease (Box 5.3)

**Box 5.3:** Neurological manifestations of HIV infection.

*Directly due to HIV:*

- Sensory neuropathy
- Vacuolar myelopathy
- *Dementia:* HIV-associated neurocognitive disorders (HAND)

*Unmask autoimmune diseases:*

- Polymyositis
- Myasthenia gravis
- Acute inflammatory demyelinating neuropathy (GBS)
- Multiple sclerosis

Opportunistic infections

Complications of ART

Immune reconstitution syndrome

### **Q. Write short essay/note on neurological manifestations of AIDS.**

## Infection of the Nervous System

It occurs at an early stage of HIV. These include: (1) meningitis (acute/aseptic meningitis); (2) HIV associated neurocognitive disorders (HAND) also known as AIDS dementia complex (ADC), and (3) sensory

polyneuropathy. These lesions are due both to the release of neurotoxic products by HIV itself and to cytokine abnormalities secondary to immune dysregulation.

**Acute meningitis:** During acute infection, CNS invasion occurs in more than 90% cases. The clinical spectrum ranges from silent CSF pleocytosis, aseptic meningitis, and infectious mononucleosis-like syndrome, multiple cranial nerve palsies to acute encephalopathy. CSF shows lymphocytosis along with raised proteins (<200 mg/dL). CT is normal and recovery is usually complete.

**Figs. 5.8A to F:** (A) Genital warts; (B) Molluscum contagiosum; (C) Genital herpes (male); (D) Genital herpes (female); (E) Herpes zoster hand; (F) Kaposi's sarcoma.

- **Aseptic meningitis** may occur any time in the course of HIV infection; however it is rare following the development of AIDS. This is probably an immune-mediated disease.

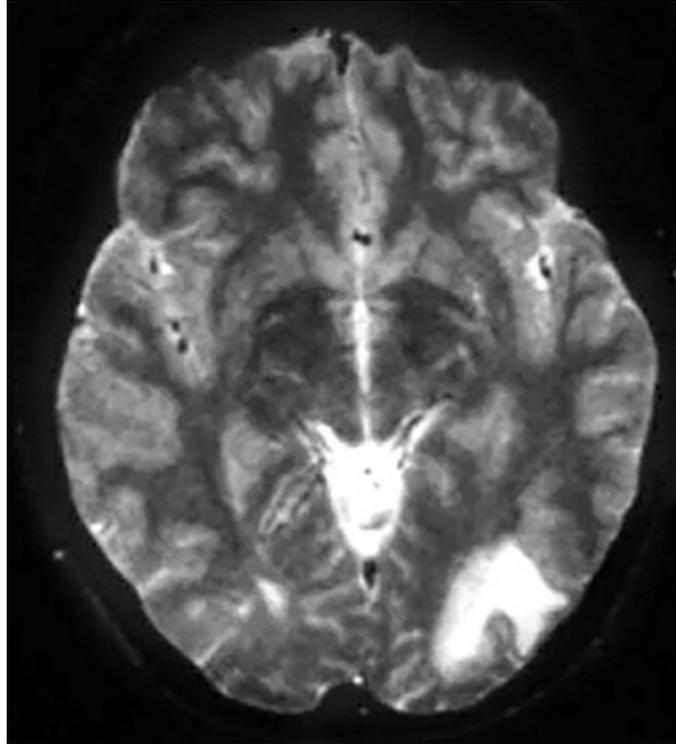

HIV-Associated Neurocognitive Disorders (HAND) include asymptomatic neurocognitive impairment (ANI), mild neurocognitive disorder (MND), and HIV-associated dementia (HAD).

Typically, HAND presents with executive dysfunction and memory impairment. There is prominent disruption of attention, multitasking, impulse control, judgment and memory encoding and retrieval. HAND can also be associated with motor dysfunction such as bradykinesia, loss of coordination and gait imbalance.

**Sensory polyneuropathy:** It develops in advanced HIV infection and occurs mainly in the legs and feet or hands. Severe forms cause intense pain (usually

in the feet), that disrupts sleep, impairs mobility and reduces the quality of life.

- *Autonomic neuropathy*: It may develop causing postural hypotension and diarrhea.

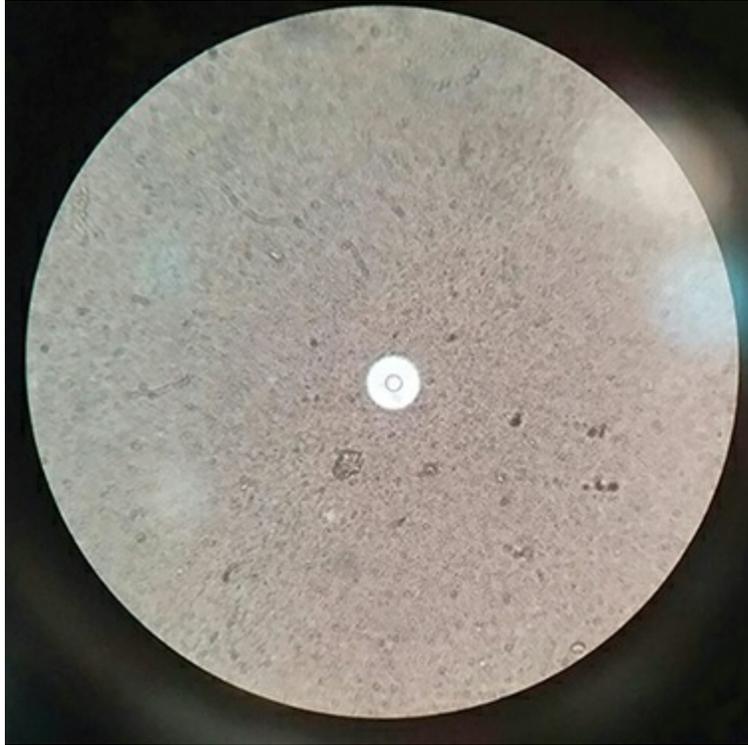

**Fig. 5.9:** MRI of progressive multifocal leukoencephalopathy (PML).

## ***Viral Infections***

**Progressive multifocal leukoencephalopathy (PML):** It is a progressive disease caused by JC virus (JCV). It presents with stroke-like episodes and cognitive impairment characterized by focal neurological abnormalities including impairment of vision (blindness due to involvement of the occipital cortex), aphasia, hemiparesis and ataxia that progress to altered sensorium and death within 6 months.

CT scan shows non-enhancing, focal hypodense lesions. MRI shows characteristic appearances characterized by distinct white matter lesions in areas of the brain corresponding to clinical deficits (Fig. 5.9). Confirmation is by detection of JC virus DNA in the cerebrospinal fluid (CSF) by PCR is diagnostic.

**Treatment** is mainly by starting ART and prognosis remains poor despite ART.

**Fig. 5.10:** Indian ink preparation of CSF showing *Cryptococcus*.

**Herpes simplex encephalitis:** It may be insidious in onset as compared to an immunocompetent host. Despite treatment with acyclovir, prognosis is poor.

- Herpes zoster may also produce myelitis or radiculitis.

**CMV encephalitis:** This presents as slowly progressive disease with behavioral disturbance, cognitive impairment and a reduced level of consciousness. Identification of CMV DNA in the CSF supports the diagnosis. Response to anti-CMV therapy is poor. Cytomegalovirus may also cause myelitis and retinitis (retinal hemorrhage resulting in blindness).

### ***Fungal Infections***

**Q. Write short note on cryptococcal meningitis, its diagnosis and management.**

**Cryptococcal meningitis:** *Cryptococcus neoformans* is the **most common cause of meningitis in AIDS** patients affecting 5–7% of patients.

- Patients usually present with headache, vomiting and mild confusion.
- Lumbar puncture opening pressure will be characteristically high. CSF pleocytosis may be mild or even absent, and protein and glucose

concentrations are variable. However, CSF cryptococcal antigen tests and culture are usually positive and this test has as sensitivity and specificity of almost 100%. Indian ink staining on CSF (Fig. 5.10) may show the *Cryptococcus neoformans*.

**Treatment** is with amphotericin B (0.7 mg/kg/day) (plus flucytosine 25 mg/kg QID if available) for 2 weeks, followed by fluconazole (400 mg/day) for 8–10 weeks. Relapse rates are high and hence, continuous therapy with fluconazole (200 mg/day) is recommended.

## ***Bacterial Infections***

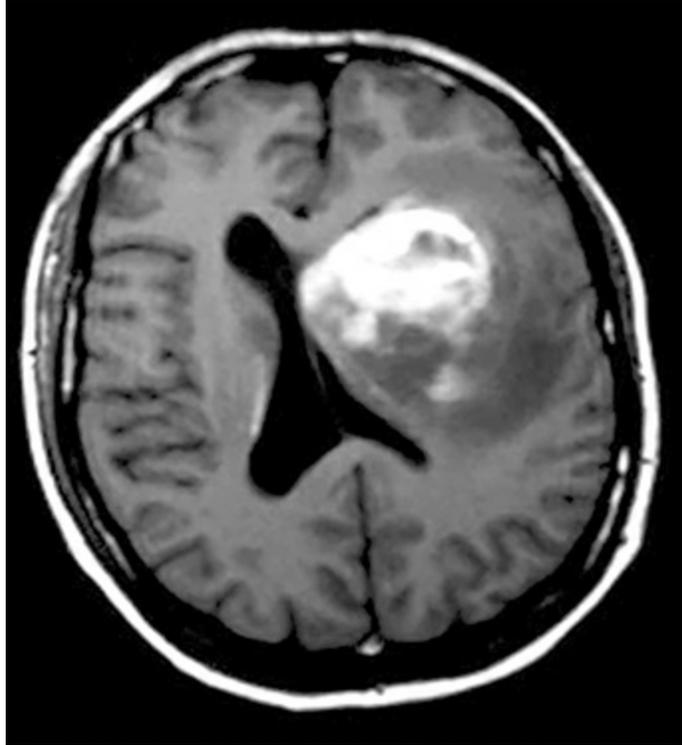

**Tuberculosis meningitis:** It is common in AIDS patients. It may present in a manner similar to cryptococcal meningitis. CSF findings of tuberculous meningitis are similar to those in HIV-uninfected patients. It usually shows elevated cell counts (lymphocytes) and protein along with low glucose. CT scan may show multiple ring lesions suggestive of tuberculomas.

**Syphilis:** It may present as neurosyphilis, manifestations of which include optic neuritis, uveitis, meningitis, encephalitis and cerebral infarction.

## ***Protozoan Infections***

**Cerebral toxoplasmosis:** It is the most common opportunistic infection of CNS caused by *Toxoplasma gondii*.

- It presents with headache, confusion, seizures, ataxia and focal deficits. The characteristic findings on contrast CT scan (Fig. 5.11) are multiple contrasts enhancing lesions space-occupying lesions with ring enhancement on contrast and surrounding edema.
- Appearance of Toxoplasma choroiretinitis is shown in Figure 5.12.
- *Toxoplasma* serology shows evidence of previous exposure [positive immunoglobulin (Ig) G antibodies].
- Definitive diagnosis is by brain biopsy but this is usually not necessary.

**Fig. 5.11:** MRI of cerebral toxoplasmosis

**Treatment** is sulfadiazine 1000-1500 mg four times a day with pyrimethamine 200 mg loading, followed by 50 mg once daily, together with folinic acid, to reduce the risk of bone marrow suppression. However, cotrimoxazole is also effective and less toxic. Clindamycin can be substituted, if patients are sensitive to sulfadiazine.

- **Prophylaxis:** is given in toxoplasma-seropositive patients with a CD4+ count  $<100$  cells/ $\mu$ L. Preferred regimen is one double-strength tablet of TMP-SMX daily. If patients cannot tolerate TMP-SMX, alternative is to give dapsone + pyrimethamine + leucovorin.

### ***Miscellaneous CNS Manifestations***

**Primary CNS lymphoma (PCNSL)** is a high-grade B-cell lymphomas associated with EBV infection. It occurs in about 5% of cases and may present with encephalopathy, focal deficits, seizures or lymphomatous meningitis. Characteristically, CT scan demonstrates a single, homogeneously enhancing, periventricular lesion with surrounding edema. PCR for EBV DNA in the CSF has a high sensitivity and specificity for PCNSL. Brain biopsy is definitive, but carries a risk of morbidity. The prognosis is very poor.

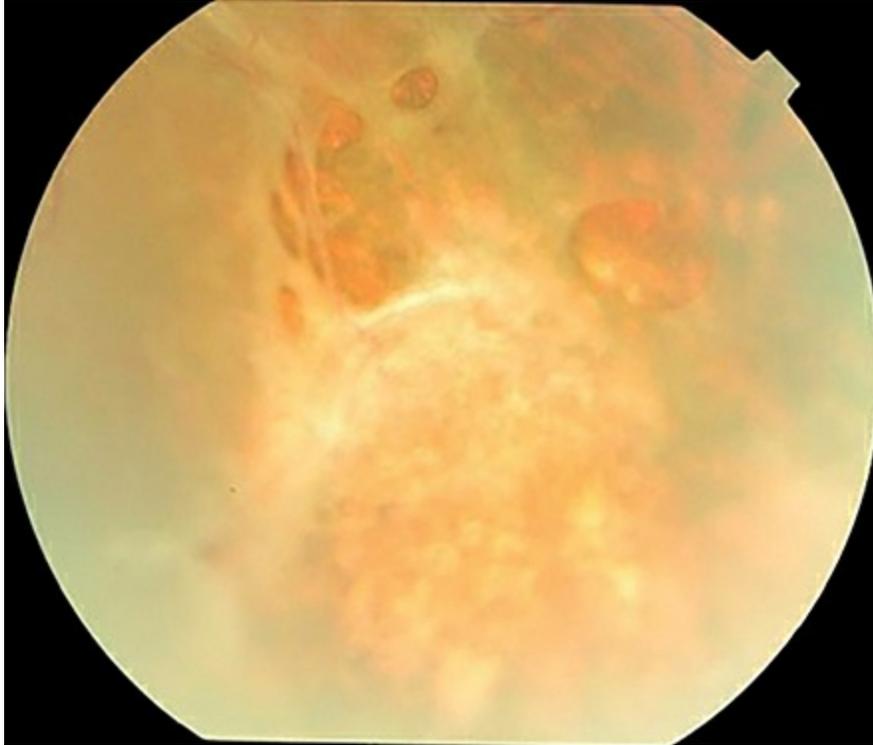

**Fig. 5.12:** Toxoplasma choroiretinitis.

## Ocular Diseases

### *Retinopathy*

- Ocular toxoplasmosis usually presents with a vitritis and retinitis without retinal hemorrhages.
- HIV retinopathy is a microangiopathy that causes cotton-wool spots, which are of benign in nature.
- Herpes zoster may lead to ocular pain, conjunctival infection and corneal opacification.
- Varicella zoster virus can also cause rapidly progressive outer retinal necrosis.

**Fig. 5.13:** Fundoscopic appearance of CMV retinitis.

### ***CMV Retinitis***

- CMV retinitis is the most serious infection of the eyes. It occurs when the CD4 count is below 100 cells/ $\mu$ L.
- Usually unilateral but may progress to involve both eyes.
- **Presenting features:** Depend on the area of retina involved. Painless, progressive loss of vision being most common with macular involvement.
- **Fundoscopy (Fig. 5.13):** Hemorrhages and exudates are seen in the retina, which follow the vasculature of the retina (so-called 'pizza pie' appearances/'frosted branch angiitis').
- **Diagnosis** is usually clinical. However, demonstration of CMV DNA by PCR of vitreous fluid is diagnostic.

**Treatment** should be started immediately, with either oral valganciclovir (900 mg twice daily), IV ganciclovir (5 mg/kg twice daily) or foscarnet (90 mg/kg twice daily) given intravenously for at least 3 weeks or until retinitis is quiescent. Ganciclovir or valganciclovir stops progression of the disease, but vision does not recover. Ganciclovir may cause myelosuppression and foscarnet is nephrotoxic.

### **Cardiovascular Diseases**

- The most common heart disease is coronary heart disease. Cardiovascular

disease may result from the classical risk factors, a direct consequence of HIV infection or as a result of ART.

- Dilated cardiomyopathy associated with congestive heart failure (CHF) in a HIV-infected patient is referred to as HIV-associated cardiomyopathy.
- Pericardial effusions may be seen in advanced HIV infection. Predisposing factors include TB, CHF, mycobacterial infection, cryptococcal infection, pulmonary infection, lymphoma, and KS (Kaposi's sarcoma).

## Psychiatric Diseases

- Anxiety and mood disturbance may be caused by pre-test issues such as worries about being infected and disclosure, receiving a positive result.
- Mild cognitive dysfunction is a common in later-stage disease and usually improves with HAART.
- Disorders of mental state may also result from drugs directly (e.g. depression with efavirenz) or indirectly.

## Diseases of Kidney and Genitourinary System

Due to direct consequence of HIV infection, due to opportunistic infection, neoplasms or due to drug toxicity.

- **HIV-associated nephropathy (HIVAN)** presents with proteinuria. Edema and hypertension are rare.
  - Ultrasound examination shows enlarged and hyperechoic kidneys.
  - Definitive diagnosis is by renal biopsy.
- **Nephrotic syndrome** subsequent to focal segmental glomerulosclerosis is seen in 80%, and mesangial proliferation in 10–15% of the cases.
- **Drug-induced toxicity:** Many *nephrotoxic drugs* are used in the management of HIV-associated pathology, particularly pentamidine, amphotericin B, adefovir, tenofovir foscarnet and sulfadiazine. Cotrimoxazole may compete with tubular secretion of creatinine and cause its increase in the blood.

## Hematological Conditions

- **Anemia** is caused by bone marrow infiltration with opportunistic infections, neoplasms, bone marrow suppression with drugs, as a direct affect of HIV, blood loss from Kaposi's sarcoma or malabsorption as a result of a GI infection.

- **Leucopenia** results from bone marrow infiltration or due to drug toxicity. Lymphopenia is a good marker of HIV.
- **Thrombocytopenia** occurs very early and may be the first indicator of HIV in some cases.
- **Pancytopenia** may develop due to opportunistic infection, malignancies, *Mycobacterium avium intracellulare* infection, disseminated cytomegalovirus and lymphoma.

**Table 5.7: Various cancers associated with HIV infection.**

<i>Malignant tumor</i>	<i>Causative virus</i>
<b>AIDS-Defining</b>	
Kaposi's sarcoma	<i>KS herpes virus</i> (KSHV), also called <i>human herpes virus 8</i> (HHV8)
Non-Hodgkin's lymphoma (systemic and CNS)	<i>Epstein-Barr virus</i> (EBV), HHV8
Invasive cervical carcinoma	<i>Human papilloma virus</i> (HPV)
<b>Non-AIDS Defining</b>	
Anal cancer	HPV
Hodgkin's disease	EBV
Leiomyosarcoma (pediatric)	EBV
Squamous carcinoma (oral)	HPV
Merkel cell carcinoma	Merkel cell polyoma virus (MCV)
Hepatocellular carcinoma (hepatoma)	Hepatitis B virus (HBV), Hepatitis C virus (HCV)

## CANCERS IN HIV (TABLE 5.7)

**Q. List important cancers in AIDS.**

**Q. Write short note on Kaposi's sarcoma.**

Kaposi's sarcoma (refer Fig. 5.8F) is a vascular neoplasm involving skin, mucus membrane and viscera (lymph nodes, GIT, lungs). Skin lesions are erythematous/violaceous macules. plaques or nodules. Cutaneous lesions can be treated with radiation, cryotherapy or intralesional vinblastine. Extensive disease will need interferon-alpha with liposomal doxorubicin and paclitaxel.

# DIAGNOSIS OF HIV INFECTION OR AIDS

**Q. Write short note on laboratory tests for the diagnosis HIV infection.**

HIV infection is diagnosed either by the detection of virus specific antibodies (anti-HIV) or by direct identification of viral material.

## Detection of Virus Specific Antibodies (anti-HIV)

Antibodies against the virus are detectable within 3–12 weeks after infection.

- **Detection of IgG antibody to envelope components:** This is the most commonly used marker of infection. The routine tests used for screening are based on ELISA techniques. Confirmation is by western blot test. **ELISA** detects antibodies against viral proteins and is the **most sensitive** and best screening test for the diagnosis of AIDS. Up to 3 months (mean 6 weeks) may be needed (from the initial infection) for the detection of antibody in the serum (*serological latency, or window period*). These antibodies to HIV have no protective function and persist for life. Similar to all IgG antibodies, anti-HIV will cross the placenta. This is responsible for the presence of antibody at birth in all babies of HIV-infected mother. In this situation, anti-HIV antibody is not a reliable marker of active infection and in uninfected babies anti-HIV antibody will be gradually lost over the first 18 months of life.
- **A Serologic Testing Algorithm for Recent HIV Seroconversions (STARHS)** is being used in research studies to see how many people were recently infected within the previous 4–6 months.
- **IgG antibody to p24 (antip-24):** This antibody can be found during the earliest weeks of infection and during the asymptomatic phase. It is frequently lost as the disease progresses.
- **Genome detection assays:** Nucleic acid based assays that amplify and test for components of the HIV genome are used to aid diagnosis of HIV in the babies of HIV-infected mothers or in early infection when antibody may not be present, or in subtyping HIV variants for medicolegal reasons.
- **Viral p24 antigen (p24ag):** This is detectable shortly after infection but has usually disappeared by 8–10 weeks after exposure. It can be a useful marker in individuals who have been infected recently but have not had time to mount an antibody response.
- **Western blot assays: Most specific or the confirmatory test** for HIV.

## Direct Detection of Viral Material/Infection

- **p24 antigen capture assay**
- **Reverse transcriptase polymerase chain reaction (RT-PCR)**
- **DNA-PCR:** For measuring the amount of viral particles (HIV-RNA) in the blood (viral load).
- **Isolation of virus in culture:** Culture of virus from the monocytes and CD4+ T-cells. This is a specialized technique available in some laboratories to aid diagnosis and as a research tool.

## Hematological Abnormalities

Normochromic, normocytic **anemia**, **lymphopenia**, **leucopenia**, **thrombocytopenia** and **decrease in T-helper cells (CD4+ counts)**.

# MANAGEMENT OF A PATIENT WITH HIV INFECTION

**Q. Write short essay/note on monitoring HIV therapy.**

### General Measures

- These include balanced diet, quitting smoking and intake of alcohol, adequate rest and **practice of safer sex** so as to avoid infection of partner and also to avoid infection with other organism that may hasten the progress of the disease.
- An important aspect of treatment is counseling and proper education of the patient.

### Antiretroviral Drugs

**Q. Write short essay/note on antiretroviral therapy/highly active antiretroviral therapy (HAART) with dosages in AIDS and side effects.**

- Antiretroviral drugs are **capable of suppressing viral replication**. This has transformed HIV from a progressive illness with a fatal outcome to a chronic manageable disease. **Combination antiretroviral therapy (cART)**, also called as **highly active antiretroviral therapy (HAART)**, is the cornerstone of management of patients with HIV infection.

### Goals of cART (Box 5.4):

Indications for antiretroviral therapy are mentioned in Box 5.5.

**Box 5.4:** Goals of combination antiretroviral therapy (cART).

- Reduce the viral load
- Improve the CD4 count to over 200 cells/mm<sup>3</sup> which reduces the HIV-related disease
- Improve the quantity and quality of life
- Reduce transmission of HIV.

*Categories of Antiretroviral Drugs (Table 5.8)*

Site of action of antiretroviral therapy (ART) is depicted in Figure 5.14.

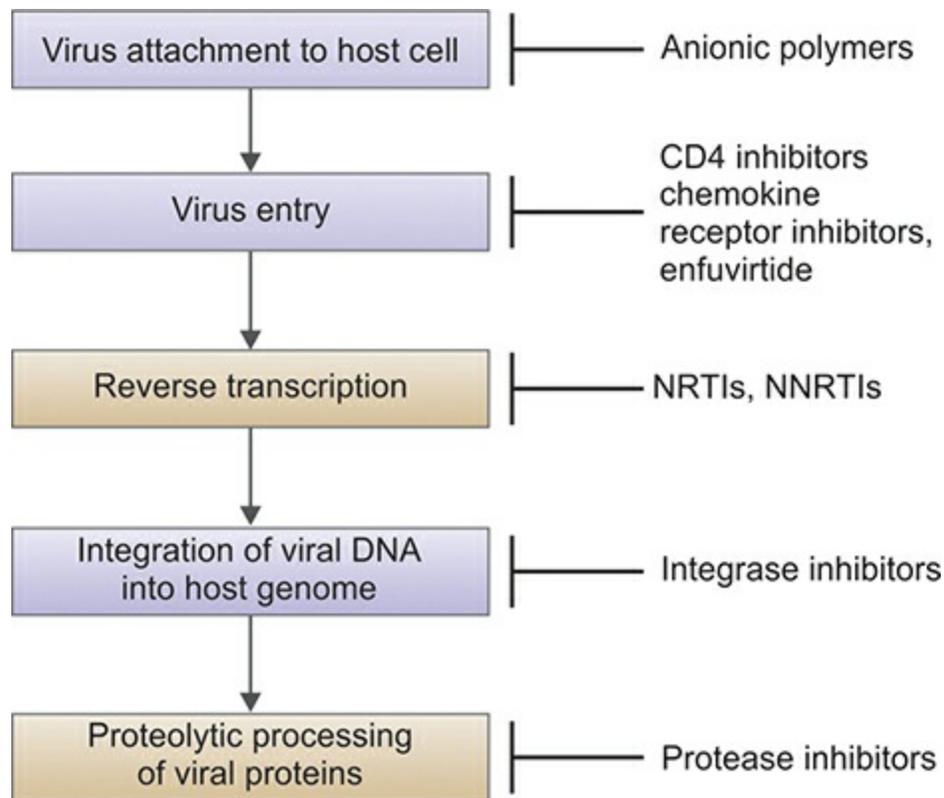

### **Reverse transcriptase inhibitors**

**Nucleoside/nucleotide analog:** Nucleoside reverse transcriptase inhibitors (NRTIs)

- **Mechanism of action:** NRTIs need to be phosphorylated intracellularly for activity to occur. They diffuse into the infected cells and inhibit the synthesis of DNA by reverse transcription. These active nucleosides are incorporated into the growing viral DNA and cause premature termination of DNA chain.
- These were the first group of agents to be used against HIV, initially as monotherapy and later as dual drug combinations. Usually, two drugs of this class are combined to provide the 'backbone' of a HAART regimen. All the drugs in this class cause mitochondrial toxicity, which manifests as peripheral neuropathy, pancreatitis, lipoatrophy, and hepatic steatosis.

### **Box 5.5:** Indications for antiretroviral therapy.

- ART should be initiated in all adults living with HIV, regardless of WHO clinical stage and at any CD4 cell count.
- As a priority, ART should be initiated in all adults with severe or advanced HIV clinical disease (WHO clinical stage 3 or 4) and adults with CD4 count  $\leq 350$  cells/mm<sup>3</sup>.
- ART at any CD4 count in PLHIV (people living with HIV)
  - Active TB disease
  - HBV co-infection with severe chronic liver disease
  - HIV-positive partners in serodiscordant couples
  - Pregnant and breastfeeding women
  - Children younger than five years of age.
  - Infants diagnosed in the first year of life.

**Fig. 5.14:** Site of action of antiretroviral therapy (ART).

### Table 5.8: Categories of antiretroviral drugs used for the treatment of HIV infection.

#### 1. Drugs that inhibit the viral reverse transcriptase enzyme

##### A. Nucleoside reverse transcriptase inhibitors (NRTIs)

- Zidovudine (AZT, ZDV)
- Zalcitabine (ddC)
- Didanosine (ddI)
- Abacavir (ABC)
- Stavudine (d4T)
- Lamivudine (3TC)
- Emtricitabine (FTC)

##### B. Nucleotide reverse transcriptase inhibitor (nRTI)

Tenofovir disoproxilfumarate (TDF)

##### C. Non-nucleoside reverse transcriptase inhibitors (NNRTIs)

- Nevirapine (NVP)
- Delavirdine (DLV)
- Efavirenz (EFV)

#### 2. Protease inhibitors (PIs)

- Indinavir (IDV)
- Ritonavir (RTV)
- Saquinavir (SQV)
- Lopinavir/ritonavir (LPV/RTV)
- Atazanavir (ATV)
- Darunavir (TMC114)

- Nelfinavir (NFV)
- Amprenavir (APV)
- Fosamprenavir (FOSAPV)
- Tipranavir (TPV)

### 3. Integrase strand transfer inhibitors (INSTIS)

- Oral—raltegravir, elvitegravir, and dolutegravir
- Injectable, long-acting INSTI (cabotegravir)

### 4. Drugs that interfere with viral entry

- Fusion inhibitors:** Enfuvirtide (eT20)
- CCR5 antagonists (CCR5 inhibitors):** Maraviroc

### 5. Pharmacokinetic enhancers (CYP3A inhibitors)

**Cobicistat:** PIs and integrase inhibitor elvitegravir, are administered in combination with another agent (e.g. low-dose ritonavir or cobicistat) to increase trough plasma drug concentrations, increase drug half-lives, and increase maximum plasma concentrations). This improves the potency of the antiviral agent and enables lower and less frequent dosing of the parent drug, thereby decreasing pill burden

Dosage and adverse events of antiretroviral drugs that inhibit the viral reverse transcriptase enzyme is presented in Table 5.9.

**Nucleotide analogs (nucleotide reverse transcriptase inhibitors (NtRTIs))** have a similar mechanism of action but only require two intracellular phosphorylation steps for activity (as opposed to the three steps for nucleoside analogs).

- They include nucleotide analogs that inhibit reverse transcriptase inhibitor.
- At present, only **tenofovir disoproxil fumarate** is available for use.

### **Non-nucleoside reverse transcriptase inhibitors (NNRTIs)**

- **Mechanism of action:** NNRTIs bind directly to the reverse transcriptase enzyme causing inhibition of its function. NNRTIs affect cytochrome P450.
- **Advantages:** They are generally small molecules and are widely disseminate throughout the body and have a long half-life.
- They are highly active against HIV-1 but are ineffective against HIV-2.
- **Side effects:** Nevirapine may produce **skin rash** (refer Fig. 23.3) and elevation of liver enzymes (hepatitis). Second generation NNRTIs (e.g. etravirine and rilpivirine) are with fewer adverse effects have some activity against viruses resistant to other compounds of the NNRTI class.
- Avoid Efavirenz during first trimester of pregnancy.

Dosage and adverse events of non-nucleoside reverse transcriptase inhibitors (NNRTIs) is presented in Table 5.10.

### **Protease inhibitors (PIs)**

#### **Q. Write short essay/note on antiretroviral protease inhibitor drugs.**

- **Mechanism of action:** These drugs act competitively on the HIV aspartyl protease enzyme (inhibit enzyme protease of HIV), which is involved in the production of functional viral proteins and enzymes. It leads to impaired viral maturation and immature dysfunctional viral particles are produced.
- **Side effects:**
  - *Abnormalities of fat metabolism and control of blood sugar:* PIs have been linked with abnormalities of fat metabolism. It has been associated with body fat redistribution that

manifests physically as thinning of arms, legs and face and/or deposition of fat in the abdominal and shoulder regions along with lipomas (**lipodystrophy**). The effects on fat metabolism may produce raised serum cholesterol and triglycerides, **insulin resistance** and rarely elevated blood glucose levels, which may increase cardiovascular risk. Some PIs (e.g. indinavir) may produce hyperglycemia.

- Associated with deterioration in clotting function in people with hemophilia.

Dosage and adverse events of protease inhibitors (PIs) is presented in Table 5.11.

**Table 5.9: Dosage and adverse events of antiretroviral drugs that inhibit the viral reverse transcriptase enzyme.**

<i>Name of the drug</i>	<i>Adult dose</i>	<i>Adverse events</i>
Abacavir	600 mg PO QD or 300 mg PO BID	Hypersensitivity reaction (may include fever, rash, nausea, vomiting, diarrhea, malaise, shortness of breath, cough, pharyngitis); <i>patients positive for HLA-B*5701 are at highest risk for hypersensitivity (perform HLA screening before initiating) risk of myocardial infarction.</i>
Didanosine	>60 kg: 400 mg PO QD <60 kg: 250 mg PO QD	Peripheral neuropathy, pancreatitis, nausea, lactic acidosis
Emtricitabine	200 mg PO QD	Minimal toxicity, hyperpigmentation
Lamivudine	300 mg PO QD or 150 mg PO BID	Minimal toxicity, severe acute exacerbation of hepatitis may occur with HBV-coinfection upon discontinuation, pancreatitis
Stavudine	>60 kg: 40 mg PO BID <60 kg: 30 mg PO BID	Peripheral neuropathy, pancreatitis, lactic acidosis, lipodystrophy, hyperlipidemia
Tenofovir	300 mg PO QD (once daily)	Renal insufficiency, proteinuria, glycosuria, hypophosphatemia, osteopenia, and acute tubular necrosis
Zidovudine	300 mg BID	Headache, malaise, anorexia, nausea, vomiting, lactic acidosis, and loss of limb fat.

**Table 5.10: Dosage and adverse events of non-nucleoside reverse transcriptase inhibitors (NNRTIs).**

<i>Name</i>	<i>Adult dose</i>	<i>Adverse events</i>
Delavirdine	400 mg PO (per oral) TID (thrice daily)	Rash, headache
Efavirenz	600 mg PO once daily. Take on empty stomach	Rash, CNS (e.g. somnolence, vivid

	to decrease adverse drug reactions	dreams, confusion, visual hallucinations), hyperlipidemia
Etravirine	200 mg PO BID (twice daily)	Rash, nausea
Nevirapine	200 mg PO (per oral) TID (thrice daily)XR (extended release): 400 mg PO qd	Rash, hepatitis
Rilpivirine	25 mg PO qd with meal	Depressive disorders, insomnia, headache, rash

**Table 5.11: Dosage and adverse events of protease inhibitors (PIs).**

<i>Name</i>	<i>Adult dose</i>	<i>Adverse events</i>
Atazanavir	400 mg PO qd or 300 mg + ritonavir 100 mg PO qd (once daily)	Indirect hyperbilirubinemia, prolonged PR interval, hyperglycemia, skin rash (20%), hyperlipidemia
Darunavir	800 mg qd + ritonavir 100 mg PO qd or 600 mg BID + ritonavir 100 mg PO BID	Rash, nausea, diarrhea, hyperlipidemia, hyperglycemia
Fosamprenavir	700 mg BID + ritonavir 100 mg PO BID or 1400 mg PO BID or 1400 mg + ritonavir 100–200 mg PO qd	Rash, nausea, vomiting, diarrhea, hyperlipidemia, hyperglycemia
Indinavir	800 mg PO TID (thrice daily)800 mg PO BID + ritonavir 100–200 mg PO BID	Nephrolithiasis, nausea, indirect hyperbilirubinemia, hyperlipidemia, hyperglycemia
Lopinavir/ritonavir	400 mg/100 mg PO BID or 800 mg/200 mg PO qd	Nausea, vomiting, diarrhea, asthenia, hyperlipidemia, hyperglycemia
Nelfinavir	1250 mg PO BID or 750 mg PO TID	Diarrhea, hyperlipidemia, hyperglycemia
Ritonavir	Boosting dose for other PIs: 100–400 mg/day Nonboosting dose 600 mg BID	Nausea, vomiting, diarrhea, asthenia, hyperlipidemia, oral paresthesias, hyperglycemia
Saquinavir	1000 mg + ritonavir 100 mg PO BID Unboosted not recommended	Nausea, diarrhea, headache, hyperlipidemia, hyperglycemia, PR and QT interval prolongation
Tipranavir	500 mg + ritonavir 200 mg PO BID Unboosted not recommended	Hepatotoxicity, rash, hyperlipidemia, hyperglycemia, intracranial hemorrhage

### **Integrase Strand Transfer Inhibitors (INSTIS)**

- They selectively inhibit HIV integrase, thereby by blocks viral replication by preventing insertion of HIV-DNA into the human DNA genome.
- These are very well tolerated with rare side effects of insomnia, depression, dizziness and skin reactions.

## Drugs that interfere with viral entry

### Fusion inhibitors

- They block the initial fusion of HIV with host cell-surface receptors.
- **Enfuvirtide** (T20) is being used from this class of drugs. It is an injectable peptide derived from HIV gp41 that inhibits gp41-mediated fusion of HIV with the target cell. It is given by subcutaneous route. It does not inhibit HIV-2.
- It is synergistic with NRTIs and PIs.
- *Advantage:* Because it has an extracellular mode of action, drug–drug interactions is minimal.
- *Side effects:* Related to the subcutaneous route of administration and may cause reactions at the injection site.

### Coreceptor blockers (CCR5 inhibitors)

- **Maraviroc** is a chemokine receptor antagonist which blocks the cellular CCR5 receptor entry by HIV. The drug is metabolized by CYP p450 (3A), hence has the potential for drug–drug interactions. A specialized assay is therefore needed to screen for coreceptor tropism.

### Advantages of early ART

- **Reduces risk of progression to AIDS** and/or death, TB, non-AIDS-defining illness and increased the likelihood of immune recovery.
- **Reduces sexual transmission** in HIV-serodiscordant couples
- **More convenient and less toxic regimens** widely available
- **Costs and epidemiological benefits**

The increased cost of earlier ART would be partly offset by subsequent reduced costs (such as decreased hospitalization and increased productivity) and preventing new HIV infections.

## Evaluation Before Initiating HAART (Table 5.12)

**Table 5.12: Evaluation before initiating HAART.**

<i>Phase of HIV management</i>	<i>Recommended</i>	<i>Desirable (if feasible)</i>
HIV diagnosis	HIV serology, CD4 TB screening	HBV (HBsAg) serology <i>Cryptococcus</i> antigen if CD4 $\leq$ 100 cells/ $\mu$ L Screening for STIs (sexually transmitted infections) Assessment for major NCDs (non-communicable diseases) and comorbidities
Follow-up before ART	CD4 cell count (every 6–12 months)	
ART initiation	CD4 cell count	Hemoglobin for AZT (Zidovudine) Pregnancy test Blood pressure Urine dipsticks for glycosuria and serum creatinine for TDF LFT (liver function tests) for NVP (Nevirapine)
Receiving ART	CD4 (every 6 months)	Serum creatinine for TDF (tenofovir)

HIV viral load (at 6 months after initiating ART and every 12 months)	disoproxilfumarate)
---	---------------------

(HAART: highly active anti-retroviral therapy)

## Antiretroviral Regimens (Table 5.13)

### Q. Write short essay/note on antiretroviral regimens in HIV.

- **Most commonly used regimen:** PI with two NRTIs, or one NNRTI with two NRTIs or three NRTIs.
- **Initiation therapy: Begin with an effective regimen.** Consideration should also be given to the number of pills/day, frequency of dosing, food requirements, toxicity and drug interactions with other drugs used by the patient.
- **Starting ART: All drugs should be started simultaneously** at full dose (except ritonavir and nevirapine where dose escalation is recommended). Fixed-dose combinations and once-daily regimens are preferred for antiretroviral therapy.
- With EFV no increased risk of birth defects compared with other ARV drugs during the first trimester of pregnancy.
- TDF/FTC or TDF/3TC is the preferred NRTI backbone for: (i) HIV + HBV; (ii) HIV with TB; and (iii) pregnant women. Infants born to mothers with HIV who are at high risk of acquiring HIV should receive dual prophylaxis with AZT (twice daily) and NVP (once daily) for the first 6 weeks of life, whether they are breastfed or formula fed

**Table 5.13: Various antiretroviral regimens in ART as per 2017 guidelines.**

<i>First-line ART</i>	<i>Preferred first-line regimens</i>	<i>Alternative first-line regimens</i>
Adults (including pregnant and breastfeeding women and adults with TB and HBV coinfection)	Tenofovir disoproxilfumarate (TDF) + Lamivudine (3TC) or Emtricitabine (FTC) + Efavirenz (EFV)	AZT + 3TC + EFV AZT + 3TC + NVP (Nevirapine) TDF + 3TC (or FTC) + NVP TDF + 3TC (or FTC) + DTG or TDF + 3TC (or FTC) + EFV 400
Adolescents (10 to 19 years) ≥ 35 kg		TDF (or ABC) + 3TC (or FTC) + DTG TDF (or ABC) + 3TC (or FTC) + EFV400 ABC + 3TC + EFV ABC + 3TC + NVP AZT + 3TC + EFV AZT + 3TC + NVP TDF + 3TC (or FTC) + NVP
Children 3–10 years and adolescents < 35 kg	Abacavir (ABC) + Lamivudine (3TC) + Efavirenz (EFV)	ABC + 3TC + NVP AZT + 3TC + EFV AZT + 3TC + NVP TDF + 3TC (or FTC) + EFV

		TDF + 3TC (or FTC) + NVP
Children <3 years	Abacavir (ABC) or Zidovudine (AZT) + Lamivudine (3TC) + Lopinavir/ritonavir (LPV/RTV)	ABC + 3TC + NVP AZT + 3TC + NVP

(ART: active anti-retroviral therapy; 3TC: lamivudine; ABC: abacavir; AZT: zidovudine; DTG: dolutegravir; EFV: efavirenz; FTC: emtricitabine; NVP: nevirapine; PI: protease inhibitor; TDF: tenofovir)

- EFV is the preferred NNRTI for
  - HIV and TB (pharmacological compatibility with TB drugs)
  - HIV + HBV coinfection (less risk of hepatic toxicity)
  - Pregnant women including first trimester.

- **Immune recovery following HAART**

- **First phase (3–6 months)–Redistribution:** Release of activated memory CD4 cells trapped in lymphoid tissues and reduction in apoptotic cell death.
- **Second phase (6 months to 4 years)–Reconstitution:** Naive CD4 cells and memory CD4 contribute to reconstitution.

Treatment of common opportunistic infections in AIDS is presented in Table 5.14.

**Table 5.14:** Treatment of common opportunistic infections in AIDS.

<i>Opportunistic infection</i>	<i>Treatment</i>	
	<i>First line</i>	<i>Alternate</i>
1. <i>Candida</i> (mucosal)	Clotrimazole 200–600 mg OR fluconazole 50–100 mg/day	Ketoconazole 200 mg/day
2. <i>Candida</i> (systemic)	Amphotericin 0.3 mg/kg/day	
3. <i>Cryptococcus</i>	Amphotericin 0.3 mg/kg/day + flucytosine 25–37 mg/kg QID	Amphotericin 0.7 mg/kg/day plus Fluconazole
4. Cytomegalovirus	Ganciclovir 5 mg/kg BID (twice daily) IV	Foscarent 60 mg/kg TID
5. <i>H. simplex</i> (oral)	Acyclovir 200–400 mg five times/day	
6. <i>H. simplex</i> (encephalitis)	Acyclovir 10 mg/kg TID IV	Vidarabine 15 mg/kg/day

7. <i>Herpes zoster</i> (local)	Acyclovir 30 mg/kg/day in five doses	
8. <i>Herpes zoster</i> (disseminated)	Acyclovir 10 mg/kg TID (thrice daily)	Vidarbine 10 mg/kg/day
9. <i>Isospora belli</i>	Co-trimoxazole 7 mg/kg	
10. <i>Pneumocystis jirovecii</i>	Refer Table 5.5	Refer Table 5.5
11. Toxoplasma	Pyrimethamine 50–100 mg/day + sulphadiazine 2 g QID (four times daily)	Pyrimethamine 5–100 mg/day + clindamycin 500 mg QID

## Treatment Failure (Table 5.15)

**Table 5.15: Definition of various types of treatment failure in HIV infections.**

<b>Failure</b>	<b>Definition</b>
Clinical failure	<p><b>Adults and adolescents:</b> New or recurrent clinical event indicating severe immunodeficiency (WHO clinical stage 4 condition) after 6 months of effective treatment</p> <p><b>Children:</b> New or recurrent clinical event indicating advanced or severe immunodeficiency (WHO clinical stage 3 and 4 clinical condition with exception of TB) after 6 months of effective treatment</p>
Immunological failure	<p><b>Adults and adolescents:</b> CD4 count falls to baseline (or below) or persistent CD4 &lt;100 cells/μL</p> <p><b>Children</b></p> <ul style="list-style-type: none"> <li>• &lt;5 years—persistent CD4 &lt;200 cells/μL or &lt;10%</li> <li>• &gt;5 years—persistent CD4 &lt;100 cells/μL</li> </ul>
Virological failure	<p>Plasma viral load &gt;1000 based on two consecutive viral load measurements after 3 months, with adherence support</p> <p><b>Treatment of failure:</b> Second-line ART in adults should consist of two nucleoside reverse-transcriptase inhibitors (NRTIs) plus a ritonavir-boosted protease inhibitor (PI). The following sequence of second-line NRTI options is recommended:</p> <ul style="list-style-type: none"> <li>• After failure on a TDF + 3TC (or FTC)-based first-line regimen, use AZT + 3TC as the NRTI backbone in second-line regimens.</li> <li>• After failure on an AZT or d4T + 3TC-based first-line regimen, use TDF + 3TC (or FTC) as the NRTI backbone in second-line regimens.</li> </ul>

## Tuberculosis in HIV Infection

**Q. Write short essay on tuberculosis in HIV infection, HAART and antitubercular drugs.**

- Leading cause of morbidity and mortality in HIV infection. Most common opportunistic infection. Can occur at any CD4 level.
- **About 25–65%** persons with HIV infection have tuberculosis.
- Estimated annual risk of re-activation among those co-infected with HIV and TB is about 5–8% with a cumulative lifetime risk of 30% or more compared to a cumulative lifetime risk of 5–10% in HIV-negative adult patients.
- Course of HIV infection is accelerated subsequent to the development of TB.
- Prevalence of multidrug resistant TB is higher in HIV-positive compared to HIV-negative persons. However, this is not caused directly by HIV infection.

### ***Clinical Features***

- Active TB occurs throughout the course of HIV disease.
- Clinical presentation of TB in HIV-infected persons depends on the level of immunosuppression resulting from HIV infection. In patients with relatively intact immune function (CD4+ count >200/mm<sup>3</sup>), pulmonary TB is more frequently seen than extrapulmonary TB.
- Chest radiographic findings include upper lobe infiltrates and cavitation, similar to those in HIV-negative individuals with pulmonary tuberculosis, lower lobes are also frequently involved (Fig. 5.15A), sputum smears is often positive for acid-fast bacilli. In patient with tuberculoma CT head may show space occupying lesion (Fig. 5.15B). Patient may present with matted cervical lymph nodes (Fig. 5.15C) or cutaneous tuberculosis—lupus vulgaris (Fig. 5.15D)
- As immune suppression progresses, extrapulmonary tuberculosis becomes increasingly common. The disease is often disseminated.

### **Treatment**

#### **Q. Write short note on HAART and antitubercular drugs in HIV.**

- **ART should be commenced in all HIV-infected individuals with active tuberculosis irrespective of CD4 cell count**
- TB treatment should be commenced first and ART subsequently, as soon as possible within the **first 8 weeks** of starting TB treatment
- The recommended preferred ART regimen in naive patients on TB treatment is AZT + 3TC + EFV or TDF + 3TC or FTC + EFV

- In case of intolerance or contraindications to EFV, a NVP-based regimen or a triple NRTI regimen (AZT + 3TC + ABC or AZT + 3TC + TDF) are recommended.
- Protease inhibitors (PIs) and NNRTIs are antiretroviral agents that may inhibit or induce cytochrome P-450 isoenzymes (CYP450). Rifampicin induces CYP450 and may substantially decrease blood levels of the antiretroviral drugs.
- NRTIs are not metabolized by CYP450. Concurrent use of NRTIs and rifampicin is not contraindicated and does not require dose adjustments.
- Rifampicin can be used for the treatment of active TB in three situations:
  1. A patient on NNRTI efavirenz and two NRTIs.
  2. Patient on PI ritonavir and one or more NRTIs.
  3. A patient on combination of two PIs, ritonavir and saquinavir (not used in most cases).

**Figs. 5.15A to D:** (A) Chest X-ray showing tuberculosis involving left lower lobe; (B) CT head showing space occupying lesion- tuberculoma; (C) Matted cervical lymph nodes due to tuberculosis; (D) Cutaneous tuberculosis—lupus vulgaris in a HIV patient.

- In individuals who need a boosted PI-based regimen, rifabutin based TB treatment is recommended. If rifabutin is not available, use of rifampicin and LPV/r or SQV/r containing regimen with additional RTV dosing is recommended with close monitoring.
- Rifabutin may be used in a dose of 300 mg/day in patients on NRTIs, NVP and SQV alone. However, its dose should be reduced to 150 mg two or three times per week when it is administered to patients taking ritonavir or ritonavir/iopinavir and to 150 mg once a day when used with IDV or NFV. On the other hand, its dose should be increased to 450–600 mg daily when it is used concurrently with efavirenz.

#### Risks

- Immune reconstitution inflammatory syndrome (IRIS) (refer page 241)

- Reduced adherence due to high pill burden
- More laboratory monitoring needed (LFTs: liver function tests, Hb: hemoglobin estimation)

### Management of HIV/AIDS during Pregnancy

#### **Q. Write short essay/note on the management of HIV/AIDS during pregnancy.**

- All pregnant women should routinely be tested for HIV at an early stage in pregnancy, with rapid tests for those presenting in or just after labor.
- The course of HIV disease progression is not altered by pregnancy.
- Pre-ART dramatically reduced the risk of mother-to-child transmission of HIV to less than 1%.
- All pregnant women who qualify for ART for their own HIV infection should start treatment at the beginning of the second trimester. If they have severe disease, they should start ART in the first trimester itself. Efavirenz should be avoided in the first trimester.
- Two ART strategies are presently used to prevent mother-to-child transmission: commence standard ART and discontinue at delivery or after weaning; or **zidovudine monotherapy, usually started at 28 weeks, augmented with single-dose nevirapine at delivery.**
- The risk of mother-to-child transmission is lower in cesarean section than vaginal delivery.

#### **Breastfeed**

- HIV is also transmitted by breastfeeding.
- WHO recommends that where replacement feeding is 'acceptable, feasible, affordable, sustainable and safe' ('AFASS' criteria), HIV-infected women should avoid breastfeeding.
- In resource-limited situations, breastfeeding is still recommended.

## Immune Reconstitution Inflammatory Syndrome (IRIS)

#### **Q. Give a brief account of immune reconstitution inflammatory syndrome (IRIS).**

- A pathologic inflammatory immune recognition of antigens associated with a known or unknown replicating infection or persistent non-replicating antigens from a previous infection.
- Results in spectrum of presentations ranging from clinical worsening of a treated opportunistic infection (OI), atypical presentation of an unrecognized OI or autoimmune disorders such as Graves' disease.
- The constellation of clinical symptoms, signs or investigational parameters resulting from such inflammatory response is called immune reconstitution inflammatory syndrome (IRIS).
- **Categories**
  1. Related to underlying opportunistic infection
    - **Inflammatory 'unmasking'** of a previously untreated infection.
    - **Paradoxical clinical deterioration** of an infective process for which patient is on appropriate treatment.

2. **Autoimmune:** Graves' disease
  3. **Malignancies:** Worsening of Kaposi's sarcoma
- The term immune reconstitution disease (IRD) is sometimes used to distinguish IRIS manifestations related to opportunistic diseases from IRIS manifestations related to autoimmune diseases. A variety of fungal, parasitic, mycobacterial and viral opportunistic infections are associated with manifestations of IRIS. IRD is common in patients with underlying untreated mycobacterial or fungal infections and IRIS is found in 10–30% of patients.
  - IRIS is most common in patients with CD4+ T-cell counts <50 cells/ $\mu$ L and who have a sudden drop in HIV-RNA levels following the initiation of cART.
  - Signs and symptoms may develop from 2 weeks to 2 years after the initiation of cART. These include localized lymphadenitis, prolonged fever, pulmonary infiltrates, hepatitis, increased intracranial pressure, uveitis, sarcoidosis, and Graves' disease.
  - Clinical course can be protracted, and severe cases can be fatal.

#### Management

- Continue HAART in the majority of cases. However, if the manifestations of IRIS are considered to be life or organ-threatening, discontinuation of HAART is sometimes necessary.
- Corticosteroids or NSAIDs may help decrease the inflammatory response in some patients with IRIS.
- Treat the infection or malignancy.

## Postexposure Care of a Healthcare Worker

**Q. Write short note on postexposure care of a healthcare worker (HCW).**

#### *Risk of Transmission*

- HIV—0.3% after a percutaneous exposure and 0.09% after a mucous membrane exposure, if the source patient has HIV infection.
- HBV—2-40% (source patient is positive for both HBsAg and HBeAg—37-62%; source patient is positive for HBsAg but is HBeAg negative—23-37%)
- HCV—1.8%

#### *Determine Risk Associated with Exposure*

- **Type of fluid** to which healthcare worker (HCW) has been exposed (e.g.

blood, visibly bloody fluid, other potentially infectious fluid or tissue is considered infectious).

- **Type of exposure:** Percutaneous injury, mucous membrane or non-intact skin exposure is considered significant.
  - **Less severe:** solid needle or superficial injury
  - **More severe:** Large-bore hollow needle, deep puncture, visible blood on device, needle used in patient’s artery or vein
- **Infection status of source**
  - *Class 1:* Asymptomatic HIV infection or known low viral load (<1,500 copies/mL)
  - *Class 2:* Symptomatic HIV, AIDS, acute seroconversion, or known high viral load
- A known source: Patient should be tested for anti-HIV, HbsAg and anti-HCV with their consent.
- **Indication for postexposure prophylaxis (PEP):** When the risk is deemed to be significant after a careful risk assessment, in both occupational and non-occupational settings.
- PEP is also given for rape victims.

## **Q. Postexposure prophylaxis of HIV**

### **Management of Postexposure**

Postexposure prophylaxis (PEP) is **80%** effective

### **Decontamination**

- Wash the area with soap and water.
- Avoid squeezing or milking the wound.
- Do not use caustic agents (e.g. bleach).

### **Initiating postexposure prophylaxis (PEP)**

- Start within 72 hours
- 2–3 drug regimen based on risk
- PEP should be given for 28 days, if tolerated.

**Table 5.16: Postexposure prophylaxis (PEP) regimens.**

<i>Exposure Type</i>	<i>Infection Status of Source</i>	
	<i>HIV+, class 1</i>	<i>HIV+, class 2</i>
Less severe	Recommend basic	Recommend expanded ≥3-

	2-drug PEP	drug PEP
More severe	Recommend expanded 3-drug PEP	Recommend expanded $\geq$ 3-drug PEP
	<b>Unknown HIV status</b>	<b>Unknown source</b>
Less severe	Generally, no PEP warranted; consider basic 2-drug PEP if source has HIV risk factors	Generally, no PEP warranted; consider basic 2-drug PEP if exposure to HIV-infected persons is likely
More severe	Recommend expanded 3-drug PEP	Recommend expanded $\geq$ 3-drug PEP

#### Postexposure prophylaxis (PEP) regimens (Table 5.16)

- **Basic regimen for PEP**

- One nNRTI and one NRTI (tenofovir + emtricitabine), or
- Two NRTIs (zidovudine + lamivudine, zidovudine + emtricitabine, lamivudine + stavudine, lamivudine + tenofovir, stavudine + didanosine).

- **Expanded regimen** includes an additional third drug (ritonavir/lopinavir, indinavir, nelfinavir or efavirenz). Most commonly used third drug is ritonavir/lopinavir.

- **Agents not recommended for PEP** includes nevirapine, delavirdine, abacavir and zalcitabine.

- **Zidovudine is no longer recommended:** because there is: (i) no clear advantage in efficacy over tenofovir; and (ii) higher rates of treatment-limiting side effects.
- Recommendations place emphasis on the importance of initiating occupational PEP as soon as possible, **ideally within 2 hours of exposure.**
  - ◆ First dose of PEP should be offered while evaluation is underway.
  - ◆ PEP should not be delayed while awaiting source patient or results of the exposed baseline HIV test.

- **Preferred HIV-PEP regimen:** Raltegravir 400 mg PO twice daily **PLUS** tenofovir DF 300 mg + emtricitabine 200 mg—Fixed Dose Combination once daily.

#### Monitoring the exposed healthcare worker (HCW)

- HCW should be monitored **for any serious side effects of the antiretroviral drugs.**
- **Complete blood counts and renal and hepatic function** tests should be done at baseline and then 2 weeks after initiating chemoprophylaxis.
- **Baseline HIV-antibody test and test for hepatitis B and C** infections should be done that are repeated at 6 weeks, 12 weeks and 6 months postexposure.

#### Postexposure Prophylaxis for Hepatitis B (Table 5.17)

*Management depends on:*

- Source hepatitis B surface antigen status.
- Whether exposed person vaccinated.
- Whether exposed person has immunity.

**Table 5.17: Recommended PEP for hepatitis B (HB) virus.**

<i>Vaccination/Ab response status of exposed patient</i>	<i>Treatment when source patient is</i>		
	<i>HBsAg hepatitis B surface antigen positive</i>	<i>HBsAg negative</i>	<i>Source unknown or not available for testing</i>
Unvaccinated/nonimmune	HBIG (Hepatitis B immunoglobulin) ×1; initiate HB vaccine series	Initiate HB (hepatitis B) vaccine series	Initiate HB vaccine series
Previously vaccinated, known responder	No treatment	No treatment	No treatment
Previously vaccinated, known nonresponder	HBIG (Hepatitis B immunoglobulin) × 1 and initiate revaccination or HBIG × 2	No treatment	No treatment unless high-risk source; if high-risk source, treat as if source were HBsAg positive
Previously vaccinated, response unknown	Single vaccine booster dose	No treatment	No treatment unless high-risk source; if high-risk source, treat as if source were HBsAg positive
Still undergoing vaccination	HBIG × 1; complete series	Complete series	Complete series

### Postexposure Prophylaxis for Hepatitis C

- **No vaccine or treatment will prevent infection.** Immune globulin not recommended; does not work
- **Early infection effectively treated with Peg-interferon +/- ribavirin**

### Preexposure prophylaxis (PrEP)

Guidelines for preexposure prophylaxis (PrEP) were released in May 2014. Addresses the role of PrEP in the following adult populations:

- Men who have sex with men
- Heterosexual men and woman
- Injection drug users
- Sero-discordant couples

Only medication to be used in this setting is tenofovir/emtricitabine.

### HIV Vaccine

- **Need:** In spite of the remarkable achievements in development of antiretroviral therapies and

recent advances in new prevention technologies, the rate of new HIV infections continues to outpace efforts on prevention and control.

- **Challenges**

- HIV mutates rapidly; HIV mutates in one day as much as influenza viruses do in a year.
- The virus has developed multiple mechanisms to evade the body's defenses.
- Targets the cells (CD4) that coordinate the immune response to viral infections.
- Broadly neutralizing antibodies usually appear between 2–4 years but by that time the antibodies cannot save them because they are overwhelmed by the mutating virus.

#### **AIDS Vaccines**

- Recombinant protein (HIV gp120) adjuvant with alum. Failed in Phase II trials
- Recombinant adeno-associated virus vaccine (rAAV)
- Recombinant adenovirus type-5 vaccine containing HIV **gag**, **pol** and **nef** genes
- **RV144**: Canarypox vector prime + monomeric gp120 boost, 31% efficacy in Phase III trials.

### ***Mississippi Baby***

*The 'Mississippi baby' was born to an HIV-positive mother who had not received any treatment during pregnancy. Doctors began treating the child by the time she was 30 hours old, but the family stopped antiretroviral therapy at 18 months. She remained off the drugs for the next 27 months with no signs of the virus in her blood. She was monitored closely. However, at 4 months of age the CD4 cells dropped and in a few weeks the HIV virus levels were detectable. She is presently on treatment.*

### ***Berlin Patient***

*Timothy Ray Brown had HIV for 12 years before he became the first person in the world to be cured of the infection following a stem cell transplant in 2007. The stem cell donor had a specific genetic mutation called CCR5 Delta 32 that protects a person against HIV infection. After the stem cell transplant, Brown was able to stop all antiretroviral treatment and the HIV has not returned till now.*

# **Respiratory System**

# CHAPTER 6

## INTRODUCTION, BASIC APPROACH, SYMPTOMATOLOGY AND INVESTIGATIONS

**Q.** Write short note on the normal arterial blood gas (ABG) levels.

Table 6.1 depicts normal arterial blood gas levels.

**Table 6.1:** Normal arterial blood gas (ABG) levels.

Arterial oxygen tension (PaO <sub>2</sub> )	90–104 mm Hg
Arterial carbon dioxide (PaCO <sub>2</sub> )	35–45 mm Hg
Arterial oxygen saturation (SaO <sub>2</sub> )	95 to 99%
Arterial blood pH (pH)	7.35–7.45 Units
Arterial bicarbonate (HCO <sub>3</sub> )	22–30 meq/L
Base excess (BE)	0 ± 2 mmol/L

### Hypercapnic Encephalopathy

**Q.** Write short essay/note on hypercapnic encephalopathy [Carbon dioxide (CO<sub>2</sub>) narcosis].

#### *Definition*

- **Hypercapnia** is defined as a raised **arterial carbon dioxide (PaCO<sub>2</sub>) of 45 mm Hg (6 kPa)** at rest.
- **Hypercapnic encephalopathy:** When **PaCO<sub>2</sub> exceeds 90 mm Hg (12 kPa)**, severe hypercapnia causes confusion, progressive drowsiness and CO<sub>2</sub> narcosis.

#### *Causes of Hypercapnia (Table 6.2)*

Usually results from **alveolar hypoventilation**.

**Table 6.2: Causes of hypercapnia.**

<b>Central depression of respiratory drive</b> <ul style="list-style-type: none"><li>• Brain-stem lesions</li><li>• Central sleep apnea, obesity hypoventilation</li><li>• Sedatives: Morphine</li></ul>	<b>Reduced alveolar ventilation due to pathology within the lungs</b> <ul style="list-style-type: none"><li>• Chronic bronchitis</li><li>• Emphysema</li></ul>
<b>Neuromuscular</b> <ul style="list-style-type: none"><li>• Peripheral neuropathy, GB syndrome, poliomyelitis</li><li>• Myasthenia gravis</li><li>• Myopathies</li></ul>	<b>Reduced chest wall</b> (including diaphragmatic) <b>movements</b> <ul style="list-style-type: none"><li>• Trauma</li><li>• Kyphoscoliosis pectus excavatum</li><li>• Ankylosing spondylitis</li></ul>

### ***Clinical Features***

- **Headache:** Severe generalized or bilateral frontal or occipital headache (especially **severe on waking up**).
- **Depresses the level of consciousness.** Hypercapnia depresses the level of consciousness.
  - In mild cases, it produces intermittent drowsiness, indifference or inattention, reduction of psychomotor activity and forgetfulness.
  - In severe cases, it causes mental dullness, drowsiness, confusion, seizures stupor and coma. If left untreated, acute hypercapnic respiratory failure can cause death.

### ***Signs (Box 6.1)***

**Box 6.1:** Signs of hypercapnia.

Asterixis  
Altered sensorium  
Flushed warm extremities  
Bounding peripheral pulses  
Fasciculations (muscle twitching)  
Papilledema

### ***Investigations***

- **Arterial Blood Gas (ABG) study:** For confirmation of hypercapnia.
- **Other relevant investigations** depending on the underlying cause.

### Treatment

- Mechanical ventilation with intermittent positive-pressure respirator. Non-invasive ventilation (NIV) may be sufficient in patients with mild symptoms. BiPAP: 8–12 cm H<sub>2</sub>O (inspiratory pressure) and 3–5 cm H<sub>2</sub>O (expiratory pressure).
- Maintenance of acid-base and electrolyte balance.
- Treatment of the underlying cause. Respiratory stimulants (Doxapram, Medroxyprogesterone, Acetazolamide) are used with variable benefits.

**Precaution:** In chronic hypercapnia [e.g. chronic obstructive pulmonary disease (COPD)], oxygen should be administered in a controlled manner (about 2 L/minute) and morphine and other sedatives should be avoided.

## Hypoxemia

**Q. Write short note on hypoxemia.**

**Definition:** Hypoxemia is defined as **arterial oxygen tension (PaO<sub>2</sub>) of less than 80 mm Hg (10.6 kPa)** in a young healthy adult. As the age advances, the normal arterial oxygen tension (PaO<sub>2</sub>) falls gradually.

### Causes of Hypoxemia (Table 6.3)

**Table 6.3: Causes of hypoxemia.**

#### Ventilation-perfusion mismatch in the lung

- Chronic bronchitis
- Emphysema
- Acute asthma
- Pulmonary embolism
- Interstitial lung diseases

#### Right-to-left shunts

- Congenital cyanotic heart diseases
- Pulmonary collapse/atelectasis
- Consolidation, e.g. pneumonia

#### Hypoventilation

- **Central depression of respiratory drive:** Brainstem lesions, central sleep apnea
  - **Peripheral neuromuscular disease:** Myasthenia gravis peripheral, neuropathy, myasthenia gravis, myopathies
  - Malfunctioning of mechanical ventilators
- Decreased inspired oxygen concentration**
- High altitudes
  - Malfunctioning of mechanical ventilators

Hypoxemia is rare due to reduced diffusion.

### Clinical Features

- **Acute hypoxemia:** It closely resembles acute alcoholism and is characterized by impaired judgment and motor incoordination. On examination patient has tachypnea, cyanosis, cold peripheries, thready

pulses, hypotension.

- **Chronic hypoxemia:** Of long-standing duration presents with fatigue, drowsiness, inattentiveness, apathy, delayed reaction time and reduced work capacity.
- **Consequences:** Centers in the brainstem gets affected and death may occur due to respiratory failure.

### ***Investigations***

- **Arterial Blood Gas (ABG) study:** For confirmation of hypoxemia.
- **Calculate the alveolar-arterial O<sub>2</sub> (PAO<sub>2</sub>-PaO<sub>2</sub>) gradient:** To differentiate various causes of hypoxemia.

**Treatment:** Treat the underlying cause or mechanism.

### **Clubbing**

**Q. Define clubbing. Enumerate the causes and give the mechanism of clubbing. Enumerate cardiac causes.**

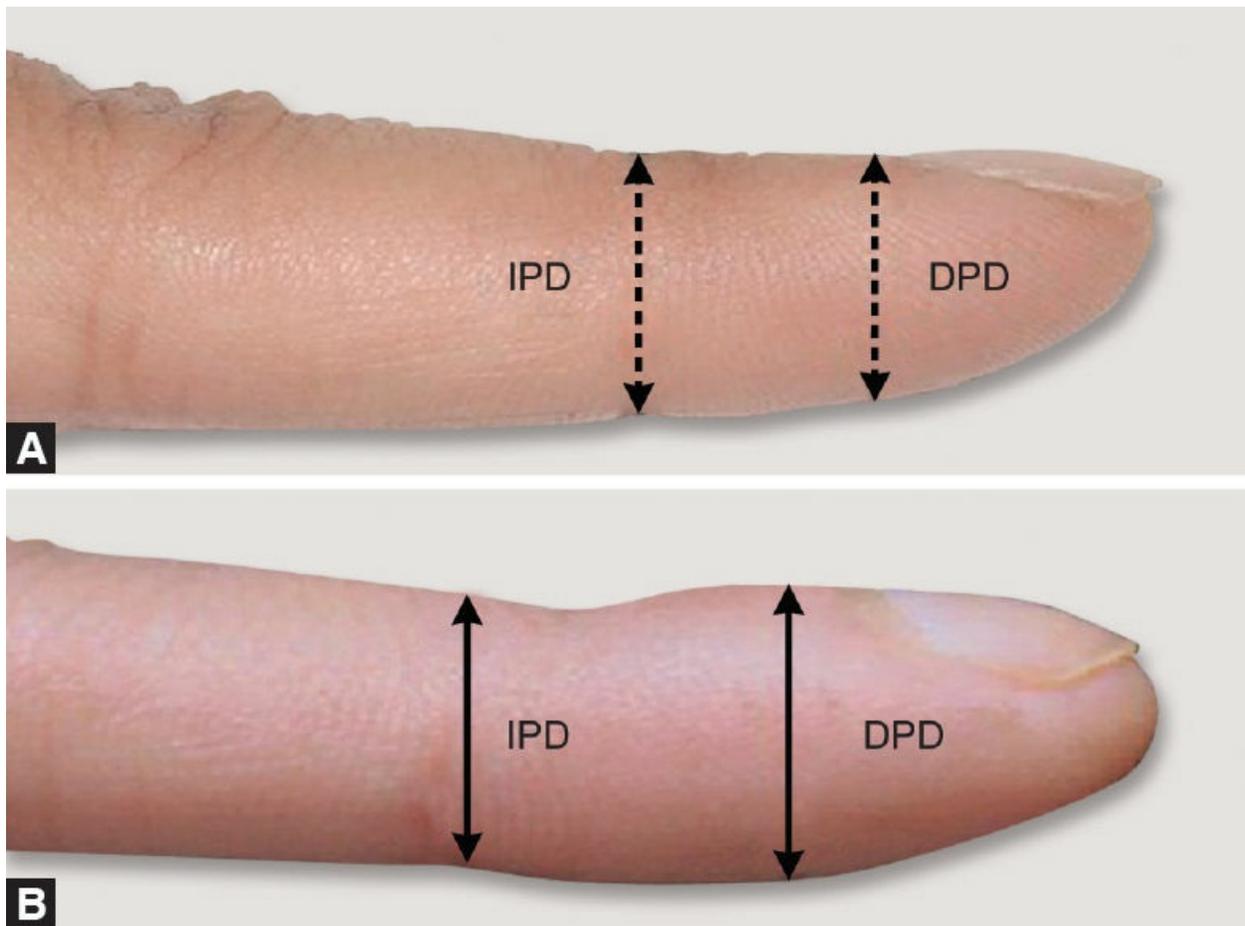

**Definition:** Clubbing (also called Hippocrates fingers) is defined as a **selective bulbous enlargement of the distal segment of a digit** (fingers and toes) due to an increase in connective tissue especially on the dorsal aspect resulting in loss of the onychonychia angle (Figs. 6.1A and B).

### ***Mechanisms***

Some of hypotheses are:

- **Role of platelets:** Megakaryocytes from the bone marrow normally break up to the platelets in the pulmonary capillaries. Whenever there are shunts or abnormal circulation (e.g. neoplasm), these megakaryocytes bypass the pulmonary capillaries and reach the systemic circulation. These megakaryocytes preferably lodge in the tips of the digits and locally release platelet derived growth factor (PDGF) and vascular endothelial growth factor (VEGF). These growth factors along with other mediators increase endothelial permeability and activate and cause proliferation of connective tissue cells (e.g. fibroblasts).
- **Humoral:** Unknown humoral substances dilate vessels in the fingertip (e.g. acromegaly)

- **Persistent hypoxia:** Causes opening of deep arteriovenous fistula in fingers (e.g. tetralogy of Fallot).
- **Reduced ferritin** in systemic circulation: Causes dilation of arteriovenous anastomoses.
- **Vagal theory:** Persistent vagal stimulation causes vasodilation and clubbing (e.g. lung carcinoma).
- **Toxic:** Subacute bacterial endocarditis (SABE).
- **Metabolic:** Thyrotoxicosis.

**Figs. 6.1A and B:** (A) Normal finger; (B) Clubbing of finger.  
(IPD: interphalangeal distance; DPD: distal phalangeal distance).

### ***Grades of Clubbing (Table 6.4)***

The process of clubbing usually takes years but in few conditions (e.g. lung abscess, empyema), it may develop quite fast.

**Table 6.4: Grades of clubbing.**

Grade	Features
1	Increased fluctuation due to softening of the nail bed (increased ballotability)
2	Loss of the normal $<165^\circ$ onychodermal angle (Lovibond angle) between the nail bed and the nail fold (cuticula)
3	Thickening of the whole distal (end part of the) finger (resembling a parrot beak or drumstick)
4	Hypertrophic osteoarthropathy (Pain and tenderness at distal end of long bones due to subperiosteal new bone formation)

**Causes (Table 6.5):** Clubbing may be hereditary, idiopathic, or acquired and associated with a variety of disorders. Various methods of eliciting clubbing are listed in Box 6.2.

**Table 6.5: Causes of clubbing.**

#### Respiratory

- **Neoplasms:** Bronchogenic carcinoma (especially squamous cell carcinoma), metastasis to lung, mesothelioma
- **Suppurative lung disease:** Bronchiectasis, lung abscess, cystic fibrosis, empyema
- Asbestosis (with mesothelioma)
- Sarcoidosis
- Cystic fibrosis
- Pulmonary AV fistula
- Interstitial lung diseases

#### Cardiovascular

- Infective endocarditis
- Cyanotic congenital heart diseases, atrial myxoma, Eisenmenger's syndrome

#### Gastrointestinal

- Inflammatory bowel disease (ulcerative colitis and Crohn's disease)
- Primary biliary cirrhosis
- Hepatoma

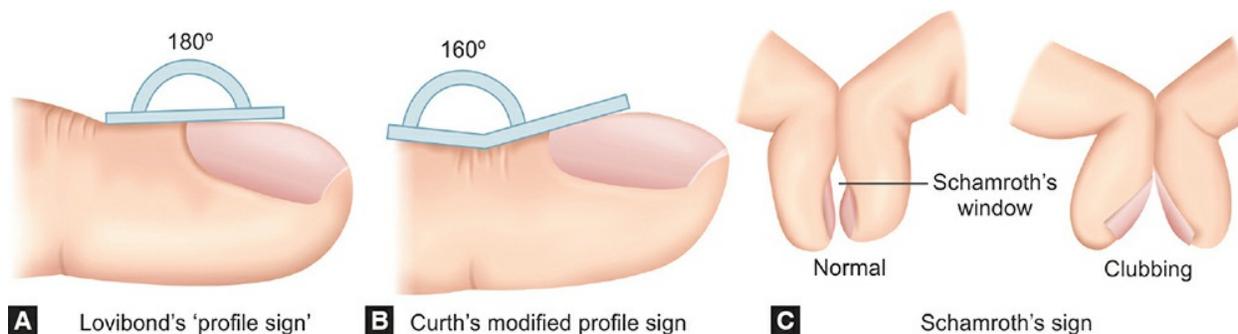

#### Miscellaneous

- Hereditary, idiopathic (pachydermoperiostitis or Touraine-Solente-Gole syndrome)
- Unidigital clubbing occurs in repeated trauma

#### Unilateral Clubbing

- Hemiplegia (long standing)
- Vascular disease
  - **Aneurysm:** Subclavian artery, brachiocephalic trunk
  - Pre-subclavian coarctation of aorta (left-sided clubbing)
  - Pancoast tumor
  - Unilateral erythromelalgia
  - AV fistula used for hemodialysis
  - Infected arterial graft

**Phalangeal depth ratio:** It is defined by the ratio of digit's depth measured at the junction between skin and nail (nail bed) and at the distal interphalangeal joint. Normally, the depth at distal interphalangeal joint is more than the depth at nail bed. In clubbing fingers, there is reversal of this ratio. A phalangeal depth ratio of over 1 indicates clubbing. It can be measured by a caliper or a digital photograph.

**Figs. 6.2A to C:** Various signs of clubbing.

**Pseudoclubbing:** It is **increase in longitudinal curvature of the nail with loss of nail and nail plate material.** It is characterized clinically by asymmetrical involvement of fingers and radiographically by resorption of the terminal tufts (acro-osteolysis). There is no over-growth of connective tissue as observed in clubbing.

**Box 6.2:** Various methods of eliciting the signs of clubbing.

1. Lovibond's profile sign (Fig. 6.2A)
2. Curth's modified profile sign (Fig. 6.2B)
3. Fluctuation test
4. Schamroth's window test (Fig. 6.2C)
5. Phalangeal depth ratio

**Causes of pseudoclubbing:** (1) Subungual tumor or cyst and (2) subperiosteal bone resorption (e.g. scleroderma, thyroid acropachy, vinyl chloride poisoning, acromegaly, hyperparathyroidism, leprosy, chronic renal failure, acrometastasis, etc.).

**Primary hypertrophic osteoarthropathy (PHO),** a rare hereditary disorder with digital clubbing, subperiosteal new bone formation, and arthropathy. It is associated with mutations in the 15-hydroxy-prostaglandin dehydrogenase (15-PGDH).

### Abnormalities in Nails due to Systemic Diseases (Table 6.6)

**Q.** Write short note/essay on abnormalities in nails due to systemic diseases.

**Table 6.6:** Abnormalities in nails due to systemic diseases.

<i>Abnormality and description</i>	<i>Associated systemic disease</i>
------------------------------------	------------------------------------

## SHAPE OR GROWTH CHANGE

<ul style="list-style-type: none"> <li>• <b>Clubbing</b></li> </ul>	<ul style="list-style-type: none"> <li>• Discussed above (Table 6.5)</li> </ul>
<ul style="list-style-type: none"> <li>• <b>Koilonychia:</b> Spoon-shaped nails (transverse and longitudinal concavity)</li> </ul>	<ul style="list-style-type: none"> <li>• Iron deficiency anemia, rarely in hemochromatosis, Raynaud's disease, SLE, hypothyroidism or hyperthyroidism</li> </ul>
<ul style="list-style-type: none"> <li>• <b>Pitting:</b> Punctate depressions in nails</li> </ul>	<p>Psoriasis, Reiter's syndrome, pemphigus, lichen planus, alopecia areata, rheumatoid arthritis</p>
<ul style="list-style-type: none"> <li>• <b>Onycholysis:</b> Distal nail plate separated from nail bed, white discoloration of the affected part of the nail</li> </ul>	<p>Psoriasis, local infection, hyperthyroidism, sarcoidosis, trauma, amyloidosis, connective tissue disorders, pellagra</p>
<ul style="list-style-type: none"> <li>• <b>Beau's lines:</b> Transverse linear depressions over nails, move distally with the growth of nail</li> </ul>	<p>Any severe systemic illness that disrupts nail growth, Raynaud's disease, pemphigus, trauma</p>
<ul style="list-style-type: none"> <li>• <b>Onychomadesis:</b> Proximal separation of nail plate from nail bed</li> </ul>	<p>Trauma, drug sensitivity, poor nutrition, pemphigus vulgaris, Kawasaki disease</p>
<ul style="list-style-type: none"> <li>• <b>Yellow nails:</b> Nail has a 'heaped-up' or thickened appearance, yellow in color, with obliteration of lunula</li> </ul>	<p>Lymphedema, pleural effusion, immunodeficiency, bronchiectasis, sinusitis, rheumatoid arthritis, nephrotic syndrome, thyroiditis, tuberculosis, Raynaud's disease</p>

## COLOR CHANGE

<ul style="list-style-type: none"> <li>• <b>Terry's (white) nails:</b> Most of the nail plate turns white with obliteration of lunula, uniformly affects all nails</li> </ul>	<p>Liver failure, cirrhosis, diabetes mellitus, CHF, hyperthyroidism, malnutrition</p>
<ul style="list-style-type: none"> <li>• <b>Half-and-half nails (Lindsay's nails):</b> Proximal portion of nail bed is white because of nail-bed edema (half-brown, half-white appearance)</li> </ul>	<p>Renal failure, HIV infection, Crohn's disease</p>
<ul style="list-style-type: none"> <li>• <b>Azure lunula (blue nails)</b></li> </ul>	<p>Hepatolenticular degeneration (Wilson's disease), silver poisoning, quinacrine therapy</p>
<ul style="list-style-type: none"> <li>• <b>Mees' lines:</b> Transverse white bands affecting multiple nails, move distally with nail growth</li> </ul>	<p>Arsenic poisoning, Hodgkin's lymphoma, CHF, leprosy, malaria, chemotherapy</p>
<ul style="list-style-type: none"> <li>• <b>Muehrcke's lines:</b> Pairs of transverse white lines that disappear on applying pressure, do not move with growth of nail</li> </ul>	<p>Specific for hypoalbuminemia of any cause</p>
<ul style="list-style-type: none"> <li>• <b>Dark longitudinal streaks</b></li> </ul>	<p>Melanoma, benign nevus, chemical staining, normal variant in darkly pigmented people</p>
<ul style="list-style-type: none"> <li>• <b>Splinter hemorrhage:</b> Longitudinal, thin, reddish lines occurring beneath the nail plate</li> </ul>	<p>Subacute bacterial endocarditis, SLE, rheumatoid arthritis, peptic ulcer disease, malignancies, oral contraceptive use, pregnancy, psoriasis, trauma</p>
<ul style="list-style-type: none"> <li>• <b>Telangiectasia:</b> Irregular, twisted and dilated vessels at the distal portion of cuticle covering the nail bed</li> </ul>	<p>Rheumatoid arthritis, SLE, dermatomyositis, scleroderma</p>
<ul style="list-style-type: none"> <li>• <b>Longitudinal striations</b></li> </ul>	<p>Alopecia areata, vitiligo, atopic dermatitis,</p>

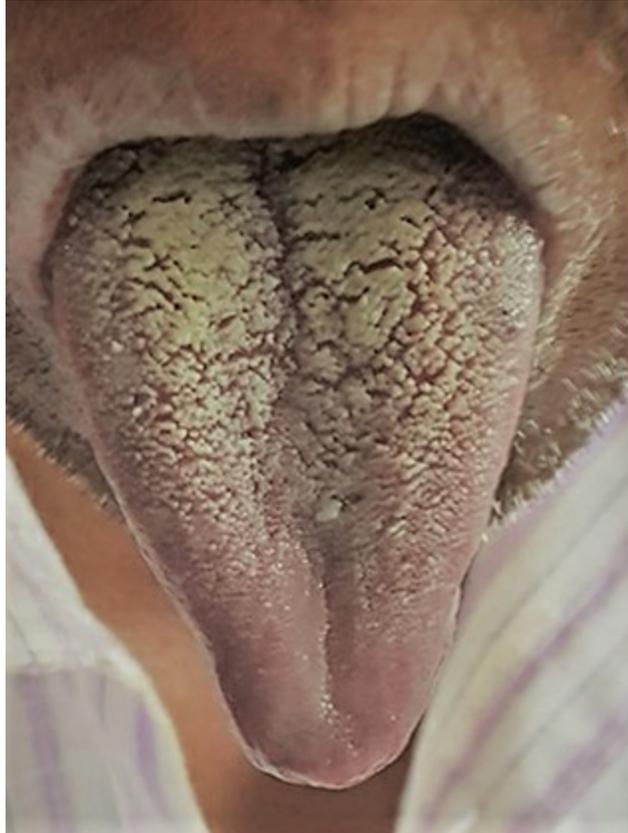

## Cyanosis (Fig. 6.3)

**Definition:** Bluish discoloration of the skin and mucous membrane. It results from an increased concentration of reduced hemoglobin/deoxyhemoglobin (>5 g/dL) or abnormal hemoglobin derivatives (e.g. methemoglobin, sulfhemoglobin, etc.) in the capillary blood perfusing the area. Cyanosis is normally detected when the oxygen saturation ( $\text{SaO}_2$ ) is <85%.

### Types of Cyanosis (Table 6.7)

**Table 6.7:** Types of cyanosis and difference between them.

<i>Features</i>	<i>Central cyanosis</i>	<i>Peripheral cyanosis</i>
Mechanism	Inadequate oxygenation of systemic arterial blood (hypoxic hypoxia)	Sluggish peripheral circulation (stagnant hypoxia)
Sites to look	Tongue and oral mucosa	<i>Acral:</i> Tip of the nose, ear lobules, outer aspect of lips, finger tips, nail bed, extremities
Associations	Clubbing, polycythemia	
Extremities	Warm	Cold
Warming extremities	No change	Cyanosis disappears
Oxygen inhalation	Slight improvement	No change
ABG $\text{PaO}_2$	Low <85%	Normal 85–100%
Pulse volume	May be high	Usually low
Dyspnea	Usually present	Usually absent
Exercise	Worsens	May improve

**Fig. 6.3:** Cyanosis characterized by bluish discoloration of mucous membrane of tongue.

## ***Causes of Cyanosis***

### *Central cyanosis*

- **Cardiac**
  - Congenital cyanotic heart diseases (*Remember 5 'T's and 2 'E's*): Transposition of great arteries, tetralogy of Fallot, truncus arteriosus, tricuspid valve abnormalities, total anomalous pulmonary venous return (TAPVR), Eisenmenger's syndrome (cyanosis tardive) and Ebstein's anomaly.
  - Acute pulmonary edema (due to left-sided heart failure).
- **Pulmonary:** Acute severe asthma, COPD, cor pulmonale, respiratory failure, respiratory depression, lobar and bronchopneumonia, tension pneumothorax, acute laryngeal edema, acute pulmonary embolism
- **High altitude** (due to low partial pressure of oxygen)
- **Polycythemia**
- **Enterogenous or pigment cyanosis:** Methemoglobinemia and sulfhemoglobinemia.

### *Peripheral cyanosis*

- **Low cardiac output:** Congestive heart failure.
- **Local vasoconstriction:** Cold, frostbite, Raynaud's phenomenon, shock.
- **Arterial obstruction:** Peripheral vascular diseases (atherosclerosis, Buerger's disease).
- **Venous obstruction:** Superior vena caval syndrome.

- **Hyperviscosity syndrome:** Multiple myeloma, polycythemia, macroglobulinemia.
- **Others:** Cryoglobulinemia, mitral stenosis.

*Mixed cyanosis*

- All causes of central cyanosis may also cause peripheral cyanosis
- Cardiogenic shock with pulmonary edema
- Congestive cardiac failure due to left sided heart failure
- Polycythemia (rarely).

**Differential cyanosis:** Cyanosis only in lower limbs seen in PDA with reversal of shunt.

**Cyanosis only in upper limbs** (reverse differential cyanosis): Coarctation of aorta (ductal type) with transposition of great arteries.

**Cyanosis in left upper limb and both lower limbs:** PDA with reversal of shunt and preductal coarctation of aorta

**Intermittent cyanosis:** Ebstein's anomaly

**Cyclical cyanosis:** Bilateral choanal atresia

**Orthocyanosis:** Development of cyanosis only in upright position due to hypoxia occurring in erect posture. Seen in pulmonary arterio-venous malformation.

**Cyanosis absent despite of sufficient reduced hemoglobin:** In severe anemia, carbon monoxide poisoning.

**Hyperoxia test (Cardiac vs Pulmonary cyanosis):** After giving 100% oxygen for 10 minutes, a repeat ABG is done and if PaO<sub>2</sub> is <150 mm Hg then the cause is cardiac and if the PaO<sub>2</sub> improves to >200 mm Hg, the cause is respiratory.

**Pseudocyanosis:** Caused by metals (gold, silver, mercury, arsenic) and drugs (minocycline, phenothiazines, chloroquine, amiodarone).

## Respiratory (Pulmonary) Function Tests (Table 6.8)

**Q. Write short note on pulmonary function tests and give their clinical significance.**

**Q. Write short note on FEV<sub>1</sub> (Forced expiratory volume in one second).**

### Table 6.8: Pulmonary function test (PFT).

PFT tracings have:

- **Four lung volumes:** Tidal volume, inspiratory reserve volume, expiratory reserve volume, and residual volume
- **Five capacities:** Inspiratory capacity, expiratory capacity, vital capacity, functional residual capacity, and total lung capacity
- Flow-volume curves
- Blood gases and pulse oximetry
- Transfer factor (diffusion)
- Exercise tests
- Exhaled nitric oxide

Abbreviations used in pulmonary function tests are presented in Table 6.9.

**Table 6.9: Abbreviations used in pulmonary function tests.**

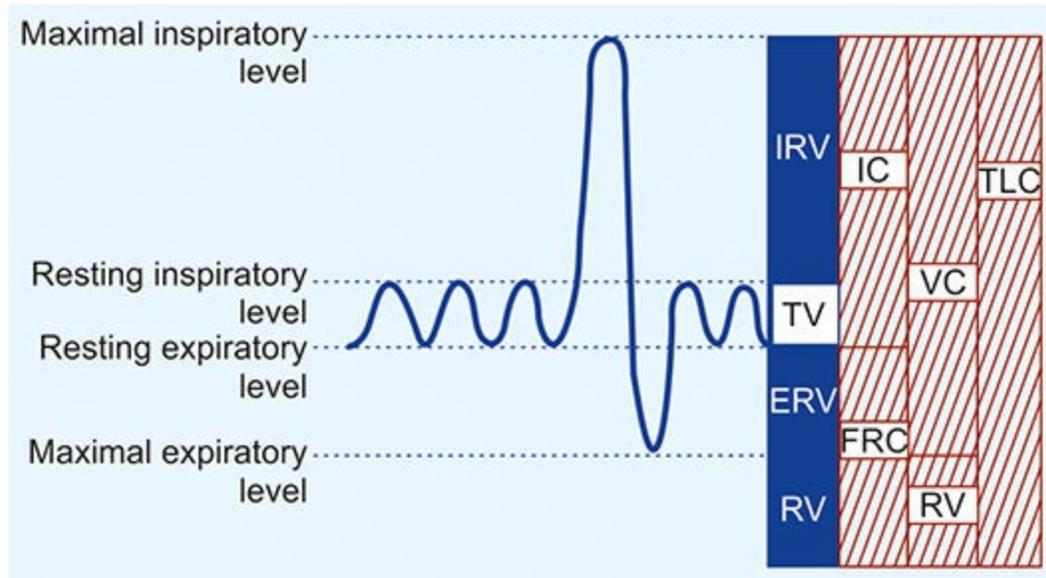

<b>Abbreviations</b>	<b>Explanation</b>
FVC (Forced vital capacity)	Volume of air expired with a maximal effort after deep inspiration
FEV <sub>1</sub> (Forced expiratory volume in one second)	Volume of air expired in the first second after deep inspiration
VC (Vital capacity)	Maximum amount of air that can be expelled from the lungs after the deepest possible breath TLC minus RV or maximum volume of air exhaled from maximal inspiratory level (60–70 mL/kg) (3100–4800 mL). VC decreases with age
PEF (Peak expiratory flow)	Volume of forcibly expired air during the first 10 seconds after deep inspiration
TLC (Total lung capacity)	Sum of all volume compartments or volume of air in lungs after maximum inspiration (4–6 L)
FRC (Functional residual capacity)	Sum of RV and ERV or the volume of air in the lungs at end-expiratory tidal position (30–35 mL/kg) (2300–3300 mL) Measured with multiple-breath closed-circuit helium dilution, multiple-breath open-circuit nitrogen washout, or body plethysmography It cannot be measured by spirometry
RV (Residual volume)	Volume of air remaining in lungs after maximum exhalation (20–25 mL/kg) (1700–2100 mL) Indirectly measured (FRC-ERV) It cannot be measured by spirometry. RV increases with age
IRV (Inspiratory reserve volume)	Maximum volume of air inhaled from the end-inspiratory tidal position (1900–3300 mL)
ERV (Expiratory reserve volume)	Maximum volume of air that can be exhaled from resting end-expiratory tidal position (700–1000 mL)
TV (Tidal volume)	Volume of air inhaled or exhaled with each breath during quiet breathing (6–8 mL/kg)
IC (Inspiratory capacity)	Sum of IRV and TV or the maximum volume of air that can be inhaled from the end-expiratory tidal position (2400–3800 mL)
EC (Expiratory capacity)	TV + ERV
DLCO (Diffusing capacity of lung for carbon monoxide)	Also known as transfer factor, DLCO measures the transfer of inhaled gases into the pulmonary capillaries

## Measurement of Airway Obstruction (Fig. 6.4)

### Ventilatory capacity

**Ventilatory capacity** include **FEV<sub>1</sub>** (volume of air expired in the first second after deep inspiration) and **FVC** (volume of air expired with a maximal effort after deep inspiration) and **PEF** (peak expiratory flow rate).

Normally, FEV<sub>1</sub>/FVC ratio is around 75%.

**Fig. 6.4:** Diagrammatic representation of various lung volume measurements.

(TLC: total lung capacity; VC: vital capacity; RV, residual volume; IC: inspiratory capacity; FRC: functional residual capacity; IRV: inspiratory reserve volume; TV: tidal volume; ERV: expiratory reserve volume; RV: residual volume)

### Patterns of abnormalities:

- i. **Obstructive ventilatory defect:** It is characterized by narrowing of airways during expiration (e.g. bronchial asthma, chronic bronchitis and emphysema). These disorders show **markedly reduced FEV<sub>1</sub>, reduced or normal VC and reduced FEV<sub>1</sub>/VC**. In airflow limitation, the FEV<sub>1</sub> is reduced as a percentage of FVC. With increasing airflow limitation FEV falls proportionately more than FVC, so the FEV<sub>1</sub>/FVC ratio is reduced.
  - **Reversibility of airflow limitation:** When FEV<sub>1</sub> is disproportionately reduced resulting in FEV<sub>1</sub>/FVC ratios of less than 70%; spirometry should be repeated following inhaled short-acting  $\beta_2$ -adrenoceptor agonists (e.g. salbutamol). A large improvement in FEV<sub>1</sub> (over 400

mL) is seen in bronchial asthma and, to some extent, in chronic bronchitis.

- ii. **Restrictive ventilatory defect:** In restrictive lung disease, **FEV<sub>1</sub> and FVC are reduced proportionately and the FEV<sub>1</sub>/FVC ratio may be normal** or may even increase because of enhanced elastic recoil. This pattern is seen in interstitial inflammation and/or fibrosis that lead to progressive loss of lung volume.

*Peak expiratory flow rate (PEFR):*

- Peak flow meters are cheap and simpler than spirometer. Patient is asked to take a full inspiration to total lung capacity and then blow out forcefully into the peak flow meter. PEFR measures the volume of forcibly expired air during the first 10 seconds after deep inspiration. Reduced values are found in airflow obstruction and are not useful in assessing restrictive ventilatory defect. It is mainly useful for diagnosis, to monitor exacerbations and response to treatment in asthma.

*Lung volumes*

Lung volumes include total lung capacity (TLC) and residual volume (RV). Both can be measured by spirometry.

**Total lung capacity (TLC)**—the total amount of air in the lungs after taking the deepest breath possible).

**Vital capacity (VC)** is the maximum amount of air that can be expelled from the lungs after the deepest possible breath is recorded separately. Patient is asked to make a full but unhurried ('relaxed') exhalation into the spirometer.

**Residual volume (RV)** is the volume of air in the lungs at the end of full expiration. It is calculated by subtracting the VC (vital capacity) from the TLC (total lung capacity).

**Interpretation:**

- In obstructive lung disease, both TLC and RV are increased.
- In restrictive lung diseases (due to parenchymal lung disease), both TLC and RV are reduced.
- Extraparenchymal diseases with restriction during both inspiration and expiration (ankylosing spondylitis, kyphoscoliosis), RV is increased while TLC is reduced.

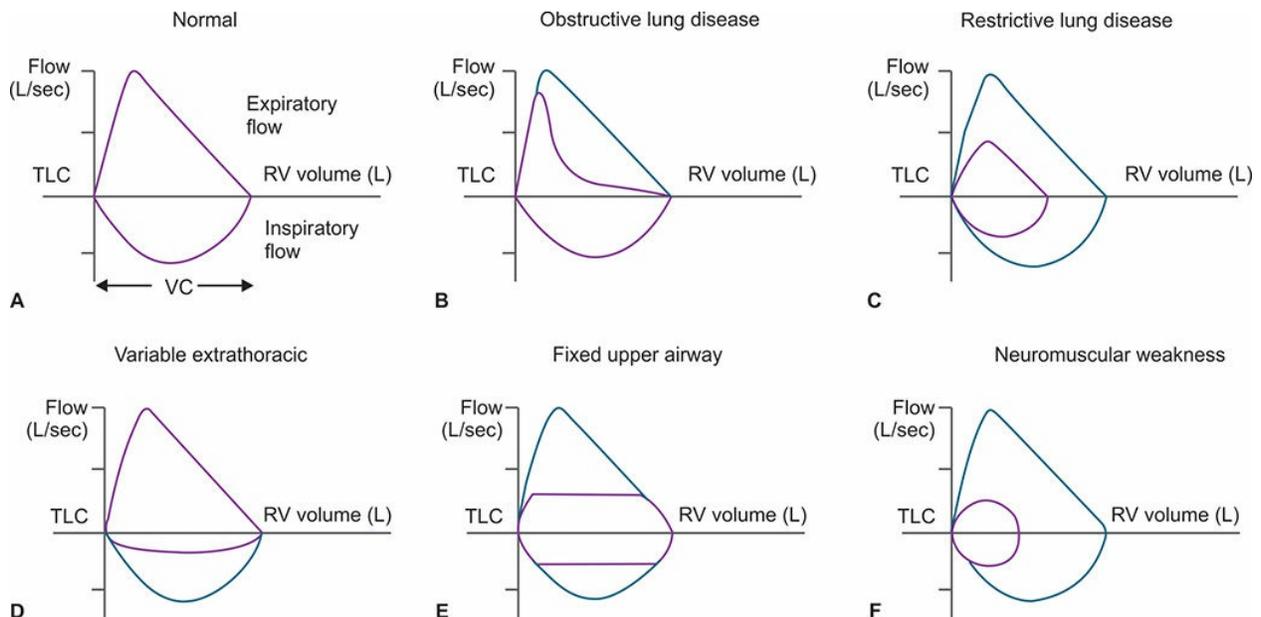

*Flow volume loops (Table 6.10 and Fig. 6.5)*

Flow volume loops measure flow rates against expired volume and shows the

site of airflow limitation (obstruction) within the lung. At the start of expiration from TLC, maximum resistance is from the large airways. This affects the flow rate for the first 25% of the curve. As air is exhaled, lung volume reduces and the flow rate depends on the resistance offered by smaller airways.

**Table 6.10:** Flow volume loops in various disorders.

<i>Disease states</i>	<i>FVC</i>	<i>FEV<sub>1</sub></i>	<i>FEV<sub>1</sub>/FVC</i>
Obstructive	Normal	Reduced	Reduced
Stiff lungs	Reduced	Reduced	Normal
Respiratory muscle weakness	Reduced	Reduced	Normal

**Fig. 6.5:** Flow volume loop for common respiratory diseases.

- **FEV<sub>1</sub>** is the volume exhaled during the first second of the FVC maneuver. **Decreased in both obstructive and restrictive lung disorders.**
- FEF 25–75% is the mean expiratory flow during the middle half of the FVC maneuver; reflects flow through the small (<2 mm in diameter) airways.
- Interpretation of percent predicted: Normal (>79%), mild obstruction (60–79%), moderate obstruction (40–59%), severe obstruction (<40%).
- **FEV<sub>1</sub>/FVC** is the ratio of FEV<sub>1</sub> to FVC × 100 (expressed as a percent); an

important value because a reduction of this ratio from expected values is specific for obstructive rather than restrictive diseases. Normal value ( $FEV_1/FVC$ ) is 75–85 %, <70% of predicted value in mild obstruction, <60% of predicted value in moderate obstruction and <50% of predicted value in severe obstruction.

**Spirometry Interpretation:** Obstructive versus restrictive defect (Table 6.11).

*Arterial blood gases (ABG) and oximetry (refer Table 6.1)*

These tests include measurement of (i) hydrogen ion ( $H^+$ ) concentration, (ii)  $PaO_2$  and  $PaCO_2$ , and (iii) oxygen saturation and bicarbonate concentration (derived from the above values) in an arterial blood. These are performed by automatic analyzers.

**Uses:** (1) To assess the degree and type of respiratory failure (for management of status asthmaticus and acute respiratory distress syndrome—ARDS) and (2) for measuring acid-based status.

### ***Tests for Gas Exchange Function***

#### **a. Alveolar-arterial $O_2$ tension gradient:**

- Sensitive indicator of detecting regional V/Q inequality
- It is the difference between the amount of the oxygen in the alveoli [i.e. the alveolar oxygen tension ( $PAO_2$ )] and the amount of oxygen dissolved in the plasma ( $PaO_2$ ).

#### **b. Dyspnea differentiation index (DDI):**

- To differentiate dyspnea due to respiratory/cardiac diseases

$$DDI = \frac{PEFR \times PaCO_2}{1000}$$

- DDI-Lower in respiratory pathology

#### **c. Diffusing capacity of lung (DL):** Defined as the rate at which gas enters into blood divided by its driving pressure.

- The diffusing capacity for carbon monoxide (DLCO) is also known as the transfer factor. It measures the ability of the lungs to transfer gas from inhaled air in the alveoli to the red blood cells in pulmonary capillaries.

- Diseases associated with reduced and increased gas transfer are listed in Table 6.12.

**Table 6.11: Spirometry interpretation—obstructive versus restrictive defect.**

<b>Obstructive disorders</b>	<b>Restrictive disorders</b>
Limitation of expiratory airflow as airways cannot empty as rapidly compared to normal (e.g. narrowed airways from bronchospasm, inflammation, etc.)	Characterized by reduced lung volumes/decreased lung compliance
<ul style="list-style-type: none"> <li>• FVC normal or ↓</li> <li>• FEV<sub>1</sub> ↓ (significantly decreased)</li> <li>• FEF<sub>25–75%</sub> ↓</li> <li>• FEV<sub>1</sub>/FVC ↓ (&gt;0.7)</li> <li>• TLC normal or ↑</li> </ul>	<ul style="list-style-type: none"> <li>• FVC ↓ (significantly decreased)</li> <li>• FEV<sub>1</sub> ↓</li> <li>• FEF 25–75% normal to ↓</li> <li>• FEV<sub>1</sub>/FVC normal to ↑ (&gt;0.7)</li> <li>• TLC ↓</li> </ul>
Examples: Asthma, emphysema, cystic fibrosis	Examples: Interstitial fibrosis, scoliosis, obesity, lung resection, neuromuscular diseases, cystic fibrosis

**Table 6.12: Diseases associated with reduced and increased DLCO.**

<b>Reduced DLCO (ventilation is in excess of blood flow [a high VQ,-DEAD SPACE- “wasted air”])</b>	<b>Increased DLCO (blood flow is in excess of ventilation [a low VQ, - SHUNT- “wasted blood”])</b>
<ul style="list-style-type: none"> <li>• Emphysema, lung resection, pulmonary embolism, anemia</li> <li>• Pulmonary fibrosis, sarcoidosis—increased thickness</li> </ul>	Severe obesity, asthma, polycythemia, supine position, exercise, and left to right shunt

### **Tests for Cardiopulmonary Interactions**

- Reflects gas exchange, ventilation, tissue O<sub>2</sub>, CO<sub>2</sub>.
  - **Qualitative:** History, examination, ABG, stair climbing test
  - **Quantitative:** 6 minute walk test.
1. **Stair climbing test:** If able to climb 3 flights of stairs without stopping/dyspnea at his/her own pace-reduced morbidity and mortality. If not able to climb 2 flights: High-risk.
  2. **6 minute walk test:** Gold standard. Cardiopulmonary reserve is measured by estimating maximum O<sub>2</sub> uptake (VO<sub>2</sub> Max) during exercise. Modified if patient cannot walk—bicycle/arm exercises. If patient is able to walk

for >2000 feet during 6 min period  $\text{VO}_2$  max >15 mL/kg/min, if 1080 feet in 1 min:  $\text{VO}_2$  of 12 mL/kg/min. Simultaneously oximetry is done and if  $\text{SpO}_2$  falls >4% high-risk.

### ***Exhaled Nitric Oxide***

- Nitric oxide is produced by the bronchial epithelium. Its production increases in asthma and other diseases associated with inflammation of airway.
- Measurement of exhaled NO may be helpful in asthma that is difficult to control. Measuring **fractional exhaled nitric oxide** (FeNO) helps to identify patients who are likely to benefit from treatment with corticosteroids. FeNO also predicts the likelihood of steroid responsiveness more consistently than spirometry, bronchodilator response, peak flow variation, or airway hyperresponsiveness to methacholine. A FeNO greater than 50 ppb in adults or greater than 35 ppb in children suggests eosinophilic airway inflammation.

## **BRONCHIAL ASTHMA**

**Q. Define and classify bronchial asthma. Discuss the etiology, pathophysiology, clinical features, investigations, diagnosis, complications and management/treatment of bronchial asthma.**

### **Definition**

**Definition:** Asthma is a **chronic inflammatory disorder** of the airways (bronchial tree) in which **breathing is periodically rendered difficult** by **widespread narrowing of the bronchi** (reversible bronchoconstriction).

It is **clinically, characterized by recurrent episodes** (paroxysms) of **wheezing, breathlessness (dyspnea), tightness of the chest, and cough.**

### ***Global Initiative for Asthma (GINA)—2015 Definition of Asthma***

“Asthma is a heterogeneous disease, usually characterized by chronic airway inflammation. It is defined by the history of respiratory symptoms such as wheeze, shortness of breath, chest tightness and cough that vary over time and in intensity, together with variable expiratory airflow limitation.” *These episodes are usually associated with widespread but variable airflow*

obstruction that is often reversible either spontaneously or with treatment.

## Characteristics of Asthma

1. **Airflow narrowing:** It is due to combination of muscle edema and viscid bronchial secretion. It is generally reversible spontaneously or with treatment.
2. **Airway hyper-reactivity (AHR)/bronchial hyper responsiveness (BHR):** It is characterized by increased tendency for airways (tracheobronchial tree) to narrowing response to triggers (stimuli) that have little or no effect in normal individuals.
3. **Bronchial inflammation:** Inflammation of the bronchial walls by T lymphocytes, mast cells, eosinophils with associated plasma exudation, edema, smooth muscle hypertrophy, mucus plugging and epithelial damage.

**Table 6.13:** Classification of asthma.

### According to type of antigen

1. Early-onset asthma (**atopic/allergic/extrinsic**)
2. Late-onset asthma (**non-atopic/intrinsic/idiosyncratic**) without evidence of allergen sensitization

### According to the agents or events that trigger bronchoconstriction

1. Seasonal
2. Exercise-induced
3. Drug-induced (e.g. aspirin)
4. Occupational asthma
5. Asthmatic bronchitis in smokers
6. Cough variant asthma (CVA) in which cough is the only asthma symptom

## Classification (Table 6.13)

Differentiating features of early-onset asthma and late-onset asthma is presented in Table 6.14.

**Q. How will you differentiate early-onset (atopic) asthma from late-onset (non-atopic) asthma?**

**Table 6.14:** Differentiating features of early-onset asthma and late-onset asthma.

Features	Early-onset (atopic) asthma	Late-onset (non-atopic) asthma
----------	-----------------------------	--------------------------------

Onset	Early age usually begins in childhood	Late age
Individuals	Atopic individuals	Non-atopic individuals
Role of external allergens	Have strong role	No role
Family history	Positive history of asthma or allergic diseases (e.g. eczema, urticaria, or hay fever)	Less common or absent
Triggering events	Environmental allergens (e.g. dusts, pollens, animal dander, and foods)	Respiratory infections due to viruses (e.g. rhinovirus, parainfluenza virus) Inhaled air pollutants (e.g. smoke, fumes)
Serum level of IgE	Increased	Normal
Skin hypersensitivity test to common inhalant allergens	Positive	Negative
Response to provocation tests	Positive	Negative

## Risk Factors and Triggers (Table 6.15)

**Table 6.15:** Risk factors and triggers involved in asthma.

### *Risk factors*

#### **Endogenous factors**

- Genetic predisposition
- Atopy
- Airway hyperresponsiveness
- Gender and age
- Ethnicity
- Obesity
- Early viral infections

#### **Environmental factors**

- Allergens (indoor/outdoor)
- Occupational sensitizers
- Respiratory infections

### *Triggers*

- |   |  |
|---|--|
| <ul style="list-style-type: none"> <li>• Inhaled allergens</li> <li>• Upper respiratory tract viral infections</li> <li>• Air pollution (e.g. sulfur dioxide, irritant gases)</li> <li>• Passive smoking (tobacco smoke)</li> </ul> | <ul style="list-style-type: none"> <li>• Drugs (<math>\beta</math>-blockers, aspirin)</li> <li>• <i>Physical factors:</i> Exercise, cold air and hyperventilation</li> <li>• Emotional stress</li> <li>• Irritants (household sprays paint fumes)</li> </ul> |
|---|--|

## **Risk Factors**

### *Endogenous factors*

- **Genetic predisposition:** Major etiological factor in atopic asthma is genetic predisposition to **type I hypersensitivity (atopy) reaction** and exposure to environmental trigger. One of the **susceptibility locus is on**

**the chromosome 5 (5q)** → several genes involved in regulation of IgE synthesis and mast cell and eosinophil growth and differentiation.

- **Atopy:** Atopic individuals tend to **have higher serum IgE levels**, and a positive family history of allergy is found in 50% of atopic individuals. Patients with asthma commonly suffer from other atopic diseases (e.g. allergic rhinitis, atopic dermatitis/eczema).
- **Airway hyperresponsiveness:** It is an abnormality in which there is **excessive tendency for airways to contract** (bronchoconstrictor) too easily in response to multiple inhaled triggers that usually does not have any effect on normal individuals.
- **Gender and age:** More common in boys than girls and, after puberty, women slightly more commonly than men. Most cases **begin before the age of 25 years**.

#### *Environmental factors*

**Hygiene Hypothesis** proposes that individuals with **lack of infections in early childhood** are more prone to asthma than children brought up on farms who are exposed to a high level of endotoxin. Intestinal parasite infection may also be associated with a decreased risk of asthma. Conversely, early childhood in a ‘dirtier’ environment (exposure to inhaled and ingested products of microorganisms) may allow the immune system to avoid developing allergic responses.

## **Pathogenesis (Pathophysiology) of Asthma**

### **A. Airway inflammation**

- **Inflammation** is chronic and involves many cell types and inflammatory mediators.
- **Strong T<sub>H</sub>2 response: Genetic predisposition** with susceptibility genes makes individuals prone to develop **strong T<sub>H</sub>2** (type of T lymphocytes) **reactions against environmental antigens** (allergens).
- **T<sub>H</sub>2 cells secrete cytokines:** Which promote allergic inflammation and **stimulate B cells to produce IgE**.

#### *Cells involved in the inflammatory response*

Important cells involved in asthma are: **Mast cells, eosinophils, dendritic cells (macrophages) and lymphocytes**.

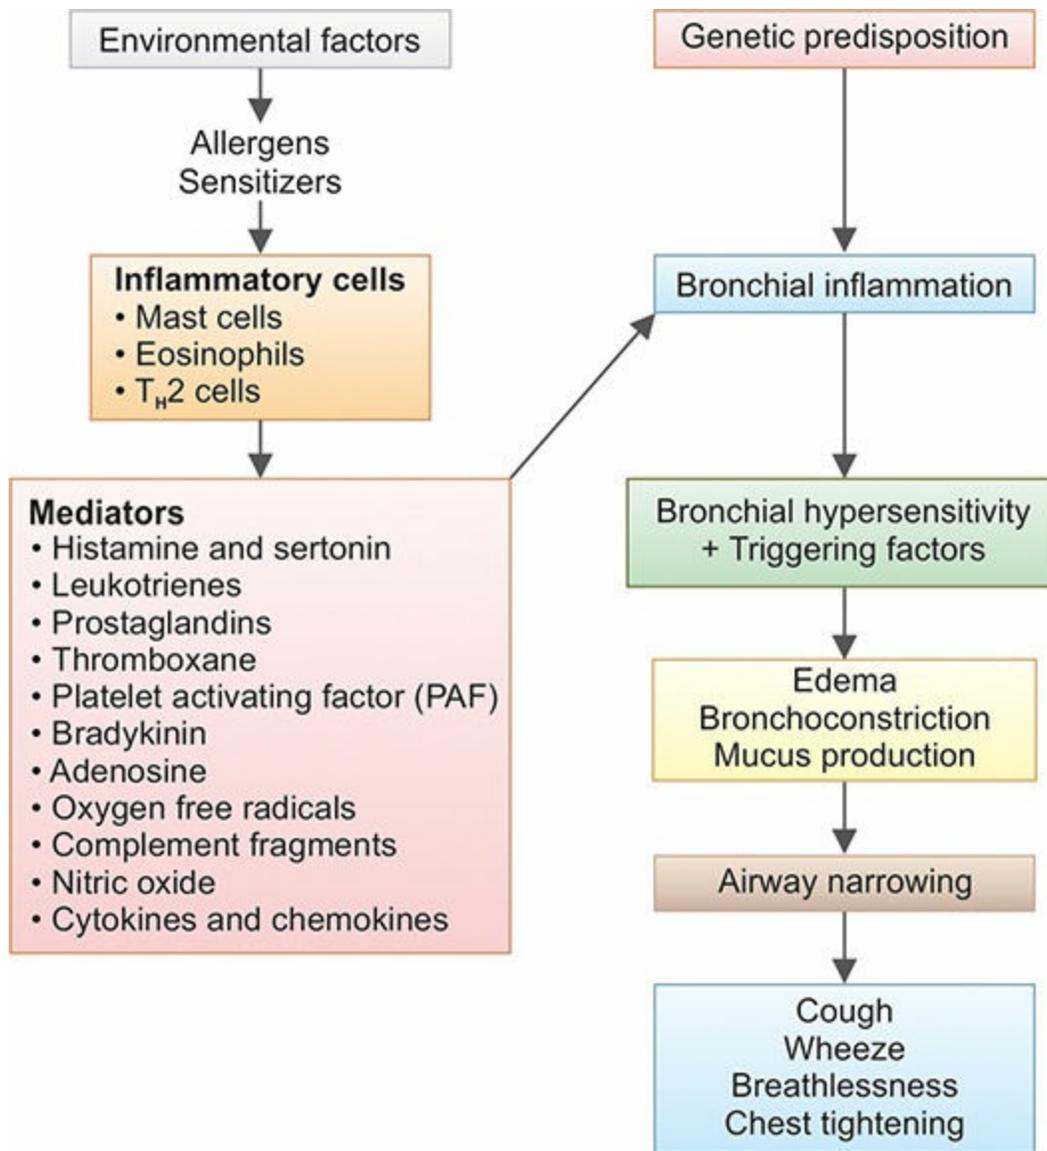

1. Mast cells

- **Early reaction** is characterized by **bronchoconstriction, increased mucus production, and vasodilation with increased vascular permeability** (causes edema).
- **Late phase reaction:** It is characterized by **inflammation and airway remodeling**.

2. Eosinophils

- **Mediators release from eosinophils:** LTC<sub>4</sub>, and basic proteins such as major basic protein (MBP), eosinophil cationic protein (ECP) and eosinophils peroxidase (EPX). They are toxic to epithelial cells.
- Corticosteroid rapidly decreases the number and reduces the activation of eosinophils.
- Sputum eosinophilia is of diagnostic help and is a biomarker of response to therapy.

3. Dendritic cells and lymphocytes.

**Fig. 6.6:** Pathogenesis of asthma.

They release prostaglandin, thromboxane, LTC<sub>4</sub>, LTB<sub>4</sub> and platelet activating factor (PAF).

### ***B. Airway Remodeling***

**Airway remodeling** is the **group of structural and functional changes in the bronchial wall due to repeated bouts of inflammation** observed in chronic asthma.

- An **increase in size and number** (hypertrophy/hyperplasia) of the **submucosal glands**

- **Hypertrophy and/or hyperplasia of the bronchial wall smooth muscle**
- **Increased vascularity**
- **Deposition of subepithelial collagen** accompanied by fibrosis and thickening of the basement membrane.

Pathogenesis of asthma is summarized in Figure 6.6.

## Clinical Features

**Q. Write a short note on the clinical presentation of severe acute asthma (status asthmaticus).**

- Clinical features are studied under three headings namely (1) episodic, (2) severe acute (status asthmaticus), and (3) chronic asthma.
- Usually, atopic individuals develop episodic asthma and non-atopic individuals develop chronic asthma.

### 1. *Episodic Asthma*

- Occurs as episodes with asymptomatic between asthmatic attacks.
- Frequency and duration of attacks vary.
- Present with relatively sudden onset of paroxysms of **wheezing and dyspnea**.
- May develop spontaneous or triggered by allergens, exercise or viral infections.
- It may be mild to severe and may last for hours, days or even weeks.

### 2. *Severe Acute Asthma (Status Asthmaticus)*

**Q. Write a short note on the clinical presentation of severe acute asthma (status asthmaticus).**

- It is the **most severe form of asthma** in which the severe acute paroxysm persists for days and even weeks.
- Presents with severe dyspnea and unproductive cough.
- During this attack, patients prefer an upright position fixing the shoulder girdle to assist the accessory muscles of respiration.
- Physical signs include sweating, central cyanosis, tachycardia and pulsus paradoxus. The **bronchoconstriction** and asthmatic symptoms **does not**

**respond** despite the initial administration of standard **acute asthma therapy**.

- It may cause **severe airflow obstruction leading to severe cyanosis and even death**.

### **3. Chronic Asthma**

- Chronic persistent symptoms and include chest tightness, wheeze and breathlessness on exertion.
- Characterized by episodes of spontaneous cough and wheeze worst during the night.
- Chronic productive cough with mucoid sputum, punctuated by recurrent attacks of purulent expectoration from frank infection. They are prone to repeated attacks of 'severe acute asthma'. Features sometimes resemble those of chronic bronchitis.

### **Physical Signs**

- **During an attack:**
  - *Inspection:* Increased respiratory rate with use accessory muscles of respiration.
  - *Percussion:* Hyperresonant percussion note over the lungs.
  - Auscultation
    - ◆ Breath sounds are vesicular with prolonged expiration.
    - ◆ High-pitched polyphonic expiratory and inspiratory rhonchi.
    - ◆ Very severe attacks may results in a silent chest which is ominous sign.
- **In between the attacks:** Chest may not reveal any abnormal physical signs.
- **Chronic asthmatics:** Usually reveal few scattered rhonchi.

Table 6.16 shows classification of asthma severity and initiating treatment in persons  $\geq$  years of age.

### **Various Causes of Wheeze (Box 6.3)**

**Q.** Write short essay/note on wheeze and its causes.

### **Investigations**

The diagnosis is mainly clinical and based on a characteristic history. There is no single satisfactory diagnostic test for asthma.

### 1. Lung Function Tests

Pulmonary function tests useful in asthma are FEV<sub>1</sub>, VC and PEF<sub>R</sub>.

- **Spirometry:** It is useful, especially in assessing reversibility. Simple spirometry useful in confirming the airflow limitation with a reduced FEV<sub>1</sub>, FEV<sub>1</sub>/FVC ratio, and PEF. Asthma can be diagnosed if there is **greater than 15% improvement in FEV<sub>1</sub> or PEF<sub>R</sub> following the inhalation of a bronchodilator.**
- **Peak expiratory flow rate (PEFR):** It is useful in demonstrating the variable airflow limitation. PEFR measurements to be done on waking, prior to taking a bronchodilator and before bed after a bronchodilator. The diurnal variation in PEFR of more than 20% (the lowest values typically being recorded in the morning) is considered diagnostic. It is also provides good measure of disease severity.
- *Carbon monoxide (CO) transfer test:* Increased in asthma.

**Table 6.16:** Classification of asthma severity and initiating treatment in persons ≥12 years of age.

Components of Severity		Classification of Asthma Severity (≥12 years of age)			
		Intermittent	Persistent		
			Mild	Moderate	Severe
Impairment Normal FEV <sub>1</sub> /FVC: 8–19 years: 85% 20–39 years: 80% 40–59 years: 75% 60–80 years: 70%	Symptoms	≤2 days/week	>2 days/week but not daily	Daily	Throughout the day
	Nighttime awakenings	≤2x/month	3–4x/month	>x/week but not nightly	Often 7x/week
	Short-acting beta <sub>2</sub> -agonist use for symptom control	≤2 days/week	>2 days/week but not daily, and not more than 1x on any day	Daily	Several times per day
	Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
	Lung function	<ul style="list-style-type: none"> <li>• Normal FEV<sub>1</sub> between exacerbations</li> <li>• FEV<sub>1</sub> &gt;80%</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &gt;80% predicted</li> <li>• FEV<sub>1</sub>/FVC normal</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &gt;60% but &lt;80% predicted</li> <li>• FEV<sub>1</sub>/FVC</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub> &lt;60% predicted</li> <li>• FEV<sub>1</sub>/FVC reduced &gt;5%</li> </ul>

		↑ predicted • FEV <sub>1</sub> /FVC normal	normal	↓ reduced 5%	
Risk	Exacerbations requiring oral systemic corticosteroids	0–1/year	← ————— ≥2/year ————— →		
			← ————— Consider severity and interval since last exacerbation ————— → Frequency and severity may fluctuate over time for patients in any severity category Relative annual risk of exacerbations may be related to FEV <sub>1</sub>		
Recommended step for initiating treatment		Step 1	Step 2	Step 3	Step 4 or 5
		in 2–6 weeks, evaluate level of asthma control that is achieved and adjust therapy accordingly			
		and consider short course of oral systemic corticosteroids			

**Exercise tests:** It used in the diagnosis of asthma in children. The child is asked to run for 6 minutes on a treadmill (heart rate should be above 160 beats per minute). A negative test does not rule out asthma.

**Box 6.3:** Various causes (D/D) of wheeze.

- Bronchial asthma
- Cardiac asthma
- Chronic obstructive lung disease (COPD)
- Recurrent pulmonary emboli
- Systemic vasculitis, including Churg Strauss syndrome and polyarteritis nodosa
- Carcinoid tumors
- *Others:* Eosinophilic pneumonia, GERD, foreign body aspiration, mediastinal mass, tracheomalacia, vocal cord dysfunction

**Airway Responsiveness (AHR):** AHR is sensitive but nonspecific.  
**Histamine or methacholine bronchial provocation test:**

- To detect the presence of airway hyperresponsiveness (a feature of asthma).
- Useful in patients whom cough is the only/main symptom and is useful in the differential diagnosis of chronic cough.
- Contraindicated on individuals who have poor lung function (FEV<sub>1</sub> <1.5 L) or a history of ‘brittle’ asthma.

**Indirect challenge tests** release of endogenous mediators that cause the contraction of airway smooth muscle. These include exercise eucapnic voluntary hyperpnea (EVH), ultrasonically nebulizer hypertonic saline and dry-powder mannitol.

## 2. **Imaging**

### • **Chest X-ray**

- Usually normal between attacks without any diagnostic features.
- During an acute episode or in chronic severe disease there may hyperinflated lungs (overinflation).
- May be helpful in excluding complications such as pneumothorax, lobar collapse (if mucus occludes large bronchus) or in detecting the pulmonary infiltrates associated with allergic bronchopulmonary aspergillosis.

- **High-resolution computed tomography (CT):** May show areas of bronchiectasis (complication) and thickening of the bronchial walls, but these changes are not diagnostic of asthma.

## 3. **Measurement of Allergic Status**

- **Skin prick tests (SPT):** SPT is performed by intradermal injections of common allergens (house dust mite, cat fur, grass pollen) and checking the development of a wheal and flare reaction. They are positive in allergic asthma and negative in intrinsic asthma.
- **Elevated serum IgE levels:** Measurement of total and allergen-specific IgE in serum may be seen.

## 4. **Blood and Sputum Tests**

- Patients with asthma may show increased numbers of eosinophils (eosinophilia) in peripheral blood ( $>0.4 \times 10^9/L$ ) but sputum eosinophils is a more specific diagnostic finding. Sputum examination may reveal Curschmann spirals, Creola bodies and Charcot-Leyden crystals. **Serum periostin** is also a marker of Th2 associated airway inflammation and a better predictor of airway eosinophilia than blood eosinophil counts or FENO.

## 5. **Exhaled Nitric Oxide (FENO)**

- It is used as a noninvasive test to measure airway inflammation and as an index of efficacy of corticosteroid response in children (demonstration of insufficient response to anti-inflammatory therapy).

## 5. **Trial of Corticosteroids**

- Patients with severe airflow limitation should be given a formal trial of corticosteroids. Prednisolone 30 mg orally/day is given for 2 weeks with lung function measured before and immediately after the course.

A substantial improvement in FEV (>15%) confirms the presence of a reversible airflow obstruction and indicates that the administration of inhaled steroids will be beneficial to the patient.

7. **Arterial Blood Gas Analysis**

- Hypoxia and hypocarbia during acute attack
- Hypercarbia during sever acute asthma.

**Differential Diagnosis of Asthma (Table 6.17)**

**Q. Give the differential diagnosis of a 45-year-old male presenting with acute breathlessness.**

**Table 6.17: Differential diagnosis of asthma.**

<i>Disease</i>	<i>Features</i>
Chronic obstructive pulmonary disease (COPD)	History of smoking Less reversible airflow obstruction Reduced DLCO (diffusing capacity of lung for carbon monoxide)
Bronchiectasis	May be secondary to many disorders Copious purulent sputum Computed tomography usually diagnostic
Reactive airways viral syndrome	Transient, usually resolves after several weeks
Rhinosinusitis	Nasal congestion and postnasal drip Common comorbid illness accompanying asthma
Gastroesophageal reflux disease	Common comorbid illness accompanying asthma
Congestive heart failure	Exertional dyspnea Moist basilar rales, S <sub>3</sub> gallop, orthopnea, pink frothy/blood-tinged sputum Echocardiography helpful
Laryngeal dysfunction	Stridor May co-exist with asthma
Upper airway obstruction	May or may not exhibit stridor Flow-volume loop may be helpful Endoscopy diagnostic
Recurrent episodes of bronchospasm	Carcinoid tumors, recurrent pulmonary emboli. Churg Strauss syndrome

Differences between bronchial asthma and cardiac asthma are present in Table 6.18.

**Q. Write short essay/note on:**

- Enumerate the drugs used in the treatment of chronic bronchial asthma.
- Management of acute severe asthma.
- List the drugs used for prophylaxis against asthma.
- Status asthmaticus.
- Long-term complications of asthma.

### Management

Management is discussed under following headings namely:

#### ***Avoid Identified Aggravating Factors/Allergens***

- This is important in the management of occupational asthma and atopic asthma.
- Avoid causative allergens such as pets, moulds and certain foodstuffs particularly in childhood.
- If it is due to single allergen, it is easy to reduce or avoid the exposure. However, when multiple allergens are responsible, avoidance is difficult.

**Table 6.18: Differences between bronchial asthma and cardiac asthma.**

<b>Features</b>	<b>Bronchial Asthma</b>	<b>Cardiac Asthma</b>
<b>Pathology</b>	Bronchospasm	Pulmonary edema
<b>Age</b>	Young	Elderly (above 50–60 years)
<b>Sex/gender</b>	Both genders	Mostly male
<b>Past history</b>	Of eczema, urticaria (allergy) susceptibility to cold, allergy to pollen, groundnuts, eggs	No history of allergy, history of left ventricular failure, right ventricular failure
<b>Family history</b>	Other family members may have similar disease	Hypertension may run in families
<b>Personal history</b>	Highly sensitive individual	Nil
<b>Onset</b>	Acute, usually in early hours of morning or late hours of night	Acute usually at midnight (very specific) 2 to 3 hours after sleep
<b>Symptoms</b>		
Dyspnea	Expiratory dyspnea	Both expiratory and inspiratory dyspnea
Expectoration	Scanty and mucoid sputum	Profuse and frothy sputum
Palpitation	Absent	Present
<b>On examination</b>		
Respiratory	Expiratory wheeze present	Basal crepitations and sweating present
Cyanosis	Present during acute severe asthma	Cyanosis present
Pulse rate	May be high	Very high (may be pulsus alternans)
Blood pressure	Normal or slightly more systolic	BP usually high

Heart sounds

Heart sounds are distant

S3, Gallop rhythm may be present

### **Control of Risk Factors Causing Exacerbation**

The rapid identification and removal of extrinsic causes of asthma and risk factors that exacerbate asthma should be done.

- Active and passive smoking should be avoided.
- Control if there is associated rhinitis and GERD (gastroesophageal reflux disease).
- Control obesity.
- Individuals intolerant to aspirin should avoid NSAIDs.
- Avoid inadequate use of inhaled corticosteroids.
- Avoid overuse of inhaled short acting  $\beta$ -agonists (e.g. more than one canister of 200 doses/month).
- Follow proper inhalation techniques.

### **Desensitization or Immunotherapy**

Desensitization is performed by repeated subcutaneous injections of gradually increasing doses of the extracts of allergen(s). However, its benefit is doubtful. GINA 2017 recommends adding **SLIT (sublingual immunotherapy)** in adult HDM (house dust mite)-sensitive patients with allergic rhinitis who have exacerbations despite ICS treatment, provided FEV1 is 70% predicted.

### **Drug Therapy (Table 6.19)**

Drug therapy is used to control or suppress clinical manifestations.

The drugs useful in asthma can be divided into bronchodilators (rapidly relieve of symptoms through relaxation of airway smooth muscle), and controllers (inhibit the underlying inflammatory process).

**Table 6.19: Drugs useful in asthma.**

<b>Bronchodilators</b>	<b>Controllers</b>	
$\beta$ -adrenoreceptor agonists	Inhaled Corticosteroids	Anti-IgE Immunotherapy
Methylxanthines	Systemic Corticosteroids	Alternative Therapies
Anticholinergics	Steroid-sparing therapies, cromones	Miscellaneous agents, SLIT
	antileukotrienes	

### **Bronchodilators**

#### 1. $\beta_2$ -adrenoreceptor agonists

- **$\beta$ -adrenoreceptor:** There are two types of  $\beta$ -adrenoreceptor namely,  $\beta_1$  and  $\beta_2$ -adrenoreceptors.  $\beta_1$ -adrenoreceptors are expressed in the heart and  $\beta_2$ -adrenoreceptors are widely expressed in the airways (in bronchial smooth muscles).
- **$\beta_2$ -adrenoreceptors agonists** ( $\beta_2$ -agonists) can be divided into **short-acting  $\beta_2$ -agonists** (SABAs) (e.g. salbutamol, levosalbutamol, and terbutaline) and **long-acting  $\beta_2$ -agonists**

(LABAs) (e.g. bambuterol, salmeterol and formoterol).

- a. **Catecholamines:** Catecholamines used are adrenaline, isoprenaline and isoetharine.  
**Adrenaline:** Most commonly used agent in this group. However, it is not a  $\beta_2$ -selective and produces significant undesirable cardiovascular side effects. The usual dose is 0.3–0.5 mL of a 1:1000 solution administered subcutaneously. It may be repeated thrice at an interval of 20 minutes. They are useful in children.
- b. **Salbutamol, levosalbutamol, terbutaline, fenoterol:** These drugs are highly selective for  $\beta_2$ -adrenoreceptors and act predominantly on the respiratory tract.
  - ◆ **Powerful and rapidly but short acting** bronchodilators that relaxes bronchial smooth muscles.
  - ◆ **Routes of administration:** They are active by inhalation, oral, intravenous, subcutaneous route of administration, but the **preferred route is inhalation**. Inhalation is extremely effective, since, it rapidly decreases airflow obstruction. Intravenous administration has no advantages over inhalation. Other routes of administration are preferable avoided and reserved for selected indications.
  - ◆ **Dose:**
    - ◇ *Salbutamol:* 2–4 mg thrice a day orally or two puffs of 100  $\mu\text{g}$  each as required.
    - ◇ *Terbutaline:* 2.5–5 mg thrice a day or two puffs of 100  $\mu\text{g}$  each as required.
    - ◇ *Levosalbutamol:* Two puffs of 50  $\mu\text{g}$  each as required.
  - ◆ **Side effects:** Main untoward effects are tremor and palpitation. Prolonged use of  $\beta_2$ -adrenoreceptor agonists are preferable avoided because they worsen bronchial hyper-responsiveness. Tachycardia which is less with levosalbutamol compared to salbutamol.
- c. **Bambuterol:** It is a long acting  $\beta_2$ -adrenoreceptor agonist which is converted into terbutaline in the body.
  - ◆ **Dose:** 10–20 mg once in a day orally.
  - ◆ **Side effects:** More than inhaled  $\beta$ -agonists and include tachycardia, palpitations and tremors.
- d. **Salmeterol and formoterol:** They are highly selective, potent and long-acting  $\beta_2$ -adrenoreceptor agonist. They are given once or twice a day by inhalation (either as aerosol or dry powder).
  - ◆ **Uses:** Routinely used in place of short-acting  $\beta_2$ -stimulants when the patient requires regular  $\beta_2$ -stimulant therapy. Not to be used as monotherapy but to be used as add on therapy along with ICS (inhaled corticosteroids) when the response to ICs is suboptimal.
  - ◆ Salmeterol has a slow onset of action whereas formoterol has a rapid action. Hence, formoterol is suitable for immediate control of symptoms as well.
  - ◆ **Dose:**
    - ◇ *Salmeterol:* Two puffs of 25  $\mu\text{g}$  each two to three times a day.
    - ◇ *Formoterol:* Two puffs of 6  $\mu\text{g}$  each one to three times a day.

**Q. Write a short note on action of methylxanthines.**

**2. Methylxanthines**

They are of little value as monotherapy but they are beneficial as add-on therapy in patients not controlled with inhaled corticosteroids (ICS). Methylxanthines as an add-on therapy are less effective than long-acting inhaled  $\beta_2$ -agonists.

**a. Theophylline**

- Theophylline is a medium-potency bronchodilator.
- **Actions:** i) improve the movement of airway mucus, ii) improves diaphragm contractility and iii) reduces the release of mediators.
- **Route of administration:** Intravenous, oral or as suppository. Therapeutic plasma concentrations of theophylline range from 10 to 20 µg/mL. However, the dose required to achieve this concentration varies from patient to patient.
- **Type of preparation:**
  - ◆ Acute attacks are treated with short-acting theophylline preparations.
  - ◆ For maintenance therapy, long-acting theophylline preparations are used. They are given once or twice a day. Single daily dose in the evening controls nocturnal asthma.
- **Dose:** Usual dose is 100–200 mg (of plain preparation) three times/day, and 300 mg twice/day or 450–600 mg once/day for sustained-release preparation.
- **Side effects:** Nervousness, nausea, vomiting, anorexia and headache. When plasma levels exceed 30 µg/mL, seizures and cardiac arrhythmias can occur.
- **Precautions:** Theophylline (and aminophylline) clearance is decreased in elderly, liver disease, congestive heart failure, and with concurrent use of erythromycin, allopurinol and cimetidine. Its clearance is increased with concurrent use of phenobarbitone and phenytoin, and in smokers.

**Q. Write short essay/note on adverse effects of and precautions in using aminophylline.**

**b. Aminophylline**

- Aminophylline is a bronchodilator that is effective when given orally, intravenously and as a suppository. The preferred route of administration is intravenous and may have some role in the management of status asthmaticus (severe acute asthma).
- **Mechanism of action:** Bronchodilator effect is by inhibition of phosphodiesterases in airway smooth-muscle cells which increases cyclic AMP.
- **Dose:** Loading dose of 5 mg/kg given slowly intravenously over 20 minutes. This is followed by a maintenance dose of 0.5 mg/kg/hour delivered as a continuous intravenous infusion. Patients already on theophylline, loading dose is preferably withheld or in extreme cases given in a reduced amount at 0.5 mg/kg.
- Rapid infusion of the bolus can lead to sudden death due to cardiac arrhythmias.

**c. Doxophylline (doxofylline)**

- ◆ **Mechanism of action:** Bronchodilator effect is by inhibition of phosphodiesterases in airway smooth-muscle cells which increases cyclic AMP. It has a better safety profile than theophylline. It also inhibits PAF-induced bronchoconstriction and subsequent production of thromboxane A<sub>2</sub>.
- ◆ **Dose:** 400 mg twice a day.

**3. Anticholinergics**

- **Antimuscarinic bronchodilators:** They are less effective than β<sub>2</sub>-agonists in asthma therapy, but may be used as an additional bronchodilator in patients with asthma that is not controlled by Inhaled corticosteroids (ICS) and LABA combinations. They may be useful during asthma exacerbations, but are less useful in stable asthma. For example, Ipratropium, Tiotropium.

## **Controller Therapies**

**Q. Write short essay/note on inhaled corticosteroid therapy.**

**1. Inhaled corticosteroids (ICS)**

- Inhaled corticosteroids are the most effective controllers for asthma.
- **Mechanism of action:** Corticosteroids are not bronchodilators, but they are the most effective anti-inflammatory agents used in asthma which reduces number of inflammatory cells as well as their activation in the airways. They decrease bronchial hyper-responsiveness and relieve or prevent airflow obstruction. They also reverse  $\beta_2$ -receptor down regulation produced by long-term use of  $\beta_2$ -agonists.
- **Uses:** Beneficial in treating asthma of any severity and age. They are now given as first-line of therapy for persistent asthma.
- **Dose:** Usually given twice daily. Higher doses may be necessary in severe cases.
  - **Beclomethasone dipropionate (200  $\mu\text{g}$ ), budesonide (200  $\mu\text{g}$ ) or fluticasone (125  $\mu\text{g}$ ) is given twice daily as aerosols or dry powder form.**
  - **Ciclesonide is given in a dose of 80–160  $\mu\text{g}$  once a day. Others include flunisolide and mometasone.**
- **Advantages:**
  - **Rapid improvement** of the **symptoms** and **lung function** (within several days).
    - ◆ They are effective in preventing asthma symptoms exercise-induced asthma (EIA) and nocturnal exacerbations and also prevent severe exacerbations.
    - ◆ Early treatment with ICS can prevent irreversible changes in airway function that develops in chronic asthma.
  - **Reduces airway responsiveness (AHR)**
  - Reduces the number of courses of oral corticosteroid therapy (OCS).
- **Side effects:**
  - **Local:** Hoarseness (dysphonia/husky voice) and oropharyngeal candidiasis. These side effects can be minimized by the use of a spacing device along with the metered-dose inhaler, and gargling with water after use.
  - **Systemic:** Relatively free from systemic side effects at the conventional doses. Long-term use may result in osteoporosis, skin thinning and adrenal suppression.

## 2. Systemic corticosteroids

### a. Oral corticosteroids and steroid sparing agents

- **Oral corticosteroids (OCS):** Oral corticosteroids are necessary in patients controlled by inhaled corticosteroids (ICS).
- **Dose:** It should be kept as low as possible to minimize side effects. Prednisolone is started as a single morning dose of 40–60 mg oral/day. Thereafter, the dose is reduced by half every 6 hours. Methyl prednisolone is given in a dose of 40–125 mg every 6 hours.
- **Steroid sparing agents:** Some patients may require continuing treatment with oral corticosteroids. Various immunomodulatory treatments can be used to in these patients with severe asthma who have serious side effects with this therapy. Treatment of these patients with low doses of methotrexate (15 mg weekly) can reduce the dose of oral steroids needed to control the disease. Ciclosporin also improves lung function in few steroid-dependent asthmatics.

### b. Parenteral corticosteroids

- Corticosteroids are used intravenously (hydrocortisone or methylprednisolone) for the treatment of acute severe asthma.
- **Dose:**
  - ◆ Hydrocortisone: Loading dose of 4 mg/kg intravenously followed by 2–3 mg/kg every 6 hours.

- ◆ Methylprednisolone: 40–125 mg every 6 hours.

Indications for corticosteroids in bronchial asthma

- Acute asthma which does not respond to or even worsen despite bronchodilator therapy.
- Severe acute asthma (status asthmaticus).

### 3. Cromones (anti-inflammatory drugs)

- Cromones are not bronchodilator. They inhibit the degranulation of mast cells, thereby preventing release of mediators from these cells.
- Cromones are not beneficial in the long-term control of asthma due to their short duration of action.
- Only used as a prophylactic treatment of asthma. For example, **sodium cromoglycate, cromolyn, nedocromil and ketotifen**.
- **Sodium cromoglycate:** Useful in children with atopic asthma and in few cases of non-atopic asthma. Sodium cromoglycate is administered as an inhalation. Therapy is started between the attacks or in periods of relative remission. If there is no response within 4 to 6 weeks, the drug can be discontinued.
- **Nedocromil sodium:** It is given as an inhalation at a dose of 4 mg two to four times daily.
- **Ketotifen** is not a chromone. It is an antihistaminic that inhibits release of mediators. It is useful in the prophylactic treatment of asthma at a dose 1–2 mg twice daily by mouth. The main side effects are drowsiness and weight gain.

### 4. Anticholinergics

#### **Q. Write short note/essay on tiotropium/ipratropium bromide uses and side effects.**

- Anticholinergics such as atropine sulfate and atropine methyl nitrate were previously used, but they are presently not used because of their systemic side effects.
- Currently used anticholinergics are **ipratropium bromide and tiotropium**. These are non-adsorbable quaternary ammonium compounds with minimal side effects. These are administered as aerosol or in dry-powder form. Ipratropium is also given as nebulization solution.
- **Uses:** They are useful in two situations:
  1. Patients with co-existent heart disease, in whom methylxanthines and  $\beta_2$ -adrenoreceptor agonists causes significant tachycardia.
  2. In refractory cases, bronchodilator action of  $\beta_2$ -adrenoreceptor agonists is enhanced by the addition of ipratropium bromide or tiotropium.
- **Dose:**
  - *Ipratropium:* Two puffs of 20  $\mu\text{g}$  each four times/day.
  - *Tiotropium:* Two puffs of 9  $\mu\text{g}$  each once a day.
  - *Ipratropium:* 250–500  $\mu\text{g}$  nebulization; may be repeated if necessary.
- **Side effects:** Dryness of mouth and bitter taste.

### 5. Leukotriene modifiers

- These include leukotriene receptor antagonists—**LTRAs** (montelukast, zafirlukast, pranlukast) and 5-lipoxygenase inhibitors (Zileuton).
- **Uses:** Used as add on therapy.
  - In patients who do not respond to the conventional agents.
  - In patients who require high doses of inhaled steroids (ICS). They can be used as a second choice to inhaled corticosteroids in mild persistent asthma.
- **Dose**

- *Zafirlukast*: 20 mg BID
- *Montelukast*: 10 mg once a day in the evening.
- **Side effects:** Uncommon and include headache, abdominal pain, skin rashes, angioedema, pulmonary eosinophilia and arthralgia. Zileuton may cause liver damage.

### Anti-IgE—Monoclonal Antibodies

- **Omalizumab**, recombinant humanized monoclonal antibody against IgE that neutralizes/chelates free circulating IgE without binding to cell-bound IgE. It prevents the binding of circulating IgE to receptors on mast cells and basophils, and decrease release of mediators. Thus, it inhibits IgE-mediated reactions. Monoclonal antibodies (**mepolizumab and reslizumab**) against interleukin-5 (IL-5), a potent chemoattractant for eosinophils, are indicated for the treatment of severe eosinophilic asthma poorly controlled with conventional therapy.
- Useful in patients with allergic asthma.
- *Disadvantage:* Treatment is very expensive. Patients should be given a 3- to 4-month trial of therapy to show objective benefit.
- *Administration:* Given as a subcutaneous injection once every 2–4 weeks, depending on total serum IgE level and body weight.
- *Side effects:* No significant side effects, very rarely can produce anaphylaxis.
- **Anti-TNF therapy** (infliximab or etanercept): May be beneficial in severe corticosteroid refractory asthma.

### Miscellaneous

Proton pump inhibitor (PPI) may be used in patients with symptomatic gastroesophageal reflux disease and suboptimally controlled asthma.

### Bronchial Thermoplasty

- Invasive procedure for severe asthma. In this therapy, controlled thermal energy is delivered to the airway wall during a series of bronchoscopies. It results in a prolonged reduction in airway smooth muscle mass. But patient still needs to use their asthma-maintenance medications after the procedure.
- **Risks:** Lung collapse, bleeding and additional breathing problems, mostly related to the bronchoscope.
- **Benefits:** Patient may use rescue inhalers less often and are able to engage strenuous physical activity than before.

### General Measures in Asthmatics

- *Avoid:*
  - Opiates, sedatives and tranquilizers in acutely-ill patients with asthma.
  - $\beta$ -blockers and parasympathetic agonists in asthmatics.
- Expectorants and mucolytic agents have no significant role in the management of bronchial asthma.

### Prevention/treatment of exercise-induced asthma

- Prevention of episode by the inhalation of 2 metered doses of salbutamol or terbutaline a few minutes before exercise. However, regular use may lead to loss of their effect.
- Regular use of sodium cromoglycate or leukotriene modifiers is often needed. Additional use of inhaled  $\beta_2$ - adrenoreceptor agonists may be necessary before exercise.

### Assessment of asthma control (Table 6.20)

- Features which suggest that asthma is under control are listed in Box 6.4.

- Complications of asthma is mentioned in Box 6.5.

**Box 6.4:** Features of controlled asthma.

- Daytime symptoms develop two times or less/week
- No limitation of daily activities including exercise
- No awakening in the night due to symptoms
- Need for short-acting  $\beta$ -agonists twice or less/week
- No exacerbations

**Box 6.5:** Complications of asthma.

- Pneumonia
- Collapse of part or all of the lung
- Respiratory failure
- Status asthmaticus

**Global Initiative for Asthma (GINA) Severity Grades (refer Table 6.22)**

- *Severe asthma:*
  - It is an asthma which requires treatment with high dose inhaled corticosteroids and long-acting  $\beta_2$ -agonist and/or leukotriene receptor antagonists for the previous year or systemic corticosteroids for >50% of the previous year to prevent from becoming uncontrolled asthma or
  - Asthma which remains uncontrolled despite this therapy.

**Table 6.20:** Assessment of asthma control.

<b>Characteristics</b>	<b>Controlled asthma</b>	<b>Partly controlled asthma</b>	<b>Uncontrolled asthma</b>
Daytime symptoms more than twice/week	No	Any 1 or 2 characteristics present	Any 3 or more characteristics partly controlled asthma
Limitation of activities due to asthma	No		
Nocturnal symptoms/awakening due to asthma	No		
Need for reliever/rescue medicine more than	No		

twice/week

*Stepwise Management of Chronic Asthma (Table 6.21 and Fig. 6.7)*

**Q.** Write short essay/note on step care management of bronchial asthma.

All asthmatics should be educated regarding self-monitoring and correct use of inhalers.

**Table 6.21:** Stepwise management of asthma.

<b>Step</b>	<b>Management</b>
Step 1: (only for intermittent/less frequent symptoms)	Short-acting inhaled $\beta_2$ -agonist as required (required in all steps)
Step 2: Daily symptoms	<b>Regular inhaled preventer therapy</b> <ul style="list-style-type: none"><li>• Low-dose inhaled corticosteroids up to 800 <math>\mu\text{g}</math> daily OR</li><li>• Leukotriene receptor antagonists (LTRA), (if patient develops side effects to inhaled corticosteroids), SLIT (Sublingual immunotherapy)</li></ul>
Step 3: Severe symptoms	<b>Inhaled corticosteroids and long-acting inhaled <math>\beta_2</math>-agonist</b> <ul style="list-style-type: none"><li>• Continue low-dose inhaled corticosteroids plus long-acting <math>\beta_2</math>-agonist OR</li><li>• Medium or high dose inhaled corticosteroids OR</li><li>• Low-dose inhaled corticosteroids plus leukotriene receptor antagonists (LTRA), OR</li><li>• Low-dose inhaled corticosteroids plus sustained-release oral theophylline</li></ul>

Step 4: Severe symptoms uncontrolled with high dose inhaled corticosteroids

**High dose inhaled corticosteroid and regular bronchodilators**

- Medium or high dose inhaled corticosteroids (up to 2000 µg daily) plus long-acting β<sub>2</sub>-agonist
- May add leukotriene receptor antagonists (LTRA)
- May add sustained-release theophylline

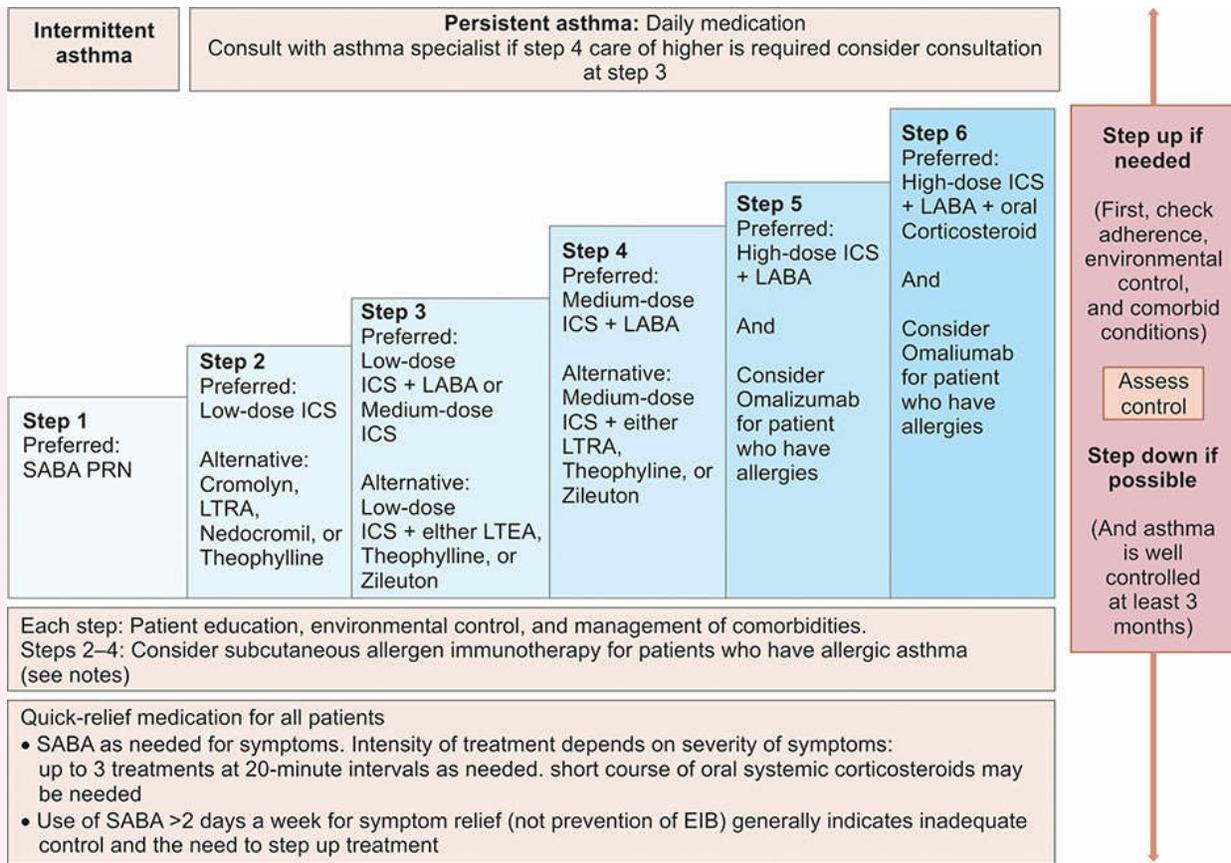

Step 5: Severe symptoms deteriorating

**Regular oral corticosteroids**

- Add oral corticosteroids (prednisolone 40 mg daily)
- Consider anti-IgE treatment (omalizumab)
- Anti-IL5: reslizumab (IV) added to mepolizumab (SC) for ≥18 years

Step 6: Severe symptoms deteriorating in spite of prednisolone

Hospital admission

**Fig. 6.7:** Stepwise management of asthma in adults.

(LABA: long-acting inhaled b2-agonist; LTRA: leukotriene receptor antagonists; SR: sustained-release)

- Once the patient is on treatment for several months, asthma severity can be assessed by using stepwise criteria.
  - *Mild asthma*: Well controlled with step 1 and 2.
  - *Moderate asthma*: Controlled with step 3 treatment
  - *Severe asthma*: Needs step 4 or 5 treatment to prevent it to progress to uncontrolled asthma.

### Step-down Therapy

Once asthma is controlled, the dose of inhaled (or oral) corticosteroid should be reduced to the lowest dose at which effective control of asthma is maintained.

### The Control-based Asthma Management Cycle GINA 2017 (Fig. 6.8)

#### Treatment of Severe Acute Asthma (Status Asthmaticus)

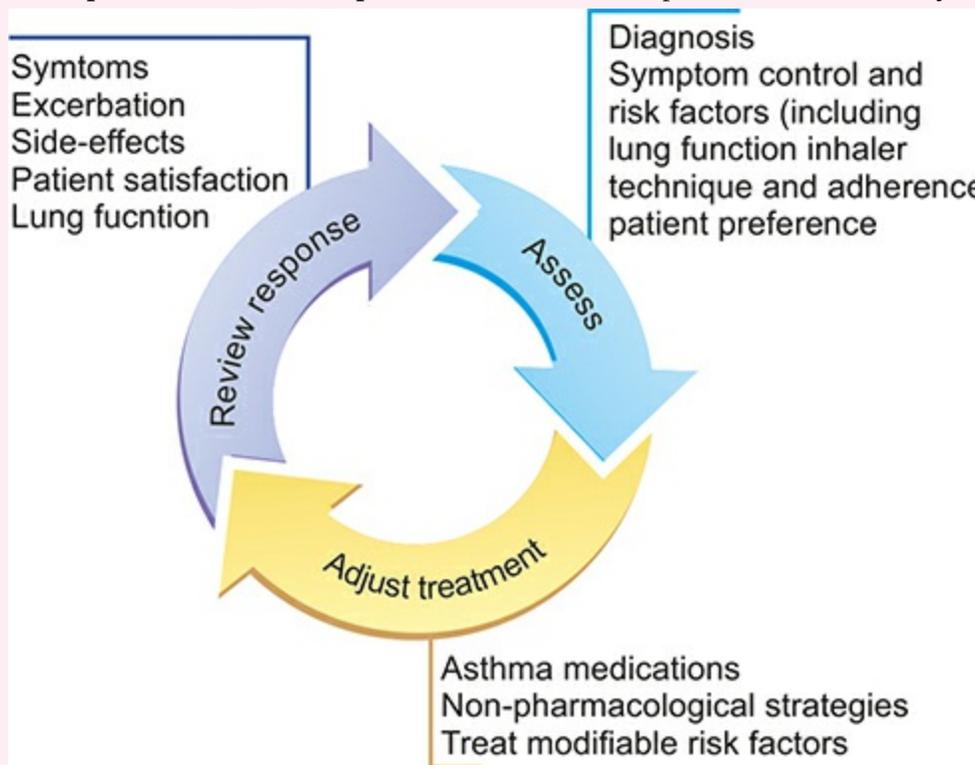

**Q. Write short essay/note on management of status asthmaticus.**

Acute severe asthma is the term used for an exacerbation of asthma that has not been controlled by the use of standard medication.

#### Treatment at Home

- **Give high concentrations of oxygen** (40–60%) through a mask if available.
- **Bronchodilator therapy:** Any one of the following should be given.
  - Nebulized **salbutamol** 5 mg or **terbutaline** 10 mg every 20 minutes for 3 doses.

- Salbutamol/terbutaline through metered-dose inhalers (four to eight puffs with a spacer every 20 minutes for 3 doses), followed by 4–8 puffs every 2–4 hours.
- **Corticosteroids**
  - Give IV hydrocortisone sodium succinate 200 mg.
  - Give oral prednisolone 60 mg.
- **Admit to hospital if there is no response** within 1 hour or if patient becomes drowsy.

**Fig. 6.8:** The control-based asthma management cycle GINA 2017.

**Management in Hospital**

**Initial assessment:** Take brief history, perform rapid examination of the patient and assess the severity (Table 6.22).

Administer high concentration of oxygen (40–60%).

**Table 6.22:** Assessment of severity of asthma.

	<i>Mild</i>	<i>Moderate</i>	<i>Severe</i>	<i>Respiratory arrest imminent</i>
Breathless	Walking Lying down possible	Taking Sitting preferred	At rest Hunched forward	
Talking in	Sentences	Phrases	Words	

Alertness	Possibly agitated	Usually agitated	Usually agitated	Drowsy or confused
Respiratory rate	Increased	Increased	Often >30/min	
Accessory muscles/suprasternal retractions	Usually not	Usually	Usually	Paradoxical thoracoabdominal movement
Wheeze	Moderate	Loud	Usually loud	Absent
Pulse/min	<100	100–120	>120	Bradycardia
Pulsus paradoxus	Absent	May be present	Often present	Possibly absent due to muscle fatigue
PEF after bronchodilator	>80%	Approx. 60–80%	<60%	

Adapted from: O’Byrne P. GINA. Executive Committee.

Global strategy for asthma management and prevention. 2004. National Institutes of Health. Publication No. 02-3659.

### Management Algorithm of Acute Asthma (Flowchart 6.1)

#### Exacerbations of Asthma

#### **Q. Write short essay on management of acute severe asthma.**

- *Precipitating factors of exacerbations:* Viral infections (most common), others include moulds, pollens and air pollution.

#### **Treatment of Mild-to-Moderate Exacerbation**

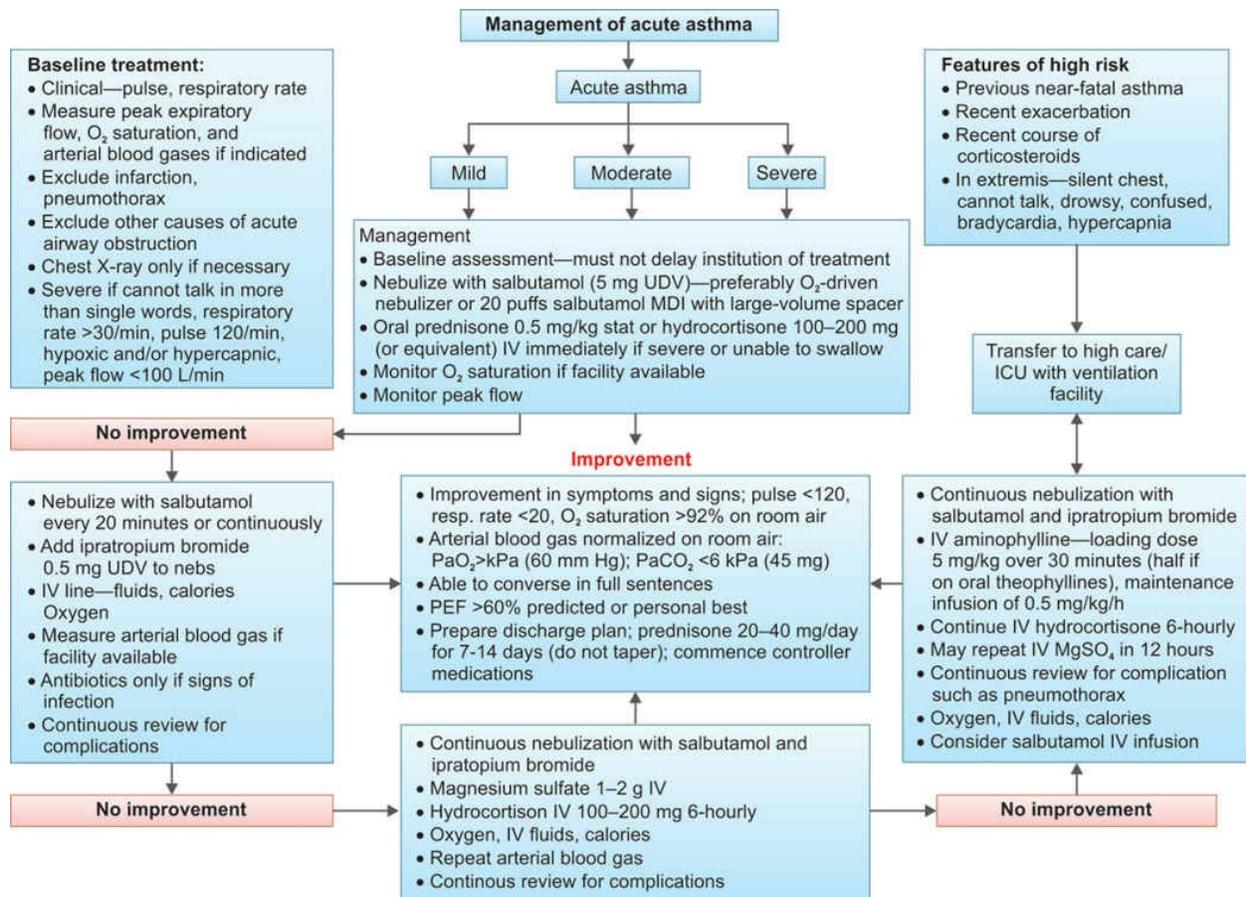

- $\beta_2$ -agonists (via inhaler or nebulizer) every 20 minutes for 3 doses (as mentioned above).
- Oral corticosteroids if there is no immediate response.
- Patient is reassessed every hour.

#### **Treatment of Severe Exacerbation**

- Give **high concentration of oxygen** (40–60%).
- **Bronchodilators**
  - Administer **nebulized (in oxygen) salbutamol** (5 mg) or terbutaline (10 mg) or levosalbutamol (1.25–2.5 mg) immediately and may be repeated after a few minutes if there is no response.
  - $\beta_2$ -agonist (**subcutaneously or intravenously**) are indicated in patients with excessive cough, too weak to inspire adequately or moribund.
  - **Terbutaline** is administered subcutaneously (0.25–0.5 mg) or intravenously (0.1–10  $\mu\text{g}/\text{kg}/\text{minute}$ ).
  - **Epinephrine (adrenaline)** may be administered in children and young adults. Adult dose is 0.2–0.5 mg as 1:1000 solution subcutaneously every 20 minutes

- **Add nebulized ipratropium bromide** 0.5 mg to nebulized salbutamol 5 mg/terbutaline 10 mg to those patients who do not respond within 15–30 minutes. It can be repeated every 20 minutes for 3 doses.
- **Aminophylline** can be given intravenously to those patients who do not respond to nebulized bronchodilators. Give a loading dose of 5 mg/kg/hour as an infusion.
- **Corticosteroids**
  - In severely ill patients, **hydrocortisone sodium succinate 100 mg** is administered intravenously at presentation and then repeated 4–6 hourly for 24 hours.
- **Antibiotics** are indicated only if there is respiratory infection.
- Role of magnesium sulfate either intravenously or by nebulization is not clear.
- **If no improvement** with above measures, perform **endotracheal intubation** and **mechanical ventilation**.
  - **Indications for intubation:** Cardiac or respiratory arrest, severe hypoxia ( $\text{PaO}_2 < 60$  mm Hg), hypercapnia ( $\text{PaCO}_2 > 50$  mm Hg), acidosis ( $\text{pH} < 7.3$ ), exhaustion or deterioration in mental status.
- **NIV (non-invasive ventilation)** using continuous positive pressure of BiPAP machines and tight fitting face mask reduces the work of breathing without intubation. It is useful in assisting breathing. It is used in a cooperative and alert patient who has impending respiratory failure but does not require immediate intubation.
- Treatment with 70–80% helium with oxygen may be useful, since it reduces airway resistance and improves efficacy of bronchodilators.
- Assessment of response to treatment is done by noting the patient distress, respiratory rate,  $\text{FEV}_1$ , heart rate, presence of pulsus paradoxus and serial arterial blood gas (ABG) studies.
- More severe cases should remain in hospital for 2–5 days with regular monitoring of oxygen saturation and peak flow rates. Bronchial thermoplasty may be beneficial for moderate to severe persistent asthma. This reduces the mass of airway smooth muscle, reducing bronchoconstriction.

**Flowchart 6.1:** Management algorithm of acute asthma.

(UDV: unit dose vial).

## Occupational Asthma

**Q. Write a short note on occupational asthma.**

Occupational asthma is relatively common.

### *Etiology*

- It is a type of asthma caused by specific occupational sensitizer (proteins or glycopeptide). Often associated with allergic rhinitis/conjunctivitis.
- Once the individual is sensitized, subsequent low exposure is capable of producing specific IgE antibodies and can induce asthma.
- Latency period between first exposure to sensitizer and onset of work-related symptoms can range from weeks to years.
- Triggering occupational agents include: Fumes (epoxy resins, plastics), organic and chemical dusts (wood, cotton, platinum), gases (toluene diisocyanate), animal allergens, plants and plant products (flours and

cereals) and other chemicals (formaldehyde, penicillin products). **Work-exacerbated asthma** is defined as preexisting or concurrent asthma that subjectively worsens in the workplace.

#### Management

- Primary prevention (e.g. avoiding sensitizer agent).
- Secondary prevention (e.g. medical surveillance program).
- Tertiary prevention (e.g. appropriate treatment), i.e. treatment as per asthma severity.

## Hypersensitivity Pneumonitis (Extrinsic Allergic Alveolitis)

**Q. Discuss the clinical features, diagnosis and management of hypersensitivity pneumonitis (extrinsic allergic alveolitis).**

**Q. Write short note on farmer's lung.**

### *Definition*

Hypersensitivity pneumonitis (HP) or extrinsic allergic alveolitis is an immune-mediated lung disease that occur secondary to inhalational exposure to a variety of antigens leading to a widespread diffuse inflammatory reaction in the alveoli and small airways (bronchioles).

### *Pathogenesis*

It is an immune-mediated condition that develops in response to inhaled antigens that are small enough to deposit in distal airways and alveoli. It involves  $T_H1$  and  $T_H17$  lymphocyte subsets. Examples of hypersensitivity pneumonitis are presented in Table 6.23.

### *Clinical Features*

Depend on type, intensity and duration of exposure to offending antigen. Most of the present following months or years of continuous or intermittent inhalation of offending agent.

**Clinical forms:** It can present as acute, subacute or chronic form. Most patients (80–95%) are non-smokers.

#### 1. Acute form

- *Onset:* Usually manifests 4–8 hour following exposure to the causative antigen and is often intense in nature.

- *Symptoms:* Fevers, chills, cough and malaise accompanied by dyspnea.
  - *Resolution:* Symptoms resolve within hours to days, if there is no further exposure to the causative antigen.
2. **Subacute form:** Onset of respiratory (cough, dyspnea and cyanosis) and systemic symptoms is more gradual lasting for weeks or months.
  3. **Chronic form:**
    - Present with an even more gradual onset of symptoms than subacute form with progressive dyspnea, cough, fatigue, weight loss, and clubbing of the fingers.
    - It usually occurs in patients with continuous low-dose exposure to the causative antigen.
    - Clinically cannot be distinguished from pulmonary fibrosis due to other causes.

**Complications:** Long-standing disease leads to diffuse pulmonary interstitial fibrosis, pulmonary hypertension resulting in cor pulmonale.

**Table 6.23:** Examples of hypersensitivity pneumonitis.

<i>Disease</i>	<i>Sources of antigen</i>	<i>Antigen</i>
<b>Farming/Food processing</b>		
Farmer's lung	Grain, moldy hay	Thermophilic actinomycetes, fungus
Bagassosis	Sugarcane	Thermophilic actinomycetes
Mushroom worker's lung	Mushroom	Thermophilic actinomycetes; mushroom spores
Coffee worker's lung	Coffee beans	Coffee bean dust
Malt worker's lung	Mouldy barley	Aspergillus species (clavatus)
Miller's lung	Infested wheat flour	Sitophilus granarius (wheat weevil)
Tobacco grower's lung	Tobacco	Aspergillus species
<b>Birds and other animals</b>		
Bird fancier's lung	Avian droppings (most often from pigeons and parakeets)	Protein in avian excreta, feathers
<b>Other occupational and environmental exposures</b>		
Humidifier fever and air-conditioner lung	Humidifiers and air conditioners (contaminated water)	<i>Bacillus subtilis</i> , <i>Aureobasidium pulluans</i> ; <i>Candida albicans</i> , amoeba, thermophilic actinomycetes)
Woodworker's lung	Wood dust	<i>Alternaria</i> species

## ***Investigations***

- **Chest X-ray:** Findings are nonspecific. It may show diffuse micronodular shadowing with the subsequent development of streaky shadows, particularly in the upper zones. Very advanced cases produce honeycomb lung.
- **High resolution computed tomography (HRCT):** Shows reticular and nodular changes with ground-glass opacity.
- **Blood:** Raised ESR and neutrophilia (especially in acute form). Eosinophil counts and IgE levels are usually normal.
- **Lung function tests:** Show a restrictive ventilatory defect with normal FEV<sub>1</sub>: FVC ratio. Diffusion capacity for carbon monoxide may be significantly impaired in chronic cases.
- **Precipitating antibodies:** In the serum against offending agent indicates the evidence of exposure, but not disease.
- **Bronchoscopy with bronchoalveolar lavage (BAL):** Although not a specific, BAL shows increased T-lymphocytes and granulocytes. Most often, CD4:CD8 ratio <1 (normal is about 0.9–2.5). In sarcoidosis, it is usually above 3.5.
- **Lung biopsy:** May show chronic inflammatory cells, ill-defined non-caseating granulomas and fibrosis in late stages.
- **Provocation test:** If about 4–10 hours after exposure to the inhaled antigen, there is respiratory or systemic findings (e.g. fever, leukocytosis); reduced diffusing capacity, diminished VC (vital capacity), or both; increased radiographic abnormalities; worsening alveolar-arterial oxygen pressure suggests a positive response.

### **Treatment**

- **Prevention:** It should be the aim and can be achieved by identification and avoidance of the offending antigen.
- **Corticosteroids:** Because acute form is usually a self-limited disease treatment is not necessary. However, corticosteroid has some role in subacute and chronic forms. Prednisolone in large doses (1 mg/kg/day) orally for 1–2 weeks, followed by gradual tapering over the next 4–6 weeks. It may achieve regression during the early stages but not those with established fibrosis.
- **Oxygen therapy** in severely hypoxemic individuals. Symptomatic bronchodilator therapy.

## **Drug-induced Asthma**

### ***Drugs Implicated***

- Most common due to **aspirin (aspirin-induced asthma, AIA) followed by ibuprofen, indomethacin, naproxen, phenylbutazone, mefenamic acid**. About 10% of asthma patients are aspirin-sensitive
- **Drugs that can cause bronchospasm:** Adenosine, prostaglandin analogues, BBs (beta-blockers), cholinergic drugs, streptomycin, pentazocine, penicillin.
- **Non-pharmaceutical agents:** Tartrazine (coloring agent), sulfating agents (preservatives in food/medicines)

**Mechanism:** Decreased production of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) and enhanced production of leukotriene B<sub>4</sub> (LTB<sub>4</sub>).

**Associations:** Nasal polyps, vasomotor rhinitis, hyperplastic rhinosinusitis (**Samter's triad**).

**Aspirin-induced Asthma (AIA):** Two distinct forms:

- **Cutaneous form:** Associated with urticaria and angioedema
- **Respiratory form:** Resulting in rhinoconjunctivitis and bronchospasm.

**Diagnosis:** Bronchial Challenge with aspirin.

**Drug treatment of AIA:** Treat the underlying asthma and the strict avoidance of aspirin and cross-reacting NSAIDs. Acetaminophen and selective COX2 inhibitors are safe.

## CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD)

**Q. Write short essay/note on COPD (chronic obstructive pulmonary disease), COLD (chronic obstructive lung disease) or COAD (chronic obstructive airway disease).**

### Introduction

COPD is also known as chronic obstructive lung disease (COLD), chronic obstructive airway disease (COAD), chronic airflow limitation (CAL) and chronic obstructive respiratory disease (CORD).

### Definition

- COPD is a **preventable and treatable pulmonary disease** associated **with** some **significant extrapulmonary effects** that may contribute to the severity in individual patients.

- Pulmonary disease is characterized by **airflow limitation** which is **not fully reversible**.
- The airflow limitation is usually progressive and associated with an abnormal inflammatory response of the lung to various noxious particles or gases.

**Conditions included under COPD:** Disease is considered COPD, only if chronic airflow obstruction occurs.

- **Emphysema:** An anatomically defined condition characterized by abnormal and permanent enlargement of the airspaces distal to the terminal bronchioles. It is accompanied by destruction of the airspace walls, without obvious fibrosis (i.e. there is no fibrosis visible to the naked eye).
- **Chronic bronchitis:** It is defined as a chronic productive cough for three months in each of two successive years in a patient in whom other causes of chronic cough (e.g. bronchiectasis) have been excluded.
- **Small airways disease:** A condition in which small bronchioles are narrowed.

### *Pathogenesis*

- **Major physiologic change** in the COPD is **airflow limitation**. It can develop due to both small airway obstruction and emphysema. The small airways may become narrowed by cells (hyperplasia and accumulation), mucus, and fibrosis.
- Activation of transforming growth factor- $\beta$  (TGF- $\beta$ ) contributes to airway fibrosis, whereas absence of TGF- $\beta$  may produce parenchymal inflammation and emphysema. The mechanism involved in emphysema is better understood than small airway obstruction.

### **Chronic Bronchitis**

**Q. Define chronic bronchitis. Describe the etiology, pathology, clinical features, investigations, course, prognosis, treatment and complications of chronic bronchitis.**

**Q. Discuss the etiology, pathology, clinical features, investigations, course, prognosis, treatment and complications of chronic obstructive pulmonary disease.**

### *Incidence*

- **Age and gender:** Occurs during **middle and late adult life**. It is more

common in **males than in females**.

- More common **in smokers than in non-smokers**. Also more often develops in urban than in rural dwellers.

**Types of Chronic Bronchitis:** (1) Simple chronic bronchitis; (2) chronic mucopurulent bronchitis; (3) chronic asthmatic bronchitis; and (4) chronic obstructive bronchitis.

**Table 6.24: Risk factor for COPD.**

#### **Environmental**

- Tobacco smoke
- Indoor air pollution. Cooking with biomass fuels
- Toxic industrial inhalants: Occupational dust exposure (e.g. coal dust, silica and cadmium)
- Respiratory infections: Recurrent infection; HIV infection (associated with emphysema), previous tuberculosis
- Low birth weight and bronchopulmonary dysplasia
- Lung growth: Childhood infections or maternal smoking may affect growth of lung during childhood
- Low socioeconomic status, antioxidant deficiency
- Cannabis smoking

#### **Host factors**

- Genetic factors:  $\alpha$ 1-antitrypsin deficiency, TGF Beta 1 polymorphism, Serpin 2 gene expression.
- Airway hyper-reactivity

## ***Etiology***

*Risk Factors (Table 6.24)*

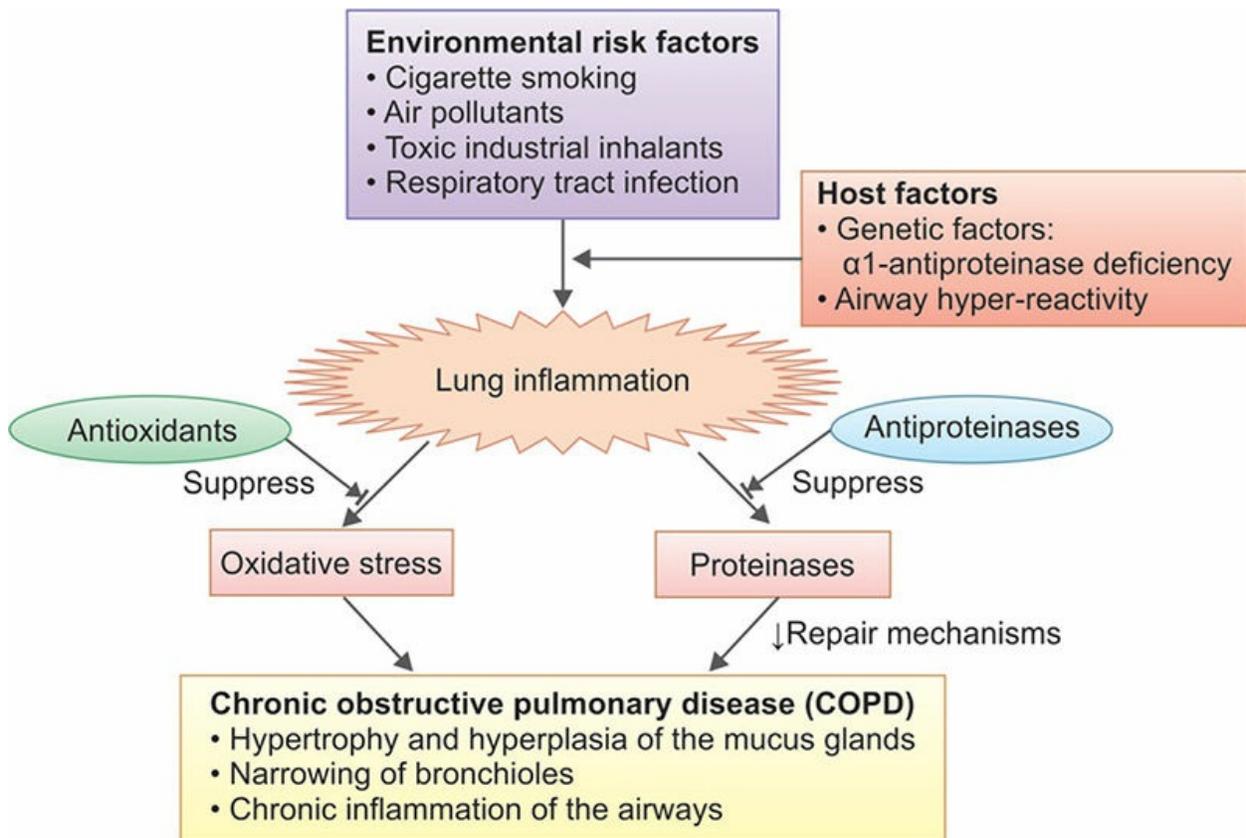

**Q. Write short note on risk factors of chronic obstructive pulmonary disease.**

### *Smoking and COPD*

- **Cigarette smoking:** It is the most important risk factor for the development of COPD. The risk of developing COPD relates to both the amount and the duration of smoking. However, only about 15–20% of smokers develop clinically significant COPD. This suggests that genetic predisposition and environmental factors play a role in the pathogenesis.
- **Second-hand smoke:** Environmental tobacco smoke that is inhaled involuntarily or passively by someone who is not smoking.
- **Environmental tobacco smoke** is generated from the **side stream** (the burning end) of a cigarette, pipe or cigar or from the exhaled **mainstream** (the smoke puffed out by smokers) of cigarettes, pipes, and cigars.

- **Abnormalities due to smoking:** Cigarette smoking is associated with a variety of abnormalities of the respiratory system that predispose to the development of chronic bronchitis. These include:
  - Sluggishness of movement of cilia.
  - Bronchoconstriction brought through constriction of smooth muscle
  - Hypertrophy and hyperplasia of mucus secreting glands. **The ratio of the thickness of the mucous gland layer to the thickness of the bronchial wall** between the base of the surface epithelium and the inner limit of the cartilage plates is called **Reid index**. It is useful for detecting the increase in the size and number of the mucus glands. Reid index (normally  $0.44 \pm 0.094$ ) is increased in chronic bronchitis ( $>0.51$ ). There is a direct correlation between the value of Reid Index and the volume of daily sputum production by the patient.
  - Release of proteolytic enzymes from polymorphonuclear leucocytes and release of inflammatory mediators in lungs.
  - Inhibits the function of alveolar macrophages.
  - Adverse effect on surfactant and favors overdistension of the lungs.

**Flowchart 6.2:** Pathogenesis of chronic obstructive pulmonary disease.

### ***Pathogenesis (Flowchart 6.2)***

Major physiologic change in COPD is airflow limitation. It can result from both small airway obstruction and emphysema.

- Irritants cause inflammation → infiltration by CD8 + T-lymphocytes,

macrophages and neutrophils.

- **Hypersecretion of mucus**

- **Hyperplasia/hypertrophy of the submucosal glands in large airways (trachea and bronchi):** Develops as response to inhaled **environmental irritants** and **proteases released from neutrophils** (e.g. elastase and cathepsin). This leads to **hypersecretion of mucus**.
- **Marked increase of goblet cells in small airways (small bronchi and bronchioles):** They produce **excessive mucus** → mucus plugging of bronchial lumen → inflammation and fibrosis of bronchial wall → **leads to airway obstruction**.

### *Clinical Features*

**History:** Most common three symptoms in COPD are impressive history of cough, sputum production, and exertional dyspnea (breathlessness).

- **Cough:** Initially, the cough is present only in the winter seasons (often referred as ‘winter cough’ or ‘smoker’s cough’), especially in the mornings (‘morning cough’). Later, cough increases in frequency, severity and duration.
- **Sputum:** Usually **scanty, mucoid** and more in the mornings. It may be occasionally blood-stained (hemoptysis) or frankly purulent (‘mucopurulent relapse’).
- **Breathlessness:** It is **relatively insidious in onset** and is due to airflow obstruction. It is aggravated by infection; excessive smoking and adverse atmospheric conditions. Breathlessness severity can be assessed by the modified MRC dyspnea scale (Table 6.25).

**Table 6.25:** Modified Medical Research Council (mMRC) scale for dyspnea.

<b>Grade</b>	<b>Features</b>
0	No breathless except on strenuous exercise
1	Breathless when hurrying on the level or walking up a slight hill
2	Walks slower than people of same age on the level ground because of breathlessness or has to stop for breath while walking at his own pace on the level ground
3	Stops for breath after walking 100 meters or after

**Other symptoms:** Fever during mucopurulent relapses, wheezing and tightness in the chest.

### *Physical signs*

- Patient is usually overweight.
- In the early stages, patients are entirely normal on physical examination. At rest, there is no respiratory distress, respiratory rate is normal and accessory muscles of respiration are not acting.
- **Auscultation:** (i) Vesicular breath sounds with prolonged expiration; (ii) inspiratory and expiratory rhonchi; and (iii) crepitations that either disappear or change in location and intensity after coughing; (iv) forced expiratory time >4 sec.

**Associated comorbidities in COPD** (Table 6.26): Although COPD affects the lungs, it is associated with comorbidities probably a part of a generalized systemic inflammatory process.

**Table 6.26:** Common comorbidities in COPD.

#### **Cardiovascular disorders**

- Pulmonary hypertension
- Right heart failure, cor pulmonale
- *Vascular disease:* Coronary artery disease, cerebrovascular disease, peripheral vascular disease
- Systemic hypertension

**Nutritional disorders:** Cachexia

#### **Musculoskeletal disorders**

- Muscle dysfunction
- Osteoporosis

**Cancer:** Lung cancer

**Other:** Sleep disorders, sexual dysfunction, diabetes, depression, anxiety, anemia, osteoporosis, peptic ulcer, glaucoma.

## **Investigations**

**Q.** Write short note on pulmonary function tests in chronic obstructive airway disease.

**Table 6.27: Pulmonary function tests findings in COPD.**

<b>Reduced FEV<sub>1</sub>, FEV<sub>1</sub>/FVC (less than 0.7), FVC, PEF</b>	<b>Increased RV, FRC, TLC</b>
<ul style="list-style-type: none"><li>• <b>Gas transfer</b> may be normal or mildly reduced</li></ul>	

- **Radiological examination**

- **Chest X-ray:** May assist in the classification of the type of COPD. There is no reliable radiographic signs that indicate the severity of airflow limitation
  - ◆ **Features of emphysema:** Presence of bullae, paucity of parenchymal markings, or hyperlucency
  - ◆ **Features of hyperinflation:** Increased lung volumes and flattening of the diaphragm.
  - ◆ **Chronic bronchitis:** No characteristic abnormality.
  - ◆ **Essential to identify complications** such as cardiac failure, other complications of smoking (e.g. lung cancer).
- **High-resolution CT scans (HRCT):** Useful in detection, characterization and quantification of emphysema.

- **Pulmonary function tests (Table 6.27):** Patients with diffuse obstructive disorders, pulmonary function tests show decreased maximal airflow rates during forced expiration, usually expressed as the forced expiratory volume at 1 second (FEV<sub>1</sub>) over the forced ventilatory capacity (FVC).
- **Arterial blood gases (ABG) study:** Demonstrate resting or exertional hypoxemia. It is an important in the evaluation of patients with symptoms of an exacerbation.
- **Measurement of lung volumes:** It assesses hyperinflation and is usually performed by using the helium dilution technique.
- **Exercise testing:** Six-minute walk test used to assess exercise tolerance, response to bronchodilator therapy, disability and effectiveness of pulmonary rehabilitation.
- **Blood:**
  - **Hemoglobin** level and **PCV** may be elevated due to persistent hypoxemia (secondary polycythemia). In patients with normal kidney function, an elevated serum bicarbonate may indirectly identify

chronic hypercapnia.

- **$\alpha_1$ -antiproteinase:** It should be assayed in younger patients with predominantly basal emphysema,
- **Electrocardiography:** Often normal. In advanced cases, it may show features of right atrial and ventricular hypertrophy (tall P waves-P-Pulmonary; right bundle branch block; RSR pattern in  $V_1$ ).
- **BODE index**
  - A multidimensional prognostic index.> Takes into account several indicators of COPD prognosis (**body mass index [BMI], obstructive ventilatory defect severity, dyspnea severity, and exercise capacity**).
  - The components are derived from measures of the body mass index (weight in kg/height  $m^+$ ), FEV<sub>1</sub> percent predicted, the modified Medical Research Council dyspnea and 6 minute walk test.
  - A BODE score greater than 7 is associated with a 30% 2-year mortality;
  - A score of 5 to 6 is associated with 15% 2-year mortality.
  - If score is less than 5, the 2-year mortality is less than 10%.

## Complications of COPD

### Q. Write short note on complications of chronic bronchitis/emphysema.

- **Mucopurulent relapses:** It may develop due to secondary bacterial infection by *Strep. pneumoniae*, *H. influenzae* or *M. catarrhalis*. Presents with fever and increased production of purulent sputum.
- **Carbon dioxide narcosis:** Persistent retention of  $CO_2$  (hypercarbia: high  $PaCO_2$ ) manifests as clouding of consciousness, altered behavior, drowsiness, headache and papilledema.
- **Respiratory failure:**
  - *Type 1 respiratory failure (low  $PaO_2$  normal  $PaCO_2$ ):* In mild-to-moderate COPD.
  - *Type II respiratory failure:* Acute or chronic in severe COPD.
- **Secondary polycythemia:** Due to hypoxemia which stimulates erythropoiesis.
- **Pulmonary hypertension and right ventricular failure (cor pulmonale)**
- **Pneumonia**
- **Tuberculosis**

- **Lung cancer**
- **Pneumothorax (emphysema)**
- **Deep vein thrombosis**
- **Pulmonary embolism**

## ***Pathogenesis of Complications (Flowchart 6.3)***

### **Management**

#### ***General measures***

- Regular exercises and management of nutritional status.
- Weight loss, if the patient is obese.

#### ***Reducing exposure to noxious particles and gases that cause bronchial irritation***

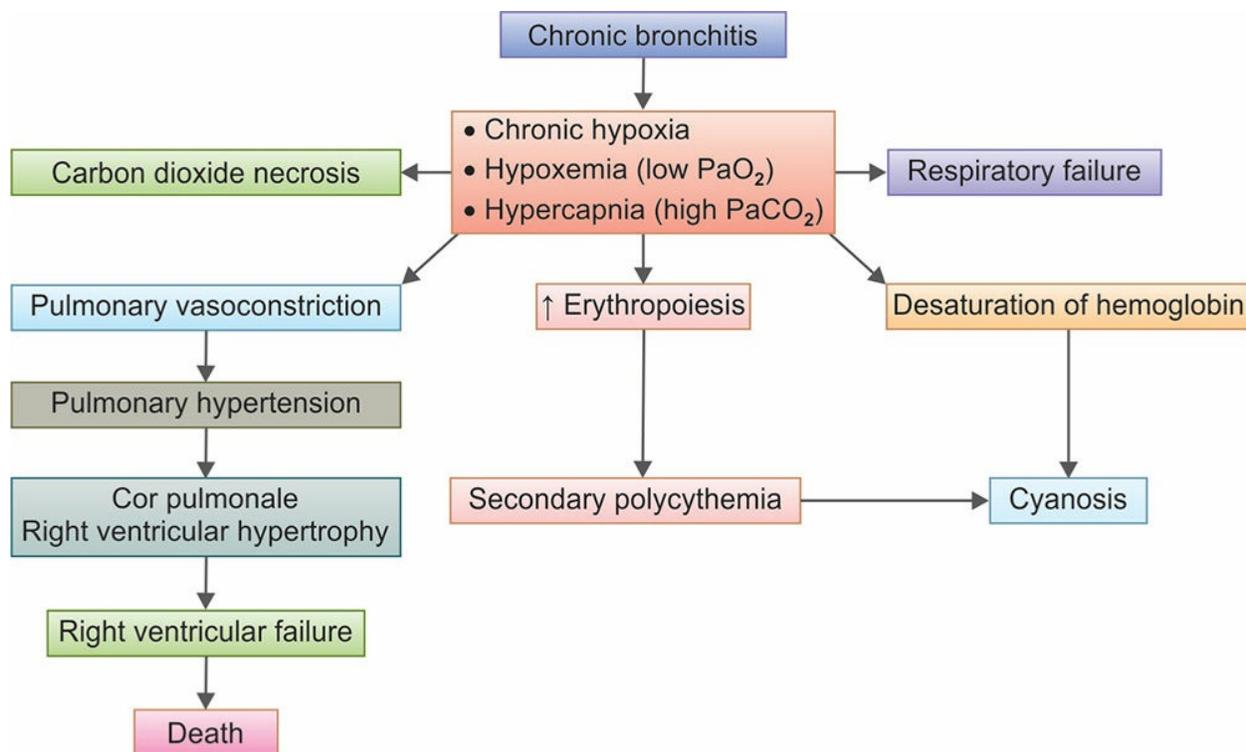

- **Smoking cessation:** Stop smoking completely and this may be aided by bupropion (a noradrenergic antidepressant) nicotine replacement therapy (by gum, transdermal patch lozenge inhaler or nasal spray) or varenicline [partial agonist of the nicotinic acetylcholine receptor (nAChR) subtype alpha4beta2].
- **Reduce smoke:** Reducing the risk from indoor and outdoor air pollution. Reduce exposure to smoke from biomass fuel, particularly among women and children.
- **Avoid:** Dusty and smoke-laden atmospheres.

#### ***Drug therapy (Table 6.28)***

Used both for the short-term management of exacerbations and for the long-term relief of symptoms. However, none of the medications for COPD reduce the rate of decline of lung functions.

- **Bronchodilators:** They are central to the management of breathlessness.
  - **$\beta_2$ -Adrenergic agonists:** The inhaled route is preferred.
    - ◆ *Mild disease:* Short-acting agents namely salbutamol 200  $\mu\text{g}$  or terbutaline 500  $\mu\text{g}$  6 hourly.
    - ◆ *Moderate-to-severe disease:* Long-acting agents such as salmeterol 50  $\mu\text{g}$  twice daily or formoterol (12  $\mu\text{g}$  powder inhaled twice daily) or indacaterol (150–300  $\mu\text{g}$  daily) achieve bronchodilation and also reduce the incidence of infective exacerbations. LABAs include salmeterol, formoterol, arformoterol, indacaterol, vilanterol, and olodaterol; all are beta-2 selective.
  - **Antimuscarinic (anticholinergic) drugs:** More prolonged and greater bronchodilatation is achieved by adding ipratropium bromide (40–80  $\mu\text{g}$  6 hourly) or tiotropium bromide (18  $\mu\text{g}$  once a day) or oxitropium (200  $\mu\text{g}$  twice daily) in severe disease.
  - Oral long-acting theophylline or doxophylline may be beneficial in selected cases. Umeclidinium, aclidinium, glycopyrronium are newer long acting anticholinergic drugs available.
- **Phosphodiesterase type 4 inhibitors:** Roflumilast is an inhibitor with anti-inflammatory properties. It may be used as an adjunct to bronchodilators. Weight loss is a significant side effect.

**Flowchart 6.3:** Pathogenesis of complications of chronic bronchitis

**Table 6.28: Drug therapy in chronic bronchitis.**

<ul style="list-style-type: none"> <li>• <b>Beta<sub>2</sub>-agonists</b> <ul style="list-style-type: none"> <li>– Short-acting beta<sub>2</sub>-agonists (SABA)</li> <li>– Long-acting beta<sub>2</sub>-agonists (LABA)</li> </ul> </li> <li>• <b>Anticholinergics/muscarinic antagonists</b> <ul style="list-style-type: none"> <li>– Short-acting anticholinergics (SAMA)</li> <li>– Long-acting anticholinergics (LAMA)</li> </ul> </li> <li>• <b>Combination short-acting beta<sub>2</sub>-agonists + anticholinergic in one inhaler</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>Methylxanthines</b></li> <li>• <b>Inhaled corticosteroids (ICS)</b></li> <li>• <b>Combination long-acting beta<sub>2</sub>-agonists + corticosteroids in one inhaler</b></li> <li>• <b>Systemic corticosteroids</b></li> <li>• <b>Phosphodiesterase-4 inhibitors</b></li> <li>• <b>Acebrophylline:</b> An airway mucoregulator and anti-inflammatory agent.</li> </ul>
--	--

- **Corticosteroids**

- Inhaled corticosteroids (ICS) reduce the frequency and severity of exacerbations, and are used in moderately severe COPD. These include beclomethasone, budesonide, fluticasone, ciclesonide, flunisolide, beclometasone
- Oral corticosteroids are useful during exacerbations and should be avoided as a maintenance therapy because it may lead to osteoporosis and impaired skeletal muscle function.

*Respiratory infections*

- **Treatment of infection:** Bacterial infection precipitates exacerbations. Azithromycin (has both

anti-inflammatory and antimicrobial properties) administered daily to subjects with a history of exacerbation in the past 6 months may reduce the exacerbation. If patient develops purulent (yellow or green) sputum oral tetracycline or ampicillin 250 mg 6 hourly or cotrimoxazole 960 mg 12 hourly for 10 days should be given. If there is no response, sputum culture and sensitivity is done and the antibiotic is changed accordingly.

- **Prevention of infection:** Patients with COPD should receive **vaccination with polyvalent pneumococcal and influenza vaccines.**

#### *Symptomatic measures*

- **Antimucolytic agents:** They reduce viscosity of sputum and can reduce the number of acute exacerbations and total number of days of disability. Mucolytic agents include bromhexine, N-acetylcysteine carbocysteine, ambroxol and erdosteine can be tried.
- **Antitussives:** Regular use of antitussives to control cough in stable COPD is not recommended.
- Chest physiotherapy.

#### *Pulmonary rehabilitation*

- It is an individually designed treatment program consisting of education and cardiovascular conditioning (reverse muscular and cardiovascular dysfunction).
- Program includes breathing technique, chest physiotherapy, postural drainage, activities of daily living (work simplification, energy conservation) and exercise conditioning (upper and lower extremity).

#### *Oxygen therapy*

**Q. Write short note on oxygen therapy in chronic obstructive pulmonary disease (COPD).**

#### **Long-term domiciliary oxygen therapy (LTOT)**

- **Aim of therapy:** To increase the  $PaO_2$  to at least 8 kPa (60 mm Hg) or  $SaO_2$  to at least 90%. It is administered through nasal cannulae for at least 15 hours per day at a low-dose (2 L/minute)
  - **Indications:** in COPD patient with exertional hypoxemia or nocturnal hypoxemia
  - Daytime  $PaO_2 \leq 55$  mm Hg at rest or oxygen saturation  $< 88\%$  with or without hypercapnia during a period of clinical stability OR
  - Daytime  $PaO_2$  between 56 and 59 mm Hg or oxygen saturation  $> 88\%$  in the presence of secondary polycythemia, nocturnal hypoxemia, peripheral edema or evidence of pulmonary hypertension
  - **Benefits:** LTOT has significant benefits and reduces mortality rates in selected patients. It decreases pulmonary hypertension and prolongs life in hypoxemic COPD patients with right heart failure. It also reduces polycythemia, pulmonary artery pressures, dyspnea, and hypoxemia during sleep and reduced nocturnal arrhythmias.
- **Treatment of pulmonary hypertension:** by long-term oxygen therapy, sildenafil, bosentan synthetic prostacyclin (epoprostenol).

Pharmacologic therapy in COPD depending on severity is presented in Figure 6.9.

#### *Surgical treatments*

**Lung volume reduction surgery (LVRS)** is more efficacious than medical therapy among patients with upper-lobe predominant emphysema and low exercise capacity.

In appropriately selected patients with very severe COPD, **lung transplantation** has been shown to improve quality of life and functional capacity.

Exacerbations in the prior year	Symptoms	
	Fewer	More*
Fewer <2 outpatient	<b>Group A</b> Bronchodilator [usually a short-acting beta agonist (SABA) or short-acting antimuscarinic antagonist (SAMA)]	<b>Group B</b> Long-acting beta agonist (LABA) or Long-acting antimuscarinic antagonist (LAMA)
	<b>Group C</b> LAMA ↓ LAMA + LABA	<b>Group D</b> LABA + LAMA ↓ LABA + LAMA + inhaled corticosteroid (ICS)
More ≥2 outpatient or ≥1 hospitalization		

Fig. 6.9: Pharmacotherapy based on severity of COPD.

## Acute Exacerbations of COPD

- **Definition:** ‘An event in the natural course of the COPD characterized by a change in the patient’s baseline dyspnea, cough, and/or sputum that is beyond normal day-to-day variations. It is acute in onset, and may warrant a change in regular medication in a patient with underlying COPD.’
- **Causes of exacerbation:** (1) Infection of the tracheobronchial tree, and (2) air pollution. In about one-third of cases, no cause can be identified.
- **Triggering factors:** Infections by bacteria, viruses or a change in air quality.

**Q. Write short note/essay on management of a case of acute exacerbation of chronic bronchitis.**

### Treatment of Severe Acute Exacerbations

#### Oxygen

- Adequate oxygenation (i.e. to achieve an oxygen saturation of 88–92%) must be assured.
- **Method of administration:** By nasal catheter or through a facemask equipped to control the inspired oxygen fraction. Venture masks are preferred because they permit a precise fraction of inspired oxygen (FiO<sub>2</sub>).

#### Bronchodilators

Nebulized short-acting β<sub>2</sub>-agonists (salbutamol 2.5 mg every 20 minutes for initial 1–2 hours) and/or

anticholinergic agent (ipratropium bromide 0.5 mg) should be given. Intravenous aminophylline may be added, if the patient fails to respond to the above treatment.

### Antibiotics

- **Indications:** Patients with: (1) increase in sputum purulence, sputum volume, or (2) breathlessness (dyspnea), or (3) those requiring mechanical ventilation.
- **Most common organisms during exacerbations:** *S. pneumoniae*, *H influenza* and *M. catarrhalis*. Risk factors for *P. aeruginosa* infection include recent hospitalization, frequent antibiotics use and severe exacerbation.
- **Antibiotics used:**
  - **Outpatient:** Doxycycline, cotrimoxazole or amoxicillin–clavulanate can be given. Patients older than 65 years given one of the newer fluoroquinolones (levofloxacin, gemifloxacin, moxifloxacin).
  - **Hospitalized patients:** Intravenous antibiotics (azithromycin or fluoroquinolone or a third-generation cephalosporin-like ceftriaxone or cefotaxime).
  - **Severe exacerbations:** Third-generation cephalosporin plus a fluoroquinolone or an aminoglycoside.

### Corticosteroids

Intravenous or oral corticosteroids shorten the recovery time, improve lung functions (FEV<sub>1</sub>) and hypoxemia.

### Diuretics

Given to patients with gross right ventricular failure.

### Respiratory stimulants

May be used when there is no response to the conventional agents. Doxapram in the dose of 1.5–4 mg/minute as infusion is the most often used agent. Other respiratory stimulants are almitrine, nikethamide, medroxy progesterone and acetazolamide.

### Mechanical Ventilatory Support

- **Noninvasive positive airway pressure ventilation (NIPPV)**
  - NIPPV is by using tight-fitting facemask to deliver BiPAP.
- **Invasive (conventional) ventilation**
  - It is administered via an endotracheal tube.

GOLD Stage	I. Mild	II. Moderate	III. Severe	IV. Very severe
Spirometry findings	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub>/FVC &lt; 0.70</li> <li>• FEV<sub>1</sub> &gt;80% of predicted</li> </ul>	<ul style="list-style-type: none"> <li>• FEV<sub>1</sub>/FVC &lt; 0.70</li> <li>• FEV<sub>1</sub> 50–79% of predicted</li> </ul>	<ul style="list-style-type: none"> <li>- FEV<sub>1</sub>/FVC &lt; 0.70</li> <li>- FEV<sub>1</sub> 30 to &lt; 49% of predicted</li> </ul>	FEV <sub>1</sub> /FVC < 0.70 FEV <sub>1</sub> 30% of predicted or FEV <sub>1</sub> < 50% of predicted, if respiratory failure present
Management	Short-acting β <sub>2</sub> -agonists (salbutamol, terbutaline, levosalbutamol) as needed	Long-acting β <sub>2</sub> -agonists (salmeterol, formoterol) ± anticholinergics (ipratropium, tiotropium)	Add inhaled glucocorticoids (beclomethasone, budesonide, fluticasone, ciclesonide) ± methylxanthines	Add oxygen therapy, ventilator assistance, management of right-sided heart failure, surgical options
Avoid risk factors, influenza vaccination and use short-acting β <sub>2</sub> -agonists to all stages →				

**Fig. 6.10:** GOLD staging for severity of COPD and management.

### *Management of associated co-morbidities*

It is necessary to manage co-morbidities because they are responsible for mortality and hospitalization.

### *GOLD staging for severity of COPD and management (Fig. 6.10)*

It is used for both chronic bronchitis and emphysema.

## **Emphysema**

The word 'emphysema' literally means inflation or distension with air. Emphysema can be classified depending the organ or structure involved as:

- **Pulmonary emphysema** (refer below)
- **Compensatory emphysema/hyperinflation**
  - It is characterized by **dilation of alveoli without destruction of septal walls**. It develops as a compensatory response to loss of extensive lung substance elsewhere (e.g. removal of a diseased lung or lobe).
- **Mediastinal emphysema (Fig. 6.11)**
  - It occurs as a result of entry of air rapidly into the mediastinum following rupture of over distended alveoli as in severe bronchial asthma, rupture of emphysematous bulla (during coughing) and rupture of esophagus.
  - Severe mediastinal emphysema can lead to cardiac tamponade.
  - *Auscultation*: It may reveal a crunching sound (mediastinal crunch).
- **Subcutaneous emphysema (Fig. 6.11)**
  - It is characterized by the **entry of air into** subcutaneous tissue.
  - *Causes*: Penetrating chest injuries, fracture of ribs or intercostal tube introduction.
  - On palpation, it produces a characteristic crepitation or crackling sensation.
  - *Treatment*: Not needed because the air will get absorbed slowly. In severe cases, subcutaneous incisions may be necessary to relieve pressure.

**Fig. 6.11:** Chest X-ray shows subcutaneous (white arrows) and mediastinal emphysema (black arrows).

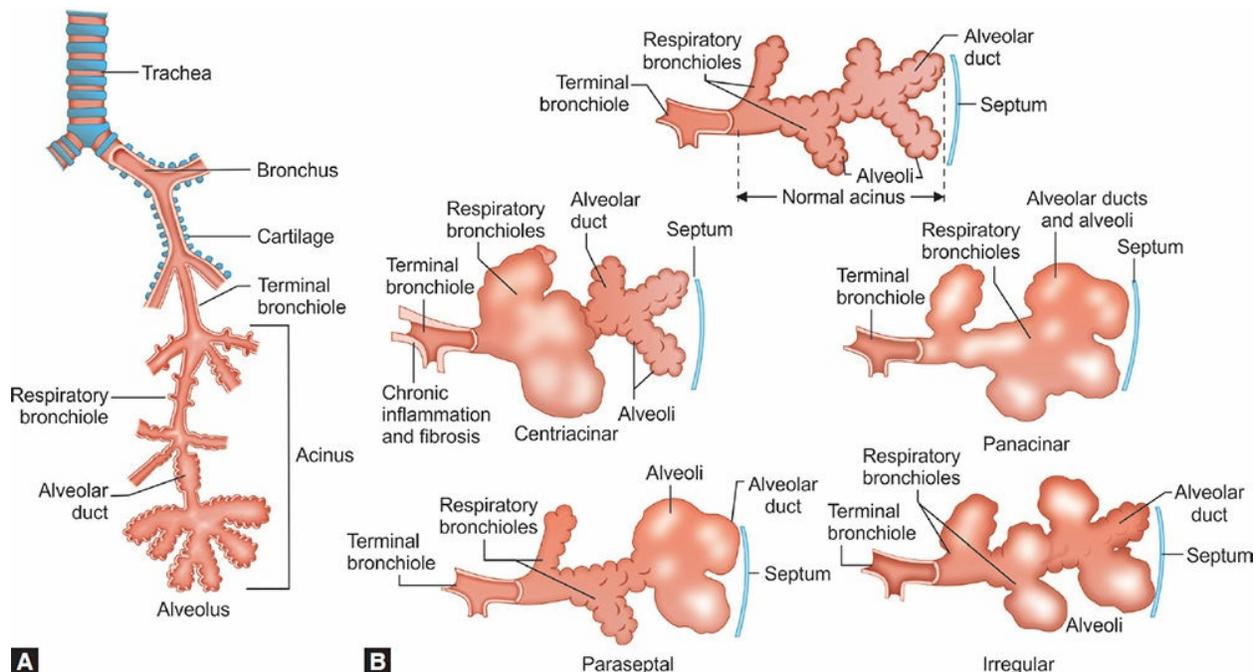

**Q. Discuss the etiology, pathology, clinical features, investigations, complications and management of pulmonary emphysema.**

**Q. Write short essay/note on definition and various types of emphysema.**

**Definition:** Emphysema (pulmonary) is a **chronic lung disease** characterized by abnormal **irreversible** (permanent) **dilatation of the airspaces distal to the terminal bronchiole**. This is associated with destruction of their walls but without obvious fibrosis.

### ***Types of Emphysema/Classification (Figs. 6.12A and B)***

Emphysema is **classified according to its anatomic distribution** (location of the lesions) within the lobule into **four major types**: (1) Centriacinar, (2) panacinar, (3) paraseptal, and (4) irregular.

**Figs. 6.12A and B:** (A) Normal components of respiratory tree; (B) Types of emphysema.

1. **Centriacinar (centrilobular) emphysema:**

- Dilatation involves the **central or proximal parts of the acini** (formed by respiratory bronchioles), whereas distal alveoli are spared.
- Common and severe in the **upper lobes**, especially in the **apical segments**.
- **Association:** Occurs in **heavy smokers** and in association with **chronic bronchitis** and **coalworkers' pneumoconiosis**.

2. **Panacinar (panlobular) emphysema:**

- All the airspaces beyond terminal bronchiole are more or less uniformly/equally dilated.
- **Site:** More common in the lower lobes, and is usually most severe at the bases.
- Associated with  **$\alpha_1$ -antitrypsin ( $\alpha_1$ -AT) deficiency**.

3. **Distal acinar (paraseptal) emphysema:**

- Dilatation affects the distal airspace at the periphery of the lobule and the proximal portion is normal.
- It is found near the pleura. **Dilated spaces of more than 1 cm in size** are known as **bullae** which may rupture and cause spontaneous pneumothorax.
- It occurs **adjacent to areas of fibrosis, scarring, or atelectasis**.

4. **Irregular (scar or cicatricial) emphysema**

- Acinus is irregularly involved and may be asymptomatic.
- Most common form of emphysema.
- Occurs **near the scar** and is commonly found **around old healed inflammatory process** such as **tuberculous scars**.

***Etiology and Pathogenesis (Fig. 6.13)***

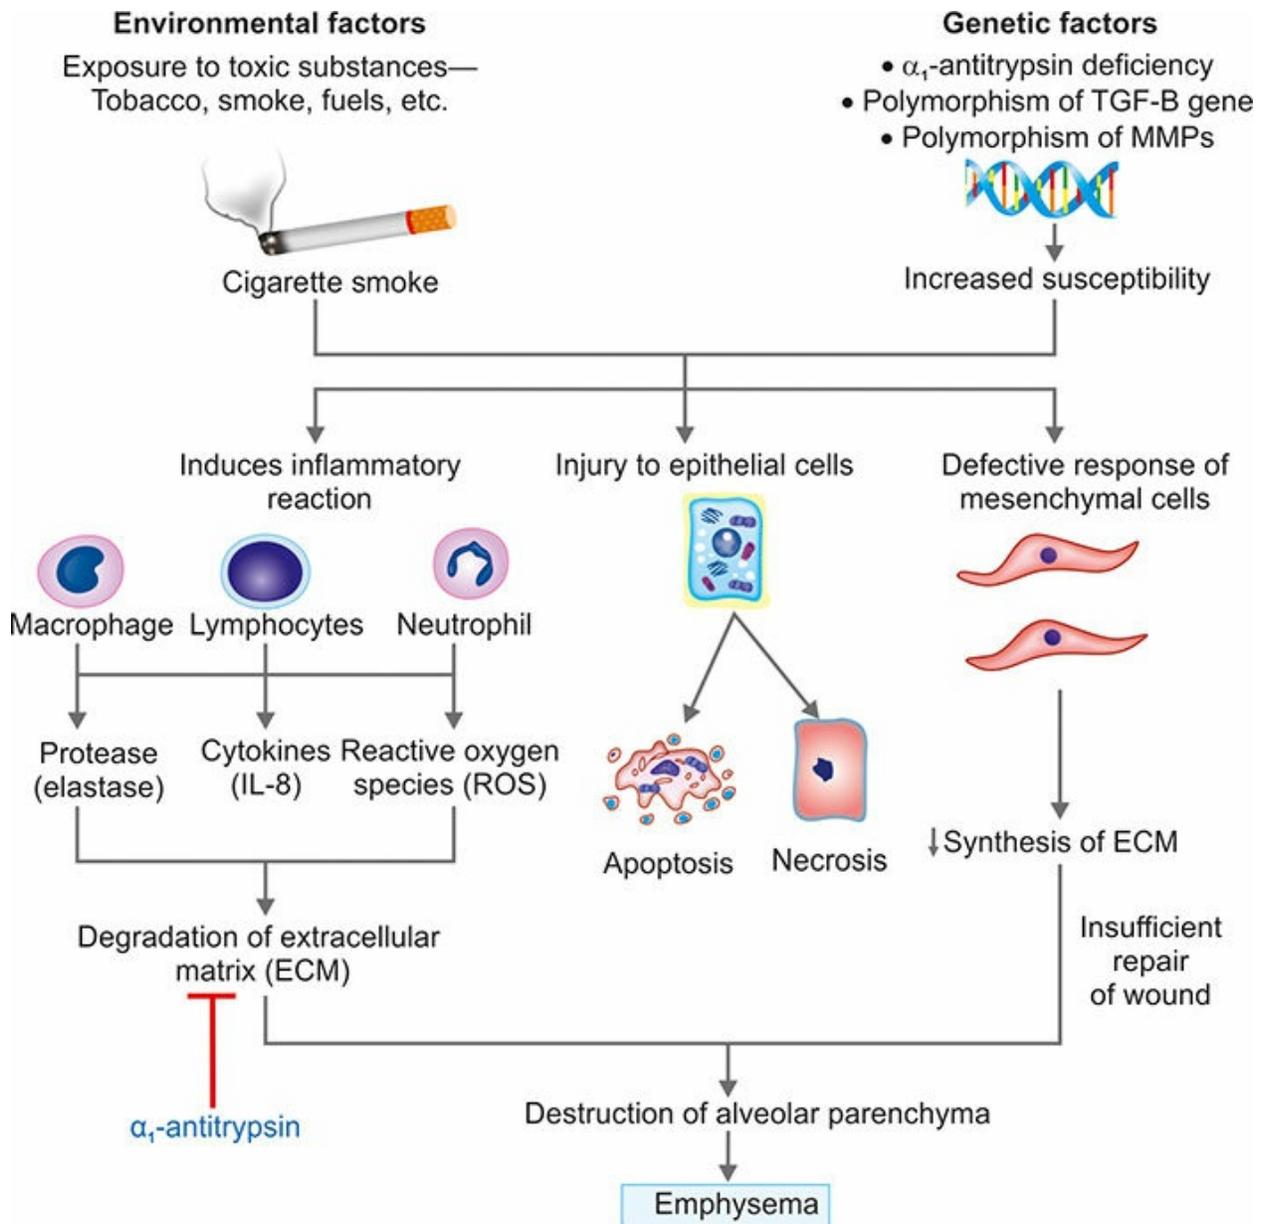

**Q. Write short essay/note on etiological factors for emphysema.**

The **major event** in emphysema is **destruction of alveolar wall**.

- **Mechanism that checks the destruction of alveolar wall:** These include: (1) **Antielastases** (e.g.  $\alpha_1$ -antitrypsin) and (2) **antioxidants**. If these two mechanisms are defective  $\rightarrow$  results in (1) **protease-antiprotease imbalance** (e.g.  $\alpha_1$ -antitrypsin deficiency) and (2) **imbalance between oxidants and antioxidants**.
  - **Unchecked inflammation and proteolysis:** Develops due to deficiency of the above protective mechanism.
- **Genetic factors**

**Q. Write short note on  $\alpha_1$ -antitrypsin deficiency.**

- **Deficiency of  $\alpha_1$ -antitrypsin:** It is inherited as **autosomal recessive**, which exhibits polymorphism  $\rightarrow$  tendency to develop emphysema.  $\alpha_1$ -**antitrypsin is a major inhibitor of proteases** (particularly elastase). It is normally present in serum, tissue fluids, and macrophages and a balance is maintained between protease and antiproteases. During inflammation, protease (proteolytic enzyme) is secreted by neutrophils and digests the connective tissue of the lung.  $\alpha_1$ - antitrypsin is a protease inhibitor (antiprotease), preventing this proteolytic digestion. Hence, a deficiency or absence of  $\alpha_1$ -antitrypsin results in the proteolytic destruction of lung. These patients develop severe panacinar emphysema.

**Fig. 6.13:** Pathogenesis of emphysema. Exposure to environmental toxins (e.g. cigarette smoke) causes inflammatory reaction, cell death and proteolysis of extracellular matrix (ECM).  $\alpha_1$ -antitrypsin ( $\alpha_1$ -AT) deficiency also results in increased degradation of ECM.

(IL-8: interleukin 8; TNF: tumor necrosis factor)

## Clinical Features

Manifestations appear late until at least one-third of the functioning pulmonary parenchyma is damaged.

- **Dyspnea** is the most striking feature that begins insidiously and steadily progresses ultimately ending in breathlessness on trivial exertion and even at rest.

- **Cough and expectoration** of scanty mucoid sputum.
- **Weight loss**, weakness, anorexia and lethargy is common with advanced disease.

### *Physical findings*

**General:** Body build is asthenic, short and thick neck, neck veins may appear distend during expiration and collapse during inspiration. Patient leans forwards, extending the arms to brace himself during sitting posture.

### *Respiratory*

- **Inspection**
  - Patient appears **distressed** and **tachypneic**, **hypertrophy of accessory muscles of respiration** (sternomastoid and scalene muscles), length of the trachea above the suprasternal notch is reduced, apical impulse is invisible or feeble
  - **During inspiration: Tracheal descent exaggerated** (Campbell's sign), excavation of the suprasternal and supraclavicular fossae, **indrawing of the costal margins**.
  - **Expiration: Prolonged through pursed lips** (purse-lip breathing) and beginning of expiration with a **grunting sound**.
  - **Chest:** Cylindrical or barrel like (**barrel-shaped chest**), anteroposterior diameter of the chest is markedly increased. Whole chest is in a fixed state of full inspiration. Ribs are placed more horizontally and widely. Chest expansion diminished symmetrically. Thoracic kyphosis is exaggerated and the subcostal angle is widened.
  - **Dahl Sign:** Above the knee, patches of hyperpigmentation or bruising caused by constant 'tenting' position of hands or elbows.
  - **Hoover's sign:** Briefly, during inspiration a paradoxical medial movement of the chest. The 'subcostal angle' is the angle between the xiphoid process and the right or left costal margin. Normally, during inhalation the chest expands laterally, increasing this angle. When the diaphragms are flattened (as in COPD), inhalation paradoxically causes the angle to decrease.
  - **Harrison's sulcus:** A horizontal groove where the diaphragm attaches to the ribs; associated with chronic asthma, COPD, and rickets.
- **Percussion:** Hyper-resonant percussion note over the lungs, reduced

cardiac dullness, and liver dullness is pushed down or absent. Tidal percussion is negative.

- **Auscultation:** Diminished intensity of the breath sound, breath sounds are vesicular with prolonged expiration. Scattered, faint, high-pitched, end-expiratory rhonchi may be audible.

**Fig. 6.14:** Chest X-ray of emphysema. (PA view) showing low set, flat diaphragm, translucent lung field, long and narrow heart ('tubular heart'), loss of peripheral vascular markings, prominent pulmonary artery shadows at the hilum.

## ***Investigations***

- **Chest X-ray (Fig. 6.14)**
  - **PA view:** Features include low set, flat diaphragm, translucent lung field, long and narrow heart ('tubular heart'), loss of peripheral vascular markings, prominent pulmonary artery shadows at the hilum and bullae.
  - **Lateral view:** Large retrosternal translucency.
- **Computed tomography:** Can identify emphysema with certainty.
- **Pulmonary function tests** (Table 6.29)

- **Arterial blood gas studies:** Slightly reduced PaO<sub>2</sub> and normal or mildly elevated PaCO<sub>2</sub>.

**Table 6.29:** Pulmonary function test findings in emphysema.

<b>Reduced:</b> FEV <sub>1</sub> , FVC, FEV <sub>1</sub> : FVC ratio, and PEF	<b>Increased:</b> TLC, RV, and RV : TLC
GAS transfer factor for carbon monoxide (diffusion) is reduced.	

## Complications

Emphysema progresses steadily and gradually.

### **Q.** Write short note on pulmonary bullae.

#### 1. Pulmonary bullae

- They represent inflated thin-walled spaces produced due to the rupture of alveolar walls.
- May be single or multiple, small or large and resembles an amulet.
- Usually located in the subpleural region along the anterior borders of lungs.
- *Complications:* A subpleural bulla may rupture producing spontaneous pneumothorax. Large bullae can interfere with pulmonary ventilation.

#### 2. Respiratory failure: Type 1 and type II respiratory failure can occur.

#### 3. Pulmonary hypertension and right heart failure (cor pulmonale): These are late complications and right ventricular failure in emphysema is usually a terminal event.

#### 4. Severe weight loss: Leading to emaciation can occur.

#### **Treatment: Treatment similar as described for COPD (refer pages 271-3).**

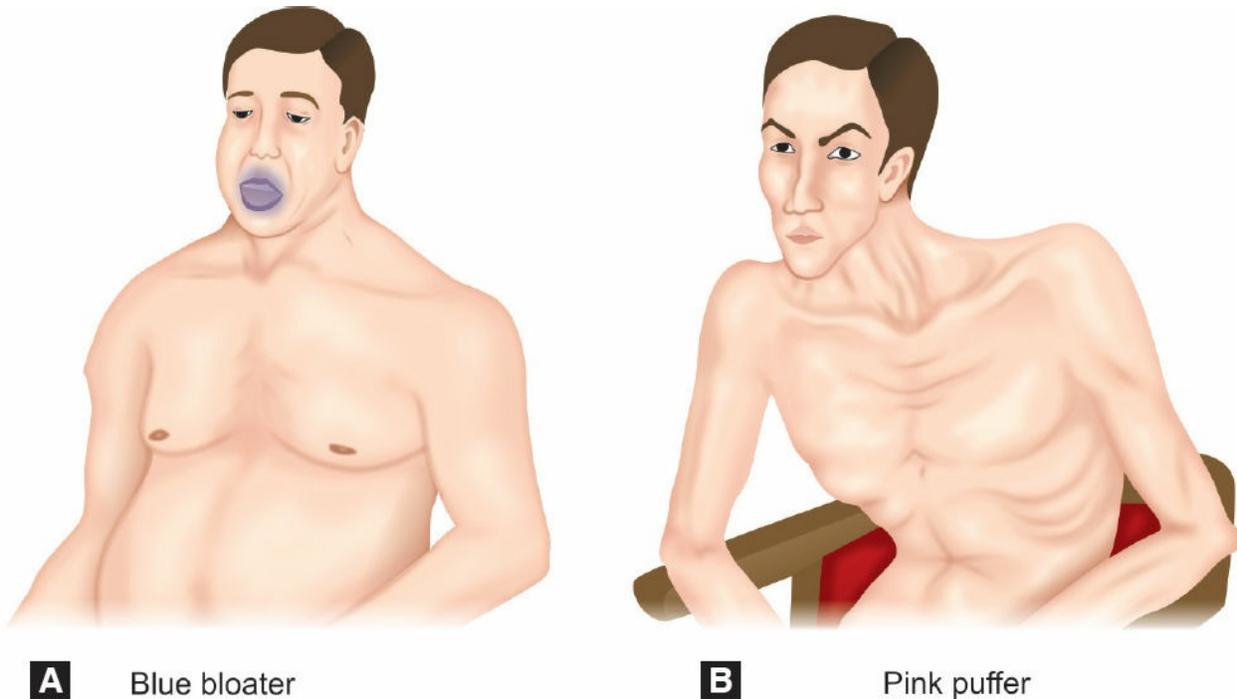

- No specific treatment for established case of emphysema. Bronchodilators and steroids may be helpful in few patients.
- **Prevention of progression:** Cessation of smoking and avoidance of occupational exposure.
- **Treatment of aggravating factors and complications:** Treatment of infections, respiratory failure and right heart failure.
- **Physiotherapy**
- **Surgical therapy: Ablation of giant bullae,** lung volume reduction surgery reduced hyperinflation of one or both lungs and/or laser resection.
- **Heart and lung transplantation:** In young patients with severe emphysema due to α<sub>1</sub>-antitrypsin deficiency.

## **Blue Bloaters (Fig. 6.15A)**

### **Q. What are blue bloaters?**

It is a distinctive clinical pattern seen in chronic bronchitis, the characteristics of which are:

- Marked/heavy cyanosis ('blue') and peripheral edema ('bloat') and secondary polycythemia.
- Current evidence demonstrates that most patients have elements of both bronchitis and emphysema and by physical examination cannot reliably differentiate 'blue bloaters' from 'pink puffers'.

**A** Blue bloater **B** Pink puffer  
**Figs. 6.15A and B:** (A) Blue bloater (in chronic bronchitis) versus; (B) Pink puffer (in emphysema).

## **Pink Puffers (Fig. 6.15B)**

### **Q. What are pink puffers?**

- It is a distinctive clinical pattern seen in emphysema of lung.
- Patients are thin and noncyanotic at rest (hence 'pink').
- They have marked dyspnea ('puffer') and have prominent use of accessory muscle. They develop steadily progressive dyspnea.

*Differences between emphysema and chronic bronchitis (Table 6.30)*

**Q. What are the differentiating features of emphysema and chronic bronchitis?**

**Table 6.30:** Differences between emphysema and chronic bronchitis.

<i>Feature</i>	<i>Emphysema</i>	<i>Chronic bronchitis</i>
<b>Clinical features</b>		
Dyspnea	Severe	Mild to moderate
Cough	Develops after dyspnea starts	Frequent, develops before dyspnea starts
Sputum—amount and nature	Scanty, mucoid	Copious, purulent
Frequency of mucopurulent relapses	Less	More
Cyanosis	Absent	Present
Pulmonary hypertension	Late and mild	Early and severe
Right ventricular failure and respiratory failure	Late and often terminal	Repeated episodes
Mechanism of airway obstruction	Loss of elastic recoil	Decreased airway lumen due to mucus and inflammation
<b>Investigations</b>		
Hematocrit (PCV)	Normal	Increased
PaO <sub>2</sub>	Normal to low ‘pink puffer’	Low ‘blue bloater’
PaCO <sub>2</sub>	Normal mildly increased	High (>40)
FEV <sub>1</sub>	Decreased	Decreased
Diffusing capacity	Reduced	Normal
Chest X-ray	Features of hyperinflation, bullae and tubular heart	Increased bronchovascular markings and cardiomegaly
Elastic recoil	Decreased	Normal
Airway resistance	Normal to slightly increased	Increased
Cor pulmonale	Late, mild	Early, marked
Prognosis	Good	Poor

***Differentiating features of asthma and chronic obstructive pulmonary disease (Table 6.31)***

**Q. What are the differentiating features of asthma and chronic obstructive pulmonary disease?**

**Table 6.31:** Differentiating features of asthma and chronic obstructive pulmonary disease (COPD).

<i>Characteristics</i>	<i>Bronchial asthma</i>	<i>COPD</i>
------------------------	-------------------------	-------------

Age of onset	Usually children and young adults	Usually older individuals
Risk factors	Family history of allergy, exposure to allergens, occupational sensitizers	Smoking, atmospheric pollution, occupational exposure, $\alpha_1$ -antitrypsin deficiency
<b>Respiratory symptoms</b>		
Main symptoms	Wheezing, cough, dyspnea	Chronic dyspnea, productive cough
Nature of symptoms	Vary from time to time and even over hours and days	Usually continuous symptoms
Triggers	Exercise, dust or exposure to allergens	Unrelated to triggers
Recovery of symptoms	Symptoms improve spontaneously or with treatment	Slowly progressive despite therapy
Comorbidities	Generally absent	Often present (cardiovascular diseases, metabolic syndrome, depression, osteoporosis, muscle wasting)
Chest X-ray	Normal	Hyperinflation
Spirometry	Reversibility of airway obstruction and normal between symptoms	FEV <sub>1</sub> /FVC < 0.7 and persistent airflow limitation

## Cigarette Smoking

**Q. Write short note/essay on the various components of cigarette smoke and list the diseases caused by smoking.**

Cigarette smoke is a complex aerosol containing gaseous and particulate compounds.

**Components of cigarette smoke:** It consists of mainstream smoke and side stream smoke.

1. *Main stream smoke:* It is produced by inhalation of air through cigarette. It is the primary source of smoke exposure in smokers.
2. *Side stream smoke:* It is produced from emitting of the smoke between cigarette puffs and is the main source of environmental smoke or second hand smoke.

**Chemical constituents of cigarette smoke:** It contains about 2000 to 4000 chemical substances and more than 60 carcinogens. About 95% of the weight of the mainstream smoke is derived from 400 gaseous compounds and about 5% of the weight is made up of about 3500 particulate components.

Tobacco addiction is due to nicotine present in cigarette smoke and is the total particulate matter responsible for carcinogenesis.

- **Carcinogens:** Tar, polycyclic aromatic hydrocarbons, benzo[a]pyrene, nitrosamine
- **Others**
  - Nicotine causes ganglionic stimulation and depression, tumor promotion
  - Phenol causes tumor promotion, mucosal irritation
  - Carbon monoxide impaired oxygen transport and utilization
  - Formaldehyde produces toxicity to cilia; mucosal irritation
  - Nitrogen oxides produces toxicity to cilia; mucosal irritation.

Diseases caused by smoking are listed in Table 6.32.

**Table 6.32:** Diseases caused by smoking.

<i>System</i>	<i>Diseases produced</i>
General	Cancers of lung, oropharynx, esophagus, stomach, pancreas, bladder, kidney, cervix, colon and acute myeloid leukemia
Respiratory	COPD, chronic cough and infections
Cardiovascular	Coronary artery disease, cerebrovascular disease, peripheral artery disease, abdominal aortic aneurysm.
Reproductive	Miscarriage, prematurity, low birth weight, ectopic pregnancy, SIDS (sudden infant death syndrome)
Gastrointestinal	Gastro-esophageal acid reflux, peptic ulcer and Crohn's diseases
Others	Poor oral and skin health, cataract, fire-related injuries, osteoporosis, macular degeneration

## Asthma COPD Overlap Syndrome (ACOS)

### **Major Criteria for ACOS:**

- Characterized by persistent airflow limitation with several features usually associated with asthma and several features usually associated with COPD.
- History or evidence of atopy (e.g. hay fever, elevated total IgE).
- Age 40 years or more
- Smoking >10 pack-years, post-bronchodilator FEV<sub>1</sub> <80% predicted and FEV<sub>1</sub>/FVC <70%.  
A ≥15% increase in FEV<sub>1</sub> or ≥12% and ≥200 mL increase in FEV<sub>1</sub> post-bronchodilator treatment

with albuterol would be a minor criteria.

## PULMONARY TUBERCULOSIS

### MYCOBACTERIA

#### Classification

**Q. Write short note on classification of mycobacteria and give an account of disease produced by them.**

Mycobacteria are classified into three groups:

1. ***Mycobacterium tuberculosis* complex** (*M. tuberculosis*, *M. bovis* and *M. africanum*).
2. ***Mycobacterium leprae*.**
3. **Atypical mycobacteria** or **non-tuberculous mycobacteria** (NTM) or **mycobacteria other than tuberculosis** (MOTT).

**Q. Write short note on mycobacteria other than tuberculosis (MOTT)/non-tuberculous mycobacteria (NTM).**

- MOTT or NTM are ubiquitous in the environment. They occur in soil and water and are **not usually pathogenic** due to their lack of virulence. Therefore, their isolation from a site that is not normally sterile (e.g. sputum, skin or urine) does not constitute proof of disease. Groups of atypical *Mycobacterium* are listed in Table 6.33.
- **Patients with NTM lung disease** often **have predisposing disease of the lung** (e.g. COPD, bronchiectasis, cystic fibrosis, pneumoconiosis, etc.).

**Table 6.33:** Groups of atypical *Mycobacterium*.

#### Slow growing

- **Group I** Photochromogens (P): Pigment producers in the presence of light, e.g. *Mycobacterium kansasii*, *M. marinum*, *Mycobacterium simiae*
- **Group II** Scotochromogens (S): Pigment producers in the absence of light, e.g. *Mycobacterium scrofulaceum*, *Mycobacterium szulgai*, *Mycobacterium gordonae*
- **Group III** Non-photochromogens (N): Do not produce any pigment, e.g. *Mycobacterium malmoense*, *Mycobacterium xenopi*, *M. avium* intracellulare)

#### Fast growing

- **Group IV** Fast growers (3–5 days), e.g. *Mycobacterium fortuitum*, *Mycobacterium chelonae*, and

## *Mycobacterium abscessus*.

- ***Mycobacterium avium intracellulare***
  - Also known as MAC (*Mycobacterium avium* complex).
  - Most common non-tuberculous mycobacterial infection associated with AIDS.
  - Symptoms include fever, swollen lymph nodes, diarrhea, fatigue, weight loss and shortness of breath.
  - May develop into pulmonary MAC.
- ***Mycobacterium marinum*** causes infections of skin and swimming pool granuloma.
- ***Mycobacterium ulcerans*** cause skin infections.
- ***Mycobacterium kansasii*** causes lung disease.

## Therapeutic options in atypical mycobacterial infections (Table 6.34)

**Table 6.34:** Therapeutic options in atypical mycobacterial infections.

<b>Atypical mycobacteria</b>	<b>Therapeutic options</b>
MAC ( <i>Mycobacterium avium</i> complex)	Clarithromycin or azithromycin + ethambutol + rifampin
<i>M. xenopi</i>	Rifampin + ethambutol + INH
<i>M. kansasii</i>	Rifampin + ethambutol should be treated for at least 18 months
<i>M. malmoense</i>	Rifampin or ethambutol
<i>M. marinum</i>	Rifampin or clarithromycin + ethambutol 2–3 months. Often resistant to isoniazid. Treatment with other antibiotics should be for at least two months
Rapid growers	Doxycycline, amikacin, imipenem, quinolones, sulfonamides, ceftazidime, clarithromycin
<i>Mycobacterium chelonae</i>	Clarithromycin in combination with another agent, sometimes surgical excision is the best approach

## TUBERCULOSIS

Tuberculosis (also called Koch's disease) is a **communicable, chronic granulomatous disease** caused by ***Mycobacterium tuberculosis***.

Tuberculosis (TB) is caused by four main mycobacterial species collectively termed *Mycobacterium tuberculosis* complex (MTb): (1) *Mycobacterium tuberculosis* (reservoir human), (2) *Mycobacterium bovis* (reservoir cattle), (3) *Mycobacterium africanum* and (4) *Mycobacterium microti*. These are obligate aerobes and facultative intracellular pathogens

which usually infect mononuclear phagocytes.

- **Majority of tuberculosis are due to *Mycobacterium tuberculosis hominis*** (human strain). The source of infection is patients suffering from active open case of tuberculosis.
- **Oropharyngeal and intestinal tuberculosis can be due to drinking of milk contaminated by *M. bovis*** (bovine strain) from infected cows. Routine pasteurization has almost eliminated this source of infection.
- ***M. avium* and *intracellulare* are non-pathogenic to normal individuals. They cause infection in patients suffering from AIDS.**

## Characteristics of Mycobacteria

### Q. Write short note on acid-fast bacilli.

- It is an aerobic, slender, and rod-shaped bacteria. It measures 2 to 10  $\mu\text{m}$  in length.
- It has a high lipid content in the cell wall which makes it difficult to stain, but **once stained resists decolorization by acids and alcohol**. Hence, it is termed as acid-fast bacilli (AFB), because once stained by carbol fuchsin (present in **Ziehl-Neelsen stain**), it is not decolorized by acid and alcohol. Acid fast organisms and structures are listed in Table 6.35.

**Table 6.35:** Acid fast organisms and structures.

Acid fast organism	Other acid fast structures
<ul style="list-style-type: none"><li>• <i>Mycobacteria</i></li><li>• <i>Nocardia</i></li><li>• <i>Isospora</i></li><li>• <i>Cryptospora</i></li><li>• <i>Microsporidia</i></li><li>• <i>Rhodococcus</i></li><li>• <i>Legionella</i></li></ul>	<ul style="list-style-type: none"><li>• Head of human sperm</li><li>• Embryophore of <i>T. saginata</i></li><li>• Hooklets of <i>E. granulosus</i></li><li>• Keratin</li></ul>

## Epidemiology

- Tuberculosis is common in India. High incidence of tuberculosis is observed with poverty, overcrowding, and chronic debilitating illness. As per WHO 2016, there are an estimated 10.4 million new TB cases worldwide, 10% of which were people living with HIV. TB statistics for India for 2016 give an estimated incidence figure of 2.79 million cases of

TB for India. An estimated 1.7 million people died from TB, including nearly 400,000 people who were co-infected with HIV.

- **Diseases associated with increased risk** of tuberculosis include diabetes mellitus, Hodgkin lymphoma, malnutrition, immunosuppression, alcoholism, chronic lung disease (e.g. silicosis), and chronic renal failure.
- **HIV is the most important risk factor.**

## Determinants of Virulence

- **Three genes:** (1) *kagG*-encodes catalase, (2) *rpo V*-signs factor (initiates transcription of many enzymes) and (3) *erp*- encodes a protein required for multiplication.
- ***NRAMP-1* gene:** *NRAMP1* is a transmembrane protein (a product of *NRAMP1* gene) **inhibits microbial growth** and it determines the susceptibility to tuberculosis. In individuals with **polymorphisms in the *NRAMP1* (natural resistance-associated macrophage protein 1) gene,** tuberculosis may progress due to the absence of an effective immune response.

## Mode of Transmission

- **Inhalation:** It is the **most common mode** of transmission. **Source of organisms is an active open case of tuberculosis to a susceptible individual.** Infection spread by the inhalation of respiratory droplet from other infected patients.
- **Ingestion:** Tuberculosis may be transmitted by drinking nonpasteurized milk from infected cows contaminated with *M. bovis*. It causes oropharyngeal and intestinal tuberculosis. Nowadays, the ingestion mode of transmission occurs when a patient with open case of tuberculosis swallows the infected sputum results in tuberculosis of intestine.
- **Inoculation:** It is **extremely rare** and may develop during postmortem examination, while cuts resulting from handling tuberculous infected organs.

## Primary Tuberculosis

- **Q. Discuss the pathogenesis, pathology, clinical manifestations and diagnosis of primary pulmonary tuberculosis.**
- **Q. Write short essay/note on primary complex of Ranke and Ghon's**

## complex/features of primary tuberculosis.

**Initial infection** that occurs on first exposure to the organism (*Mycobacterium tuberculosis*) **in an unsensitized** (previously unexposed tuberculin-negative) **individual** is known as primary tuberculosis. First infection of the lung caused by the tubercle bacillus is termed as primary pulmonary tuberculosis.

**Primary infection usually occurs during childhood.** Many patients give a history of contact with a case of active pulmonary tuberculosis. About 5% of newly infected people develop clinically significant disease. Source of the organism is always exogenous.

## Sites of Primary Tuberculosis

Lung, intestine, tonsil and skin (very rare).

### *Primary Tuberculosis of Lung*

It is the **commonest site** of primary tuberculosis. Primary pulmonary tuberculosis develop when the bacillus is inhaled and lodged in the alveoli of the lung.

#### *Ghon lesion/focus*

Following inhalation, tubercle bacilli reach the distal airspaces.

- **Site of deposit:** Lower part of the upper lobe or upper part of the lower lobe near the pleural surface (subpleural) are the usual sites of deposit.
- **Ghon focus:** About 2 to 4 weeks after the infection, a circumscribed **gray-white area of about 1- to 1.5-cm develops in the lung** known as the Ghon focus → the center of which undergoes caseous necrosis.
- **Regional lymphadenitis:** Tubercle bacilli (free or within macrophages) are carried along the lymphatics to the regional draining nodes → which often show caseous necrosis.

#### *Ghon complex*

It is the combination of subpleural parenchymal lung lesion (**Ghon focus**) and **regional lymph node** involvement.

#### *Fate of Ghon complex*

- **Healing:** In **majority** (about 95%), cell-mediated immunity controls the infection and primary tuberculosis **heals**.
  - The **hallmark of healing is fibrosis**. Ghon complex may undergo

progressive fibrosis and calcification. It is radiologically detected as a small calcified nodule (**Ranke complex**) in caseous material and very rarely undergoes ossification.

- In the majority of individuals infected by *Mycobacterium*, the immune system contains the infection and the patient develops cell mediated immune memory to the bacteria. This is termed **latent tuberculosis**.
- **Spread:** Lymphatic and hematogenous spread to other organs or parts of the body occurs during the first few weeks.
  - **Progressive pulmonary tuberculosis:** In a few patients, primary lesion in the lung may progress from the beginning (progressive pulmonary tuberculosis or progressive primary pulmonary tuberculosis).
  - **Bronchial spread:** Tuberculous lymph node may rupture/ulcerate through the bronchial wall and discharge caseous material into the bronchial lumen. This causes spread of infection to the related lobe or segment through bronchi.
  - **Hematogenous spread:** In some patients, the tubercle bacilli may enter the blood and produces tuberculous lesions in different parts of the body. The hematogenous spread can be of two types:
    - ◆ **Acute form:** It is more likely to occur in infants or young children and results in **miliary tuberculosis** or tuberculous meningitis.
    - ◆ **Chronic form:** It is characterized by tuberculosis in the lungs, bones, joints, liver and kidneys. These lesions may develop months or even years after primary infection. The infection in these secondary foci may remain dormant for years.
  - **Lymphatic spread:** In some cases, the infection may be carried by lymphatics from mediastinal lymph nodes to pleura or pericardium resulting in tuberculous pleurisy with effusion or tuberculous pericarditis with effusion.

### ***Other Sites of Primary Tuberculosis***

- **Intestine:** Primary focus always involve the small intestine (usually ileal region) and associated with mesenteric lymphadenitis.
- **Tonsils:** Primary focus in the pharynx and tonsil with cervical lymph node enlargement.

- **Skin:** Primary focus in the skin associated with regional lymphadenopathy.

### ***Bronchial Complications***

- **Middle lobe syndrome:** Enlarged mediastinal lymph nodes of primary complex may compress a bronchus causing collapse of the lung. Compression of middle lobe bronchus may lead to collapse-consolidation and bronchiectatic changes. This may be present later as the '**middle lobe syndrome, Brock's syndrome**'.
- An unusual phenomenon in primary tuberculosis is obstruction of bronchus by lymph nodes referred to as **epituberculosis** resulting in some clinical signs, e.g. localized wheeze or bronchial breathing.
- **Obstructive emphysema:** Rarely, the compression of bronchus may result in a valve action with air trapping. This leads to obstructive emphysema.
- **Broncholith:** Calcification in a Ghon focus or regional lymph node may be extruded into a bronchus leading to 'broncholith' or present as hemoptysis.

### ***Clinical Features: Pulmonary Disease***

#### *Primary pulmonary TB*

#### **Symptoms**

- Majority are asymptomatic.
- A few patients may present with self-limiting febrile illness which may last no more than 7–14 days. It occurs at the time of tuberculin conversion.
- Clinical disease only occurs if there is progressive infection. If the infection is severe or the host resistance is low, child may present with reduced appetite and failure to gain weight. Slight dry cough may be occasionally present.

#### **Physical signs**

- Majority of patients does not reveal any abnormal physical signs.
- **General features:** If the lesion is severe or extensive, signs of general debility may be present. Child is thin, pale, and fretful having less glossy

hair and less elastic skin.

- **Respiratory system:** Usually no abnormal physical signs detected in the chest. Sometimes, few crepitations may be heard over lung parenchyma involved by the primary complex. More extensive physical signs in the chest may be produced when there are complications. Rarely pleural effusion can be seen.
- **Erythema nodosum:** It may accompany primary pulmonary tuberculosis. They are bluish-red, raised, tender, skin lesions commonly seen on the shins and less commonly on the thighs. In few, it may be associated with fever and polyarthralgia.

### *Diagnosis*

- **History of contact:** With a case of active tuberculosis.
- **Tuberculin test:** It is very valuable in children. A positive test in a previously non-sensitized/immunized child strongly indicates the disease. A negative test makes the diagnosis of tuberculosis very unlikely.
- **Chest radiograph:** Primary complex may appear as a peripheral parenchymal lung lesion and an enlarged hilar lymph node.
  - **In children:** Enlargement of (e.g. hilar) lymph node of the primary complex is more prominent than the pulmonary component.
  - **In adults:** Pulmonary component (peripheral parenchymal lesion) of the complex is more obvious than the lymph node component.
- **Bacteriological examination**
  - Sputum examination—for AFB is preferable.
  - Alternatively, three laryngeal swabs or fasting gastric washings can be examined.
  - Detection of the tubercle bacilli either in the direct smear or culture confirms the diagnosis.

## **Post-Primary (Secondary) Tuberculosis**

**Q. Describe the etiology, pathogenesis, pathology, clinical features, complications and diagnosis of post-primary tuberculosis/secondary tuberculosis.**

**(Synonyms: Post-primary tuberculosis, reactivation tuberculosis)**

- **Tuberculosis developing in a previously sensitized individual (by earlier**

exposure) is known as secondary tuberculosis.

- It may develop shortly or after many years following primary tuberculosis, when resistance host is reduced.

### ***Source of Infection***

- **Endogenous:** Most common source is **reactivation of a latent infection.**
  - Direct progression of a primary tuberculous lesion
  - Re-activation of a dormant primary lesion
  - Hematogenous spread to the lungs
- **Exogenous:** Rarely exogenous new infection (re-infection)

Any location may be involved in secondary tuberculosis, but the lungs are by far the most common site.

### ***Morphology***

#### *Gross*

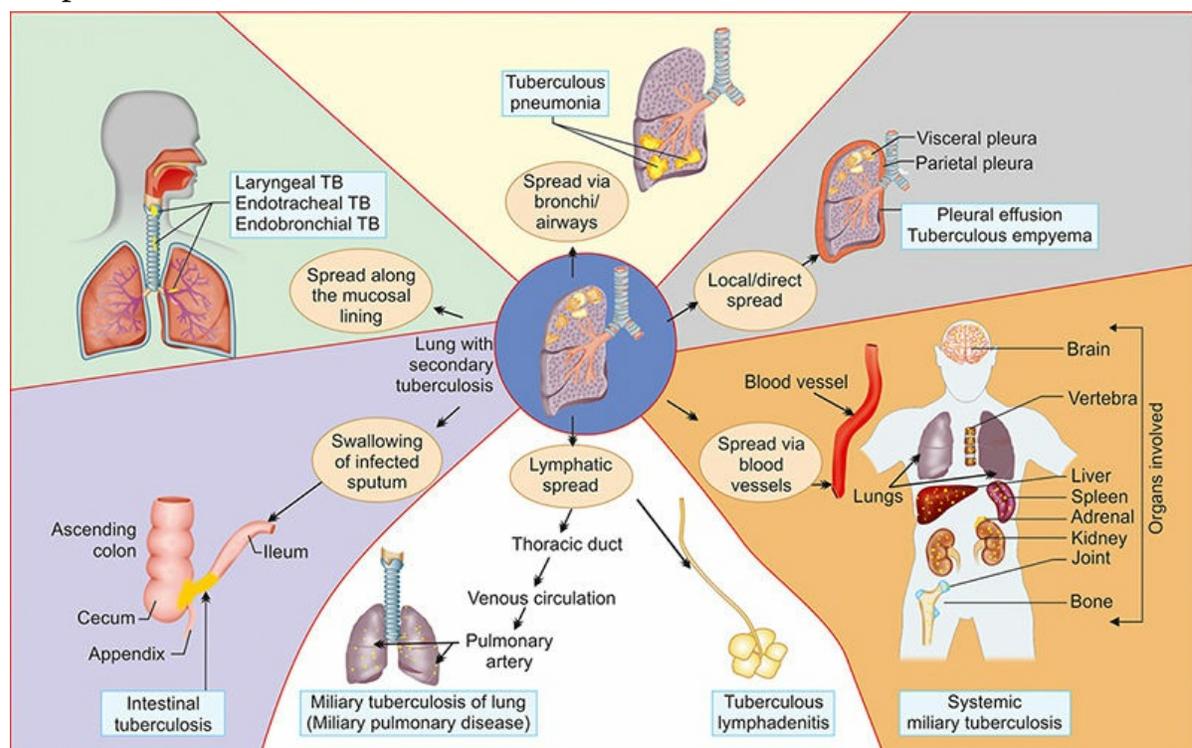

- **Site:** In the lungs, post-primary (secondary) tuberculosis usually involves the **apex of the upper lobes** of one or both lungs, **within 1 to 2 cm of the apical pleura.** It commonly involves apical and posterior segments of the upper lobe or apical segment of the lower lobe. This predilection may be due to good ventilation, decreased blood and lymphatic supply of these regions in the erect posture, and the oxygen tension that favors survival of the strictly aerobic tubercle bacilli.
- **Appearance: Initially small focus (less than 2 cm in diameter) of consolidation,** sharply circumscribed, firm, and **gray-white to yellow** in color. The central caseated liquefied material of a tuberculous primary lesion may be discharged into a bronchus and forms a tuberculous cavity in the lung.
- **Regional lymph nodes involvement is not as prominent as that seen in primary tuberculosis.**

### ***Fate of Secondary Tuberculosis (Fig. 6.16)***

**Healing:** In immunocompetent individuals, localized, apical, focus may **heal with fibrosis and calcification** rarely ossification.

**Progress:** It may occur along several different pathways.

- **Progressive pulmonary tuberculosis:** It occurs mainly in the elderly and immunosuppressed. Apical lesion may expand into surrounding lung and may erode into bronchi and vessels.
  - **Erosion into bronchi:** It leads to release of the central area of caseous necrosis → resulting in a ragged, irregular **apical cavity** surrounded by fibrous tissue. This produces an **important source of infection**, because when the patient coughs, sputum contains bacteria.
  - **Erosion of blood vessels:** It may result in hemoptysis.
- **Spread of infection:** If the treatment is inadequate or if host defenses are impaired, the infection may spread via: 1) airways, 2) lymphatics or 3) blood vessels.
  - **Local/direct spread:** Tuberculosis can directly spread to the surrounding tissue. In the lung local spread to the pleura may result in serous **pleural effusions**, **tuberculous empyema**, or **obliterative fibrous pleuritis**.
  - **Spread through bronchi/airways:** It may produce tuberculous pneumonia.

**Fig. 6.16:** Progress and complications of secondary tuberculosis of lung.

- **Spread along mucosal lining:** Spread through lymphatic channels or along the mucosal lining from mycobacteria present in the

expectorated infectious material may lead to **endobronchial, endotracheal, and laryngeal tuberculosis**. In the past, intestinal tuberculosis was due to drinking of contaminated unpasteurized milk. However, this is rare following pasteurization of milk. Nowadays caused by the **swallowing of coughed-up infective material** in patients with open case of advanced pulmonary tuberculosis. **Mainly develops in the ileum.**

- **Lymphatic spread:** Spread through lymphatic channels mainly reach regional lymph nodes. It may also cause disseminated disease.

**Miliary pulmonary disease:** It is the disseminated form of tuberculosis. If the dissemination only limited to the lungs, it is termed miliary pulmonary disease.

**Lymphadenitis:** It is most frequent presentation of extrapulmonary tuberculosis, and usually occurs in the cervical region ('scrofula').

- **Spread via blood vessels**

**Systemic miliary tuberculosis** occurs when tubercle bacilli disseminate through the systemic arterial system. Miliary tuberculosis most commonly involves liver, bone marrow, spleen, adrenals, meninges, kidneys, fallopian tubes, and epididymis. Tuberculosis can involve any organ *except nail, hair and enamel*.

**Isolated-organ tuberculosis:** Dissemination of tubercle bacilli through blood may seed any organ or tissue → resulting in isolated organ tuberculosis. Commonly involved organs are:

- Meninges (tuberculous meningitis)
- Kidneys (renal tuberculosis)
- Adrenals
- *Bones (osteomyelitis):* When it involves the vertebrae, the disease is referred to as **Pott's disease**. Paraspinal 'cold' abscesses may track along tissue planes and present as an abdominal or pelvic mass.
- Fallopian tubes (salpingitis)/orchitis.

## ***Clinical Features***

**Q. Write short note on clinical features of fibrocavitary tuberculosis.**

*Symptoms of pulmonary tuberculosis*

- Localized secondary tuberculosis may remain asymptomatic.
- Many patients are symptom free, and may be detected on routine radiography.
- Onset is usually insidious or gradual, with symptoms developing slowly over weeks or months.
- **Nonspecific:** Malaise, anorexia, loss of appetite and weight, tiredness.
- **Low-grade fever:** It is **remittent** (appearing late each afternoon and then subsiding—commonly known as **evening rise of temperature**), and **night sweats**.
- *Others:* Amenorrhea.

#### *Respiratory symptoms*

- **Chronic cough:** It is the most consistent symptom. If a patient has cough of more than 3 weeks, he/she should be investigated for pulmonary tuberculosis.
- **Hemoptysis:** It is a classical symptom. **Hemoptysis** is present in 50% of cases of pulmonary tuberculosis.
- **Sputum:** It may be mucoid, purulent or blood stained. Classical sputum is described as '**numular**'.
- **Pain in the chest:** Pain may be due to pleurisy, intercostals myalgia or cough fracture.
- **Unresolved pneumonia:** It may be another mode of presentation.
- **Breathlessness** may be a feature observed in advanced and extensive disease or due to pleural effusion.
- Localized wheeze may be observed due to local ulceration and narrowing of a major bronchus.
- Recurrent cold may be also a presenting symptom.
- Presentation due to complications: Very occasionally, it may present with one of the complications (Table 6.36).

#### *Physical signs*

- Fever, tachycardia and tachypnea.
- Pallor and cachexia may be seen in advanced stages of the disease.
- Clubbing of finger is unusual.

#### *Chest*

- Often there are no abnormal signs detected.
- **Fine crepitations:** Most common sign is fine crepitations in the upper part (apices) of one or both lungs. They are better heard particularly on taking a deep breath after coughing (**post-tussive crepitations**).
- Classical physical signs of consolidation (dullness to percussion), cavitation, fibrosis, bronchiectasis, pleural effusion or pneumothorax may be present.
- **Cavernous bronchial breathing** with **post-tussive suction** may be heard if there is a superficial collapsible cavity.
- There may be bronchial breathing in the upper part and localized wheeze due to local tuberculous bronchitis or pressure by a lymph node on a bronchus may be heard. In chronic tuberculosis when accompanied by fibrosis may show evidence of volume loss and mediastinal shift.

**Table 6.36:** Complications of pulmonary tuberculosis.

<b>Pulmonary</b>	<b>Non-pulmonary</b>
Exudative pleural effusion/empyema	Empyema necessitans
Spontaneous pneumothorax	Spread of tuberculosis to other organs (especially Addison's)
Massive hemoptysis pulmonary or bronchial arteritis and thrombosis, bronchial artery dilatation, and Rasmussen aneurysm)	Laryngitis
Cor pulmonale	<i>Following swallowing of infected sputum:</i>
Persistence of cavities even after treatment	• Enteritis
Pulmonary fibrosis/emphysema	• Anorectal disease
<i>Infection of cavities:</i>	Amyloidosis
• Atypical mycobacterial infection	Poncet's polyarthritis
• Aspergillus → aspergilloma	<b>Mediastinal lesions:</b> These include lymph node calcification and extranodal extension, esophagomediastinal or esophagobronchial fistula, constrictive pericarditis, and fibrosing mediastinitis
Lung/pleural calcification	Venous thromboembolism
Obstructive airways disease	
<b>Airway lesions:</b> These include bronchiectasis, tracheobronchial stenosis, and broncholithiasis	
Bronchopleural fistula	
Bronchogenic carcinoma	

**Extrapulmonary manifestations** depend on the organ/system involved.

Conditions/diseases that favor reactivation/reinfection of tuberculosis are presented in Table 6.37.

**Table 6.37:** Condition/diseases that favor reactivation/reinfection of tuberculosis.

Immunosuppression: HIV, anti-tumor necrosis factor (TNF) therapy, high-dose corticosteroids, cytotoxic agents  
Malnutrition  
Diabetes mellitus  
Hemophilia  
Chronic kidney disease

Silicosis  
Malignancies (e.g. lymphoma and leukemia)  
Gastrointestinal disease associated with malnutrition (gastrectomy, jejunioileal bypass, cancer of the pancreas, malabsorption)  
Deficiency of vitamin D or A

## Investigations

### **Q. Write short note on diagnosis, investigations of pulmonary tuberculosis.**

Presence of an unexplained cough for more than 2–3 weeks, particularly in regions where TB is prevalent, or typical chest X-ray changes, should prompt for further investigation.

#### *Blood examination*

- *Anemia*: Moderate degree
- *White cell count*: Usually normal or below normal
- *ESR*: Usually raised.
- *Other findings*:
  - *Serum electrolytes*: Hyponatremia and hyperkalemia may be observed in severe disease.
  - *Liver function tests*: Occasionally may be impaired.

#### *Radiological examination*

- For practical purposes, a normal chest radiograph excludes the diagnosis of pulmonary tuberculosis (Fig. 6.17).

**Fig. 6.17:** Chest X-ray of tuberculosis showing bilateral infiltrates and thin-walled cavities.

### ***Radiological Features of Pulmonary Tuberculosis (Table 6.38)***

**Q. Write short note on the radiological features of pulmonary tuberculosis.**

For all practical purposes, a normal chest radiograph excludes the diagnosis of pulmonary tuberculosis.

- **Radiological findings:** It shows ill-defined opacification in one or both of the upper lobes. As the disease progresses features of consolidation, collapse and cavitation develop to varying degrees (Fig. 6.18). It is often difficult to distinguish between active from quiescent form of tuberculosis on radiological criteria alone, but the presence of a miliary pattern or cavitation favors active disease.
- In extensive disease, collapse may cause significant displacement of the trachea and mediastinum. Occasionally, a caseous lymph node may drain into an adjoining bronchus, resulting in tuberculous pneumonia.
- *CT chest:* It may be useful in evaluating parenchymal and lymph node lesions. It may show **tree in bud appearance** (Fig. 6.18).
- $^{18}\text{F}$ -FDG PET scans and  $^{11}\text{C}$ -choline PET scans may be done in few

selected patients.

**Table 6.38:** Radiological features of tuberculosis of lung.

<i>Radiological shadows that strongly suggest tuberculosis</i>	<i>Radiological shadows that may be due to tuberculosis</i>
<ul style="list-style-type: none"><li>• Patchy or nodular shadows in the upper zone (on one or both sides)</li><li>• Cavitation (especially if more than one)</li><li>• Calcified lesion</li><li>• Pleural effusion/thickening</li></ul>	<ul style="list-style-type: none"><li>• Oval or round single shadow (tuberculoma)</li><li>• Hilar and mediastinal shadows (due to enlarged lymph nodes)</li><li>• Diffuse small nodular shadows (miliary tuberculosis)</li></ul>

### *Sputum examination*

- *Direct microscopic examination of sputum:* It remains the most important first step investigation in pulmonary TB. Three specimens of sputum should be examined and if two of these smears are positive, diagnosis of TB is certain.
  - *A first spot specimen:* Obtained when the patient presents himself.
  - *An early morning specimen:* When the patient returns with an early morning specimen.
  - *A second spot specimen:* When the patient returns with an early morning specimen.
- *Revised WHO definition of a new sputum smear-positive case of pulmonary tuberculosis:* Presence of at least one acid fast bacillus in at least one sputum sample in countries with a well-functioning external quality-assurance system. Presently, WHO recommends that the number of sputum specimens to be examined for screening of tuberculosis cases can be **reduced from three to two**, in places (i) where a well-functioning external quality-assurance system exists, (ii) where the workload is very high and (iii) human resources are scarce.
- *Stain:* Rapid identification of the presence of tubercle bacilli by immediate stains is essential and should be done within 24 hours. The most effective stains are the Ziehl–Neelsen and rhodamine–auramine. Auramine–rhodamine staining is more sensitive (though less specific) than Ziehl–Neelsen.

**Fig. 6.18:** Tree in bud appearance of tuberculosis on CT.

### *Culture of sputum*

- A **positive sputum smear is sufficient for the presumptive diagnosis of TB** but definitive diagnosis requires culture of tubercle bacillus. Smear-negative sputum should also be cultured.
- **Culture medias:** It may be
  - Liquid/broth culture (Middlebrook 7H12) or the non-radiometric mycobacteria growth indicator tube (MGIT): Faster growth (1–3 weeks) occurs in liquid media. *The BACTEC radiometric growth detection method detects mycobacterial growth by measuring the liberation of  $^{14}\text{CO}_2$ , following metabolism of  $^{14}\text{C}$ -labeled substrate present in the medium. The growth can be detected in 4–8 days.*
  - Solid media (Löwenstein–Jensen slopes): MTB grows slowly and may take between 4 and 6 weeks.
- **Drug sensitivity testing:** Should be done in selected cases. It is important in patients with a previous history of TB, treatment failure or chronic disease, and in those who are resident in or have visited an area of high

prevalence of resistance, or who are HIV-positive. Using liquid culture in the presence of antimycobacterial drugs (usually first line therapy initially) establishes the drug sensitivity for that strain and usually takes approximately 3 weeks).

- **Nucleic acid amplification (NAA) tests:** The **Amplified *Mycobacterium tuberculosis* Direct (MTD) test** and the **Gene Xpert MTB/RIF test**. NAA is more sensitive than smear but less sensitive than culture; as few as 1 to 10 organisms/mL may give a positive result. Resistance to rifampin can be detected by Xpert MTB/RIF or MTBDRplus, resistance to isoniazid can be detected by MTBDRplus.

#### *Other investigations*

- Laryngeal swab, early morning gastric lavage and bronchoalveolar lavage samples can be used for detecting AFB.
- **Tuberculin test:** It is used for diagnosis but is less valuable. However, this test may be negative in patients with active tuberculosis associated with malnutrition or other diseases. It may be positive in patients without active tuberculosis. Strongly positive test favors tuberculosis, where as a negative test does not exclude tuberculosis.

#### **Q. Write short note on newer methods of diagnosis of tuberculosis.**

- **Interferon gamma release assays (IGRAs)**
  - IGRAs are *in vitro* tests of cellular immunity. These assays measure cell-mediated immune response by quantifying interferon gamma (IFN $\gamma$ ) released by T cells in response to stimulation by *Mycobacterium tuberculosis* specific antigens. These specific antigens include early secretory antigenic target-6 (ESAT-6) and culture filtrate protein-10 (CFP10).
  - The test does not differentiate between active and latent infection. This test requires high cost and trained personnel.
- **Other methods of diagnosis**
  - **MGIT (Mycobacteria growth indicator tube) method:** In this method, growth is detected by a non-radioactive detection system using fluorochromes for detection and drug screening.
  - Identification by mycolic acids using high-pressure liquid chromatography.

- *ELISA testing for IgM and IgA*: It is commonly used but has low specificity.
- Mycobacterial-specific phages (reporter phages) to detect luciferase gene. It can be used to detect drug-resistant isolates.

## Causes of Hemoptysis in Pulmonary Tuberculosis

**Q. List the causes of hemoptysis in pulmonary tuberculosis.**

- **Hemoptysis from a pulmonary cavity**
  - **Rasmussen’s aneurysm**: Blood vessels traversing a tuberculous cavity can undergo changes due to inflammatory and necrosis. Over a period of time these vessels may develop aneurysmal dilatation (Rasmussen’s aneurysm). These aneurysms may rupture resulting in hemoptysis.
  - **Allergic response of vessel**: Occasionally, intense allergic response to antigens of tubercle bacilli can damage the walls of the blood vessels in and around the tuberculous cavities leading to hemoptysis.
- **Hemoptysis from endobronchial tuberculosis**
  - **Tuberculosis of endobronchial region** may be surrounded by vessels with small aneurysmal dilatation. Rupture of these aneurysms can produce hemoptysis.
  - Occasionally, sloughing of the part of the granuloma may result in hemoptysis.
- **Hemoptysis as a sequel of pulmonary tuberculosis**
  - **Open-healed cavities**: A tuberculous cavity may persist as a sequelae following chemotherapy which are designated as ‘open-healed cavities’/INH cysts. The aneurysmal dilations of vessels may also persist in these open-healed cavities which can rupture producing hemoptysis.
  - **Post-tuberculous bronchiectasis**: The upper lobe bronchiectasis is common sequelae of pulmonary tuberculosis. This may be characterized by repeated attacks of hemoptysis without sputum production (bronchiectasis sicca or dry bronchiectasis).
  - **Broncholith**: Calcification in a primary/Gohn focus or lymph node may be extruded into a bronchus as a ‘broncholith’ and can cause hemoptysis. Hemoptysis may also results from the broncholith eroding through blood vessels.
  - **Aspergilloma**: Treated and healed tuberculous cavities may sometimes remain open and can be infected by the fungus *Aspergillus fumigates*. This may produce a fungal ball (aspergilloma) in the cavity and can present as severe hemoptysis.
- Hemoptysis due to scar carcinoma.

## Tuberculin Skin Test

**Q. Write a short note on tuberculin test/Mantoux test?**

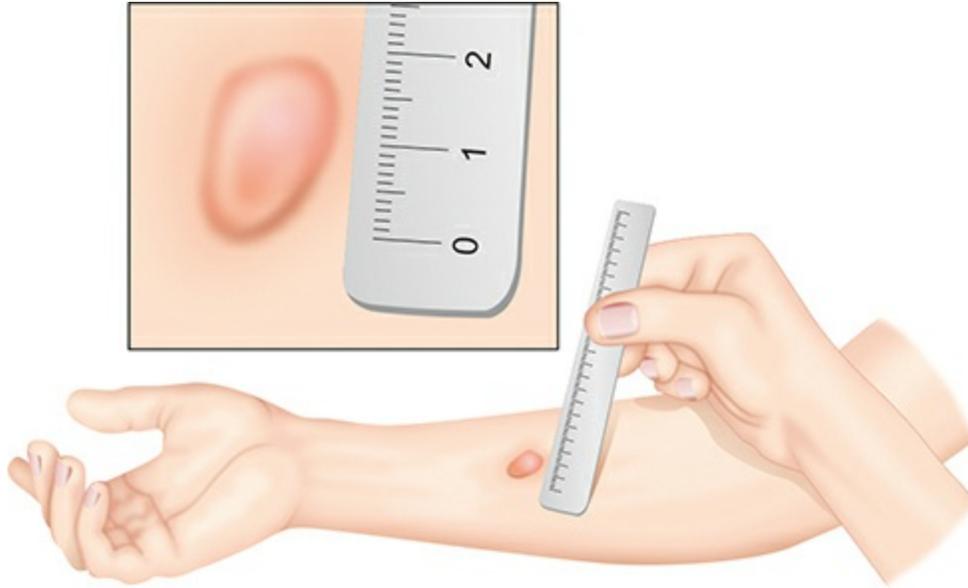

First infection with mycobacteria leads to development of delayed hypersensitivity to *M. tuberculosis* antigens (tuberculin) and this is detected by the tuberculin skin test.

**Tuberculins**: There are two commonly used tuberculins in present use:

1. PPD-S has been adopted as the international standard for PPD of mammalian tuberculin.

2. PPD-RT23 is widely used in epidemiological studies throughout the world.

**Mantoux test (Fig. 6.19):** It is ideal to begin the test with 5 IU PPD-S or 1 or 2 IU PPD-RT23.

**Fig. 6.19:** Mantoux test.

### ***Method***

- Select an area of skin at the junction of the mid and upper thirds of flexure surface of the left forearm.
- Skin is cleaned with soap and water and allowed to dry.
- Using a tuberculin syringe and an intradermal needle, inject 0.1 mL of the tuberculin solution strictly intradermally. It should result in papule in the skin measuring 5–6 mm in diameter.

### ***Reading and Interpreting the Result***

- The test is read after 48–72 hours.
- If a reaction has taken place, there will be an area of erythema (redness) and an area of induration (thickening) of the skin. Measure the diameter of induration across the transverse axis of the arm. The reaction is considered positive if an area of **induration** of the skin of **10 mm diameter or more** at the site of injection of PPD. The amount of erythema (redness) present is not important. Induration  $\geq 5$  mm is considered as positive in patients with HIV infection (or risk factors for HIV infection, but unknown status),

recent close contact to person with known active TB, patients with chest X-ray consistent with prior TB, patients with organ transplants and other immunosuppressed patient.

## **Significance**

- **Positive tuberculin test:** Indicates T-cell-mediated immunity to mycobacterial antigens. A strongly positive test is particularly valuable in children, especially very young children and favors the diagnosis of tuberculosis.
- **False-negative reactions:** If the diameter of induration is below 10 mm, the test is considered negative. But a negative test does not exclude tuberculosis. It is seen in certain viral infections, sarcoidosis, malnutrition, Hodgkin lymphoma, immunosuppression, and overwhelming active tuberculous disease, HIV infection, measles, chickenpox, glandular fever (infectious mononucleosis), cancer, corticosteroids and similar drugs.
- **False-positive reactions:** It seen in infection by **atypical mycobacteria** or prior **vaccination with BCG** (*Bacillus Calmette-Guerin*) or lymphoma. Most infants immunized with BCG at birth have a negative tuberculin test by 1–2 years. In infants immunized after 1 year, the tuberculin reaction often remains positive for some years. It may also be positive in NTM infections.

## **Latent Tuberculosis**

### **Q. Describe latent tuberculosis infection (LTBI).**

- In the majority of individuals infected by *Mycobacterium tuberculosis*, the immune system contains the infection and the patient develops cell mediated immune memory to the bacteria. These individuals do not currently have active tuberculosis disease. This is termed latent tuberculosis.
- Individuals with latent tuberculosis are at risk of progression to active tuberculosis. About 5–10% is the lifetime risk of progression. The increased risk of progression from latent tuberculosis to active tuberculosis is during the first two years after infection. Groups of individuals at high-risk of tuberculosis infection are listed in Table 6.39.

Groups at increased risk of progression to active tuberculosis are listed in Table 6.40.

### Table 6.39: Groups of individuals at high-risk of tuberculosis infection.

- Employees working at long-term care facilities, hospitals and medical laboratories
- Individuals having close contact with patients with active tuberculosis
- Residents and employees of congregate living facilities (e.g. prison and jails, nursing homes, hospitals and homeless shelters)
- Medically underserved low income populations

### Table 6.40: Groups at increased risk of progression to active tuberculosis.

- Children younger than 5 years of age
- History of tuberculous infection
  - Individuals infected with *Mycobacterium tuberculosis* within the past two years
  - Past history of untreated or inadequately treated tuberculosis
- Associated conditions
  - Individuals with HIV infection
  - Silicosis
  - I V drug users
  - Immunocompromised conditions
  - Long-term use of corticosteroids or other immunosuppressants (including anti-TNF- $\alpha$ )
  - Chronic renal failure
  - Diabetes mellitus
  - Malignancy

### ***Screening for Latent Tuberculosis***

- Tuberculin skin test
- T-cell IGRAs.

## ***Prophylaxis (to Prevent Development of Active Tuberculosis)***

Refer tuberculosis prophylaxis on page 301.

## **ANTITUBERCULOUS DRUGS (ATDs)**

**Q. Write short note on the terms ‘bactericidal action’ and ‘sterilizing action’ in relation to antituberculous drugs.**

- **Bactericidal action:** It is the capacity of antituberculous drugs to rapidly kill large numbers of actively metabolizing bacilli. Most of the antituberculous drugs (except thiacetazone and PAS) are bactericidal. Isoniazid is the most potent bactericidal. Ethambutol is bacteriostatic at low doses and bactericidal at high doses.
- **Sterilizing action:** It is the capacity of antituberculous drugs to kill special populations of slowly or intermittently metabolizing semi-dormant bacilli (so-called ‘persisters’), e.g. rifampicin and pyrazinamide.

**Q. Write short essay/note on:**

- **Management of pulmonary tuberculosis, antituberculous drugs and their dosages in adults.**
- **List the first and second line antituberculous drugs. Explain the rationale for using a multidrug regime.**
- **Bactericidal drugs used in the treatment of tuberculosis.**

## **Classification of Antituberculous Drugs (Table 6.41)**

### **First Line Antituberculous Drugs**

**Q. Write short note on:**

- **First line antituberculous drugs.**
- **Modes of action of first line drugs.**

#### **1. Isoniazid (INH)**

It is primarily tuberculocidal drug.

**Mechanism of action:** Inhibition of mycolic acid cell wall synthesis via O<sub>2</sub> dependent pathways (e.g. catalase-peroxidase reaction). Bactericidal against rapidly multiplying and bacteriostatic against resting bacilli.

**Active against both extracellular and intracellular organisms.**  
Resistance occurs spontaneously in 1 in  $10^5$  bacilli.

**Pharmacokinetics:**

- Excreted in urine: Decrease dose if creatinine clearance  $<30$  mL/minute.
- Slow vs. rapid acetylators ( $t_{1/2}$ )

**Table 6.41: Classification of antitubercular drugs.**

<b>First line antituberculous drugs</b>	
<ul style="list-style-type: none"> <li>• Isoniazid (H)</li> <li>• Rifampin (R)</li> <li>• Pyrazinamide (Z)</li> </ul>	<ul style="list-style-type: none"> <li>• Ethambutol (E)</li> <li>• Streptomycin (S)</li> </ul>
<b>Second line antitubercular drugs</b>	
<ul style="list-style-type: none"> <li>• Thiacetazone (Tzn)</li> <li>• Paraaminosalicylic acid (PAS)</li> <li>• Ethionamide (Etm)</li> <li>• Cycloserine (Cys)</li> <li>• Kanamycin (Kmc)</li> <li>• Amikacin (Am)</li> <li>• Capreomycin (Cpr)</li> </ul>	<ul style="list-style-type: none"> <li>• Newer antitubercular drugs</li> <li>• Ciprofloxacin</li> <li>• Ofloxacin</li> <li>• Moxifloxacin</li> <li>• Clarithromycin</li> <li>• Azithromycin</li> <li>• Rifabutin</li> </ul>

**Q. Write short note on toxic effects of INH.**

**Adverse effects:**

- Peripheral neuropathy:** Commoner in slow acetylators, diabetics, alcoholics, malnourished patients
  - Prevention: Pyridoxine 10 mg/day.
  - INH neurotoxicity is treated by pyridoxine 100 mg/day. Convulsions should be treated by IV pyridoxine 100 mg.
  - *Other TB-related drugs that cause peripheral neuropathy: Pyridoxine, ethambutol and cycloserine.*
- Hepatitis**
  - Increased risk: Age  $>35$  years, alcohol abuse, rapid acetylators, co-administration of rifampin, pyrazinamide, HIV infection, chronic hepatitis B, pregnant females, immediate postpartum (3 months).
  - Dose related and is reversible on stopping the drug.

cc. **Others:** Idiosyncratic reactions, SLE, gynecomastia acne, rash, anemia psychosis, memory impairment, optic neuritis (atrophy).

## 2. Rifampicin

Semisynthetic derivative of rifamycin B obtained from *Streptomyces mediterranei*.

**Mechanism of action:** Inhibition DNA-dependent RNA synthesis.  
**Bactericidal against both extracellular and intercellular organisms.**

**Adverse effects Patients have discolored (orange) body secretions,** hepatitis, thrombocytopenic purpura, respiratory syndrome, shock, renal failure (azotemia). Minor effects are:

- **Cutaneous (red man) syndrome:** Flushing, pruritis, rash (especially face and scalp). Exfoliative dermatitis is more frequent in HIV-positive TB patients
- **Influenza-like (Flu) syndrome**
- **Abdominal syndrome:** Pseudomembranous colitis (especially rifabutin).

### Newer rifampicin-related antitubercular agents

**Q. Write short essay/note on newer rifampicin-related antitubercular agents.**

#### Rifabutin

- **Actions:** It is related to rifampin. Active against rifampicin-resistant *M.tuberculosis*; more active than rifampicin against *M. avium* intracellulare complex/NTM; longer t<sub>1/2</sub>; extent of absorption unchanged with food; recommended instead of rifampicin in patients on pulmonary infections.
- **Dose:** It is recommended for tuberculosis in HIV-infected patients who are on protease inhibitors. Dose is 150 mg/day.
- **Adverse effects:** GI distress, rash, myalgias and insomnia, Flu-like syndrome, anterior uveitis, leukopenia, skin discoloration and hepatitis. Patients also have discolored (orange) body secretions.

#### Rifapentine

- **Features:** It is lipophilic and has longer duration of action. Mycobacteria resistant to rifampicin are also resistance to this drug. May be used in the treatment of pulmonary tuberculosis in place of rifampicin. Higher likelihood of relapse, but lower risk of adverse effects and less frequent administration than with rifampicin
- **Dose:** 600 mg once or twice a week
- **Side effects:** Similar to rifampicin.

**Q. Write short essay/note on uses of rifampin.**

Uses of rifampin is listed in Box 6.6.

**Box 6.6:** Uses of rifampin.

- Tuberculosis
- Leprosy
- Prophylaxis of *meningococcal* and *H. influenza meningitis* and carrier state
- Second or third choice of drug for MRSA, diphtheroids and *Legionella* infections
- Combination of doxycycline and rifampin as first line drugs in Brucellosis

### 3. Pyrazinamide

- Chemically similar to INH.
- **Mechanism of action:** Inhibition of mycolic acid cell wall synthesis and resembles INH. Bactericidal to slowly metabolizing bacilli in phagosome/granuloma. Most effective in acidic pH (<6.0).
- **Adverse effects**
  - Hepatotoxicity: Dose dependent
  - Arthralgias, polyarthralgias (especially shoulders) are common. Arthralgias are not related to the serum uric acid level.
  - Hyperuricemia is common due to inhibition of uric acid secretion by kidney. Development of new-onset gout is rare, but pre-existing gout may be exacerbated.

### 4. Ethambutol

**Q. Write short essay/note on ethambutol.**

- **Mechanism of action (MOA):** Inhibits arabinose (arabinosyl transferase) involved in arabinogalactan synthesis. Bacteriostatic.
- Excreted in urine (Dose reduction required for patients with creatinine clearance < 50 mL/min).

#### **Adverse effects**

- Retrobulbar neuritis:** Dose-dependent. Usually occurs after many months of treatment. Manifests with reduced visual acuity, central scotoma, disturbance of *red-green* discrimination (loss of ability to see green). Permanent blindness may develop if not discontinued.
- Others:** Hyperuricemia, peripheral sensory neuropathy.

### 5. Streptomycin

- It is an aminoglycoside, bactericidal antibiotic derived from *Streptomyces griseus*.

### Adverse effects

- a. **Ototoxicity, cochlear and vestibular damage, deafness and neuromuscular blockage:** Dosage should be reduced if headache, vomiting, vertigo and tinnitus occur. Avoid in young children.
- b. **Renal damage-nephrotoxicity** (non oliguric renal failure): Dosage must be reduced by half immediately if (1) urinary output falls, (2) if albuminuria occurs or (3) if tubular casts are detected in the urine.
- c. **Others:** Rare and include hemolytic anemia, aplastic anemia, agranulocytosis, thrombocytopenia and lupoid reactions.

### Mode of Action of First-Line Antituberculous Drugs

In a tuberculous lesion (particularly in a cavitory lesion), mycobacteria exist in several foci (Table 6.42).

**Table 6.42:** Tuberculous foci and the drugs acting on them.

<i>Tuberculous foci</i>	<i>Drugs acting on them</i>
Extracellular, in alkaline medium	Streptomycin
Rapidly metabolizing mycobacteria (in a cavity)	Rifampicin
Less actively multiplying bacilli in acidic and closed lesions	Isoniazid
Dormant bacilli (that cause a relapse)	Pyrazinamide

### Second Line Antituberculous Drugs

**Q. Write short note on second line antituberculous drugs.**

- **Ethionamide:** Structurally related to INH and acts by inhibiting the mycolic acid synthesis. It is effective against bacilli resistant to other drugs and are effective in infections due to atypical mycobacteria. It is effective against both intracellular and extracellular organisms.
- **Cycloserine:** Mainly bacteriostatic and acts by inhibiting the synthesis of the bacterial cell wall. It is effective against bacilli resistant to INH or streptomycin and against atypical mycobacteria. Antitubercular activity is less than that of these two drugs.
- **Fluroquinolones:** Ciprofloxacin, ofloxacin, levofloxacin, moxifloxacin and gatifloxacin are active against *M. tuberculosis*, even in cases resistant to other drugs. Given orally or IV. Useful in treating infections resistant to

standard drugs and in relapse cases.

- **Capreomycin:** It is bactericidal and its mechanism of action, pharmacokinetics and adverse reactions are similar to those of streptomycin. Administer with caution in presence of renal impairment.
- **Kanamycin and amikacin:** Both are bactericidal and are active against bacilli resistant to streptomycin, INH and cycloserine.
- **Macrolides:** Newer macrolides azithromycin and clarithromycin also have action against tubercular bacilli. They are used to treat typical mycobacterial infection as well as in relapse cases.

### ***Newer Antituberculous Drugs***

- **$\beta$ -lactams** (imipenem, amoxicillin-clavulanic acid), linezolid, clofazimine, clarithromycin, dapson and metronidazole have been used rarely for the treatment of multidrug resistant (MDR) tuberculosis. However, their roles are not well established.
- **Bedaquiline:** It is a diarylquinoline class of antibiotics that selectively targets the proton pump of ATP synthesis, leading to inadequate ATP synthesis (necessary for bacterial metabolism). It is a new drug used for MDR tuberculosis.
- **Delamanid and pretomanid:** These are nitroimidazole class of antibiotics that inhibit the synthesis of mycolic acids (components of the cell envelope of *M. tuberculosis*). It is still on clinical trials.
- **Sutezolid:** It is oxazolidinone class of antibiotics. It prevents the initiation of protein synthesis by binding to 23s RNA in the 50s ribosomal subunit of bacteria.
- **SQ109**, a 1,2-ethylenediamine: It is an analogue of ethambutol.
- **Benzothiazinones:** They inhibit the synthesis of decaprenyl-phospho-arabinose (the precursor of the arabinans) in the mycobacterial cell wall.

### **Side Effects of the Commonly Used Antituberculous Drugs (Table 6.43)**

**Q. Write short notes on side effects of the commonly used antituberculous drugs/rifampicin/INH/ethambutol/streptomycin.**

**Table 6.43:** Side effects of the commonly used antituberculous drugs.

<b>Drug (daily dosages)</b>	<b>Adverse reactions</b>	
	<b>Major</b>	<b>Less common (rare)</b>
Isoniazid (H) ( 5–10 mg/kg)	Hepatitis Peripheral neuropathy (preventable and treatable with pyridoxine) Cutaneous hypersensitivity	Giddiness, seizures, optic neuritis, mental symptoms, hemolytic anemia, aplastic anemia, agranulocytosis, lupoid reactions, arthralgia, gynecomastia
Rifampicin (R) (10 mg/kg)	Febrile reactions (‘flu’ syndrome; more common with intermittent therapy), hepatitis, cutaneous reactions, gastrointestinal disturbances	Shortness of breath, shock, hemolytic anemia, interstitial nephritis, thrombocytopenia
Pyrazinamide (Z) (20 mg/kg)	Anorexia, nausea, flushing, hepatitis, gastrointestinal disturbance, hyperuricemia	Hepatitis (dose related), vomiting, arthralgia, cutaneous hypersensitivity, gout
Ethambutol (E) (15 mg/kg)	Retrolbulbar neuritis (dose related), arthralgia	Peripheral neuropathy, rash
Streptomycin (S) and other aminoglycosides (15–20 mg/kg)	8th nerve damage, cutaneous hypersensitivity, giddiness, numbness, tinnitus	Vertigo, ataxia, deafness, hypokalemia, renal damage, aplastic anemia, agranulocytosis
Ethionamide (Etm) (10–20 mg/kg)	Anorexia, vomiting	Serious neurologic reactions, hepatitis
Cycloserine (Cys) (10–20 mg/kg)	Headache, somnolence	Psychosis, seizures, peripheral neuropathy
Quinolones (7.5–15 mg/kg)	GI intolerance, skin rashes	Phototoxicity (with sparfloxacin), dizziness, headache, insomnia
Thiacetazone (Tzn) (2.5 mg/kg)	Gastrointestinal reactions, cutaneous hypersensitivity, vertigo, conjunctivitis	Hepatitis, erythema multiforme, exfoliative dermatitis, hemolytic anemia
Paraaminosalicylic acid (PAS) (8–12 g/day)	Gastrointestinal reactions, hepatitis, cutaneous hypersensitivity, hypokalemia	Acute renal failure, hemolytic anemia, thrombocytopenia, hypothyroidism

## Antituberculous Chemotherapy

**Q.** Write short essay/note on:

- **Short-course chemotherapy and its advantages.**
- **Discuss regimen of antituberculous chemotherapy.**

Global targets of detecting 70% of infectious cases and curing 85% of those detected. Goals of antituberculous drug therapy is listed in Box 6.7.

**Box 6.7:** Goals of antituberculous therapy.

1. Kill the dividing bacilli
2. Kill the persisting bacilli
3. Prevent emergence of resistance

## **Short-Course Chemotherapy**

- Short-course chemotherapy (SCC) is regimens of 6 to 9 months duration which are highly effective and widely accepted as the treatment of choice for tuberculosis.
- All the short course regimens have two phases: An initial intensive (bactericidal) phase and a continuation (sterilizing) phase.
  - **Initial phase:** Lasts for 2 to 3 months and aimed to rapidly kill majority of mycobacteria. The symptoms resolve, sputum becomes negative and the patient becomes non-infectious.
  - **Continuation phase:** It lasts for 4 to 6 months during which the remaining bacilli are eliminated so that relapse does not occur.

Advantages of short course of chemotherapy is mentioned in Box 6.8.

### **Box 6.8:** Advantages of short course chemotherapy.

- Easy to take and produces minimal upsets in the patients.
- Patient will be better more quickly.
- Sputum becomes negative more quickly. About 85% at 2 months.
- Low relapse rate. Even if relapse occurs, the tubercle bacilli remain sensitive and the same treatment can be given repeated.

## **WHO (2009) Definitions**

- **New case:** A patient who has never had been treated for TB or not had anti-TB drugs for less than one month. New case may have positive or negative bacteriology and may have tuberculosis at any anatomical site.
- **Previously treated case:** It is defined as a newly registered episode of TB in a patient who has received one month or more of anti-TB drugs in the past. A culture and drug sensitivity test should be done before starting treatment. It is also referred to as 'retreatment cases' and forms a heterogeneous group composed of several subcategories:
  - **Relapse:** A patient who has been previously treated for TB and was declared cured and is now been diagnosed bacteriologically positive tuberculous case (either a true relapse or a new episode of TB caused by reinfection).
- **Treatment after failure:** A patient who have been previously treated for TB and whose treatment failed at the end of course of treatment. The sputum smear or culture is positive at 5 months or later during treatment. This includes patients who have a multidrug-resistance strain at any point of time during the treatment.
- **Treatment after loss to follow-up** patients have previously been treated for TB and were declared

lost to follow-up at the end of their most recent course of treatment (previously known as treatment after default patients) and now has bacteriologically positive tuberculosis.

- **Treatment after default:** A patient who returns to treatment with positive bacteriology, following interruption of treatment for two months or more.
- **Other:** All cases which does not fit the above definitions. It includes patients who are sputum smear-positive at the end of a re-treatment regimen (previously defined as chronic cases) and who may be resistant to the first-line drugs.

## Categories of Diagnosis and Treatment

Treatment regimen for tuberculosis is presented in Table 6.44.

**Table 6.44:** Treatment regimen for tuberculosis.

<b>A. DOTS (Directly observed treatment, short course)</b>	<b>Regimen</b>
<b>1. New (Category 1)</b>	
<b>Earlier CATEGORY I</b> New smear-positive patients New smear negative pulmonary TB with extensive parenchymal invasion Severe concomitant HIV disease; or New cases of severe forms of extrapulmonary TB <b>Earlier CATEGORY III</b> New cases of smear negative pulmonary TB with limited parenchymal involvement Less severe forms of extrapulmonary TB	2 months (HRZE) + 4 months (HRE) <b>Duration: 6 months</b>
<b>2. Previously Treated (Category 2)</b>	
<b>Earlier CATEGORY II</b> includes previously treated sputum smear-positive pulmonary TB: Relapse Treatment after interruption Treatment failure	2 months (HRZES) followed by 1 month (HRZE), followed by 5 months (HRE) <b>Duration: 8 months</b>
<b>B. DOTS PLUS</b>	
<b>1. Earlier CATEGORY IV</b> Includes MDR and chronic TB cases (still sputum-positive after supervised retreatment)	6–9 months (KM LVX, ETO CS, Z, E) followed by 18 months (LVX, ETO, CS, E) <b>Duration: 24–27 months</b>
<b>2. Earlier CATEGORY V</b> Extensively Drug Resistant TB (XDR TB)	6–12 months intensive phase followed by 18 months continuation phase (Capreomycin, PAS, Moxifloxacin, Clofazamine, Linezolid, Amoxicillin/clavulnate, Clarithromycin, Thiacetazone) <b>Duration: 24–30 months</b>
<b>C. NON DOTS</b>	
Rare TB patients may need non-rifampicin and non-pyrazinamide regimen	2 SHE + 10 HE OR 12 HE

Note: Since 2017 the thrice weekly regimen has been changed daily regimen.

(H: isoniazid; R: rifampin; Z: pyrazinamide; E: ethambutol; S: streptomycin; KM: kanamycin; LVX: levofloxacin; ETO: etionamide; CS: cyclosporine; PLHIV: people living with HIV)

## Severe Tuberculosis

- **Miliary, disseminated TB** is considered to be severe.
- **Forms of extrapulmonary tuberculosis (EPTB)** classified as severe include: Meningeal, pericardial, peritoneal, bilateral or extensive pleural effusive, spinal, intestinal, genitourinary.

**Less severe:** Lymph node, pleural effusion (unilateral), bone (excluding spine), peripheral joint and skin tuberculosis.

## Directly Observed Treatment, Short Course

**Q. Write short essay/note on directly observed treatment, short course (DOTS) in tuberculosis.**

- Directly observed treatment, short course is an **intermittent method** of administering potent antituberculous regimens to a patient with tuberculosis **under direct supervision**.
- Daily chemotherapy is excellent. However, it is expensive and not possible to supervise therapy and hence compliance rate is low and relapse rate is high.
- **DOTS is a five point program** (WHO) which can effectively control TB.
  1. Political and administrative support.
  2. Diagnosis in patients attending health facilities is by microscopic examination of sputum.
  3. Good antituberculous drugs are given for short course.
  4. Directly observed treatment which is easily accessible, acceptable and accountable.
  5. Systematic monitoring and accountability.

## Monitoring the Treatment and Treatment Results

**Q. Write short essay/note on monitoring the progress of treatment and the assessment of treatment result.**

Main method of monitoring is bacteriological examination. Other methods include radiological assessment, ESR and body weight changes.

- **Bacteriological examination**

Bacteriological assessment can be made by examining sputum smear and sputum culture.

a. **Serial sputum smearM examinations:** Helps to assess the progress and ultimate result.

– Sputum smear microscopy should be **performed at completion of the intensive phase** of treatment.

– **New patients:**

◆ **If sputum smear is positive at the end of the intensive phase (2 months), repeat the sputum smear at the end of the third month.**

◆ **If the smear is positive at the end of 3 months,** perform sputum culture and drug susceptibility testing (DST).

– **Previously treated patients:**

◆ If the smear is positive at the end of the intensive phase (3 months), perform sputum culture and DST.

– **Favorable response:** If sputum bacillary count steadily decreases. In most patients, sputum will be negative in 1 month and almost all in 2 months and all in 3 months. However, sputum culture may be positive for another 1 or 2 months. Finally, both smears and cultures will be negative.

– **Indications of treatment failure:**

◆ Persistence of bacilli (no response)

◆ **Fall and rise phenomenon:** Initial decline followed by a steady rise in sputum positivity

◆ Relapse: Initial decline and sputum negativity, followed much later by sputum positivity.

b. **Culture:** Confirms the diagnosis and is indicated only in selected cases.

• **Radiological assessment** by chest radiographs: Serial radiographs can assess progress and determine final result. Improvement in the serial radiographs is a favorable response. However, radiological assessment may be misleading many times and radiological improvement may be associated with persistence of tubercle bacilli in the sputum.

• **Erythrocyte sedimentation rate (ESR):** It is not a very satisfactory method of assessing the progress or activity of disease. However, a reduction in ESR can be a favorable response.

- **Body weight changes** are also not very reliable. However, a body weight gain may be a favorable response.

## Drug-Resistant TB

**Q. Write short essay/note on forms of drug resistances encountered during antituberculous chemotherapy.**

**Definition: Drug-resistant TB** is defined by the **presence of resistance to any firstline antituberculous drug/agent.**

Diagnosis is challenging (especially in developing countries) and although cure may be possible, it needs prolonged treatment with less effective, more toxic and more expensive drugs.

- **Primary drug resistance and initial drug resistance**
  - **Primary drug resistance**
    - ◆ It develops in **patients who have not received any antituberculous chemotherapy before or received it for less than 1 month.**
    - ◆ **Cause: Infection by drug resistant organism** from another patient with secondary resistance due to inadequate chemotherapy.
  - **Initial drug resistance:** When it is impossible to obtain a reliable history of previous chemotherapy from a new drug resistant patient, it is better to term it has initial drug resistance. This covers both true primary and undisclosed acquired resistance.
- **Secondary or acquired drug resistance: Resistance to one or more antituberculous drugs,** usually due to incorrect chemotherapy.
- **Natural drug resistance:** Mycobacterial strains which have never been exposed to any antibacterial drug are called ‘wild strains’. Thus, natural drug resistant strain is a wild strain resistant to a particular drug without ever having any contact with it. Thus, neither the patient with naturally resistant bacilli nor his source of infection has had chemotherapy in the past.
- **Transient drug resistance:** A positive culture of bacilli may be resistant to one or more (rarely two) drugs of a regimen during the course of successful chemotherapy. This may be due to resistant organisms for unknown reasons outlived the sensitive part of the bacterial population. Transient resistance does not need any change of treatment, since it does

not results in treatment failure.

**Q. Write short essay on multidrug-resistant (MDR) tuberculosis, its diagnosis and management.**

- **Multiple drug resistance or multidrug resistant TB**
  - Multidrug resistant tuberculosis (MDR-TB) is a form of TB that is **resistance to at least both of INH and rifampicin**, with or without other drug resistance. Hence, a patient should not be classified as multidrug resistant disease if the patient has an infection with a bacterium susceptible to rifampicin but resistant to many other drugs.
  - MDR-TB can rarely be observed in new cases. It is more common in individuals in re-treatment cases (prior history of TB, particularly if treatment has been inadequate, and those with HIV infection). It is a man-made phenomenon
  - Chronic cases and MDR-TB cases are not synonymous. Chronic patients probably have MDR-TB because they have previously received at least two full courses of treatment with essential antituberculous drugs.
- **Extensive drug resistance TB (XDR-TB)**
  - Extensively drug resistance TB is a form of TB that is resistant to at least four of the core anti-TB drugs. These drugs include most important (core) anti-TB drugs, (1) isoniazid and (2) rifampicin and (3) injectable second-line aminoglycoside drugs (amikacin, capreomycin or kanamycin) + (4) fluoroquinolone (such as ofloxacin or moxifloxacin).
- **Totally drug resistant TB or (Extremely XXDR, TDR)**
  - Totally drug resistant tuberculosis (TDR-TB) is a form of TB strains that shows in-vitro resistance to all first and second line drugs tested (isoniazid, rifampicin, streptomycin, ethambutol, pyrazinamide, ethionamide, para-aminosalicylic acid, cycloserine, ofloxacin, amikacin, ciprofloxacin, capreomycin, kanamycin).
  - First reported in 2003 from Italy. In early January 2012, twelve cases had been diagnosed in Mumbai and all cases the strain of TB was resistant to all first and second line antitubercular drugs.

Factors contributing to the emergence of drug-resistant TB are listed in Table 6.45.

**Table 6.45: Factors contributing to the emergence of drug-resistant TB.**

- |  |  |
|--|--|
| <ul style="list-style-type: none"><li>• Drug shortages</li><li>• Use of poor-quality drugs</li><li>• Inadequate treatment regimen</li><li>• Inadequate supervision of therapy</li><li>• Poor absorption of drugs</li><li>• Development of adverse drug reactions</li><li>• Inadequate duration of treatment</li><li>• Infection due to organisms with primary resistance</li></ul> | <ul style="list-style-type: none"><li>• Transmission of drug-resistant strains</li><li>• Prior antituberculosis treatment</li><li>• Treatment failure (smear-positive at 5 months)</li><li>• Lack of good laboratory facilities to monitor drug susceptibility</li><li>• Genetic factors</li></ul> |
|--|--|

**Q. Write short essay/note on common causes of drug resistance.**

### ***Suspicion of Drug Resistant TB***

- A close contact of drug resistant TB case
- All retreatment cases
- Extensive disease at start of treatment
- Extrapulmonary TB not responding to standard ATT regime.
- Treatment failures
- No sputum conversion after initial 2 months of ATT
- All HIV patients with TB

## **Drug Susceptibility Testing (DST)**

**Q. Write short essay/note on various methods for performing drug susceptibility tests for *M. tuberculosis*.**

WHO recommends DST for first-line and second-line anti-TB drugs to detect MDR-TB and XDR-TB respectively. Various methods of DST are:

- **Lowenstein Jensen (L-J) culture:** For drug sensitivity testing, it takes 6–8 weeks time.
- **Radiometric methods (BACTEC radiometric method):** Results obtained within 10 days of inoculation.
- **Mycobacteria growth indicator tube (MGIT) system:** Rapid, non-radioactive method.
- **Nitrate reduction assays:** Based on the capacity of *M.tuberculosis* to reduce nitrate to nitrite.
- **Ligase chain reaction (LCR):** Enzyme DNA ligase functions as a link two strands of DNA.
- **Luciferase reporter assay:** Useful for rapid determination of drug resistance.
- **PCR-based sequencing:** Detects mutations responsible for drug resistance.
- **Line probe assays:** Detects drug resistant (particularly rifampicin resistant) bacilli.
- **The Xpert MTB/RIF:** It is a cartridge-based, automated diagnostic test that identifies *Mycobacterium tuberculosis* (MTB) DNA and resistance to rifampicin (RIF) by nucleic acid amplification technique (NAAT). Result obtained within 2 hours.

## **Management of Multidrug Resistant Tuberculosis**

**Q. Write short essay/note on multidrug resistant (MDR) tuberculosis, its diagnosis and its management (drugs used).**

**Principles for managing a patient with MDR tuberculosis (Table 6.46)**

**Q. Write short essay/note on management of multidrug-resistant (MDR) tuberculosis.**

## **Indications for Treatment with Steroids**

**Q. Write short essay/note on the indications of corticosteroids use in the management of tuberculosis.**

- Severely ill patients, e.g. TB meningitis with decreased consciousness, neurological defects, or spinal block or severe pulmonary TB.
- Severe hypersensitivity reaction to anti-TB drugs.
- To prevent exudation, its organization and stricture formation:
  - TB pericarditis with effusion or constriction.
  - Large TB pleural effusion with severe symptoms.
  - Meningeal tuberculosis.
  - Renal tract TB to prevent ureteric scarring.
  - TB laryngitis with life-threatening airway obstruction.
- Hypoadrenalism (Tuberculosis of adrenal glands).
- Massive lymph node enlargement with pressure effects.
- In AIDS patient with severe manifestations of tuberculosis.

**Table 6.46: Principles for managing a patient with MDR tuberculosis.**

- DOTS-PLUS strategy is used.
- Use at least 4 reliable drugs.
- Do not use drugs with cross resistance.
- Eliminate drugs that are not safe for the patient.
- Include drugs from Groups 1–5 in a hierarchical order.
- Monitor and manage adverse effects of drugs.
- Never add a single drug to failing regime.

**General treatment principles**

- Provide 18–24 months’ treatment, always with intensive phase of at least 6 months (current WHO guidelines -8 months).
- Provide DOT therapy.
- Warn patients about possible side-effects.
- Manage side-effects appropriately.
- Perform cultures monthly.

## EXTRAPULMONARY TUBERCULOSIS

**Q. Write short essay/note on extrapulmonary tuberculosis.**

The term extrapulmonary tuberculosis (EPTB) is used for occurrence of tuberculosis at body sites other than the lung. However, when an extrapulmonary focus is present in a patient with pulmonary tuberculosis, such patients are categorized as pulmonary tuberculosis.

EPTB constitutes 15–20% of all cases of TB immunocompetent patients and in HIV positive patients, EPTB accounts for more than 50% of all cases of TB.

**Sites of EPTB:** In order of frequency include lymph nodes, (mediastinal and/or hilar, cervical), pleura (effusions without radiographic abnormalities in the lungs), genitourinary tract, bones and joints, meninges, peritoneum, and pericardium. However, virtually all organ systems may be affected **except nail, hair and enamel**.

### Lymph Node TB

- Most common site for EPTB is lymph node. Extrathoracic nodes are more commonly involved than intrathoracic or mediastinal. Usually, this presents as a firm, painless (nontender) enlargement of a posterior cervical or supraclavicular node (a condition historically referred to as **scrofula**). Lymph nodes are usually discrete in early disease but develop into a matted nontender mass over time. The portal of entry is through the tonsils.
- The overlying skin is frequently indurated or there can be sinus tract formation with draining caseous material but characteristically there is no erythema (**cold abscess** formation). The diagnosis is established by fine-needle aspiration biopsy. TB lymphadenitis is seen in nearly 35% of extrapulmonary TB cases.
- Antituberculous drugs are highly effective for lymph node tuberculosis. **Scrofuloderma** is a mycobacterial infection of the skin caused by direct extension of tuberculosis into the skin from underlying structures or by contact exposure to tuberculosis.

### Tuberculous Osteomyelitis

Tuberculous osteomyelitis is **usually solitary** but in patients with acquired immunodeficiency syndrome, it is frequently multifocal. It tends to be **more destructive and resistant to control** than pyogenic osteomyelitis.

- **Age:** Usually **adolescents or young adults** in developing countries.
- **Source of infection:** Pulmonary or extrapulmonary tuberculosis.
- **Predisposing factors:** Diabetes, elderly, immune compromised states and general debility.
- **Route of infection:**

- **Blood-borne:** Usually blood-borne infection, which is from a focus of **active pulmonary or extrapulmonary disease.**
- **Direct extension:** From lung into a rib and tracheobronchial nodes into adjacent vertebrae.
- **Sites:**
  - **Spine** (thoracic and lumbar vertebrae) commonly known as **Pott's disease.** The **infection breaks through intervertebral discs** to involve multiple vertebrae and **extends down into the soft tissues** forming abscesses (**cold abscess-psoas abscess**).
  - **Knees and hips.**
- **Clinical course:**
  - Low-grade fever with evening rise of temperature
  - Pain on motion, localized tenderness
  - Weight loss.
- **Complications:**
  - **Spine:**
    - ◆ **Destruction of vertebrae:** Causes severe **scoliosis or kyphosis** and neurologic deficits due to spinal cord and nerve compression.
    - ◆ **Psoas abscess:** Infection from spine may rupture into the soft tissue anteriorly and pus and necrotic debris may drain along the spinal ligaments and form a **cold abscess, i.e. an abscess lacking acute inflammation.** **Psoas abscess** is the condition in which infection from lower lumbar vertebrae dissects along the pelvis, and appears as a draining sinus of the skin in the inguinal region. It may be the first manifestation of tuberculous spondylitis.
      - **Tuberculous arthritis**
      - **Sinus tract formation**
      - **Amyloidosis.**

## Tuberculous Meningitis (refer pages 980-2)

### Gastrointestinal Tuberculosis

- TB can affect any part of the bowel.
- Upper gastrointestinal tract involvement is rare.

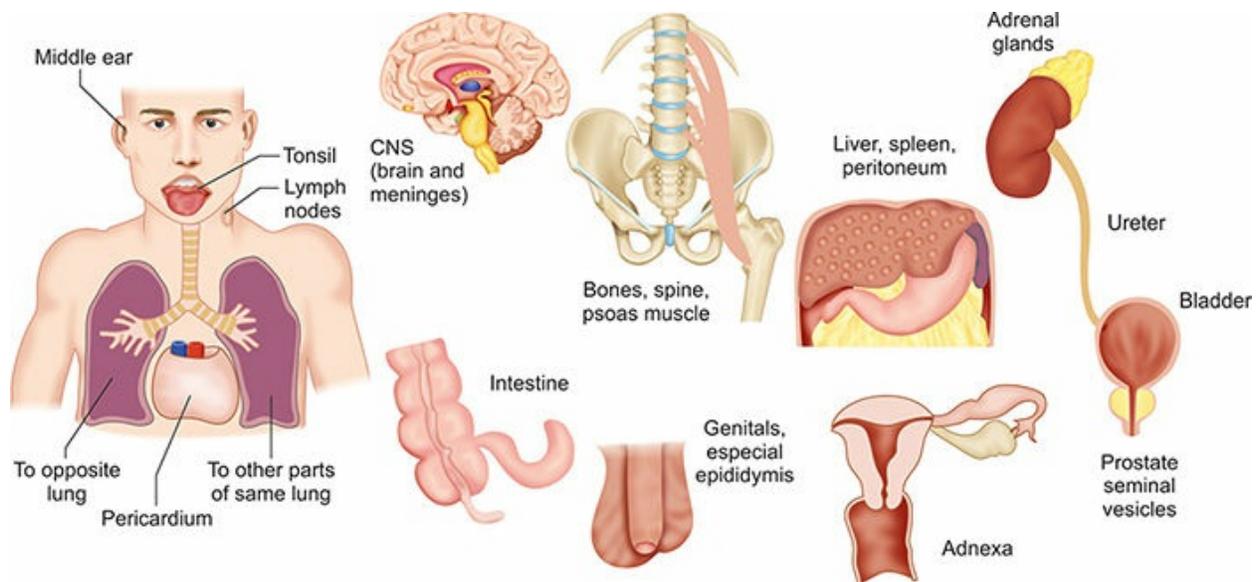

## Intestinal Tuberculosis

Discussed on pages 759-62.

Extrapulmonary sites of tuberculosis and their presentation are summarized in Table 6.47 and Figure 6.20.

**Table 6.47:** Extrapulmonary sites of tuberculosis and their presentation.

Extrapulmonary site	Presentation
Pleural	Pleural effusion, pleuritis
Lymph nodes	Tuberculous lymphadenopathy (including mediastinal) nonhealing sinuses
Skeletal system	Tuberculous osteomyelitis, cold abscess, vertebral tuberculosis, pyarthrosis
Nervous system	Tuberculous meningitis tuberculous arteritis, cerebral tuberculoma
Gastrointestinal	Ulcerations of the tongue, intestinal tuberculosis, tuberculous peritonitis
Pericardium	Pericardial effusion and tamponade, constrictive pericarditis
Genitourinary	Renal tuberculosis, salpingitis, tubal abscess, tuberculous epididymitis
Miscellaneous	Addison's disease (tuberculous adrenalitis), skin tuberculosis (Scrofuloderma, Lupus vulgaris, tuberculids), phlyctenular keratoconjunctivitis, choroiditis, iritis, erythema nodosum

**Fig. 6.20:** Various extrapulmonary sites of tuberculosis.

## Miliary or Disseminated TB

**Q.** Discuss the pathogenesis, types, clinical features, diagnosis and

## **management of miliary tuberculosis in adults.**

Miliary TB is the disseminated form of tuberculosis. The lesions are usually yellowish granulomas 1–2 mm in diameter. These lesions resemble millet seeds (hence termed miliary).

### ***Route of Spread***

Miliary tuberculosis results from widespread hematogenous dissemination of tubercle bacilli. The tubercle bacilli may enter the bloodstream either hematogenous or lymphatic route.

### ***Types***

**Q. Write short essay/note on miliary tuberculosis/non-reactive miliary tuberculosis/ disseminated non-reactive tuberculosis.**

Clinically, the miliary TB patients may be divided into three different types: (1) Classical (acute) miliary tuberculosis, (2) cryptic (obscure) miliary tuberculosis and (3) non-reactive miliary tuberculosis.

#### **1. Classical (acute) miliary tuberculosis**

- **Age:** Can occur at any age, but more commonly affects children and young adults.
- **Onset:** Sudden or gradual. Usually present with insidious onset of fever, malaise and weight loss over weeks.
- **Other symptoms:**
  - Systemic symptoms include high-grade fever, drenching night sweats and progressive pallor.
  - Cough and breathlessness are occasionally present.
- **Signs:**
  - There may not be any abnormal physical signs in the lungs. Widespread crepitations may be heard late in the disease.
  - Hepatosplenomegaly may be seen.
  - **Choroidal tubercles** on ophthalmoscopy—diagnostic.

#### **2. Cryptic (obscure) miliary tuberculosis**

**Q. Write short essay/note on cryptic miliary tuberculosis.**

- **Age:** Usually in the elderly.

- **Symptoms:**
  - Prolonged low-grade pyrexia common presenting manifestation
  - Lassitude, weight loss and general debility.
- **Signs:**
  - Hepatosplenomegaly may occur.
  - Chest is usually normal
  - Choroidal tubercles are rare.

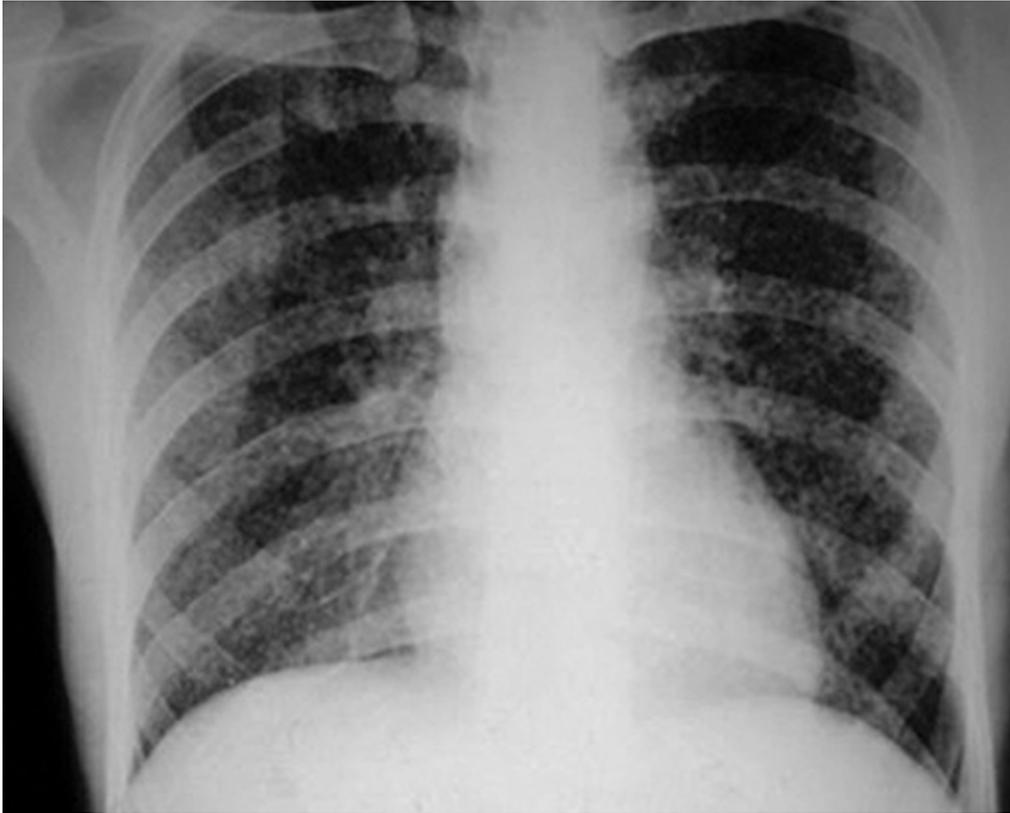

### 3. **Non-reactive miliary tuberculosis**

- Rare usually develops in elderly with disease re-activation
- Acute severe form of tuberculous septicemia, resulting in necrotic lesions without granulomatous reaction containing numerous bacilli.
- Patients are extremely ill and die rapidly.

### **Diagnosis**

- **Chest radiograph (Fig. 6.21):** If it shows the characteristic miliary shadows (miliary mottling), it is virtually diagnostic. Miliary mottling appears as diffuse small shadows of 1–2 mm diameter and evenly distributed throughout both lung fields. Upper zones are always involved. The early lesions may be difficult to appreciate. These lesions are better visualized by (1) an over penetrated (dark) radiograph and a bright light behind the outer rib spaces, (2) lateral chest film, (3) underpenetrated anteroposterior radiograph or (4) high resolution CT of chest.
- **Positron emission tomography CT (PET-CT):** Using radiopharmaceutical  $^{18}\text{F}$  labeled 2-deoxy-D-glucose (FDG) may show 'hot' spots. It can determine the activity of lesion, guide biopsy and detect occult foci.
- **Sputum** smear is usually negative but bronchoalveolar lavage and bronchial biopsy are likely to be positive.
- **Culture:** Confirmation of diagnosis should be done by culture of sputum, urine or bone marrow.
- **Hematological abnormalities:** These include anemia, leukopenia, neutrophilic leukocytosis and leukemoid reaction. Rarely DIC can develop.
- Elevation of alkaline phosphatase and other liver enzymes may be observed in patient with severe liver involvement.

- Hyponatremia may develop in about 50% cases.
- **Bone marrow biopsy:** May show miliary tubercles/bacilli on histology. Part of the specimen should be sent for culture for tubercle bacilli.
- **Liver biopsy:** May show miliary tubercles.
- **Tuberculin test:** Only of limited value in miliary tuberculosis.

**Fig. 6.21:** Chest X-ray showing miliary mottling.

**Q. Write short essay/note on management of miliary tuberculosis.**

#### Management

- **Acute and cryptic miliary tuberculosis:** Standard antituberculous chemotherapy. In severely ill patients prednisolone is given along with chemotherapy. It reduces the life-threatening toxicity and gives the time for antituberculous drugs to act.
- **If the diagnosis is not proved** (e.g. cryptic miliary tuberculosis): Therapeutic trial of antituberculous chemotherapy.

### Tuberculous Pleural Effusion

**Q. Discuss the etiology, pathogenesis, clinical features, investigations, complications and management of tuberculous pleural effusion.**

**Q. Write short note on tuberculous pleural effusion and its laboratory diagnosis.**

- **Age group:** Tuberculous pleural effusion usually occurs in **younger individuals**.
- Underlying pulmonary tuberculosis: **Only one-third** of patients show simultaneous pulmonary tuberculosis and in the majority remaining it is not found.

### ***Pathogenesis***

Involvement of pleura by *M.tuberculosis* may occur by various routes namely via lymphatics, blood-stream or by direct extension.

- **Isolated pleural effusion** usually due to **recent primary infection**. The collection of fluid in the pleural space represents a hypersensitivity response to mycobacterial antigens.
- Pleural disease may also develop from contiguous parenchymal spread from **post-primary/secondary tuberculosis of lung**.
- **Rupture of subpleural caseous focus** into the pleural cavity. This produces delayed hypersensitivity reaction to tuberculous protein. It causes increased permeability of pleural capillaries, mild lymphatic block by fibrosis. Cultures of the pleural fluid from most these patients with tuberculous pleural effusions are negative (because it is a hypersensitivity response).
- **Sequelae:** Left untreated, the pleura may become thick and fibrotic (pleural fibrosis) and pleural adhesions may develop. Pleural adhesion causes restrictive ventilator dysfunction. Early treatment is necessary to prevent these sequelae.

### ***Clinical Features, Investigations and Management***

Refer pages 313-4.

#### *Pleural fluid analysis*

**Q. Write a note on pleural fluid findings in tuberculous pleural effusion.**

- **Color:** Fluid is usually straw/amber colored, but sometimes hemorrhagic.
- **Exudative in nature:** Characteristically fluid is an exudate, with a high protein content (>3 g/dL) >50% of that in serum (usually 4–6 g/dL) a

normal to low glucose concentration, a pH of  $-7.3$  (occasionally  $<7.2$ ) and raised white blood cells (usually  $500-6000/\mu\text{L}$ ).

- **Cells: Predominant lymphocytosis.** Neutrophils may predominate in the early stage (less than 2 weeks), but lymphocytosis is the typical finding later. Mesothelial cells are usually rare or absent. If the pleural fluid shows more than 10% eosinophils, diagnosis of tuberculous effusion is unlikely unless the patient has a pneumothorax or had previously undergone thoracocentesis.
- **Smear for AFB:** Smears prepared from the centrifuged deposit may rarely show the tubercle bacilli ( $<10\%$  of immunocompetent cases).
- **Culture for *M. tuberculosis*:** Positive in approximately 25–50% of patients and are more common among postprimary/secondary cases.
- **Determination of the pleural concentration of adenosine deaminase (ADA):** It is a useful screening test, and TB can be excluded if the value is very low.

**Q. Write short note on adenosine deaminase.**

- It is a T-lymphocyte enzyme.
- In majority of cases, the levels of **ADA in the pleural fluid are elevated** ( $>40$  IU/L) and is probably due to increased activity of T lymphocytes (CD4+) in the pleural fluid.
- Other causes with high ADA, e.g. rheumatoid arthritis, lymphoma, chronic lymphatic leukemia, empyema, and mesothelioma. However, because the incidence of tuberculosis far exceeds than any other cause of a lymphocytic pleural effusion (like in India), high ADA level has a predictive value.
- Specificity of raised levels of ADA in diagnosing tuberculous effusion is nearly 0.83 and the reported sensitivity 77–100%. Specificity increased if combined with pleural fluid lymphocytes/polymorph ratio greater than 3.
- ADA not useful in HIV patients with TB.
- There are two isoenzymes of ADA namely ADA1 and ADA2. ADA1 isoenzyme is found in all cells and they are high in lymphocytes and monocytes. ADA2 isoenzyme is present only in monocytes. In **tuberculous pleural effusion, ADA2 isoenzyme** is mainly responsible for high ADA concentration.

- **Interferon-gamma (INF- $\gamma$ ):** Produced by lymphocytes specifically sensitized to PPD. Its level above  $140$  pg/mL is very suggestive of TB and is elevated irrespective of immune status. More expensive than ADA.
- **Other tests** on pleural fluid: Includes raised LDH, raised lysozymes, marked elevation in the levels of soluble interleukin-2 (IL-2) receptors, and PCR for DNA of *M. tuberculosis*. Nucleic acid amplification technology has low sensitivity.

- **Pleural biopsy:** Closed pleural biopsy shows non-caseating granulomas in 80% of patients. It should be stained with Z-N stain and cultured for mycobacteria. Diagnostic yield increases to 90% with pleural biopsy and biopsy cultures for AFB.

#### Management

- **Therapeutic aspiration of pleural fluid:** May be required in patients with severe symptoms.
- **Antituberculous chemotherapy**
- **Corticosteroid:** May reduce the symptoms of toxemia. However, they do not reduce the incidence of pleural fibrosis. Prednisolone is administered in the dose of 0.75 mg/kg/day for up to 4 weeks with gradual reduction over an additional 2–4 weeks.

## BCG Vaccination

**Q. Write short essay/note on BCG vaccination (Bacillus Calmette-Guerin vaccine).**

BCG (Bacille Calmette-Guerin) is a freeze-dried, live attenuated (lost its virulence) vaccine derived from *M. bovis*. In India, Danish strain 1331 is being used for BCG vaccine production.

**Procedure:** 0.1 mL of the reconstituted vaccine is injected intradermally at the junction of the upper and middle thirds of the left upper arm.

**Contraindications:** Generalized eczema and hypogammaglobulinemia, and immunodeficiency resulting from treatment with antimetabolites, irradiation or systemic corticosteroids.

**Advantages:** BCG vaccination reduces the risk of miliary/disseminated tuberculosis and tuberculous meningitis in children. Its efficacy in adults is very variable.

**Complications:** Secondary infection with local abscess formation, enlargement of regional lymph nodes, cold abscess of draining lymph nodes, local lupoid reactions (rare), erythema nodosum, urticaria and disseminated BCG infection (rare).

## Tuberculosis Chemoprophylaxis—Isoniazid Preventive Therapy (IPT)

**Q. Write a short note on tuberculosis chemoprophylaxis.**

- **Purpose:** To prevent progression of latent tuberculous infection to active disease.

- **Types:**
  - **Primary or infection prophylaxis:** Drug is given to individuals who have not been infected in order to prevent development of disease (e.g. breastfed infants of sputum-positive mother).
  - **Secondary or disease prophylaxis:** Drug is given to prevent development of disease in individuals already infected.

### ***Drugs Used***

- **Isoniazid (H)** at the dose of 5 mg/kg/day (not exceeding 300 mg/day) for 6 to 12 months is used for chemoprophylaxis
- **Alternate option:**
  - Isoniazid plus rifampicin (10 mg/kg daily) for 3 months or
  - Isoniazid in the dose of 5 mg/kg (adults 900 mg) plus rifampicin at a dose of 10 mg/kg twice weekly for 3 months.
- **Precaution:** Exclude active tuberculosis by history, physical examination, chest radiograph and, if necessary, by other tests before starting chemoprophylaxis.

### ***Indications***

- Close contacts of open case of tuberculosis who show recent Mantoux conversion.
- Close contacts children aged 5 years or below with strongly positive Mantoux and a TB patient in the family.
- Breast-fed neonates/infants of sputum positive mothers.
- Newly infected patients as shown by recent change in tuberculin test from negative to positive.
- Patient with old inactive disease who are assessed to have received inadequate treatment.
- Certain diseases in which tuberculosis is more likely to develop. These include HIV infection, leukemia, Hodgkin's disease, prolonged treatment with prednisolone, severe diabetes mellitus and patients on anti-malignancy drugs. In India, if tuberculin test is  $\geq 10$  mm. (WHO recommends that PLHIV who are unlikely to have active TB should receive at least 6 months of IPT as part of a comprehensive package of HIV care.)

### ***Risks***

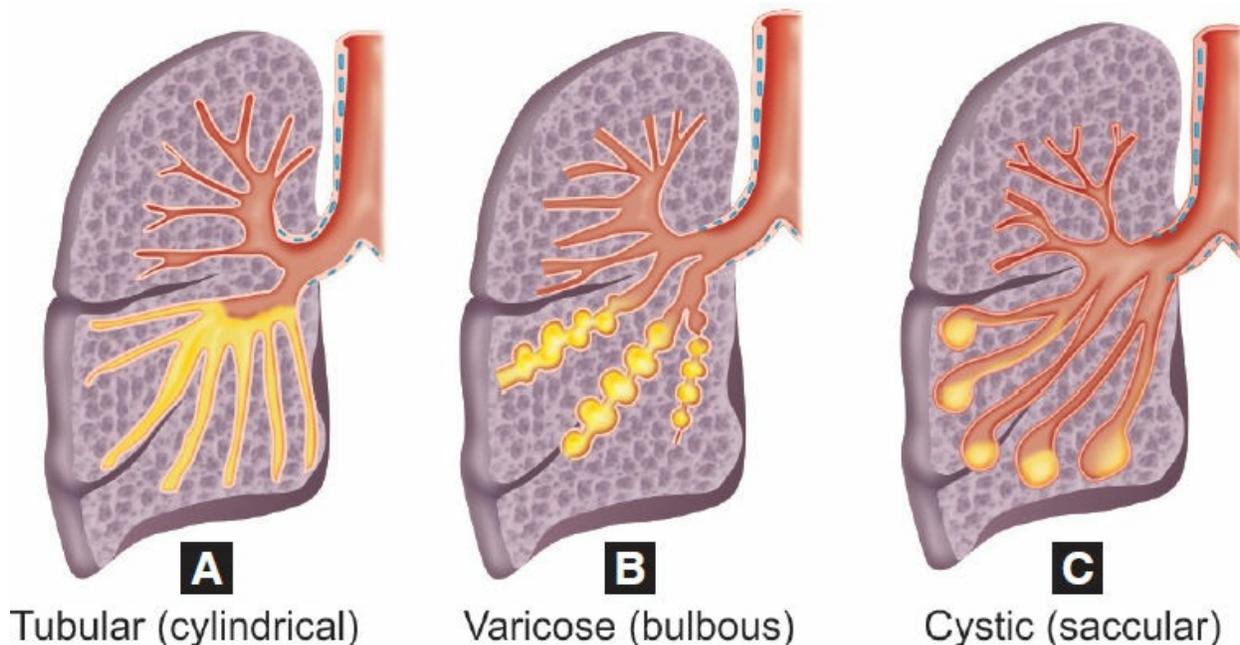

- **Isoniazid resistance** can occur especially when preventive therapy with isoniazid inadvertently given to individuals with subclinical or unrecognized tuberculosis.
- **Hepatotoxicity.**

# SUPPURATIVE LUNG DISEASE

## Bronchiectasis

**Q.** Define bronchiectasis. Describe the etiopathogenesis, classification, clinical features, investigations, complications and management of bronchiectasis.

**Definition:** Bronchiectasis is defined as an **irreversible** (permanent), **abnormal dilation of the cartilage-containing airways bronchi or bronchioles.**

Tubular (cylindrical)

Varicose (bulbous)

Cystic (saccular)

**Figs. 6.22A to C:** Morphological types of bronchiectasis:(A) Cylindrical type; (B) Fusiform type; (C) Saccular.

### **Classification**

1. **According to the shape of the bronchial dilation** (Figs. 6.22A to C) based on the bronchographic appearance (Reid's classification)
  - **Tubular (cylindrical):** Characterized by smooth dilation of the bronchi. It is the most common form.
  - **Varicose (bulbous):** In which the bronchi are dilated with multiple indentations.
  - **Cystic (saccular/balloon appearance):** In which dilated bronchi terminate in blind ending sacs.

### 3. According to the extent of involvement

- **Diffuse (generalized) bronchiectasis:** Characterized by widespread bronchiectatic changes throughout the lung. It is **usually bilateral** and commonly affects the **lower lobes. Left lobe is more commonly involved than the right.** It is most severe in the more distal bronchi and bronchioles.
- **Focal (localized) bronchiectasis:** Bronchiectatic change is **restricted to a localized area of the lung (single segment of the lung)** and usually occurs in association with obstruction of the airway (parenchymal tumor or aspiration of foreign bodies).

### 2. According to the underlying disease/mechanism

- Congenital/acquired
- Cystic fibrosis (CF) associated and non CF bronchiectasis
- Associated with post fibrosis: Traction bronchiectasis
- Without much expectorant: Dry bronchiectasis.

## *Etiology*

### **Q. Write short essay/note on causes of bronchiectasis.**

The dilatation of bronchi and bronchioles is caused by **destruction of the muscle and elastic tissue of bronchial wall**. It represents a secondary disorder as the end stage of many unrelated disorders. It may be divided into obstructive and nonobstructive (postinflammatory). It may also be divided into congenital and acquired (Table 6.48).

**Table 6.48: Causes of bronchiectasis.**

#### **Congenital**

- Cystic fibrosis (CF)
- Ciliary dysfunction syndromes
  - Primary ciliary dyskinesia (immotile cilia syndrome), Young's syndrome
  - Kartagener's syndrome (sinusitis and transposition of the viscera)
- Primary hypogammaglobulinemia, alpha-1 antitrypsin deficiency
- Others: Bronchial cysts, cul-de-sacs, bronchomalacia, atopic bronchial asthma, pulmonary sequestration, Mounier-Kuhn syndrome or tracheobronchomegaly, Williams-Campbell syndrome (bronchomalacia)

#### **Acquired: children**

- Pneumonia (complicating whooping cough or measles)

- Primary tuberculosis
- Inhaled foreign body

#### Acquired: adults

- Pulmonary tuberculosis, *M. avium complex (MAC)*
- Suppurative pneumonia
- Allergic bronchopulmonary aspergillosis complicating asthma (ABPA)
- Post-obstructive bronchiectasis: Partial or total obstruction of the bronchial lumen, e.g. endobronchial tumors or foreign bodies, enlarged hilar lymph nodes or tumor masses and bronchostenosis following endobronchial tuberculosis
- Autoimmune diseases, e.g. rheumatoid arthritis, Sjögren's syndrome, systemic lupus erythematosus, inflammatory bowel disease.
- Others: Repeated aspiration of gastric juice, inhalation of toxic gas (ammonia), HIV infection, interstitial lung fibrosis (traction bronchiectasis), radiation fibrosis, sarcoidosis, chronic hypersensitivity pneumonitis, bronchiolitis obliterans after lung transplantation.

**Proximal bronchiectasis:** In which dilatation involves larger airways:

- **Allergic bronchopulmonary aspergillosis (ABPA)**
- **Brock's syndrome/middle lobe syndrome:** Primary TB/foreign body/tumor compressing main bronchus.
- **Lady Windermere syndrome:** These women have the habit of voluntarily suppressing cough. It results in inability to clear the secretions from the right middle lobe and lingual leading to infection and later bronchiectasis.

- **Congenital syndromes: Kartagener's syndrome, yellow nails syndrome, Chandra-Khetarpal syndrome** (immuno-deficiency associated with levocardia, bronchiectasis, and paranasal sinus anomalies), **Young's syndrome, cystic fibrosis, Chédiak–Higashi syndrome.**

## Pathogenesis

### Theories of bronchiectasis

- **Pressure of secretion theory (Obstruction):** Secretions leads to mechanical obstruction and obstruction **impairs clearing mechanisms** of the lung → results in **accumulation of secretions** distal to the obstruction → **leads to secondary infection** → inflammation → weakens and dilates airway.
- **Infection theory: Chronic persistent** (recurrent) **necrotizing infection** and inflammation in the bronchi or bronchioles → increased bronchial secretion → **obstruction** of airways by secretions → inflammation and fibrosis of the airway walls → weakening and dilatation of airways.
- **Traction theory:** Traction of the bronchi walls secondary to fibrosis/scarring.

- **Atelectasis theory:** Negative intrapleural pressure resulting in collapse and bronchial dilatation.

## *Clinical Features*

### **Q. Write short essay/note on clinical features of bronchiectasis.**

- **Severe persistent (chronic) productive cough:** It is the most common symptom. Cough is chronic, daily, and persistent. **Paroxysms of cough develops when the patient rises in the morning (maximum during the first 2 hours after waking).** Because the postural changes drain the collections of pus and secretions into the bronchi. Sputum production varies with posture and in up.
- **Sputum:** It is **foul-smelling** (due to anaerobic infections), thick, copious, tenacious, and continuously purulent sometimes bloody.
- **Hemoptysis:** Streaks of blood is common with exacerbations of infection and is commonly recurrent. Rarely massive hemoptysis occurs. Hemoptysis occurs due to rupture of the thin walled blood vessels present on the walls of dilated bronchi.
- **Pleuritic (chest) pain:** It may be caused due to infection of pleura, or due to segmental collapse caused by retained secretions.
- **Infective exacerbation:** Increased sputum volumes with fever, malaise, anorexia are precipitated by upper respiratory tract infections.
- **General debility:** In severe/widespread bronchiectasis, the patient present with difficulty maintaining weight, anorexia, exertional breathlessness/dyspnea, wheezing and orthopnea.
- **Bronchiectasis sicca/dry bronchiectasis:** Occasionally, the patient is asymptomatic or has non-productive cough. It is termed bronchiectasis sicca and commonly follows tuberculosis of upper lobe. Only manifestation will be hemoptysis
- Situs inversus is found in 50% cases of ciliary dyskinesia.

## *Physical findings*

**General examination:** It may reveal anemia, **pandigital clubbing** (7% cases), fever, weight loss, night sweat, weakness, **halitosis** (may accompany purulent sputum) and sinusitis. Signs and symptoms of lung infection, such as fever may not be present.

## ***Respiratory System***

- Nasal polyps and signs of chronic sinusitis may be present.
- Signs may be unilateral, but are usually bilateral and basal. In dry bronchiectasis, no abnormal physical signs may be found.
- **Auscultation:** Reveals **crackles** and wheezing. Presence of large amounts of secretion is responsible for the characteristic '**bilateral, coarse, leathery crepitations**' of bronchiectasis which may be palpable (tactile fremitus).

## ***Investigations***

- **Blood:** Anemia, raised ESR and leukocytosis indicating suppuration. ABG studies may show respiratory alkalosis or hypoxemia.
- **Sputum examination:**
  - If sputum is collected in a conical flask and allowed to stand, it forms three layers ('**three-layered sputum**'), top mucoid layer, middle mucopurulent layer and purulent layer at the bottom.
  - Stain the sputum by Gram's stain, Ziehl-Neelsen stain for acid fast bacilli
  - Culture and sensitivity: Culture usually grows organism in the normal nasopharyngeal flora or *Pseudomonas*.
- **Chest radiograph (Fig. 6.23):** It lacks sensitivity. Signs on CXR include the identification of parallel linear densities, tram-track opacities, or ring shadows reflecting thickened and abnormally dilated bronchial walls.

**Fig. 6.23:** Chest X-ray showing bilateral bronchiectasis with dextrocardia with situs inversus.

- **Chest computed tomography (CT):** More specific sensitive, and is the imaging modality of choice for confirmation for bronchiectasis. High-resolution computed tomography. **HRCT findings (Fig. 6.24)** are:
  - Specific criteria:
    - ◆ Thickened, dilated airways (parallel ‘tram tracks’ or as the ‘signet-ring sign’). Internal diameter of the bronchus is minimum 1.5 times more than that of the nearby vessel.
    - ◆ Absence of bronchial tapering in the periphery of the chest (presence of tubular structures within 1 cm from the pleural surface)
  - Other findings: Inspissated secretions (e.g. the ‘tree-in-bud pattern) or cysts arising from the bronchial wall (in cystic bronchiectasis).
  - May suggest the etiology of bronchiectasis (e.g. proximal bronchiectasis suggests ABPA).
- **Sinus X-rays:** About 30% of patients have rhinosinusitis.
- **Bronchoscopy:** Does not establish the diagnosis.

- Indications: (i) to identify the source of secretions, (ii) to identify the site of bleeding in patients with hemoptysis, (iii) therapeutically to remove secretions, and (iv) localized bronchiectasis.

**Fig. 6.24:** HRCT image of bronchiectasis.

- Bronchography: Rarely indicated.
- **Pulmonary function tests:** It may detect mild to moderate airflow obstruction, but a restrictive pattern evolves with advanced disease.
- Urine examination: In advanced and chronic cases proteinuria may develop due to renal amyloidosis.
- Electrocardiogram: Usually normal, but right ventricular hypertrophy may be detected when cor pulmonale develops.
- **Sweat electrolytes:** Measurement of sodium and chloride concentrations in sweat is useful in cystic fibrosis.
- **Serum immunoglobulins:** Up to 10% of adults with bronchiectasis have antibody class or subclass deficiency (mainly IgA). Its estimation is also useful when primary hypogammaglobulinemia is suspected.
- **Patients suspected of ciliary dysfunction syndrome:** Assessment of ciliary function may be done by several ways:
  - **Mucociliary clearance (nasal clearance of saccharin):** Measure the time taken for a small pellet of saccharin placed in the anterior chamber of the nose to reach the pharynx, where patient can taste it. Normally, it should be <30 minutes. A prolongation of this time (>60

minutes) is found in patients with ciliary dysfunction.

- Measurement of ciliary beat frequency: Assessed by using biopsies taken from the nose.
- Electron microscopy: It can detect structural abnormalities of cilia.
- Study of the sperms.

**Table 6.49:** Complications of bronchiectasis.

1. Hemoptysis
2. Pneumonia
3. Lung abscess
4. Empyema
5. Cor pulmonale
6. Septicemia
7. Meningitis
8. Osteomyelitis
9. Metastatic abscesses (e.g. brain abscess)
10. Generalized edema (100 mL sputum/4–5 g protein) protein losing pneumopathy
11. Generalized amyloidosis
12. Aspergilloma
13. Respiratory failure
14. Microbial resistance to antibiotics

**Box 6.9:** Goals of treatment in bronchiectasis.

- Treatment of the underlying cause/disorder
- Improvements in secretion clearance and bronchial hygiene
- Antibiotics to control active infections
- Anti-inflammatory therapy
- Reversal of airflow obstruction
- Surgery

**Complications of Bronchiectasis (Table 6.49)**

**Q. Write short essay/note on complications of bronchiectasis.**

**Management**

Goals of treatment of bronchiectasis is presented in Box 6.9.

**Improvements in secretion clearance and bronchial hygiene**

- Bronchial hygiene so as to reduce the microbial load within the airways and minimize the risk of repeated infections.

- Many methods are used to increase secretion clearance in bronchiectasis. These include chest physiotherapy (e.g. postural drainage), hydration and mucolytic administration, aerosolization of bronchodilators and hyperosmolar agents (e.g. hypertonic saline).
- **Postural drainage:** Postural drainage is valuable and consists of adopting a position in which the affected lobe(s) to be drained is uppermost. Patients must be trained by physiotherapists and should be performed at least three times daily for 5–10 minutes. Lying over the side of the bed with head and thorax down is effective in most patients. Gentle mechanical chest percussion through hand clapping to the chest helps to dislodge the sputum.
- Bronchoscopic removal of inspissated secretions is rarely necessary.

### ***Antibiotic therapy***

#### *Antibiotics for eradication of bacteria*

For *Pseudomonas*: Oral ciprofloxacin (500–750 mg twice daily) or ceftazidime by intravenous injection or infusion (1–2 g three times daily) for 7–10 days

#### *Suppressive antibiotics*

- After resolution of an acute infection in patients with recurrences, the use of suppressive antibiotics may minimize the microbial load and reduce the frequency of exacerbations.
- Inhaled antibiotics are safe and effective, e.g. Tobramycin, gentamicin

#### *Antibiotics for exacerbation*

- Choice of the antibiotic depends on the results of culture and sensitivity of sputum.
- If no specific pathogen is identified and the patient is not seriously ill, an oral agents like amoxicillin, ampicillin, cotrimoxazole, tetracycline, one of the fluoroquinolones or a fixed combination of amoxicillin and clavulanic acid are recommended.
- More seriously ill patients with pneumonitis require parenteral antibiotics.
- Duration of therapy: Varies and is usually a 7–10 day course is sufficient. Few patients may need prolonged therapy for several weeks.

### ***Anti-inflammatory therapy***

- Control of the inflammatory response may be of benefit in bronchiectasis.
- Inhaled or oral steroids can reduce the rate of progression of bronchiectasis.
- Macrolide antibiotic: They have immunomodulatory action.

### ***Reversal of airflow obstruction***

- Bronchodilators ( $\beta$ -adrenoreceptor agonists, anticholinergics) improve obstruction and helps in clearance of secretion. They are useful in patients with demonstrable airflow limitation.
- Inhaled corticosteroids may be useful in some patients.

### ***Surgical treatment***

- It can be considered only in refractory cases.
- The procedure involved is excision of bronchiectatic areas. It is usually done in cases where the bronchiectasis is restricted to a single lobe or segment on CT.
- Indications of surgery:
  - Children or young adults with localized lesions, who fail to respond to medical treatment
  - Recurrent hemoptysis
  - Recurrent localized pneumonias
- Lung transplantation is considered in patients with advanced disease and respiratory failure.
- **Treatment of the hemoptysis:** Bed rest and antibiotics. Blood transfusion is given if necessary. Occasionally, fiberoptic bronchoscopy is needed to detect the source of bleeding. If the

hemoptysis continues, embolization of bronchial artery is the treatment of choice. Surgical resection may be needed if embolization fails.

#### **Other measures**

- General management: Graded exercise, routine deep breathing and maintenance of good nutrition
- Vaccination
- Promptly treat episodes of sinusitis.
- Treat complicated ABPA with prednisolone and itraconazole.
- Mucolytic dornase (DNase) is recommended in cystic fibrosis (CF)-related bronchiectasis. It reduces viscosity of sputum by breaking down DNA released from neutrophils.

Management of bronchiectasis is summarized in Flowchart 6.4.

## **Pseudobronchiectasis**

### **Q. Write short note on pseudobronchiectasis.**

Pseudobronchiectasis (functional bronchiectasis) is characterized by dilated bronchi and is reversible. It is a common in patients with pneumonia of any cause. But re-expansion of the collapsed lung in atelectasis and regeneration of the mucosa in tracheobronchitis leads to reversal of the bronchographic findings. This reversible dilatation of bronchi is termed as pseudobronchiectasis.

## **Postobstructive Bronchiectasis**

### **Q. Write short note on postobstructive bronchiectasis.**

- It is bronchiectasis that develops distal to a bronchial obstruction.
- **Causes: Partial or total obstruction of the bronchial lumen** due to endobronchial tumors and foreign body aspiration, mucus plugs, enlarged hilar lymph nodes or tumor masses, and bronchostenosis (due to endobronchial tuberculosis).

## **Bronchiectasis Sicca (Dry Bronchiectasis)**

### **Q. Write short note on bronchiectasis sicca (dry bronchiectasis).**

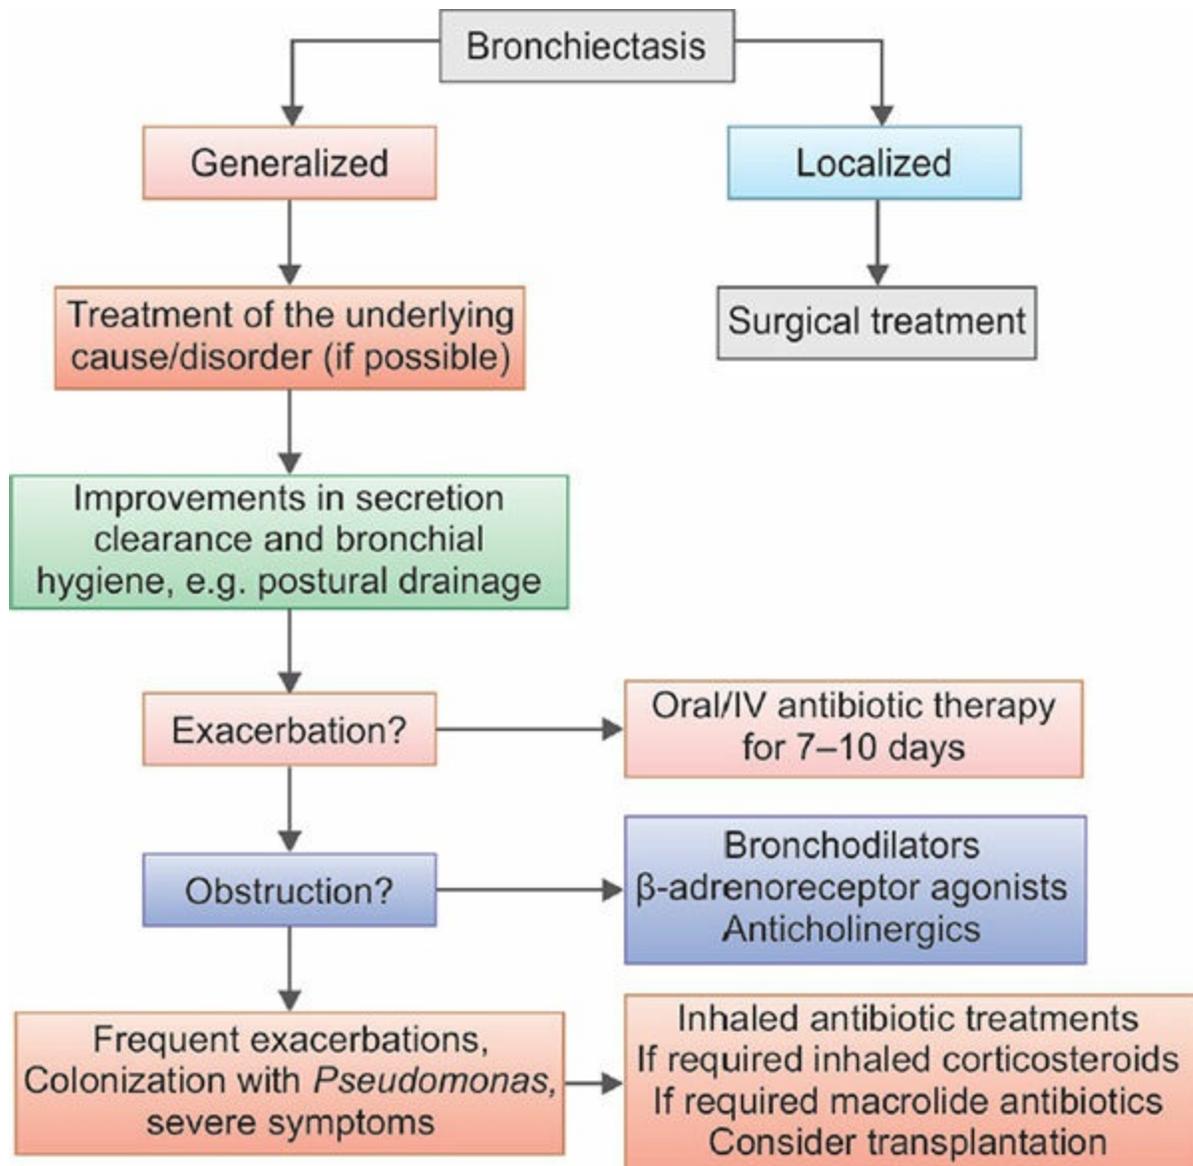

- Usually bronchiectasis present with copious sputum.
- **Bronchiectasis sicca** is a condition where bronchiectasis presents with repeated episodes of hemoptysis without sputum production.
- It usually occurs in bronchiectasis of upper lobe following tuberculosis.

## **Atelectasis**

**Q. Write short note on atelectasis and signs of lung collapse.**

- Atelectasis refers either to **incomplete expansion of the lungs** (neonatal atelectasis) or to the **complete collapse** of previously inflated lung parenchyma.
- It produces areas of relatively airless pulmonary parenchyma.

**Flowchart 6.4:** Management of bronchiectasis.

### **Classification**

Main types are acquired atelectasis:

1. **Obstructive atelectasis (absorption atelectasis)**

- Most common type
- **Mechanism:** Complete obstruction (intra-bronchial) of an airway causes obstruction of communication between the alveoli and major airways. This leads to absorption of air from the dependent alveoli → diminished lung volume → shifting of the mediastinum towards the atelectatic lung.
- **Causes:** Due to complete obstruction (intra-bronchial) of an airway.
  - Exogenous, e.g. foreign body aspiration, or recurrent aspiration of either gastric or oral contents due to a swallowing disorder
  - Endogenous, e.g. excessive secretions (e.g. mucus plugs) or exudates within smaller bronchi, (e.g. in bronchial asthma, chronic bronchitis, bronchiectasis, and postoperative states), bronchial tumors.

### 3. Nonobstructive atelectasis

- **Compression atelectasis:**
  - Develops due to compression of lung.
  - Causes: It develops from any space-occupying lesion of the thorax (e.g. tumors, cysts, enlarged lymph nodes, and cardiomegaly). It can also occur with chest wall defects (e.g. scoliosis), neuromuscular diseases and compression by emphysematous bulla.
  - In compression atelectasis, the mediastinum shifts away from the affected lung.
- **Relaxation or passive atelectasis**
  - Contact between visceral and parietal pleura is lost resulting in passive atelectasis of lung.
  - Causes: Significant volumes of fluid (transudate, exudate or blood) or air (*pneumothorax*) accumulation within the pleural cavity.
- **Fibrotic or cicatrization or contraction atelectasis:** It occurs when focal or generalized pulmonary or pleural fibrosis prevents full expansion of lung.

### 2. Atelectasis due to surfactant deficiency or dysfunction

- Surfactant deficiency or dysfunction causes increased alveolar surface tension and failure to maintain small airway patency.
- Causes: ARDS (particularly in preterm neonates and meconium

aspiration), and pneumonia in elderly.

### ***Clinical Features***

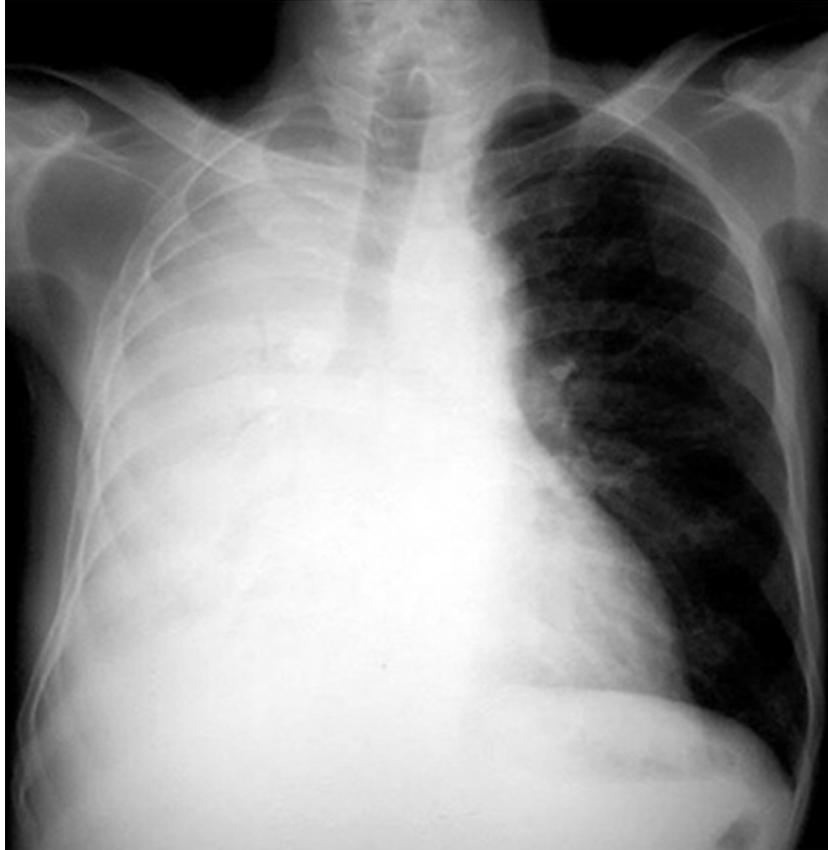

- Depends on the underlying cause, the degree of volume loss within the lung, and rate of volume loss.
- No symptoms may develop when atelectasis develops slowly.
- Chronic atelectasis may be a nidus of chronic purulent infection. This may damage bronchial wall leading to bronchiectasis.
- Physical examination:
  - Reduced chest movement during breathing on the involved region.
  - Deviation of trachea and apex beat toward affected side.
  - Dullness over the involved region
  - Absence of breath sounds over involved region. No added sounds.

### ***Investigations***

- Chest radiograph (Fig. 6.25) and CT chest findings
  - Homogenous opacification of the **atelectatic region**
  - Displacement of fissure
  - Loss of volume and shift of trachea and mediastinum
- Bronchoscopy to identify obstructive lesions and is also useful in removing the mucus plug.
- Arterial blood gas may reveal hypoxemia. Hypocapnia may develop due to tachypnea.

### ***Treatment of Collapse***

- Emergency bronchoscopy and removal of mucus plug, foreign body.
- Treatment of underlying cause.

**Fig. 6.25:** Chest X-ray shows collapse of the right lung.

## **Middle Lobe Bronchiectasis (Middle Lobe Syndrome or Brock's Syndrome)**

**Q. Write short note on middle lobe bronchiectasis (middle lobe syndrome or Brock's syndrome).**

- It usually develops as a sequel of primary pulmonary tuberculosis of lung. It can be also seen with lymphoma and other causes of mediastinal lymphadenopathy.
- It is a type of postobstructive bronchiectasis usually due to obstruction of the middle lobe bronchus by tuberculous lymph nodes.
- This syndrome is characterized by recurrent atelectasis of the right middle lobe in the absence of any endobronchial lesion. Recurrent episodes of atelectasis result in bronchiectasis and fibrosis of right middle lobe.

## **Ciliary Dysfunction Syndromes or Primary Ciliary Dyskinesia**

**Q. Enumerate the clinical features, diagnosis and treatment of ciliary**

## dysfunction syndromes (ciliary dyskinesia syndromes).

### Q. Write short note on primary ciliary dyskinesia (PCD)/Kartagener's syndrome and Young's syndrome.

- These are a group of genetic disorders characterized by dysfunction of cilia of the respiratory tract epithelium, sperms and other cells. Dysfunction of cilia causes impairment of mucociliary clearance, left-right body asymmetry, and impaired sperm motility.
- Majority are transmitted as an autosomal recessive disorder.
- **Kartagener or immotile cilia syndrome:** It is an **autosomal recessive** syndrome. It is one of the ciliary dysfunction syndromes with **lack of ciliary function** (due to absence of inner or outer dynein arms of cilia) and causes retention of secretions and recurrent infections. It comprises of recurrent **sinusitis, bronchiectasis, dextrocardia** (with or without situs inversus) and **male infertility** (sperm dysmotility).
- **Young's syndrome:** Patients develop bronchiectasis, sinusitis, and obstructive azoospermia. The cause is not known.

### *Clinical Features of Primary Ciliary Dyskinesia (Table 6.50)*

**Table 6.50:** Clinical features of primary ciliary dyskinesia.

<i>System involved</i>	<i>Clinical features</i>
Lung	Respiratory distress (in neonates), recurrent infections and bronchiectasis
Nasal sinus	Chronic sinusitis
Ear	Otitis media, cholesteatoma, hearing loss
Genital tract	Male infertility
Organ laterality	Situs inversus totalis, polysplenia or asplenia
Cardiovascular system	Complex congenital heart disease, vascular anomalies
Central nervous system	Hydrocephalus (rare)

### **Diagnosis**

- **Screening tests**
  - Exhaled nasal nitric oxide: Low
  - **Mucociliary clearance (nasal clearance of saccharin):** Tests for ciliary function described on page 281 of Chapter 6.
- **Electron microscopy:** It can detect structural abnormalities of respiratory cilia in samples of nasal or airway mucosa. It is characterized by defects in

the outer or inner dynein arms of the cilia.

- **Genetic study:** Shows mutation in PCD genes.

#### Treatment

- No definite treatment.
- Treat bronchiectasis.
- Avoid cough suppressants because cough is the only intact mechanism for mucociliary clearance in these patients.

## Suppurative Pneumonias

### Q. Write short essay on suppurative pneumonias and necrotizing pneumonias.

Suppurative pneumonia, aspiration pneumonia and pulmonary abscess are conditions which have overlap in their etiology and clinical features. Suppurative pneumonia is a type of pneumonic consolidation characterized by destruction of the lung parenchyma by the inflammatory process. Though histologically there is formation of micro-abscess, the term 'lung/pulmonary abscess' is usually used for lesions having a large localized collection of pus, or a cavity lined by chronic inflammatory tissue. The etiological factors are same for both suppurative pneumonia and lung/pulmonary abscess.

## Lung Abscess

### Q. Define lung abscess. Describe the etiology, clinical features, investigations, diagnosis, complications and management of lung abscess.

**Definition:** Lung (pulmonary) abscess is defined as a severe, **local suppurative process within the lung** associated with cavity formation. It is characterized by necrotic area of lung parenchyma containing **pus accompanied by the destruction of lung tissue.**

**Necrotizing pneumonia:** Often used to describe similar pathologic process with multiple small (<2 cm) cavities in contiguous areas of the lung.

## Classification

- **Duration of symptoms** prior to diagnosis: acute < 1 month, and chronic > 1 month
  - **Primary or secondary.**
-

**Table 6.51: Causes of lung abscess.**

**A. INFECTIOUS CAUSES**

1. **Bacteria**

- **Usual:** Mouth flora anaerobes, most frequently isolated anaerobes: *Peptostreptococcus*, *Fusobacterium nucleatum*, *Prevotella melaninogenica*
- **Less common:** *Staphylococcus aureus*, *Streptococcus pyogenes*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Streptococcus pneumoniae*, gram-negative bacilli, such as *E. coli*, *Hemophilus influenzae type B*, *Legionella*, *Nocardia asteroides*. Mixed infections occur when lung abscess develops due inhalation of foreign material
- **Mycobacteria:** *M. tuberculosis*, *M. avium complex*, *M. kansasii*, other mycobacteria

2. **Fungi:** *Aspergillus spp.*, *Histoplasma capsulatum*, *Pneumocystis Jirovecii*, *Coccidioides immitis*, *Blastocystis hominis*, *Cryptococcus*

3. **Parasites:** *Entamoeba histolytica*, *Paragonimus westermani*, *Strongyloides stercoralis* (postobstructive)

**B. NONINFECTIOUS CAUSES**

1. **Neoplasms:** Primary lung cancer, metastatic carcinoma, lymphoma

2. **Pulmonary infarction:** Due to bland embolus (may be secondarily infected in <5%)

3. **Septic embolism:** Tricuspid endocarditis due to *S. aureus* and others (typically with positive blood cultures), jugular venous septic phlebitis due to **Fusobacterium necrophorum** (**Lemierre syndrome**)

4. **Vasculitis:** Wegener's granulomatosis, rheumatoid lung nodule

5. **Developmental:** Pulmonary sequestration

6. **Airway disease:** Bullae, blebs, or cystic bronchiectasis (usually thin-walled)

7. **Other:** Sarcoidosis, transdiaphragmatic bowel herniation giving appearance of cavity with air fluid level

***Etiology (Table 6.51)***

- Infectious causes: Any pathogen can produce lung abscess
- Noninfectious causes.

***Pathogenesis***

Lung abscess may be **primary or secondary**.

1. **Secondary lung abscess:** Develops as a complication of several conditions.

- **Complication of necrotizing pneumonia:** The microbes usually associated are: *S. aureus*, *K. pneumoniae*, and the serotype type 3 *Pneumococcus*.
- **Pulmonary tuberculosis:** Important cause of lung abscess
- **Septic embolism:** The source of embolus may be from

thrombophlebitis in any part of the systemic venous circulation or from the vegetations of infective bacterial endocarditis on the right side of the heart. The embolus may be trapped in the lung causing multiple pyemic abscesses.

- **Bronchial obstruction:** By a **bronchial cancer** (primary or secondary) or foreign body (postobstructive pneumonia) → secondary infection.
- **Miscellaneous:**
  - Direct penetrating trauma to the lungs
  - Spread of infections from a neighboring organs (e.g. suppuration in the esophagus, spine, subphrenic space, or pleural cavity)
  - Spread from an amebic liver abscess
  - Secondary infection of cavitary malignancy, pulmonary infarct.

### 3. Primary cryptogenic lung abscesses

This type of lung abscess has no apparent cause and most of them develop as consequence of **aspiration of infected material**. About 80% of lung abscess is primary (50% of these associated with putrid sputum). Bacteria responsible are usually the mixed anaerobes found in the oropharynx or nasopharynx (aspiration abscess). Predominant organisms found in aspiration abscess include anerobic organisms, streptococci and *H. influenzae*. Pre-existing sources of infection for aspiration are sinusitis, dental sepsis, gingivitis, periodontal infection, etc.

- **Aspiration of infective material:** Depression of cough reflex favors aspiration from **infected nasal sinuses or tonsils** or periodontitis gingivitis. It may occur during alcoholic stupor, general anesthesia, sleep, epilepsy, coma, head injury or neurological disease causing loss of consciousness.
- **Aspiration of gastric contents:** Occurs in achalasia cardia, carcinoma of esophagus, hiatus hernia and gastroesophageal reflux disease (chemical pneumonitis—Mendelson’s syndrome).

#### Features of aspiration abscess:

- **Site and number:** Abscess due to **aspiration** is more common on the **right** lung (because of the more vertical right main bronchus) and are most often **single**.
- **Segment involved:** Aspiration abscess cavities occur in those bronchopulmonary segments that are most dependent at the time of

aspiration.

- Aspiration in supine position → produces abscess in posterior segment of the upper lobes or superior segments of the lower lobes.
- Aspiration in the upright position → produces abscess in the basilar segments (bilateral).
- About 1/3 of patients develop empyema due to direct extension.
- Amebic lung abscess typically occurs in right lower lobe due to direct extension of liver abscess through the diaphragm.

## *Clinical Features*

**Q.** Write short essay on diagnosis of acute lung abscess.

Lung abscess may present either as an acute (symptoms less than 1 month) or chronic (symptoms more than 1 month).

- **Acute:**
  - Majority present acutely with dry **cough**, high-grade **fever**, chills, rigors, and pleuritic chest pain.
  - After a few days, when the abscess ruptures into a patent bronchus, the patient suddenly starts expectorating large quantities **large amounts of foul-smelling purulent or sanguineous sputum**. The sputum may often be blood-tinged and expectoration **varies with posture**
- **Chronic:** Lung abscess secondary to aspiration often presents as chronic, insidious in onset with low-grade fever, malaise, weight loss, anorexia and a deep-seated chest **pain/discomfort**.

### *Physical findings*

**General examination:** Anemia, fever, **clubbing of the fingers and toes** (may develop rapidly), **halitosis** and oronasal sepsis.

### *Respiratory system examination*

- **Early stages:** May be normal
- **Later:**
  - **Signs of consolidation:** Dullness of percussion, increased vocal fremitus and vocal resonance, bronchial breathing, crepitations and pleural rub.
  - **Signs of cavitation:** Once the abscess opens into a bronchus, signs of

cavitation like cavernous or amphoric bronchial breathing and coarse post-tussive crepitations are heard on auscultation.

### ***Investigations***

- **Blood:** Normocytic anemia and/or raised inflammatory markers (ESR/CRP), leukocytosis and raised ESR.
- **Sputum:**
  - Gram's stain, Ziehl-Neelsen staining for acid-fast bacilli
  - Culture and sensitivity: For aerobic and anaerobic
  - Cytological examination: For malignant cells.
- **Chest radiograph (Fig. 6.26):** Reveals radiolucency in an opaque area of consolidation. The wall of the abscess cavity completely surrounds the radiolucent area. An air-fluid level may be seen in the abscess cavity.
- **CT scan of thorax:** Shows lung abscess
- **Bronchoscopy:** Indicated (i) to exclude malignancy, (ii) to obtain specimens for studies and (iii) for removal of secretions.

**Fig. 6.26:** Chest X-ray shows lung abscess in right lower zone.

## Complications (Table 6.52)

**Q. Write short essay on management of acute lung abscess/  
management of lung abscess.**

**Table 6.52: Complications of lung abscess.**

- Extension of the infection into the pleural cavity: Leading to empyema/pneumothorax/pyopneumothorax/bronchopleural effusion/pleurocutaneous fistula
- Hemorrhage into the abscess cavity
- Hemoptysis
- Septic emboli may cause metastatic brain abscesses or meningitis
- Secondary amyloidosis (type AA)
- Aspergilloma
- Residual fibrosis and bronchiectasis

### Treatment

- **Postural drainage** (refer bronchiectasis) and chest physiotherapy.
- **Antibiotic therapy:** Choice of drug depends on culture and sensitivity result. Broad guidelines include:
  - **Aspiration abscess:** Antibiotic therapy is similar to that of aspiration pneumonia.
  - **Oral treatment:** Majority respond to oral treatment with ampicillin 500 mg four times daily or cotrimoxazole 960 mg twice daily or clindamycin 300 mg thrice daily.
  - **Anaerobic bacterial infection,** e.g. patients with foul smelling sputum, oral metronidazole 400 mg 8 hourly should be combined with the above oral treatment. It should not be used alone.
  - **Parenteral antibiotic therapy:** Required in seriously ill patients and consists of Beta-lactamase inhibitor (e.g. ampicillin-sulbactam 3 g intravenously [IV] every six hours) or a carbapenem (e.g. imipenem, meropenem) with clindamycin and metronidazole.
- **Duration of antibiotic therapy:** Usually given for 4–6 weeks. Antibiotic treatment should be continued until the chest radiograph has shown either the resolution of lung abscess or the presence of a small stable lesion. There is a risk of relapse with shorter antibiotic regimen.
- **Large lung abscess:** Aspiration and placement of pigtail catheters may be useful.
- **Resectional surgery:** Indicated in few in cases. These include:
  - Massive hemoptysis.
  - Lung abscess associated with symptomatic bronchiectasis.
  - Lung abscess associated with localized malignancy.
  - Persistent lung abscess cavity.

The surgical procedure is either lobectomy or pneumonectomy. Consider lobectomy/pneumonectomy with large cavities (> 8 cm), resistant organisms like *Pseudomonas*, obstructing neoplasm or massive hemorrhage.

## Cystic Fibrosis

**Q. Write short note on complications of cystic fibrosis.**

Cystic fibrosis is a fatal multisystem genetic disorder because of abnormal ion transport function causing inability to adequately hydrate mucus.

### ***Genetics and Pathogenesis***

It is transmitted as an autosomal recessive disorder and characterized by mutation in a gene on the long arm of chromosome 7. This gene codes for a chloride channel known as cystic fibrosis transmembrane conductance regulator (*CFTR*). This influences salt and water movement across epithelial cell membranes.

#### **CFTR protein:**

- Normally present in epithelia and functions as cAMP regulated chloride ion channel and as inhibitor of Na<sup>+</sup> channels.
- Mutation in *CFTR* gene causes intracellular degradation of CFTR. Thus, epithelial membranes are unable to secrete chloride ion in response to cAMP mediated signals.

#### **Types of epithelia affected:**

- **Volume absorbing epithelia:** Airways and distal intestinal epithelium.
  - In cystic fibrosis, **Na<sup>+</sup> absorption increased and chloride ion secretion is decreased.** This leads to reduced volume of periciliary fluid (with relative dehydration of the airway epithelium), thickening of mucus, adhesion and failure to clear mucus from the airway lumen. Mucus stasis and mucus hypoxia predispose to chronic bacterial infection (favors *Pseudomonas* growth) and ciliary dysfunction. It can lead to bronchiectasis.
- **Salt absorbing epithelia:** In the sweat duct epithelium, CF is associated with increased sodium and chloride content in sweat. Aquagenic wrinkling of the palms (wrinkling and nodules) that develop after several minutes of immersion in water is quite characteristic.
- **Volume secretory epithelia:** Epithelium of proximal intestine and pancreas
  - **Pancreas:** Failure of Cl-HCO<sub>3</sub> exchanger to secrete Na<sup>+</sup>, HCO<sub>3</sub> and water → enzymes retained → steatorrhea, azotorrhea and pancreatic destruction

- **Intestine:** Reduced bicarbonate secretion → low pH in duodenum → thick intestinal mucus → predisposition to obstruction.
- **Hepatobiliary system:** Retention of biliary secretion, focal biliary cirrhosis, bile duct proliferation, chronic cholecystitis, cholelithiasis.

### ***Clinical Features***

- Most patients present in infancy. Earliest presentation is **meconium ileus**. Pancreatic and intestinal manifestations occur early.
- Pulmonary manifestations occur late. After the neonatal period, maximum morbidity and mortality is due to pulmonary disease.

#### *Respiratory tract*

- Upper respiratory tract: Chronic sinusitis, rhinorrhea and nasal polyps
- Lower respiratory tract
  - Earliest functional abnormality is small airways disease and earliest symptom is cough. Final expression is bronchiectasis. Earliest and most severe changes in **right upper lobe**.
  - Persistent cough → viscous, purulent sputum. Intermittent exacerbations → increased cough, increased sputum volume, decrements in pulmonary function, weight loss. As exacerbations become more frequent, lung function deteriorates → eventually, respiratory failure.
  - Pathogens: In newly diagnosed patients include *H. influenzae* and *S. aureus* and in established diseases *Pseudomonas aeruginosa* (mucoid form).
  - Chest X-ray: Earliest manifestation is hyperinflation later bronchiectatic changes.
  - Pulmonary function tests: Obstructive pattern with partial bronchodilator response.
  - Complications: Pneumothorax, hemoptysis, clubbing, respiratory failure, cor pulmonale.

#### *Gastrointestinal tract*

- Most common is **exocrine pancreatic insufficiency:** Steatorrhea, azotorrhea → consequent malnutrition. Recognized only when secretion of amylase and lipase falls below 90%.

- Endocrine pancreatic insufficiency occurs in 10% much later.
- Others: Intestinal obstruction, appendicitis, recurring acute or chronic pancreatitis.
- Increased incidence of GI malignancy.

### *Genitourinary tract*

- Late onset of puberty in both males and females.
- 95% azoospermic, 20% women infertile, 90% completed pregnancies produce viable infants; breastfeeding normal.
- Retardation of bone age, heat stroke.

### **Diagnosis**

- One or more characteristic clinical features + abnormal sweat chloride ions or nasal bioelectrical response (nasal TEPD-trans-epithelial potential difference). TEPD is the voltage across an epithelium, and is the sum of the membrane potentials for the outer and inner cell membranes. This test measures the salt (sodium and chloride) transport in and out of the cells in the nose in response to different salt solutions. The way nasal cells respond to the changing salt solutions can be used to make a diagnosis of CF.
- Other disorders raised sweat chloride ions: Ectodermal dysplasia, glycogen storage disorders, adrenal sufficiency, mucopolysaccharidoses, acute respiratory disorders (group, epiglottitis, and viral pneumonias), chronic respiratory disorders (Alfa 1 antitrypsin deficiency, bronchopulmonary dysplasia).
- Pilocarpine iontophoresis
- Sweat chloride ions  $>70$  mEq/L distinguishing feature
- Nasal TEPD: Increased and on amiloride application  $\rightarrow$  loss of this potential difference and with  $\beta$ -agonist  $\rightarrow$  no response.
- DNA testing (for mutation) not useful because  $>1000$  mutations exist.

### **Treatment**

- **Lung disease**
  - Clear secretions: By breathing exercises, flutter valves, chest percussion, and recombinant human DNase.
  - Infection: Long courses of culture and sensitivity guided antibiotic therapy; higher doses required; oral/IV/aerosolized.

- Inhaled  $\beta$ -agonists/anticholinergics: Short-term benefit.  $O_2$  and medical management are temporary measures.
- Long-term high dose NSAID (some patients).
- The only effective therapy for respiratory failure in CF: Lung transplantation.
- **Gastrointestinal**
  - Pancreatic enzyme replacement (microsphere formulation).
  - Replacement of fat-soluble vitamins.
  - Treatment of acute obstruction: Enema of hypertonic radio-contrast material (megalodiatrizoate).
- **Reproductive:** Assisted reproductive technology.

## PLEURAL EFFUSION

### Normal Composition of Pleural Fluid (Table 6.53)

**Q.** Discuss the causes/etiology, clinical features, investigations, radiological findings, diagnosis, pleural fluid analysis, complications and management/treatment of pleural effusion.

### Definitions

- **Pleural effusion:** Excessive accumulation of serous fluid within the pleural cavity/space (between parietal pleura and visceral pleura). It can be detected on X-ray when  $\geq 300$  mL of fluid is accumulated and clinically, when a minimum of 500 mL is present.
- **Empyema:** Accumulation of purulent fluid (frank pus) within the pleural cavity/space.
- **Hydrothorax:** Passive transudation of fluid into the pleural cavity. It occurs in congestive heart failure, nephrotic syndrome, cirrhosis of liver, severe malnutrition, etc.
- **Hemothorax:** Accumulation of blood within the pleural cavity/space.
- **Chylothorax:** Accumulation of chyle within the pleural cavity/space.

**Table 6.53:** Normal composition of pleural fluid.

<i>Feature</i>	<i>Normal value</i>
Volume	0.1–0.2 mL/kg
Cells	1000–5000/mm <sup>3</sup>
• Mesothelial cells	3–70%
• Monocytes	30–70%

• Lymphocytes	2–30%
• Granulocytes	~ 10%
• Eosinophils	0 %
Protein	1–2 gm/dL
Albumin	50–70%
Glucose	~plasma level
LDH	<50% plasma level

## Mechanism of Pleural Effusions

- Increased hydrostatic pressure (e.g. left ventricular failure)
- Decreased oncotic pressure in microcirculation (e.g. hypoalbuminemia)
- Decrease in pleural pressure (e.g. atelectasis)
- Increased permeability of microcirculation (e.g. pneumonia)
- Impaired lymphatic drainage from pleural space (e.g. malignancy)
- Movement of fluid from abdomen to pleural space (e.g. cirrhosis.)

### Box 6.10: Causes of left-sided pleural effusion.

- Pancreatitis
- Pericardial inflammation
- Rupture of esophagus
- Left-sided subdiaphragmatic abscess
- Thoracic duct involvement above D<sub>3</sub> level

## Classification and Causes (Table 6.54)

**Q. Write short essay/note on:**

- Causes of pleural effusion
- Causes and diagnosis of exudative pleural effusion
- Causes of transudative pleural effusion.

**Q. Write short essay/note on causes of left-sided pleural effusion.**

Causes of left-sided pleural effusion is listed in Box 6.10.

**Table 6.54: Classification and causes of pleural effusion.**

<i>Types of effusion</i>	<i>Causes</i>	
Transudative effusion	<ul style="list-style-type: none"> <li>• Cardiac failure</li> <li>• Hypoproteinemia (e.g. nephrotic syndrome, cirrhosis of liver, severe</li> </ul>	<ul style="list-style-type: none"> <li>• Hypothyroidism</li> <li>• Meigs' syndrome (benign ovarian tumors with</li> </ul>

	malnutrition) • Constrictive pericarditis	ascites and pleural effusion) • Peritoneal dialysis
Exudative effusion	<ul style="list-style-type: none"> <li>• Tuberculosis</li> <li>• Bacterial pneumonia</li> <li>• Malignancy</li> <li>• Pulmonary infarction</li> <li>• Autoimmune diseases (e.g. rheumatoid arthritis, systemic lupus erythematosus)</li> <li>• Acute pancreatitis</li> <li>• Post-myocardial infarction syndrome (Dressler's syndrome)</li> </ul>	<ul style="list-style-type: none"> <li>• Drug-induced effusion</li> <li>• Benign asbestos-related effusion</li> <li>• Intra-abdominal abscess</li> <li>• Meigs' syndrome (can be transudative as well)</li> <li>• Ruptured amebic liver abscess, chylous pleural effusion</li> <li>• Acute rheumatic fever</li> </ul>

## Clinical Features

- Symptoms (pain on inspiration and coughing) and signs of pleurisy (a pleural rub): They often precede the development of a pleural effusion.
- **Breathlessness:** It may be the only symptom and its severity depends on the size and rate of accumulation of fluid.

## Physical Findings in the Chest

### Q. Write short essay/note on signs of pleural effusion.

- **Inspection: Tachypnea.** Shift of trachea to opposite side.
- **Palpation:**
  - **Shift of trachea and mediastinum** (shift of apex beat) to the opposite side
  - **Reduced chest movements** on the affected side, bulging of the intercostal spaces, fullness of the affected chest and markedly reduced vocal fremitus.
  - **Measurements:** Diminished chest expansion, increase in the size of the affected hemithorax and an increase in spinoscapular distance.
- **Percussion:**
  - **Stony dullness** over the fluid. Upper level of the dullness is highest laterally in the axilla, and is lower anteriorly and posteriorly (**Ellis-S-Shaped curve**).
  - **Small effusions:** When there is a small effusion, it may be detected as follows:

- ◆ **Left sided** small pleural effusion may be detected only by the obliteration of Traube's space on percussion.
- ◆ **Right sided** small effusion may be detectable only by tidal percussion.
- **Moderate to large effusions:** Percussion reveals a triangular area of dullness or impaired note over the back of chest on the contralateral side or opposite side of the effusion. It may be due to shift of the posterior mediastinum to the opposite side by effusion.

Causes of pleural effusion without tracheal mediastinal shift are listed in Box 6.11.

- **Auscultation**

- **Breath sounds: Intensity is markedly diminished** or absent over the fluid
- **Vocal resonance: Markedly diminished** over the fluid
- **Bronchial breathing or crackles** the level of a pleural effusion
- Occasional findings: Egophony and enhanced breath sounds can often be appreciated at the superior border of the effusion because of underlying atelectatic lung tissue.

**Box 6.11:** Causes of pleural effusion without trachea/mediastinal shift.

- Minimal effusion
- Loculated effusion
- Bilateral effusion
- Effusion with underlying collapse /fibrosis
- Effusion with fixed mediastinum (malignancy/ fibrosis)

**Q. Write short note on Grocco's sign.**

- **Grocco's sign (Grocco's triangle; paravertebral triangle of dullness):** It is a triangular area of paravertebral dullness on the side opposite a pleural effusion. Boundaries of Grocco's triangle are:
  - ◆ **Medial boundary:** Midspinal line from the upper level of effusion down to the level of the tenth thoracic vertebra.
  - ◆ **Lower boundary:** A horizontal line of about 3–7 cm extending laterally from the tenth thoracic vertebra, along the lower limit of lung resonance.

- ◆ Lateral boundary: A curved line connecting the above two lines.

## Investigations

**Q. Write short note on radiological findings/X-ray features in pleural effusion.**

- **Radiological investigations**
    - 75 mL of pleural fluid: Subpulmonic space without spillover can obliterate the posterior costophrenic sulcus.
    - **Upright chest radiograph**
      - ◆ 175 mL is required to obscure the lateral costophrenic sulcus.
      - ◆ 500 mL of fluid will obscure the diaphragmatic contour.
      - ◆ 1000 mL of effusion reaches the level of the fourth anterior rib.
  - **Decubitus radiographs and CT scans:** Less than 10 mL (even as little as 2 mL) can be identified
    - Small effusions are thinner than 1.5 cm, moderate effusions are 1.5 to 4.5 cm thick, and large effusions exceed 4.5 cm.
    - Effusions thicker than 1 cm are usually large enough for sampling by thoracentesis, since at least 200 mL of liquid are already present.
    - A significant pleural effusion is large enough to produce a pleural fluid strip >10 mm wide on lateral decubitus radiographic views.
- Radiological features of pleural effusion in an erect chest film (Fig. 6.27) are as follows:
- **Shift of mediastinum** to the opposite side.
  - **Obliteration of costophrenic angle.**
  - **Opacity:** Dense uniform opacity in the lower and lateral part on the involved side. Upper border of the opacity is concave upwards and is highest laterally.
  - **Interlobar effusion:** Wider than normal interlobar fissure.
  - **Encysted interlobar effusion:** Round opacity resembling solitary pulmonary nodule (phantom tumor).
- **Ultrasonography**
    - More accurate than plain chest X-ray for detection of pleural effusion and it can detect as little as 5 mL of effusion.
    - **Interpretation**

- ◆ **Transudate versus exudate:** A clear hypoechoic space favors transudate and the presence of moving floating densities suggests an exudate.
  - ◆ Presence of septation favors an evolving empyema or resolving hemothorax.
  - ◆ Useful in differentiating loculated pleural effusion from pleural tumor or pleural thickening.
  - ◆ Useful for locating an effusion prior to aspiration and biopsy.
  - ◆ Detection of solid pleural abnormalities may suggest pleural malignancy. However a CT scanning is indicated where malignancy is suspected.
- **Pleural aspiration and fluid analysis.**

**Fig. 6.27:** Chest X-ray shows left sided massive pleural effusion.

## Pleural Fluid Analysis

- Q.** How will you differentiate transudative pleural effusions from exudative pleural effusions?
- Q.** Write short essay/note on criteria for distinguishing pleural transudate from exudate.

**Q. Write short essay/note on pleural fluid analysis in a typical pleural effusion.**

Differentiation of transudative from exudative effusion (Table 6.55).

**Box 6.12:** Light’s criteria for distinguishing pleural transudate from exudate.

- Pleural fluid protein/serum protein >0.5
- Pleural fluid LDH/serum LDH >0.6
- Pleural fluid LDH more than two-thirds the normal upper limit for serum LDH levels

**Interpretation of Pleural Fluid Parameters (Table 6.56)**

**Light’s criteria**

**Q. Write short essay/note on Light’s criteria for distinguishing pleural transudate from exudate.**

**Table 6.55:** Differentiation of transudative from exudative effusion.

<i>Characteristics</i>	<i>Transudative effusion</i>	<i>Exudative effusion</i>
Cause and mechanism	Non-inflammatory process. Ultrafiltrate of plasma, due to increased hydrostatic pressure or decreased serum oncotic pressure with normal vascular permeability	Inflammation process and is rich in proteins due to increased vascular permeability
Appearance	Clear, serous	Cloudy/purulent/hemorrhagic/chylous
Color	Straw yellow	Yellow to red
Specific gravity	<1.018	>1.018
Protein		
• Absolute value	Low, <2 g/dL, mainly albumin	High, >2 g/dL
• Pleural fluid: serum ratio	<0.5	>0.5
Clot	Absent	Clots spontaneously because of high fibrinogen
Leukocytes		
• Total leukocytes	<1000/mm <sup>3</sup>	>1000/mm <sup>3</sup>
• Type of cells Differential leukocytes	>50% lymphocytes or mononuclear cells and mesothelial cells	>50% lymphocytes (tuberculosis, malignancy) >50% polymorphs (acute inflammation)
• Erythrocytes	<500/mm <sup>3</sup>	Variable
Bacteria	Absent	Usually present

Lactate dehydrogenase (LDH)		
• Absolute value	<200 IU/L	200 IU/L
• Pleural fluid LDH: serum LDH ratio	<0.6	>0.6
Glucose	>60 mg/dL (usually same as in blood)	<60 mg/dL (variable)

**Table 6.56: Interpretation of pleural fluid parameters.**

<i>Parameter</i>	<i>Interpretation</i>
Appearance of pleural fluid	Putrid odor (anaerobic empyema), food particles (esophageal rupture), bile stained (chylothorax/biliary fistula), milky (chylothorax/pseudo-chylothorax), anchovy sauce-like fluid (ruptured amebic abscess)
Pleural fluid glucose concentration	
• Low glucose concentration (<60 mg/dL)	Suggests empyema, malignancy or tuberculosis.
• Very low glucose concentration (<15 mg/dL)	Empyema, rheumatoid effusions
Pleural fluid eosinophilia (>10% of all cells)	May be observed in resolving infections, pneumothorax, hydropneumothorax, hemothorax and asbestos-related pleural effusion, dantrolene, bromocriptine, nitrofurantoin, paragonimiasis or Churg-Strauss syndrome
Pleural fluid erythrocyte counts >100,000/mm <sup>3</sup>	Most often in malignancy or pulmonary infarction/embolism, but may result from a traumatic tap
Low pH of pleural fluid <7.2	Complicated parapneumonic effusion, esophageal rupture, rheumatoid pleuritis, tuberculous pleuritis, malignant pleural disease, hemothorax, systemic acidosis, paragonimiasis, lupus pleuritis, urinothorax
Raised pleural fluid amylase	Pancreatic diseases and esophageal rupture. However, routine amylase estimation is not recommended unless the clinical features suggest either of the two diseases
Pleural fluid antinuclear antibody titers or rheumatoid factor	No diagnostic significance and is not indicated in most cases
Mesothelial cells	Absent: Tuberculosis Markedly increased: Pulmonary embolism

- Light's criteria (Box 6.12) are used to differentiate exudative from transudative pleural effusion by measuring the lactate dehydrogenase (LDH) and protein levels in the pleural fluid. Exudative pleural effusions

must meet at least one of the following criteria, whereas transudative pleural effusions meet none.

- **Precautions:**

- **Low specificity:** These criteria are highly sensitive for exudative effusions but have lower specificity (i.e. few transudative effusions will be classified as exudative using these criteria).
- In general Light's criteria occasionally misidentify a transudative effusion as an exudative effusion as in cardiac failure with diuretic therapy

- Clinically if a patient should have a transudative effusion, but meets Light's criteria for an exudative effusion, measure serum-pleural fluid albumin gradient, or measure the serum-pleural protein gradient (**Roth's criteria**)
  - Serum-effusion albumin gradient of  $>1.2$  g/dL-transudative
  - Serum-effusion protein gradient  $>3.1$  g/dL-transudative.

### ***Causes of Lymphocytic Pleural Effusion (Table 6.57)***

- **Pleural biopsy is indicated in undiagnosed cases**
- **Other investigations in pleural effusion**
  - **Pleural fluid tumor markers:** Carcinoembryonic antigen (CEA), cancer antigen 125 (CA-125), cancer antigen 15–3 (CA 15–3) and cytokeratin 19 fragments (CYFRA). They are not used in routine investigations of pleural effusion.
  - **Blood examination:** Total and differential leukocyte counts, ESR, proteins, sugar, LDH, amylase, rheumatoid factor and antinuclear factor.
  - **Sputum examination:** For tubercle bacilli and malignant cells.
  - **Mantoux test**
  - **Repeat radiograph:** When effusion is massive, a repeat radiograph after removal of a large volume of fluid may reveal an underlying parenchymal lesion.
  - Biopsy or fine-needle aspiration of scalene lymph nodes
  - Bronchoscopy and biopsy
  - Thoracoscopy and biopsy.

**Table 6.57: Causes of lymphocytic pleural effusion.**

Malignancy

Long standing congestive cardiac failure

- Primary lung cancers
- Secondaries
- Tuberculosis
- Lymphoma

Effusion associated with rheumatoid arthritis  
Chylothorax  
Uremic pleuritis

### Management of pleural effusion

- **Treat the underlying cause** (e.g. heart failure, pneumonia, pulmonary embolism or subphrenic abscess).
- **Therapeutic aspiration:** It may be necessary to relieve breathlessness/dyspnea. At one sitting not >1 L should be removed because it is associated with a small risk of re-expansion pulmonary edema. If there is rapid re-accumulation of fluid insertion of chest tube is necessary.
- **Drainage:** If the fluid is purulent (empyema).
- **Pleurodesis:** For malignant effusion.

## Approach to the Diagnosis of Pleural Effusions (Flowchart 6.5)

### Re-expansion Pulmonary Edema

**Q.** Write short essay/note on re-expansion pulmonary edema.

- It occurs in small number of patients when the lung undergo rapid inflation of lung (e.g. evacuation of >1 L of air/fluid) after a prolonged period of collapse (usually >3 days) from either pleural effusion or pneumothorax.
- Edema usually involves the entire re-expanded lung. Occasionally, it may involve a single lobe or the contralateral lung, or bilateral.

**Mechanism:** Exact mechanism is not known. Following may be implicated in its development.

- **Reactive oxygen species:** Ventilation and reperfusion of a previously collapsed lung may cause an inflammatory response, with generation of reactive oxygen species and superoxide radicals, which leads to increased capillary permeability.
- **Increase pulmonary hydrostatic pressure:** It may be due to increased venous return.
- **Pressure-induced mechanical disruption** of alveolar capillaries.
- Reduced levels of functional surfactant.
- Increased pressure across the capillary-alveolar membrane due to bronchial obstruction.
- Alteration of lymphatic clearance.

## ***Clinical Features***

- **Onset:** Symptoms usually develop within 24 hours (majority within 1–2 hours after lung re-expansion).
- **Symptoms:** Chest discomfort, persistent severe cough, dyspnea and frothy sputum.
- **Signs:** Tachypnea, tachycardia and crackles on the affected side of the lung.
- **Chest radiograph:** Features of pulmonary edema.
- Mortality rate is about 20%.

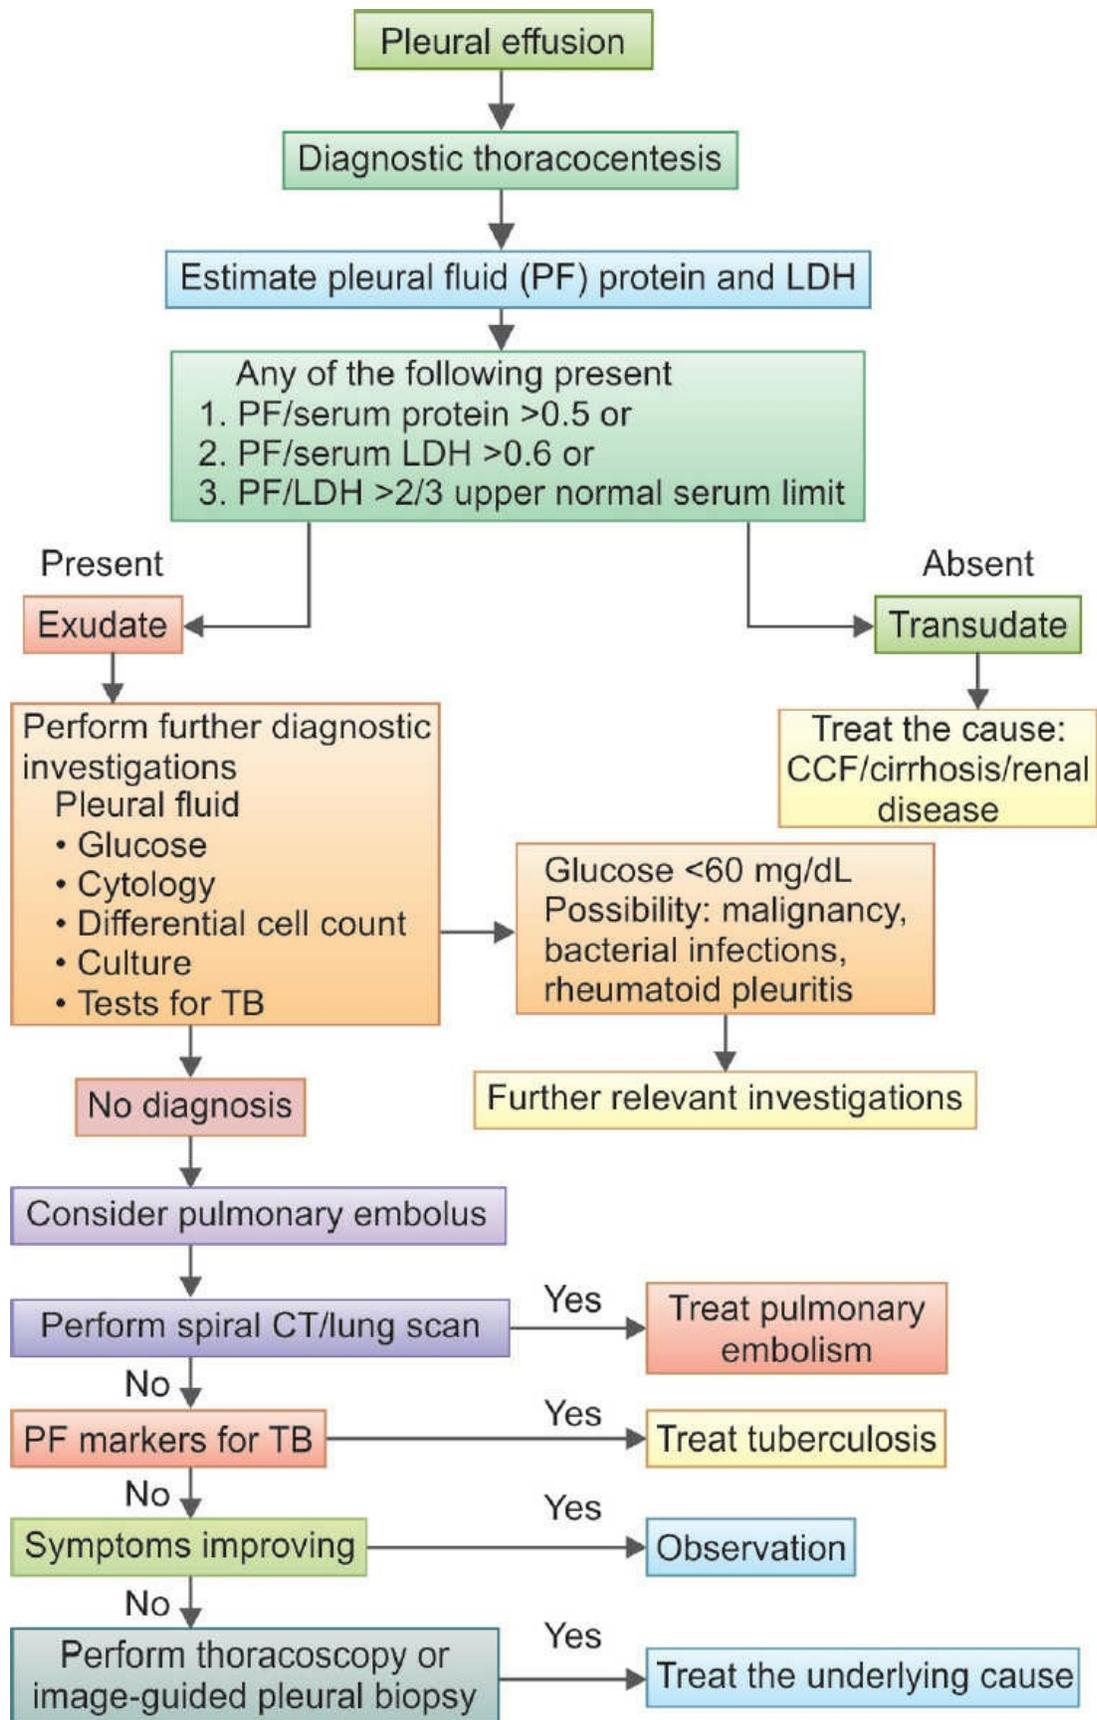

### **Treatment**

- **Supportive treatment:** Most patients recover completely within 5–7 days with supportive treatment (includes oxygen administration in mild cases to mechanical ventilation in severe cases). Patient is advised to lie on unaffected side.
- Others: Use of diuretics, bronchodilators, prostaglandin analogues (e.g. misoprostol), ibuprofen and steroids is controversial.

## ***Prevention of Reexpansion Pulmonary Edema***

- Restricting the drainage of pleural fluid to < 1 L.
- Use of low negative pressure (< –20 cm H<sub>2</sub>O) during tube thoracostomy.
- Large-volumes of fluid can be drained safely if pleural pressures are monitored. If the patient complains of vague chest pressure during thoracentesis, it suggests a sudden drop in intrapleural pressure, and the thoracentesis should be stopped.

**Flowchart 6.5:** Approach to the diagnosis of pleural effusions.

## Subpulmonic Effusion

**Q. Write short essay/note on subpulmonic effusion. How will you diagnose it?**

- It is a small pleural effusion which is seen underneath the lung. Its detection is extremely difficult.
  - Left-sided subpulmonic effusion may be show obliteration of Traube’s semilunar space of tympany.
  - Right-sided subpulmonic effusion may be suspected with an abnormal tidal percussion.
- **Chest radiograph**
  - Posteroanterior view in the erect posture
    - ◆ Mild elevation of hemidiaphragm.
    - ◆ Lateral displacement and slight flattening of the dome of the diaphragm.
    - ◆ Wide density between the gastric air shadow and upper border of the diaphragm in left-sided subpulmonic effusion.
  - Lateral decubitus view with the affected side down: Pleural fluid layering out along the lateral chest wall.
- **Ultrasonography:** Reveals subpulmonic effusion with more certainty.

## Hemorrhagic Pleural Effusion

**Q. Write short note on common causes of hemorrhagic pleural effusion.**

Causes of hemorrhagic pleural effusion (Table 6.58)

**Table 6.58:** Causes of hemorrhagic pleural effusion.

- |   |   |
|---|---|
| <ul style="list-style-type: none"><li>• Malignancy</li><li>• Pulmonary infarction</li><li>• Asbestos-related pleural effusion</li></ul> | <ul style="list-style-type: none"><li>• Tuberculosis (very rare)</li><li>• Post-cardiac injury effusion</li></ul> |
|---|---|

**Q. Write short note on hemothorax.**

*Causes of hemothorax*

- Trauma
- Rupture of a blood vessel

- Rupture of a tumor

Differentiation between hemorrhagic-effusion and hemothorax

- Differentiation of hemothorax from hemorrhagic pleural effusions can be done by performing a hematocrit on the pleural fluid.
- If the pleural fluid hematocrit is >50% of the patient's peripheral blood hematocrit, it is considered to be diagnostic of a hemothorax.

## Malignant Pleural Effusion

**Q. Write short note on malignant pleural effusion.**

Effusions secondary to metastatic disease is called malignant pleural effusion.

### Causes

- Malignant pleural effusions may be either due to a primary malignancy of pleura (e.g. mesothelioma) or secondary invasion of pleura by primary malignancy elsewhere in the body (more common). Most common malignancy-associated effusions occur with cancer of lung (35%), breast cancers (25%) and lymphomas (10%).
- **Mechanism:**
  - **Local effects:** Malignant effusion develops usually due to the local effects of the tumor, e.g. lymphatic obstruction, bronchial obstruction with pneumonia or atelectasis.
  - **Systemic effects** of tumor can also produce effusion.

*Causes of dyspnea in patients with malignancy (Table 6.59)*

Characteristic features of malignant pleural effusion:

- Effusion is usually unilateral, massive and often symptomatic.
- Rapid re-accumulation of fluid after aspiration.
- Pleural fluid
  - Often hemorrhagic, with a high erythrocyte count ( $>100,000/\text{mm}^3$ ).
  - Shows the characteristics of an exudates such as high protein content ( $>3.0 \text{ g/dL}$ ), high LDH levels ( $>200 \text{ IU/L}$ ), low glucose levels ( $<60 \text{ mg/dL}$ ) and a total leukocyte count exceeding  $1000/\text{mm}^3$ .
  - Predominant cells are lymphocytes ( $>50\%$ ).
  - Cytological examination may show malignant cells.

- Closed pleural biopsy: It may reveal malignant tumor (in about 40% of cases).

#### Treatment

- Asymptomatic effusions: Do not require any treatment.
- Mildly symptomatic effusions: Treated by repeated aspirations.
- Severely symptomatic and recurrent effusions: Treated by pleurodesis. This consists of instillation of tetracycline hydrochloride or talcum powder (more effective) or inactivated *Corynebacterium parvum* into the pleural cavity. It produces a severe inflammatory reaction in the pleura, followed by extensive pleural adhesions. Other treatment modalities include thoracotomy with pleurectomy or pleural abrasion.

**Table 6.59:** Causes of dyspnea in patients with malignancy.

<ul style="list-style-type: none"> <li>• Pleural effusion</li> <li>• Direct effects of a tumor on the lung</li> <li>• Airway obstruction</li> <li>• Chest wall invasion</li> <li>• Pericardial disease</li> </ul>	<ul style="list-style-type: none"> <li>• Underlying lung disease</li> <li>• Pulmonary vascular disease (e.g. pulmonary emboli)</li> <li>• Lymphangitis carcinomatosa</li> <li>• Radiation pneumonitis</li> <li>• Cardiac compromise</li> </ul>
---	--

## Parapneumonic Effusion (Synpneumonic Effusion and Postpneumonic Effusion)

**Q.** Write short note on parapneumonic effusion (synpneumonic effusion and postpneumonic effusion).

Parapneumonic effusion is a pleural effusion developing as complicating pneumonia or lung abscess or bronchiectasis. Empyema refers to a grossly purulent pleural effusion.

- More frequently associated with bacterial pneumonias (especially gram-negative and pneumococcal). Effusion in these cases is large and consists of predominant polymorphonuclear leukocytes.
- Less frequent with viral pneumonias and this effusion is small and predominant shows lymphocytes.

### **Clinical Presentation**

- **Acute illness:** Aerobic bacterial pneumonia with pleural effusion present with an acute illness with fever, chest pain, sputum, and leukocytosis.
- **Subacute illness:** Anaerobic infections present with a subacute illness

with weight loss, leukocytosis, mild anemia, and predisposing factor that has resulted in aspiration pneumonia.

## Categories of Parapneumonic Effusion (Table 6.60)

### Investigations

Presence of pleural fluid can be demonstrated with a lateral decubitus radiograph, computed tomography (CT) of the chest, or ultrasound.

**Table 6.60:** Parapneumonic pleural effusion and empyema: Light's classification and corresponding treatment.

Category	Type	Characteristics	Treatment
1.	Nonsignificant	<1 cm thick on an ipsilateral decubitus view. Thoracentesis not required	Antibiotic
2.	Typical parapneumonic	>1 cm thick, glucose >40 mg/dL. pH >7.20, negative Gram stain and culture	Antibiotic + consider therapeutic thoracentesis
3.	Borderline complicated	pH, 7–7.20 or LDH > 1000 Negative Gram stain and culture	Antibiotic + pleural drainage tube + consider fibrinolytics
4.	Simple complicated	pH < 7.0, positive Gram stain or culture. Not loculated, no pus	Antibiotic + pleural drainage tube + fibrinolytics
5.	Complex complicated	pH <7.0, positive Gram stain or culture. Multiloculated	Antibiotics + pleural drainage tube + fibrinolytics + consider VAT
6.	Simple empyema	Frank pus. Single loculation or free flowing fluid	Antibiotics + pleural drainage tube + fibrinolytics + consider VAT
7.	Complex empyema	Frank pus. Multiple loculations. Often requires decortication	Antibiotics + pleural drainage tube + fibrinolytics + VAT, + other surgical procedures if VAT fails

(LDH: lactate dehydrogenase; VAT: video-assisted thoracoscopy).

#### Treatment

- When there is **mild** parapneumonic effusion, patient may be **observed** and a repeat tap is done if it persists or increases.
- If the free fluid separates the lung from the chest wall by >1 cm, a **therapeutic thoracentesis** should be done.

- Indications for **more invasive procedure**, i.e. intercostal tube drainage are as following:
  - Loculated pleural fluid
  - Pleural fluid pH <7.20
  - Pleural fluid glucose <3.3 mmol/L (<60 mg/dL)
  - Positive Gram stain or culture of the pleural fluid
  - Presence of gross pus in the pleural space.
- If there is recurrence after the initial therapeutic thoracentesis and if any of above factors is present, a repeat thoracentesis should be done.
- If the fluid cannot be completely removed with the therapeutic thoracentesis, insert a chest tube and instill a fibrinolytic agent (e.g. tissue plasminogen activator 10 mg) and deoxyribonuclease (5 mg) or performing a thoracoscopy and release the adhesions.
- **Intrapleural thrombolytic agents:** Most effective in the early fibrinolytic stage (e.g. streptokinase, streptodornase, urokinase, and tPA).
  - **Indications:** (1) Occluded small-bore catheter, (2) multiloculated pleural space and (3) as a trial before committing the patient to surgery.
- **Decortication** is performed when the above measures are not effective.
- **Treatment of underlying cause.**

## Chylous Pleural Effusion (Chylothorax)

**Q. Write short note on chylous pleural effusion (chylothorax)/causes of milky pleural fluid.**

- **Definition:** It is the accumulation of chyle in the pleural cavity.
- **Mechanism:** A chylothorax results from leakage of chyle from the thoracic duct into the pleural space.
- **Causes:** Most common cause is trauma (most frequently during thoracic surgery). It may also result from lymphomas, lung cancer with mediastinal spread, mediastinal fibrosis and tumors.
- **Presentation:** Dyspnea and a large pleural effusion on chest X-ray.
- **Pleural fluid findings:**
  - Appears milky and shows the characteristics of exudates (Fig. 6.28).
  - Total triglyceride level is >110 mg/dL. The cholesterol level is very low. Sudan III staining shows fat globules.
  - Occasionally empyema can be so turbid to be confused with chyle. Centrifugation of fluid leaves a clear supernatant fluid in empyema compared to persistence of milky appearance in chylous effusion. In starved patients chyle may not be milky in appearance.
- If the trauma is not the cause of chylothorax, a contrast-enhanced CT scan of mediastinal and a lymphangiogram should be performed.

**Fig. 6.28:** Gross appearance of pleural aspirate in chylorthorax.

#### **Treatment**

Treatment of choice is insertion of a chest tube and use of octreotide. Long-term tube drainage may result in malnutrition and immune deficiency. Therefore, if patient does not respond, a pleura-peritoneal shunt may be tried. Alternatively, ligation of the thoracic duct and percutaneous transabdominal thoracic duct blockage may be useful.

## **Pseudochylous Pleural Effusion (Pseudochylothorax)**

**Q. Write short essay/note on pseudochylous pleural effusion (pseudochylothorax).**

- Rare condition in which the pleural fluid appearance is similar to that of chylous effusion (milky).
- **Causes:** Long standing benign pleural effusion (e.g. tuberculous effusion, rheumatoid effusion, etc.).
- **Pleural fluid:** Appears milky. Cholesterol level of the fluid is very high (>200 mg/dL) which is responsible for the milky appearance of fluid. Cholesterol crystals can be demonstrated and Sudan III staining does not show fat globules.
- **Differences between pseudochylous thorax and chylothorax** (Table 6.61).

## **Pleural Effusions in HIV Infection**

- A pleural effusion is seen in 7–27% of patients with HIV

- Leading causes are: Kaposi sarcoma, parapneumonic effusion, tuberculosis, lymphoma, *Pneumocystis jirovecii* pneumonia.

**Table 6.61:** Differences between pseudochyloous thorax and chylothorax.

Feature	Pseudochylothorax	Chylothorax
Triglycerides	<0.56 mol/L (50 mg/dL)	>1.24 mmol/L (110 mg/dL)
Cholesterol	>5.18 mmol/L (200 mg/dL)	<5.18 mmol/L (200 mg/dL)
Cholesterol crystals	Often present	Absent
Chylomicrons	Absent	Present
Etiology	Tuberculosis, rheumatoid arthritis, poorly treated empyema	Neoplasm (lymphoma, metastatic carcinoma), trauma (operative, penetrating injuries), miscellaneous (tuberculosis, sarcoidosis, cirrhosis, lymphangioliomyomatosis, obstruction of central veins, amyloidosis)

**Tuberculous pleural effusion** (refer pages 299-300)

## Empyema Thoracis

**Q. Discuss the etiology, clinical features, investigations, complications and management of empyema thoracis.**

### Definition

- Empyema thoracis is defined as collection of pus in the pleural space/cavity. It may be as thin as serous fluid or so thick that it is impossible to aspirate, even with a wide-bore needle. Microscopically, it shows numerous neutrophil leukocytes.
- It usually involves whole pleural space/cavity and unilateral. If only a part of the pleural space is involved, it is termed encysted or loculated empyema.

### Etiology

- **Spread of infection from neighboring structures:** For example, bacterial pneumonias, bronchiectasis, lung abscess, rupture of subphrenic abscess through the diaphragm, esophageal perforation, and infection of hemothorax following trauma or surgery.
- **From distant source:** For example, bacteremia.

- **Direct infection from external source:** For example, penetrating chest injury, chest tube placement, thoracic surgery.

**Common organisms:** *Pneumococcus*, *Streptococcus*, *Staphylococcus*, *Pseudomonas*, *M. tuberculosis*, *H. influenzae* and anaerobes.

## Clinical Features (Table 6.62)

### Q. Write short answer on:

- Clinical features of empyema
- Physical sign of right-sided empyema.

## Investigations

- **Blood:** Polymorphonuclear leukocytosis, high CRP (C reactive protein).
- **Chest X-ray:** Findings may be similar to those of pleural effusion. However, pleural adhesions may produce a 'D'-shaped shadow against the inside of the chest wall (Fig. 6.29). If air is present along with pus (pyopneumothorax), a horizontal 'fluid level' mark is detected at the air/liquid interface.
- **Ultrasound:** It shows the position of the fluid, the extent of pleural thickening and whether fluid is collected as a single locule or multiloculated.
- **CT:** It gives information regarding the pleura, underlying lung parenchyma and patency of the major bronchi. Ultrasound or CT is used to detect the optimal site for aspiration.
- **Aspiration of empyema** (Table 6.63)

**Table 6.62:** Clinical features of empyema.

### Systemic features

- High-grade, remittent fever
- Chills, rigors, sweating, malaise and weight loss

### Respiratory symptoms

Pleuritic chest pain, breathlessness and dry cough. Copious, purulent sputum develops when the empyema ruptures into a bronchus (bronchopleural fistula)

### Physical examination

Clinical signs of pleural effusion PLUS intercostals tenderness, digital clubbing and edema of the chest wall

**Fig. 6.29:** Chest X-ray of loculated effusion—D sign.

**Table 6.63:** Characteristic features of aspirated pus from empyema.

Consistency	Vary from very thin to very thick
Microscopy	Numerous polymorphonuclear leukocytes
Gram stain	May show positive organism
Culture and sensitivity	To identify the causative organism
Tubercle bacilli	May be found, if it is due to <i>M. tuberculosis</i>

**Complications (Table 6.64):**

**Table 6.64:** Complications of empyema.

<ul style="list-style-type: none"> <li>• <b>Empyema necessitans</b> is the formation of a subcutaneous abscess or sinus that develops when the pus track through the chest wall</li> </ul>	<ul style="list-style-type: none"> <li>• Pleural fibrosis</li> <li>• Secondary amyloidosis</li> <li>• Metastatic brain abscess.</li> </ul>
<ul style="list-style-type: none"> <li>• <b>Bronchopleural fistula and pyopneumothorax</b> due to rupture of pus into a bronchus</li> </ul>	

**Q. Write short essay/note on the management on non-tuberculous empyema.**

**Management of Empyema Thoracis**

**A. Non-tuberculous empyema**

**Acute**

- Antibiotics: It should be given depending on the culture and sensitivity report.
- **Drainage of pus:** The pus in the pleural cavity should be drained.
  - **Aspiration:** In early and small empyema with thin fluid, daily aspiration of the fluid with a wide-bore needle is attempted.
  - **Tube-drainage** is necessary in most cases.
  - **Limited thoracotomy:** If tube drainage fails or pus is thick or loculated limited thoracotomy is performed. It involves resection of a small segment of the rib, clearing the empyema cavity break down any adhesions and introducing a wide-bore tube (for prolonged drainage).
  - Intrapleural administration of fibrinolytic agents (e.g. streptokinase) is of no benefit.

**Chronic**

- **Surgery:**
  - Surgical ‘decortication’ of the lung may be necessary when there is gross thickening of the visceral pleura which preventing re-expansion of the lung in a chronic empyema. It involves stripping of the whole of the grossly thickened visceral pleura in order to allow the lung to re-expand.
  - Surgery is also required if a bronchopleural fistula develops.

**B. Tuberculous empyema**

- **Antituberculous chemotherapy**
- **Repeated aspiration:** Through a wide-bore needle or tube-drainage.
- Rarely, surgical treatment may be required.

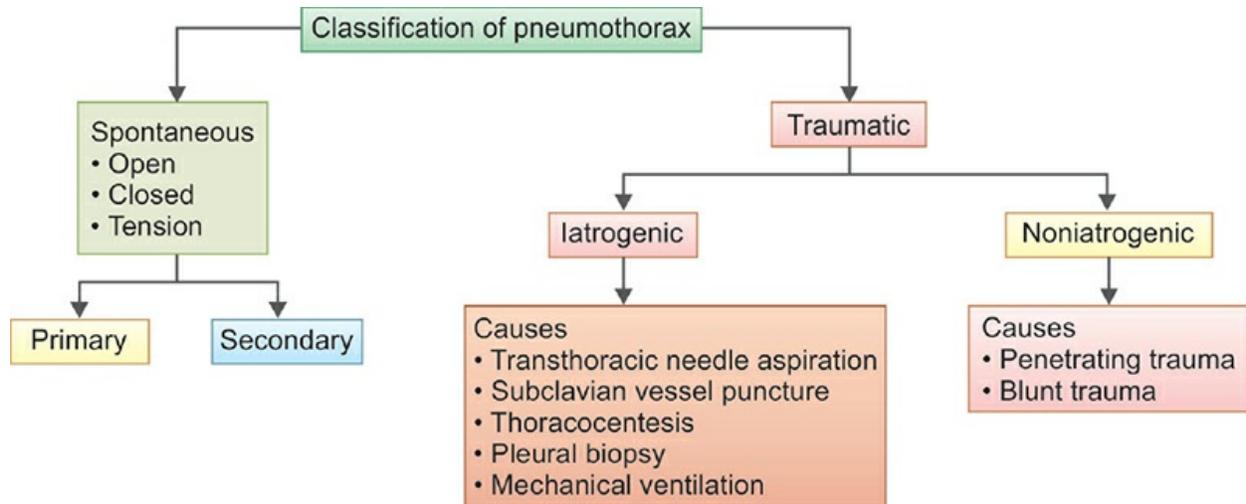

## PNEUMOTHORAX

**Q. Describe the types, etiology, clinical features, investigations and management of pneumothorax.**

**Q. Describe etiology, clinical features, investigations and treatment of tension pneumothorax.**

- **Definition:** Presence of air/gas in the pleural cavity/space is known as pneumothorax.
- Pneumothorax may be localized (if there is a prior disease causing adhesion of visceral pleura to parietal pleura), or generalized (if there are no pleural adhesions).

**Flowchart 6.6:** Classification of pneumothorax.

**Classification** (Flowchart 6.6)

## Etiology

### *Spontaneous pneumothorax*

- **Primary (simple) spontaneous pneumothorax:** Occurs in the absence (no evidence) of overt lung disease.
  - Occurs in individual without any underlying lung disease or any trauma.
  - Age: Commonly occurs between the age group of 20–40 years.
  - Risk factors: Smoking, tall stature and the presence of apical subpleural blebs, familial.
  - About 50% of patients will have a recurrence. Both lungs are affected with equal frequency
- **Secondary spontaneous pneumothorax** occurs in the presence of an underlying lung disease.
  - **Causes:** Most common causes are **COPD** (chronic bronchitis and emphysema) **and** cavitory active pulmonary **tuberculosis**. **It occurs** due to rupture of emphysematous bullae and subpleural tuberculosis focus. Other causes include bronchial asthma, suppurative diseases of lung and pleura, cystic fibrosis, *Pneumocystis jirovecii* pneumonia.

**Traumatic pneumothorax** results from penetrating or non-penetrating injuries to the chest

- **Iatrogenic:** Following diagnostic or therapeutic interventions. These include transthoracic and transbronchial needle aspiration/biopsy (24%), subclavian vessel puncture (22%), thoracocentesis (22%), pleural biopsy

(8%) and mechanical ventilation (7%).

- **Non-iatrogenic:** Blunt and penetrating injuries to the chest wall, bronchi, lung or esophagus.

## Clinical Features

**Q. Write a short note on clinical features of acute pneumothorax.**

- A small pneumothorax may be asymptomatic without any abnormal physical signs in the chest.
- Most common symptoms are **sudden onset unilateral pleuritic chest pain** and **breathlessness** (dyspnea).
- **Severity depends on:** (1) extent of lung collapse and (2) amount of pre-existing lung disease.
- **Tension pneumothorax:** Distressed with rapid labored respiration, cyanosis, marked tachycardia and profuse diaphoresis.

## Physical Signs

**General examination:** Patient will be cyanosed, tachypneic, peripheral pulses may be feeble and hypotension may be present.

### *Respiratory system*

- **Inspection and palpation**
  - **Accessory muscles of respiration in action, trachea and mediastinal (apex beat) shift to the opposite side.**
  - **On the affected side:** Fullness of the chest, diminished chest movements, increase in the size and diminished expansion of the hemithorax, increased spinoscapular distance and markedly diminished vocal fremitus. Subcutaneous emphysema may be present.
- **Percussion:** Hyper-resonant note over the affected hemithorax.
- **Auscultation**
  - **On the affected side:** Markedly diminished/absent of breath sounds and vocal resonance, absence of adventitious sounds. Open pneumothorax with a bronchopleural fistula, there may be amphoric bronchial breathing.

## Investigations

**Radiological findings** on chest radiograph (Fig. 6.30): **Standard erect chest**

**X-ray in inspiration** is recommended for the initial diagnosis of pneumothorax rather than expiratory films. Following features are observed:

- Sharply defined edge of the deflated lung.
- Complete translucency and absence of bronchovascular markings (no lung markings) in the area between the edge of the lung and chest wall. A clear **visceral pleural line/collapsed lung margin** can be seen.
- Mediastinal shift/displacement to the opposite side.

It may also reveal the presence or absence of pleural fluid, complicating empyema or underlying lung lesion. CT is used in difficult cases.

**CT scanning** is done if accurate size estimates are required.

- Recommended only in difficult cases such as patients in whom the lungs are obscured by overlying surgical emphysema.
- To differentiate a pneumothorax from suspected bulla in complex cystic lung disease.

USG signs of pneumothorax: (1) loss of lung sliding, (2) loss of comet tails, (3) loss of seashore sign (M mode) and (4) stratosphere sign or bar code sign (M mode).

**Fig. 6.30:** Chest X-ray shows right sided pneumothorax.

## Types of Spontaneous Pneumothorax (Figs. 6.31A to C)

There are three types namely: (1) closed spontaneous pneumothorax, (2) open spontaneous pneumothorax and (3) tension (valvular) pneumothorax. Differences between closed, open and tension pneumothorax are listed in Table 6.65.

### ***Closed Spontaneous Pneumothorax***

Pneumothorax where the communication between pleura space and the lung seals off and does not re-open. The mean pleural pressure remains negative and air can neither enter nor leave the pleural cavity/space. The trapped air is slowly and spontaneously re-absorbed and the lung re-expands completely in 2–4 weeks. Infection of the pleural cavity is uncommon.

**Clinical features:** Trivial breathlessness that gradually abates over a few days.

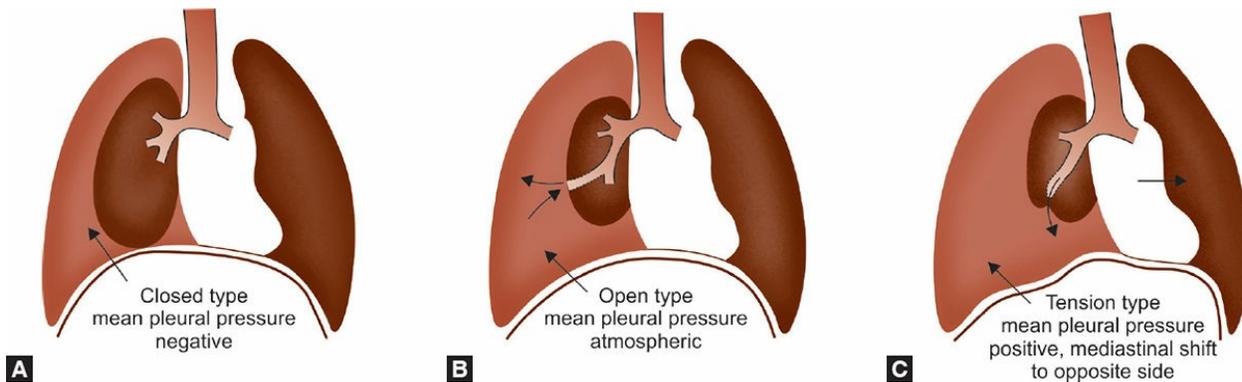

### ***Open Spontaneous Pneumothorax***

- Pneumothorax where the communication between bronchus and pleura does not seal off and remains patent and air continues to pass freely between the bronchial tree and pleural space. It results in a bronchopleural fistula.
- Free flow of air through the bronchopleural fistula results in intrapleural pressure (normally negative) same as that of atmospheric pressure throughout the respiratory cycle. This prevents the re-expansion of the collapsed lung. Development of bronchopleural fistula facilitates the spread of infection into the pleural space causing empyema.
- Open pneumothorax usually develops secondary to rupture of an emphysematous bulla, a small pleural bleb, a tuberculous cavity or a lung abscess into the pleural cavity/space.

**Clinical features:** Present with breathlessness that does not improve. If there is infection of pleural space, fever and systemic features are observed. The physical signs are those of hydropneumothorax (air and fluid in the pleural space).

**Table 6.65:** Differences between closed, open and tension pneumothorax.

<b><i>Closed pneumothorax</i></b>	<b><i>Open pneumothorax</i></b>	<b><i>Tension pneumothorax</i></b>
The pleural tear is <b>sealed</b>	The pleural tear is <b>open</b>	The pleural tear act as a <b>ball and valve</b> mechanism
The pleural cavity pressure is $<$ the atmospheric pressure	The pleural cavity pressure is $=$ the atmospheric pressure	The pleural cavity pressure is more than the atmospheric pressure

**Figs. 6.31A to C:** Types of spontaneous pneumothorax. (A) Closed type; (B) Open type; (C) Tension (valvular) type.

## ***Tension (Valvular) Pneumothorax***

**Q. Write short essay/note on clinical features and signs of tension pneumothorax.**

In tension pneumothorax, the pressure in the pleural space is positive throughout the respiratory cycle.

- Pneumothorax where communication between pleura and lung persists. This is due to formation of a valvular mechanism (one way valve through) in which air is sucked into the pleural space during inspiration (coughing, sneezing and straining) but not expelled during expiration. Large quantity of air gets ‘trapped’ in the pleural space/cavity and raises the intrapleural pressure much higher than the atmospheric pressure.
- The high intrapleural pressure causes compression of the underlying lung, shifts the mediastinum to the opposite side with consequent compression of the opposite lung also. It also decreases venous return to the heart by compressing the vena cava resulting in reduced cardiac output.

**Clinical features:** Rapidly progressive breathlessness, central cyanosis, rapid thread pulse and signs of peripheral circulatory failure. Signs of pneumothorax are present.

**Treatment**

- Tension pneumothorax should be treated as an **acute medical emergency**.
- **Emergency treatment: Insertion of a large-bore needle into the pleural space through the second anterior intercostal space.** The diagnosis is confirmed, if large amounts of air escape through the inserted needle. The needle should be left in place till a thoracostomy tube can be inserted. Cover the open end of the needle with a glove finger. Other methods:
  - Insertion of wide-bore plastic cannula. The opposite end is attached to long rubber tubing, the end of which is placed underwater in a bottle.
  - **Introduction of an intercostals catheter** connected to a water-seal drainage system.
  - If above methods cannot be performed, simple stab on chest wall to release pressure.

## Recurrent Spontaneous Pneumothorax

- After primary spontaneous pneumothorax, recurrence occurs within a year in about 25% of patients.
- Recurrent pneumothorax is common with emphysematous bullae. The recurrence usually occurs on the same side. It can also occur with LAM (lymphangioliomyomatosis).

### Treatment

- Obliteration of the pleural space by artificial pleurodesis. This can be accomplished by intrapleural instillation of an irritant like tetracycline hydrochloride or talc powder.
- Pleurodesis is recommended for all patients following a second pneumothorax. Pleurodesis is achieved by pleural abrasion or parietal pleurectomy at thoracotomy or thoracoscopy.

## Catamenial Pneumothorax

### Q. Write a short note on catamenial pneumothorax.

- Rare condition occurring in females above the age of 25–30 years.
- Presents with repeated attacks of spontaneous pneumothorax usually on the right side, in association with menstruation. Attacks usually occur within 2 days before or after the onset of menstruation. Hemoptysis may also develop. Most frequently associated with endometriosis of thorax.

**Treatment:** Ovulation-suppressing drugs, surgical exploration and pleurodesis.

## Clicking Pneumothorax

### Q. Write a short note clicking pneumothorax.

- In clicking pneumothorax, a small left-sided pneumothorax get localized in front of the pericardium. This produces alteration of the heart sounds so that the sound becomes loud and resonant ('clicking').

## Complications of Pneumothorax

### Q. Write a short note on causes of pyopneumothorax.

- **Pyopneumothorax:** Caused by aspiration or intercostal chest tube insertion (iatrogenic). It may also result from necrotic pneumonia, lung abscess, or caseous pneumonia. Its causes are listed in Box 6.13.
- **Hydropneumothorax**
- **Hemopneumothorax:** Bleeding in pleural space and commonly caused due to rupture of vessels in adhesions. When lung re-expands, bleeding will stop. If bleeding persists, surgical ligation may be required.
- **Mediastinal and subcutaneous emphysema**

### Box 6.13: Causes of pyopneumothorax.

- Complication of pneumothorax
- Thoracocentesis
- Trauma to thorax
- Bronchopleural fistula
- Esophagopleural fistula

### Q. Write a short note on management of acute pneumothorax.

#### Treatment of Pneumothorax

- **Goals:** (1) To promote lung expansion, (2) to eliminate the pathogenesis and (3) to decrease recurrence of pneumothorax.
  - **Treatment options according to** (1) Classification of pneumothorax, (2) pathogenesis, (3) pneumothorax frequency, (4) the extension of lung collapse, (5) severity of disease, and (6) complication and concomitant underlying diseases.
1. **Primary spontaneous pneumothorax (PSP): Observation:** Small, closed mildly symptomatic spontaneous pneumothoraces do not require hospital admission. Patient is asked to return directly to hospital in the event of developing breathlessness.
  2. **Secondary spontaneous pneumothorax (SSP):**
    - **Hospitalization and observation:** Small SSP of < 1 cm depth or isolated apical pneumothoraces in asymptomatic patients, supplemental high flow (10 L/min) oxygen inhalation of high concentration of oxygen may reduce the total pressure of gases in pleural capillaries by reducing the partial pressure of nitrogen. This should increase the pressure gradient between the pleural capillaries and the pleural cavity. Thereby increasing absorption of air from the pleural cavity. The rate of resolution/reabsorption of spontaneous pneumothoraces is 1.25–1.8% of volume of hemithorax/24 hours.  
**Active intervention:** All other cases will require active intervention (aspiration or chest drain insertion).
    - **Simple aspiration**
      - Recommended as first line treatment for all PSP requiring intervention.

- Less likely to succeed in secondary pneumothoraces and in such cases, it is only recommended as an initial treatment in small (<2 cm) pneumothoraces in minimally breathless patients under the age of 50 years.
- **Repeated and catheter aspiration:** It is reasonable for primary pneumothorax when the first aspiration has been unsuccessful. A volume of <2.5 L has been aspirated on the first attempt.
- **Intercostal tube and under water seal drainage:** Suction to an intercostal tube should not be applied directly after tube insertion. But can be added after 48 hours for persistent air leak or failure of a pneumothorax to re-expand. High volume, low pressure (–10 to –20 cm H<sub>2</sub>O) suction systems are recommended.
- **Chemical pleurodesis**

**Q. Write a short note on indications for pleurodesis.**

- Goals: (1) to prevent pneumothorax recurrence and (2) to produce inflammation of pleura and adhesions.
- **Indications:** Persist air leak and repeated pneumothorax, bilateral pneumothoraces, those complicated with bullae, occupations where pneumothorax should not occur (e.g. drivers, pilots).
- Sclerosing agents: **Tetracycline, minocycline, doxycycline, talc, erythromycin.**
- The instillation of sclerosing agents into the pleural space should lead to an aseptic inflammation with dense adhesions.
- Other types pleurodesis:
  - Biological pleurodesis using *Corynebacterium parvum*.
  - Physical pleurodesis **mechanical abrasions.**

**Surgical treatment**

- Indication: No response to medical treatment, persistence of air leak, hemopneumothorax, bilateral pneumothoraces, recurrent pneumothorax, tension pneumothorax failed to drain, thicken pleura makes lung unable to re-expansion, and multiple blebs or bullae.
- **Open thoracotomy and pleurectomy** remains the procedure with the lowest recurrence rate for difficult or recurrent pneumothorax.
- Minimally invasive procedures, thoracoscopy (VATS), pleural abrasion, and surgical talc pleurodesis are all effective alternative strategies.

## Physical Signs of Hydropneumothorax

**Q. Write short note on the physical signs of hydropneumothorax.**

Similar findings as pneumothorax (*refer physical signs of pneumothorax on page 322*) except the following findings:

- **Percussion note** is **hyper-resonant over the upper air-containing part** and **stony dull over the lower fluid-containing part.**
- Straight line dullness. **Shifting dullness** can be elicited.
- **Amphoric bronchial breathing** in case of bronchopleural fistula.
- **Coin-test** is positive over the upper air-containing part.
- **Succussion splash** can be elicited on the affected side.

# PNEUMONIA

**Q. Describe the etiology, classification, investigations, complications, indications of hospitalization and treatment of pneumonia.**

**Definition:** Pneumonia is as an acute respiratory illness, defined as inflammation with exudative solidification of the lung parenchyma. It causes the alveoli to be filled with inflammatory exudates and usually results in consolidation (solidification) of lung.

- **Pathological definition:** Infection of the alveoli, distal airway, interstitium of the lung. Characterized by increased weight, replacement of the normal sponginess by the consolidation. Alveoli filled by the WBC, RBC and fibrin.
- **Clinical definition:** Constellation of symptoms and signs (fever, chills, cough, pleural chest pain, sputum, bronchial breathing, egophony, crackles, wheeze, pleural friction rub) with at least one opacity on chest X-ray PA view.

## Classification of Pneumonia

Pneumonias can be classified in a different ways (Table 6.66).

**Table 6.66:** Classification of pneumonia.

1. Classification depending on the anatomic distribution
  - Lobar pneumonia
  - Bronchopneumonia
  - Interstitial pneumonia
2. Etiological classification
  - Primary
  - Secondary
  - Suppurative
3. Clinical setting in which the infection occurs (if no pathogen can be isolated)
  - Community-acquired acute pneumonia
  - Community-acquired atypical pneumonia
  - Nosocomial pneumonia or hospital-acquired pneumonia
  - Pneumonia in immunocompromised host
  - Health-care associated pneumonia

## 1. *Classification depending on the anatomic distribution*

- a. **Lobar pneumonias (alveolar or air space pneumonia):** The organism causes inflammatory exudates involving many contiguous alveoli (e.g. pneumococcal pneumonia). This radiologically appear as non-segmental consolidation.
- b. **Bronchopneumonia:** Inflammation is involves conducting airways, especially terminal and respiratory bronchioles, and the surrounding alveoli (e.g. staphylococcal pneumonia).
- c. **Interstitial pneumonia:** The inflammation is confined to interalveolar septa. X-ray chest gives a reticular pattern (e.g. *Mycoplasma pneumoniae*, *Pneumocystis jirovecii* and viruses).

## 2. *Etiological classification*

- a. **Primary pneumonia:** It is caused by a specific pathogenic organism and there is no pre-existing abnormality of the respiratory system. The causative organisms are listed in Table 6.67.

### **Q. Write short essay on list the bacteria causing pneumonia.**

- b. **Secondary pneumonia (including aspiration pneumonia):** (discussed earlier)
- c. **Suppurative pneumonia (necrotizing pneumonia):** (discussed earlier)

## 3. **Clinical setting in which the infection occurs (if no pathogen can be isolated):**

Pneumonia is classified by the setting in which the person has contracted their infection.

### a. **Community setting or community acquired pneumonia (CAP)**

- It is defined as an acute pulmonary infection in a patient who is not hospitalized or living in a long-term care facility 14 days or more before presentation and does not meet the criteria for health care associated pneumonia (HCAP). This category includes both immunocompetent and immunocompromised patients as causative agents are almost similar in both the conditions.

### b. **Nosocomial pneumonia or hospital acquired pneumonia**

- **Definition:** Hospital-acquired pneumonias are pulmonary infections acquired in the course of a hospital stay (development of pneumonia after more than 48 hours of hospitalization).

- Most of this pneumonia occurs outside intensive care units. However, the highest risk is observed in patients on mechanical ventilation [ventilator associated pneumonia (VAP)]
  - **Etiology:** Predisposing factors include severe underlying disease, immunosuppression, prolonged antibiotic therapy, patients on mechanical ventilation or invasive access devices such as intravascular catheters. The hospital-acquired pneumonias are serious and may be life-threatening. The various causative organism causing hospital-acquired pneumonia are shown in Table 6.68.
- c. **Pneumonia in immunocompromised host:** This is a type of pneumonia found in a patient whose immune system is compromised, through either genetic defect, immunosuppressive medication, or acquired immunodeficiency such as HIV infection and malignancies.
- It may be caused by classical organisms, atypical organisms, *Mycobacterium tuberculosis* or *Pneumocystis jirovecii*.
  - Usually symptoms are more than the signs.
- d. **Health care associated pneumonia (HCAP)**
- **Definition:** Hospital-acquired pneumonias are pulmonary infections acquired in the course of a hospital stay. It occurs
    - ◆ Within 90 days of a 2 day or longer hospitalization. In a nursing home or long-term care residence.
    - ◆ Within 30 days of receiving intravenous antibacterial therapy, chemotherapy, or wound care or after a hospital or hemodialysis clinic visit; or in any patient in contact with a multidrug resistant pathogen.
  - Features of HCAP more closely resemble nosocomial pneumonia and may require treatment accordingly.

**Table 6.67:** List of organism causing primary pneumonia.

Common	Less common
<ul style="list-style-type: none"> <li>• <i>Streptococcus pneumoniae</i> (most common)</li> <li>• <i>Haemophilus influenzae</i></li> <li>• <i>Moraxella catarrhalis</i></li> <li>• <i>Staphylococcus aureus</i></li> <li>• <i>Legionella pneumophila</i></li> <li>• <i>Mycoplasma pneumonia</i></li> </ul>	<ul style="list-style-type: none"> <li>• <i>Enterobacteriaceae</i> (<i>Klebsiella pneumoniae</i>) and <i>Pseudomonas</i> spp.</li> <li>• <i>Streptococcus pyogenes</i></li> <li>• <i>Pseudomonas aeruginosa</i></li> <li>• <i>Coxiella burnetii</i> (Q-fever)</li> <li>• <i>Chlamydia</i> spp. (<i>C. pneumoniae</i>, <i>C. psittaci</i>,</li> </ul>

*C. trachomatis*)

- Viruses: Respiratory syncytial virus, H1N1 influenza virus, seasonal influenza virus, parainfluenza virus and human metapneumovirus (children); influenza A and B (adults); adenovirus (military recruits); corona virus producing severe acute respiratory syndrome (SARS)
- *Actionomyces Israelii*

### Table 6.68: Various etiological agents causing hospital- acquired pneumonia.

Gram-negative rods, Enterobacteriaceae (*Klebsiella* spp., *Serratiamarcescens*, *Escherichia coli*) and *Pseudomonas* species.

*Staphylococcus aureus* (penicillin and usually methicillin-resistant)

### Noninfective Pneumonias

#### • Lipid/Lipoid pneumonia:

- Aspiration of fatty/oily material into lungs.
- Decreasing order of severity of manifestations: Mineral oil > animal oil > vegetable oil (because vegetable oil to some extent, animal oils can be hydrolyzed in the body).
- Liquid paraffin causes the most cases of lipoid pneumonia
- Chronic persistence of the oil in the lung can produce fibrosis/paraffinomas (paraffin granulomas).

#### • Radiation pneumonitis

- Dose >25 Gy. Risk depends on radiation dose and volume of lung irradiated.
- Early phase: Cough, fever, chest X-ray infiltrate.
- Late phase (3–6 weeks): Dyspnea
- Lung fibrosis: With excessive dose/large lung volume irradiation.
- Treatment: Glucocorticoids improve symptoms, but have no ultimate effect on the development of fibrosis.
- Recall pneumonitis: Pneumonitis due to chemotherapy, within the distribution of a previous radiotherapy field (the radiation sensitizes the lung tissue to the toxic effects of chemotherapy).

#### • Chemical pneumonitis

- If aspirated fluid: pH <2.5 and volume >0.3 mL/kg results in chemical pneumonia (Mendelson syndrome)—ARDS/secondary bacterial infection.
- If gastric pH alkaline: Colonization of gastric mucosa by enteric gram-negative bacilli-pneumonitis.
- Poor orodental hygiene with gross aspiration and lung abscess.
- Pathogenesis: Most common mechanism by which pathogenic organisms reach the lower respiratory tract through microaspiration.
- Others: Hematogenous/inhalation (droplet nuclei/aerosols)/contiguous spread.

## Community-Acquired Pneumonia (CAP)

**Q. Write essay on community-acquired pneumonia (CAP)—its definition, etiology/causative organisms, clinical features, investigations, diagnosis, complications and treatment/ management.**

**Q. Write essay on streptococcal pneumonia—its etiopathogenesis, clinical features, complications and management.**

**Q. Write short essay on etiology/organisms causing community acquired pneumonia.**

- Community-acquired pneumonia affects all ages, but is commoner at the extremes of age.
- Most cases are spread by droplet infection.
- CAP may occur in previously healthy individuals. However, several factors may impair the effectiveness of local defenses and predispose to CAP (Table 6.69).
- Pneumonia can be classified either according to the organism responsible for infection or anatomical distribution of infection.
- *Streptococcus pneumoniae* (*Pneumococcus*) is the most common cause. Viral infections are important causes of CAP in children.
- Depending upon the anatomical distribution of infection, it may be classified as lobar pneumonia (localized with the whole of one or more lobes affected) or bronchopneumonia (diffuse in which lobules of the lung are mainly affected, often due to infection centered on the bronchi and bronchioles).
- Potential causative agents in CAP: Bacteria, fungi, viruses, and protozoa.
- Causative agent and salient feature of community-acquired acute pneumonia are presented in Table 6.70.

### Table 6.69: Predisposing conditions for community-acquired pneumonia.

- Extremes of age
- Upper respiratory tract infections
- Comorbidities: For example, congestive heart failure, diabetes, chronic kidney disease, recent influenza infection and malnutrition
- Cigarette smoking
- Alcohol

- Corticosteroid therapy
- Congenital or acquired immune deficiencies, e.g. HIV
- Decreased or absent splenic function, e.g. sickle cell disease or post-splenectomy (risk for infection with encapsulated bacteria).
- Other respiratory conditions: Cystic fibrosis, bronchiectasis, COPD, obstructing lesion (endoluminal cancer, inhaled foreign body)
- Indoor air pollution

**Table 6.70:** Causative agent and salient feature of community-acquired acute pneumonia.

<b>Microorganism</b>	<b>Features</b>
<i>Streptococcus pneumoniae</i> or <i>Pneumococcus</i>	Most common cause
<i>Haemophilus influenzae</i>	Most common bacterial cause in COPD
<i>Moraxella catarrhalis</i>	Elderly
<i>Staphylococcus aureus</i>	Secondary bacterial pneumonia following viral respiratory illnesses
<i>Enterobacteriaceae</i> ( <i>Klebsiella pneumoniae</i> )	In debilitated and malnourished people
<i>Pseudomonas aeruginosa</i>	Common in patients with neutropenia
<i>Legionella pneumophila</i>	Organ transplant recipients

**Table 6.71:** Types of presentations of community-acquired pneumonia (CAP).

<b>Classical</b>	<b>Atypical</b>
<ul style="list-style-type: none"> <li>• Sudden onset of CAP</li> <li>• High fever, shaking chills</li> <li>• Pleuritic chest pain, sudden onset of breathlessness</li> <li>• Productive cough</li> <li>• Rusty sputum, blood tinge</li> <li>• Poor general condition</li> <li>• High mortality up to 20% in patients with bacteremia</li> <li>• Cause: <i>S. pneumoniae</i></li> </ul>	<ul style="list-style-type: none"> <li>• Gradual and insidious onset</li> <li>• Low grade fever</li> <li>• Dry cough, no blood tinge</li> <li>• Low mortality 1–2%; except in cases of legionellosis</li> <li>• Cause: <i>Mycoplasma</i>, <i>Chlamydiae</i>, <i>Legionella</i>, rickettsiae, viruses</li> <li>• Systemic manifestations present</li> </ul>

**Q. Write short essay on etiology/organisms causing community acquired pneumonia.**

### ***Types of Presentations of Community-Acquired Pneumonia (CAP)***

Two types of presentations of CAP is presented in Table 6.71.

## ***Clinical Features of CAP***

- The clinical features vary according to the immune status of the patient and the infecting agent.
- **Systemic features:** Pneumonia (especially lobar pneumonia), usually presents as an acute illness. Sudden onset of fever, rigors, shivering and malaise are predominant symptoms and delirium may be present. The appetite is lost and there may be headache. Fever can be as high as 39.5–40°C. Swinging fevers often indicates empyema.
- **Pulmonary symptoms**
  - **Cough:** First, it is characteristically short, painful and dry. Later, it is productive with expectoration of mucopurulent sputum. Characteristically rusty sputum may be seen in patients with *Strep. pneumoniae* (pneumococcal pneumonia) and the occasional hemoptysis can occur.
  - **Chest pain:** It is commonly pleuritic chest pain and may be a presenting feature. It is due to inflammation of the pleura. A pleural rub may be heard. Occasionally pain may be referred to the shoulder or anterior abdominal wall. Upper abdominal tenderness is sometimes apparent in patients.
  - **Breathlessness:** The alveoli become filled inflammatory exudate impairs gas exchange producing breathlessness.
  - **Other features:** CAP can present with confusion or nonspecific symptoms in the elderly. When symptoms have been present for several weeks or have failed to respond to standard antibiotics, the possibility of tuberculosis should always be considered.
- **Extrapulmonary features (Table 6.72):** They are more common in certain infections and sometimes give a clinical clue to the etiology.

### *Examination*

- **Fever:** About 80% are febrile, although this finding is frequently absent in older patients. This is a helpful diagnostic clue if present.
- Respiratory and pulse rate may be raised and the blood pressure low and this may be the most sensitive sign in the elderly.
- **Tachycardia** is common. However, relative bradycardia is a characteristic feature of Legionnaire's pneumonia. There may be delirium.

- Oxygen saturation on air may be low, and the patient cyanosed and distressed.
- **Chest examination:**
  - Chest signs vary, depending on the phase of the inflammatory response.
  - During consolidation phase: Lung is typically dull to percussion and, as conduction of sound is enhanced, auscultation reveals tubular bronchial breath sounds over areas of consolidated lung bronchophony and whispering pectoriloquy. Coarse crackles are heard throughout on auscultation, due to consolidation of the lung parenchyma.

**Table 6.72:** Extrapulmonary features of community- acquired pneumonia.

<i>Extrapulmonary symptoms</i>	<i>Infectious agent</i>
Myalgia, arthralgia and malaise	<i>Legionella</i> and <i>Mycoplasma</i>
Myocarditis and pericarditis	<i>Mycoplasma pneumoniae</i>
Headache, abdominal pain, diarrhea and vomiting	<i>Legionella pneumoniae</i>
Labial herpes simplex reactivation	Pneumococcal pneumonia
Skin rashes: Erythema multiforme and erythema nodosum	<i>Mycoplasma pneumoniae</i>

### ***Investigations in CAP (Table 6.73)***

**Q.** Write short essay on radiological findings in pneumonias.

### ***Complications of Pneumonia***

**Q.** Write short essay on complications of pneumonia.

*General complications (Box 6.14)*

*Local complications*

**Box 6.14:** General complications of pneumonia.

- Respiratory failure ARDS
- **Bacteremic dissemination** (bacteremia): It can cause:
  - Endocarditis (heart valves)
  - Pericarditis (pericardium)
  - Meningitis (meninges)
  - Suppurative arthritis (joint)
  - Metastatic abscesses in kidneys or spleen

– Sepsis—multisystem failure.

- **Lung abscess**
- **Organization:** Delayed and incomplete resolution can cause **ingrowth of granulation tissue into the alveolar exudate**. The intra-alveolar plugs of granulation tissue are known as organizing pneumonia. Gradually, **increased alveolar fibrosis leads to a shrunken and firm lobe and is called as cornification**.
- **Spread of infection to the pleural cavity:** It may result in:
  - **Pleuritis**
  - **Parapneumonic pleural effusion**.
  - **Pyothorax:** Which may lead to fibrothorax
  - **Pneumothorax**, especially in *Staphylococcus pneumoniae* due to pneumatocele rupture.

#### Management Guidelines for CAP

- Rational use of microbiology laboratory.
- Pathogen directed antimicrobial therapy whenever possible.
- Prompt initiation of antibiotic therapy.
- Decision to hospitalize based on prognostic criteria CURB 65

**Severity:** The need to hospitalize (severity) a patient is commonly assessed by CURB 65 or the CRB 65 score (Table 6.74). The CRB 65 score is used in the community where the serum urea level is not usually available. Other severity score available is Pneumonia Severity Index (PSI), which combines several clinical, and laboratory features and co-morbid conditions.

#### General Management (Treatment) of Pneumonia

- Check the airway, breathing and circulation. The most important aspects are: oxygenation, fluid balance and antibiotic therapy.
- **Oxygen:** Oxygen is indicated in all patients with tachypnea, hypoxemia, hypotension or acidosis. The aim is to maintain saturations between 94% and 98%. In patients with known COPD, high concentrations (35% or more), preferably humidified oxygen should be used to maintain a saturation between 88% and 92%. If hypoxia continues or patient develops increasing hypercapnia, ventilate the patient mechanically.
- **Intravenous fluids:** These are required in patients with severe illness, older patients and those who are vomiting. Treat shock (hypotensive showing any evidence of volume depletion) with intravenous fluids initially. Otherwise, an adequate oral intake of fluid is enough.

#### New Treatment Paradigm

- **Hit Hard Early With Antibiotics → De-Escalate.**
1. **Antibiotics:** Administer antibiotics as soon the diagnosis of CAP is established preferably within 4 hours of presentation in hospital and treatment should not be delayed while investigations are awaited. Prompt administration of antibiotics improves the outcome.  
Empiric regimens (Table 6.75)  
Duration of therapy: Minimum of 5 days (usually 7–10 days). Afebrile for at least 48–72 hours.

Duration is 10–14 days for patients with *Mycoplasma* and *Chlamydia pneumoniae*. Patients initially treated with intravenous antibiotics can be switched to oral agents when they become febrile. Longer duration of therapy is needed if initial therapy was not active against the identified pathogen or complicated by extrapulmonary infection.

2. **Mild analgesics for pleuritic pain:** Pleural pain may prevent the patient from breathing normally and coughing efficiently resulting in sputum retention, atelectasis or secondary infection. Hence, it is relieved by simple analgesia such as paracetamol, codeine or NSAIDs

**Table 6.73: Investigations in community-acquired pneumonia (CAP).**

<b>Investigation</b>	<b>Significance</b>
<b>Complete blood count</b>	
<ul style="list-style-type: none"> <li>• Very high (<math>&gt;20 \times 10^9/L</math>) or low (<math>&lt;4 \times 10^9/L</math>) WBC count</li> </ul>	Marker of severity. In viral and atypical pneumonias, total leukocyte count is often less than $5000/mm^3$
<ul style="list-style-type: none"> <li>• Neutrophilic leukocytosis <math>&gt;15 \times 10^9/L</math></li> </ul>	Suggests bacterial pneumonia
<ul style="list-style-type: none"> <li>• Hemolytic anemia</li> </ul>	Occasionally complicates <i>Mycoplasma</i>
<b>Urea and electrolytes</b>	
<ul style="list-style-type: none"> <li>• Urea <math>&gt;7</math> mmol/L (<math>\sim 20</math> mg/dL)</li> </ul>	Marker of severity
<ul style="list-style-type: none"> <li>• Hyponatremia</li> </ul>	Marker of severity may occur in patients with Legionnaire's disease.
<b>Liver function tests</b>	
<ul style="list-style-type: none"> <li>• Abnormal transaminitis, raised bilirubin</li> </ul>	When basal pneumonia inflames liver, or in atypical pneumonia
<ul style="list-style-type: none"> <li>• Hypoalbuminemia</li> </ul>	Marker of severity
<b>Erythrocyte sedimentation rate/C-reactive protein</b>	Non-specifically elevated
<b>Blood culture</b>	Bacteremia is a marker of severity. Causative organism may be grown (e.g. pneumococcal pneumonia). However, blood cultures are recommended only in hospitalized patients
<b>Serological and antigen detection tests</b>	Pneumococcal antigens can be detected in the serum or urine in pneumococcal pneumonia Acute and convalescent titers for <i>Mycoplasma</i> , <i>Chlamydia</i> , <i>Legionella</i> and viral infections
<b>Cold agglutinins</b>	Positive in 50% of patients with <i>Mycoplasma</i>
<b>Arterial blood gases</b>	Measure when $SaO_2 < 93\%$ or when severe clinical features to assess ventilatory failure or acidosis
<b>HIV testing</b>	Since pneumonia is a common in previously undiagnosed HIV infection, a test should be offered to all patients with pneumonia
<b>Sputum:</b> It can be distinguished from saliva by microscopic examination. Sputum contain	Gram stain, culture, antimicrobial sensitivity testing and Ziehl-Neelsen staining

alveolar macrophages	
<b>Oropharynx swab</b>	PCR for <i>Mycoplasma pneumoniae</i> and other atypical pathogens
<b>Urine</b>	Pneumococcal and/or <i>Legionella</i> antigen. Hematuria may occur in patients with Legionnaire's disease
<b>Chest X-ray</b>	Essential for the confirmation of diagnoses, follow-up and detection of complications like parapneumonic effusion and empyema
• Lobar pneumonia	Patchy opacification evolves into homogeneous consolidation of affected lobe Air bronchogram (air-filled bronchi appear lucent against consolidated lung tissue) may be present
• Bronchopneumonia	Patchy and segmental shadowing
• Complications	Para-pneumonic effusion, intrapulmonary abscess or empyema
• <i>Staph. aureus</i>	Multilobar shadowing, cavitation, pneumatoceles and abscesses
• <i>Mycoplasma</i>	Usually one lobe is involved but infection can be bilateral and extensive.
• <i>Legionella</i>	There is lobar and then multilobar shadowing, with the occasional small pleural effusion. Cavitation is rare
<b>Aspiration</b>	Percutaneous transtracheal aspiration of secretions Percutaneous transthoracic needle aspiration, preferable under CT guidance
<b>Fiberoptic bronchoscopy with BAL and brushings</b>	Gram stain, AFB stain, culture and cytology
<b>Biopsy</b>	A transbronchial biopsy of the lung tissue for culture and histopathology may be done in selected cases. Diagnostic open-lung biopsy, which carries a high-risk, is reserved for selected patients
<b>Pleural fluid</b>	Aspirate and culture when present in more than trivial amounts, preferably with ultrasound guidance

**Table 6.74: CURB 65 Rule.**

Confusion : New mental confusion

Urea >7 mmol/L (mg/dL)

Respiratory rate >30 breaths per minute

Blood pressure: Diastolic BP <60 mm Hg or systolic blood pressure <90 mm Hg

Age ≥65 years of age (1 point for each)

Group 1: 0 or 1 of the above—mortality low—1.5%. Likely suitable for treatment at home

Group 2: 2 of the above—mortality—9.2%. Hospitalization for treatment

Group 3: 3 or more of the above—mortality—22%. Likely requires admission to ICU.

**Table 6.75: Empiric regimens for pneumonia.**

<i>Setting</i>	<i>Therapeutic options</i>
Ambulatory, not requiring hospitalization, age under 60 years	Oral macrolide (erythromycin or azithromycin)
Ambulatory, not requiring hospitalization, comorbidity or age over 60 years	Oral $\beta$ -lactam/ $\beta$ -lactamase inhibitor + macrolide <b>or</b> Oral antipneumococcal fluoroquinolone
Requiring hospitalization	$\beta$ -lactam (cefoperazone or ceftriaxone) + macrolide or antipneumococcal fluoroquinolone
Aspiration pneumonia requiring hospitalization	$\beta$ -lactam/ $\beta$ -lactamase inhibitor alone (ampicillin/sulbactam, piperacillin/tazobactam)

**Table 6.76: Antibiotic treatment for community-acquired pneumonia (CAP).**

<i>Antibiotic</i>	<i>Dosage, Route, Frequency and Duration</i>
Doxycycline	100–200 mg PO/IV BID for 7 to 10 days
Azithromycin	500 mg OD IV –3 days + 500 mg OD PO for 7–10 days
Clarithromycin	250–500 mg BID PO for 7–14 days
Telithromycin	800 mg PO OD for 7–10 days
Levofloxacin	750 mg PO/IV OD for 5 days
Gatifloxacin	400 mg PO or IV OD for 5 to 7 days
Moxifloxacin	400 mg PO or IV OD for 5 to 7 days
Gemifloxacin	320 mg PO OD for 5–7 days
Amoxyclav	2 g of Amoxicillin +125 mg of Clavulanic acid PO BID for 7 to 10 days
Ceftriaxone	2 g IV BID for 3 to 5 days + PO 3G CS
Ertapenum	1 g OD IV or IM for 7 to 14 days

(PO: per oral; IV: intravenous; IM: intramuscular; OD: once daily; BID: twice daily)

Antibiotic treatment for community-acquired pneumonia (Table 6.76)

### Unresolved/Slow Resolving Pneumonia

- Patient is considered to have responded if: (1) fever declines within 72 hours, (2) temperature normalizes within 5 days, (3) respiratory signs (tachypnea) return to normal. The expected time course for resolution is controversial.
  - In 1975, Hendin defined slowly resolving as **pulmonary consolidation persisting more than 21 days.**

- In 1991, Kirtland and Winterbauer defined slowly resolving CAP in immunocompetent patients based upon radiographic criteria. **>50% clearing by 2 weeks** or **> complete clearing at 4 weeks**.
- **Nonresolving pneumonia** is defined as a clinical syndrome in which focal infiltrates begin with some clinical association of acute pulmonary infection and despite a minimum of 10 days of antibiotic therapy patients either do not improve or worsen or radiographic opacities fail to resolve within 12 weeks.
- **Progressive pneumonia:** Increase in radiographic abnormalities and clinical deterioration during first 72 hours of treatment.
- Causes of unresolved/slow resolving pneumonia (Table 6.77).

**Table 6.77: Causes of unresolved/slow resolving pneumonia.**

Incorrect microbiological diagnosis (e.g. tuberculosis instead of classical organisms) or incomplete antimicrobial treatment	<ul style="list-style-type: none"> <li>• Underlying antibiotic resistance</li> <li>• Inadequate dose/duration</li> <li>• Nonadherence</li> <li>• Malabsorption</li> </ul>
Complication of CAP (community-acquired pneumonia)	<ul style="list-style-type: none"> <li>• Parapneumonic pleural effusion (exudative), empyema, lung abscess</li> </ul>
Underlying neoplastic lesion or other lung disease	<ul style="list-style-type: none"> <li>• Bronchial obstruction causing partial or complete obstruction, bronchoalveolar cell carcinoma, bronchiectasis</li> </ul>
Alternative diagnosis	<ul style="list-style-type: none"> <li>• Pulmonary thromboembolic disease, cryptogenic organizing pneumonia, eosinophilic pneumonia, pulmonary hemorrhage</li> </ul>
Host factors	<ul style="list-style-type: none"> <li>• Age especially &gt;50</li> <li>• Co-morbid illness: Diabetes, COPD (chronic obstructive pulmonary disease)</li> <li>• Others, e.g. alcoholism, immunosuppressive/cytotoxic therapy</li> </ul>
Superinfection	<ul style="list-style-type: none"> <li>• Fungi, <i>Mycobacterium tuberculosis</i></li> </ul>
Defects in defense	<ul style="list-style-type: none"> <li>• For example, impaired cough (sedatives, neuromuscular illness, stroke), impaired mucociliary transport (chronic bronchitis), immune deficiency states-primary and secondary (B-cell and T-cell.)</li> </ul>

**Recurrent pneumonia:** Many conditions cause recurrent pneumonias (Table

6.78).

**Table 6.78: Conditions causing recurrent pneumonias.**

- Bronchial obstruction (e.g. foreign body, bronchial stenosis, compression of bronchus, endobronchial lesions)
- Bronchiectasis
- Immunocompromised state
- Sequestration of lung
- Ciliary dyskinesia
- Multiple myeloma and other lymphoreticular malignancies

### ***Prevention of Further Episodes of Pneumonia***

- **Cessation smoking**
- **Influenza vaccine** (Flu shot—Oct through Feb): It offers 90% protection and reduces mortality by 80%.
- **Pneumococcal vaccine** (Pneumonia shot): It protects against 23 types of Pneumococci. About 70% of individuals have Pneumococci in the respiratory tract. Vaccination reduces mortality.

### **Pneumococcal Pneumonia (Lobar Pneumonia)**

**Q.** Discuss the etiology, clinical features, investigations, diagnosis, complications and treatment/management of pneumococcal pneumonia (lobar pneumonia/*Streptococcus pneumoniae*).

**Definition:** Lobar pneumonia is characterized by **diffuse inflammation** affecting the **part or entire lobe, usually the lower lobes.**

### ***Etiology***

- **Causative organism:** Most common form of pneumonia and is caused by *Streptococcus pneumoniae* (e.g. *Pneumococcus*, a Gram-positive, lancet-shaped *Diplococcus*).
- **Mode of infection:** By droplet infection.

### ***Risk factors for pneumococcal pneumonia***

- **Age:** Younger than 2 years or older than 65 years
- **Strongest independent risk factor for invasive pneumococcal disease: Cigarette smoking**

- **Strongest independent risk factor for CAP: Alcoholism**  
(ALPS: Alcoholism, leucopenia, pneumococcal sepsis: Mortality rate 80%)
- Poverty and overcrowding
- **Lowered systemic resistance of the host:** It may be due to:
  - **Chronic diseases:** Diabetes mellitus, severe liver disease, chronic lung disease
  - **Immunological deficiency:** Defects in innate immunity and humoral immunodeficiency (complement or immunoglobulin), defects in cell-mediated immunity (congenital and acquired), HIV infection
  - **Treatment with immunosuppressive agents**
  - **Leukopenia**
  - Asplenia or hyposplenia
- **Impaired local defense mechanisms**
  - **Loss or suppression of the cough reflex:** For example, **coma, anesthesia, drugs, chest pain**, or neuromuscular disorders. It may lead to aspiration of gastric contents into the lung.
  - **Damage or injury to the mucociliary apparatus:** It may be due to **cigarette smoke, viral diseases, inhalation of hot or corrosive gases**, or genetic defects of ciliary function (e.g. the immotile cilia syndrome).
  - **Accumulation of secretions:** Cystic fibrosis and bronchial obstruction.
  - **Interference with the phagocytic or bactericidal action of alveolar macrophages:** It may be due to **alcohol intoxication, tobacco smoke, anoxia, or oxygen intoxication**. Antecedent influenza
  - **Pulmonary congestion and edema.**

### *Clinical Features*

- **Sudden onset of high fever, chills** and rigors, **coughs**, and vomiting. Fever is usually high grade (39–40 °C). Convulsions may occur in children.
- Cough is initially short, painful and dry, but soon becomes productive with **mucopurulent sputum**. Rust colored sputum (**‘rusty’ sputum**) is characteristic but occasionally may be frankly blood stained.

- Nonspecific symptoms include loss of appetite, headache and pains in the body and limbs
- Localized pleuritic chest pain develops at an early stage due to fibrinosuppurative pleuritis. It may be referred to the shoulder or abdominal wall. It may be accompanied by pleural friction rub. Breathing is rapid and shallow due to pleuritic pain.
- Other features are tachycardia, hot and dry skin, herpes labialis, and flushed face.

### ***Physical signs in the chest***

#### **Q. Write short note on signs of consolidation**

- First 2 days: The physical signs are minimal and include diminished respiratory movements, slight impairment of percussion note and pleural rub. In early stages, numerous fine crepitations are audible.
- After 2 days: Frank signs of consolidation appear (Box 6.15).

#### **Box 6.15: Signs of consolidation.**

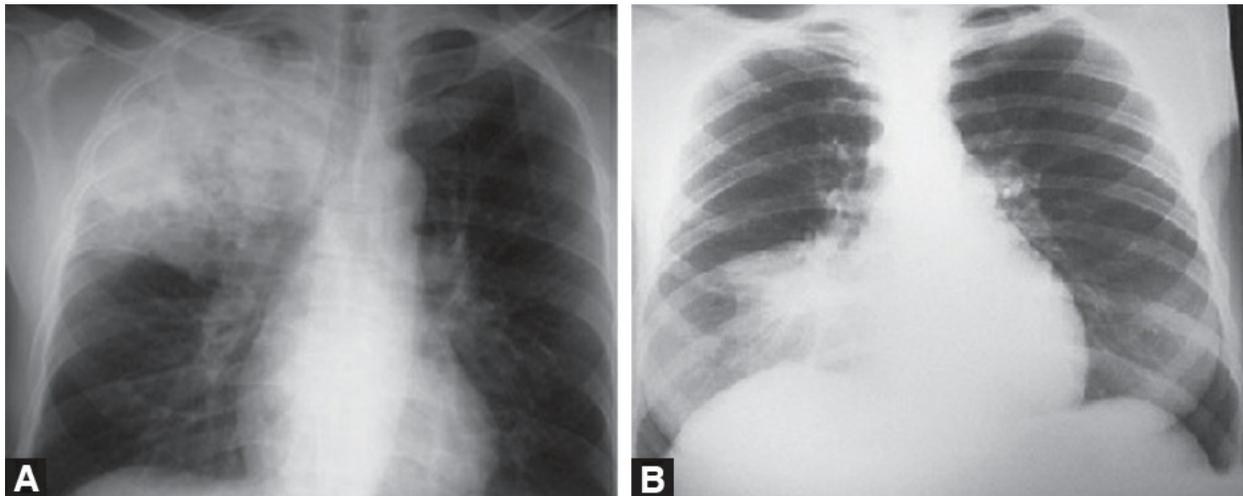

- Diminished respiratory movements
- Dull percussion note
- No mediastinal shift
- Markedly increased vocal fremitus and vocal resonance
- High-pitched tubular bronchial breathing
- Bronchophony, egophony and whispering pectoriloquy may be present.
- During resolution coarse crepitations
- If parapneumonic effusion develops, additional signs of pleural effusion

### ***Investigations***

- **Blood**
  - Severe neutrophil leukocytosis
  - Blood culture may show *Streptococcus pneumoniae*.
- **Sputum**
  - Gram staining of the sputum may show pneumococci which appear as gram-positive, lancet-shaped diplococci.
  - Sputum culture may show *Streptococcus pneumoniae*.
  - Assays on sputum are based on detecting nucleic acids for

pneumococci.

- **Serological tests:** They can detect pneumococcal antigen in serum, urine and sputum. Detection of C-polysaccharide (part of pneumococcal cell wall) in urine by an immunochromatography assay is quite sensitive. Urinary antigen remains positive for weeks after onset of severe pneumococcal pneumonia. However, it is often negative in mild pneumococcal pneumonia.
- **Chest radiograph (Figs. 6.32A and B)**
  - Involved lobe or segment appears homogeneous radiopaque with air bronchograms.
  - Associated parapneumonic effusion or empyema can also be detected.
- **Others:** In rare instances fibroptic, bronchoscopic aspiration or transthoracic needle aspiration may be necessary.

**Figs. 6.32A and B:** Chest X-ray. (A) Shows right upper lobe pneumonia; (B) Shows right middle lobe pneumonia.

### ***Complications (Table 6.79)***

**Q. Write short essay on complications of lobar pneumonia.**

**Table 6.79:** Complications of lobar pneumonia.

#### **Pulmonary**

- Delayed/incomplete resolution
- Spread to other lobes (rare)

#### **Cardiovascular**

- Acute circulatory failure
- Acute pericarditis
- Endocarditis (rare)

**Pleural:** Spread of infection to the pleural cavity:

- Sterile pleural effusion
- Empyema
- Pyothorax

**Neurological**

- Mental confusion
- Meningism
- Meningitis (rare)

## Treatment

### General measures

- Administration of oxygen in high concentration to all hypoxemic patients.
- Treatment of pleuritic pain with mild analgesics like paracetamol and NSAIDs. However, few may require pethidine 50–100 mg or morphine 10–15 mg intramuscularly or intravenously.

### Antibiotic therapy (Discussed earlier on pages 304-5)

**Vaccine:** Two types:

1. **Pneumococcal polysaccharide vaccine (PPV):** Consists of 23 most common capsular serotypes that produce invasive pneumococcal disease. However, it has poor protection in individuals at greatest risk for severe pneumococcal disease namely elderly, immunocompromised, and infants younger than 2 years.
2. **Polysaccharide-protein conjugate pneumococcal vaccine** (pneumococcal conjugate vaccine—PCV): It targets seven serotypes responsible for most of pneumococcal infections in children. Hence, it is used mainly in children younger than 2 years.

## Indications for Vaccination (Table 6.80)

### Staphylococcal Pneumonia

#### **Q. Write short essay/note on staphylococcal pneumonia.**

- It produces bronchopneumonia that is characterized by **widespread focal/patchy areas of acute suppurative inflammation**.
- They are **centered on bronchioles and bronchi** with subsequent spread to surrounding alveoli. The involved alveoli show **consolidation**.
- **Causative agent:** *Staphylococcus aureus*. Methicillin-resistant *Staphylococcus aureus* (MRSA) is an important pathogen in nosocomial pneumonia. Recently, community-acquired MRSA (CA-MRSA) infections (skin and soft tissue infections, and necrotizing pneumonia) developing in previously healthy persons has emerged as a serious clinical condition.
- **Predisposing factors:** Common following influenza, in debilitated patients in hospital, and patient with cystic fibrosis.
- **Characteristic features:**
  - Abscess formation is very common. These abscesses are multiple and often bilateral.

- Abscesses may rupture into pleura leading to pneumothorax or pyopneumothorax.
- **Chest radiograph** shows bronchopneumonia. It is often bilateral, with multiple thin-walled cyst-like lesions (**pneumatocoles**).
- Sputum smear shows gram-positive *Staphylococcus aureus* in clumps.

### Table 6.80: Indications for vaccination.

- Age 65 years
- Patients with risk factors: Congestive heart failure, asthma and COPD, diabetes mellitus, chronic liver disease, alcoholism
- Splenectomized patients including patients with sickle cell anemia
- Persons living in long-term care facilities
- Immunocompromised persons

#### Treatment

- Drug of choice is Penicillin.
- Methicillin-sensitive *Staphylococcus aureus*: Oxacillin or flucloxacillin.
- Methicillin-resistant *Staphylococcus aureus*: Vancomycin, Teicoplanin.
- Ceftaroline and Ceftabiparole, new fifth generation cephalosporins.
- Drugs used in treatment of resistant *Staphylococcus* discussed on page 120.

## Complications

**Toxic shock syndrome (TSS)** (Discussed on page 119).

## *Klebsiella Pneumoniae* (Friedlander's Pneumonia)

**Q. Write short note on diagnosis and treatment of *Klebsiella pneumoniae* (Friedlander's pneumonia).**

- **Causative agent:** *Klebsiella pneumoniae* (Friedlander's bacillus).
- **Predisposing factors:** Common in alcoholics and diabetics.
- **Characteristics:**
  - Severe illness with a high mortality rate.
  - Massive consolidation of one or more lobes. The **upper lobes** most often affected.
  - Abscess formation and pleural effusion are common.

## Investigations

- **Sputum:**
  - It may be viscid, jelly-like and blood stained (**red-current-jelly sputum**). Sometimes it may be purulent or rusty.
  - Sputum smear shows gram-negative *Klebsiella pneumoniae*. *Klebsiella Pneumoniae* can be cultures from the sputum.
- **Chest radiograph**
  - It shows air space pneumonia, usually in one of the upper lobes, with abscess formation and pleural effusion.
  - **Bulging interlobar fissure** is a characteristic finding.

**Treatment:** Antibiotic therapy

- Gentamicin, ceftazidime or ciprofloxacin for 2–3 weeks.
- Severe cases: Piperacillin + tazobactam or meropenem.
- Extended-spectrum-lactamases (ESBL) producing organisms: Meropenem (or imipenem + cilastin), amikacin and tigecyclin. Polymyxin B for highly resistant strains.

## Atypical Pneumonias

**Q. Discuss the etiology (organisms causing atypical pneumonias), clinical features, investigations and treatment of atypical pneumonias**

- Causes: *Mycoplasma pneumoniae*, *L. pneumophila*, *C. pneumoniae*, *C. burnettii*, viruses (influenza, adeno. RSV, measles, VZV, CMV).
- Evolve much more slowly than bacterial pneumonias.
- Symptoms >> signs.
- They tend to have a slower onset, often with more prominent extrapulmonary symptoms and complications.
- Suspicion of atypical pathogens as the cause of pneumonia should be thought if patient has three or more of the parameters listed in Table 6.81.

**Table 6.81:** Parameters that favor the diagnosis of atypical pneumonias.

1. Age 60 years
2. Absence of any underlying co-morbid condition
3. Paroxysmal cough
4. No expectoration
5. Few clinical signs on examination of chest

If total WBC count  $10,000/\text{mm}^3$  is added to the above five parameters, then presence of 4 features

indicates a strong likelihood of atypical pneumonia.

## Mycoplasma Pneumoniae

**Q. Discuss the clinical features, laboratory diagnosis and treatment of pneumonias caused by *Mycoplasma pneumoniae*.**

**Cause:** *Mycoplasma pneumoniae* which lacks cell wall. It is most often associated with atypical pneumonia.

### ***Clinical Presentation***

- Onset is insidious ranging from several days to a week.
- Constitutional symptoms include headache exacerbated by cough, sore throat, malaise, and myalgias. Cough is dry, paroxysmal and worse at night.
- Clinical course is usually mild and self-limited.

### ***Complications***

- **Pulmonary complications:** Pleural effusion, empyema, pneumothorax and respiratory distress syndrome.
- Infection is severe in sickle cell disease and other HbS-related hemoglobinopathies (functional asplenia). Especially prone to digital necrosis in patients with high titer of cold antibodies.

- **Extrapulmonary complications**

- Ear pain: Bullous myringitis
- Erythema multiforme: Target/iris lesion, SJ (Stevens-Johnson) syndrome
- Digital necrosis (especially in patients with sickle cell disease)
- Neurological: Encephalitis, cerebellar ataxia, GBS (Guillain-Barré Syndrome), transverse myelitis, peripheral neuropathy.
- Hematological: Hemolytic anemia and coagulopathy
  - ♦ *M. pneumoniae* evoke IgM antibodies which agglutinate human RBC's at 4°C
- Others: Myocarditis, pericarditis and pancreatitis.

### ***Laboratory Findings and Diagnosis***

- Mild leukocytosis can be found.
- Four-fold increase in antibody titers.
- Cold agglutinins are non-specific but helpful in diagnosis.

**Treatment of Mycoplasma:** Macrolides ( azithromycin ) is the drug of choice, followed by doxycycline and fluroquinolones.

## Chlamydia Pneumonia

- **Cause:** *Chlamydophila (Chlamydia) pneumoniae* which is an obligate intracellular organism. Another species of Chlamydophila, i.e. *Chlamydia psittaci* can also cause pneumonia. It usually infects birds but occasionally infects humans (psittacosis).
- **Mode of transmission:** Through respiratory secretions.
- **Incubation period:** Several weeks.
- **Predisposing factor:** Old age with comorbid diseases.
- **Clinical presentation:** Sore throat, headache, low grade fever and cough that can persist for months.
- **Chest radiographs:** Show less-extensive infiltrates than those with other causes of pneumonia.

**Treatment:** Doxycycline is the drug of choice.

## Legionella Pneumoniae or Legionnaire's Disease

**Q. Give short essay/note on *Legionella pneumoniae* (Legionnaire's disease).**

- Pontiac fever: Acute self-limiting febrile illness
- Legionnaire's disease: Pneumonia
- Most common species causing human infections: *L. pneumophila*
- Most common serogroup causing CAP: 1
- Most common serogroup causing nosocomial pneumonia: 6
- **Mode of transmission:** Through water droplets originated from infected **humidifier cooling systems**, and from stagnant water in cisterns and shower heads.

### **Clinical Features**

- Fever, chills and cough with scanty mucoid sputum. Gastrointestinal symptoms like nausea, abdominal pain and diarrhea are common. **Mental confusion or delirium** may also develop.
- Uncommon features: Myocarditis, pericarditis and prosthetic valve

endocarditis, glomerulonephritis, pancreatitis and peritonitis.

## **Investigations**

- **Chest X-ray:** Shows parenchymal lesions progressing from patchy to lobar consolidation. Pleural effusion may be observed in more than one-third patients. Complete clearing of lung infiltrates may take 1–4 months.
- **Blood:** Relative lymphopenia, very high ESR, hyponatremia, proteinuria and microscopic hematuria.
- **Culture:** Definitive and most sensitive method, requires 3–5 days.
- **Gram stain:** Many PMN's, no organisms-suggestive (usual picture with all atypical pneumonias).
- **False +ve AFB stain:** *Legionella micdadei* also known as Pittsburgh pneumonia agent.
- **Direct fluorescent antibody (DFA) test:** Sensitive and specific.
- **Antibody:** Four fold rise in titer from acute to convalescent stage is diagnostic. Serology has only epidemiologic significance
- Urinary antigen: Second to culture in terms of both sensitive and specificity
- **Prognosis:** Among the atypical pneumonia, Legionnaires' disease presents with most severe clinical course and can progress more severely if the infection is not treated appropriately and early.

### **Q. Give short essay/note on antibiotics used in atypical pneumonias.**

**Treatment:** Antibiotic therapy of atypical pneumonias

- Drug of choice: Erythromycin or one of the other macrolides (clarithromycin or azithromycin).
- Doxycycline is also an effective drug.
- Fluoroquinolones have excellent activity against *Mycoplasma pneumoniae*, *Chlamydomphila pneumoniae* and *Legionella pneumophila*. Additional advantage of fluoroquinolones is once daily dose and excellent bioavailability, whether they are given intravenously or orally.
- $\beta$ -lactams are not effective.

## **Actinomycosis**

### **Q. Write short note/essay on actinomycosis.**

- **Cause:** *Actinomyces israeli*, an anaerobic organism present in the oral cavity as a commensal. When local defenses are impaired, it can produce

disease. Companion bacteria

- **Forms:**
  - **Oral-cervicofacial actinomycosis:** Present as soft tissue swelling, abscess and discharging sinuses.
  - **Abdominal actinomycosis:** Presents with discharging sinuses, abdominal mass or abscess.
  - **Pulmonary actinomycosis:** Causes widespread suppurative pneumonia, empyema (often bilateral) and persistent discharging chest wall sinuses.
- Pus obtained from the sinuses show '**sulfur grains**'.

**Treatment:** Antibiotic therapy with benzylpenicillin 18–24 million units intravenously (four divided doses) for 4–6 weeks. This is followed by oral penicillin for 6–12 months.

## Acute Bronchopneumonia

### **Q. Write short note on acute bronchopneumonia.**

- **Bronchopneumonia** is characterized by **patchy** (scattered solid foci) **area consolidation in the same or several lobes** of the lung.
- It is a type of secondary pneumonia, invariably preceded by bronchial infection. Common in patients with chronic bronchitis.
- Bronchopneumonia is characterized by **widespread focal/patchy areas of acute suppurative inflammation**. They are **centered on bronchioles and bronchi** with subsequent spread to surrounding alveoli. The involved alveoli show **consolidation**. The **consolidated areas larger and more numerous in lower lobes** (because of the tendency of secretions to gravitate into the lower lobes) and **frequently bilateral**.
- **Predisposing factors:**
  - In children: As a complication of **measles or whooping cough**.
  - In adults: As a complication of **acute bronchitis or influenza**.
  - In elderly or debilitated patients: As **hypostatic pneumonia**.
- Viral pneumonias and 'atypical' pneumonias may also present as bronchopneumonia.

**Fig. 6.33:** Chest X-ray of bronchopneumonia.

### ***Clinical Features***

- High fever, severe cough with purulent expectoration, breathlessness, tachypnea, tachycardia, and central cyanosis.
- **Physical signs in the chest:** Early stage signs of acute bronchitis, later stage numerous crepitations.
- Investigations
  - Chest X-ray: Bilateral mottled opacities, predominantly in the lower zones (Fig. 6.33).
  - Blood: Neutrophilic leukocytosis common.

#### **Treatment:** Antibiotic therapy

- Mild cases: Ampicillin or cotrimoxazole given orally is effective.
- Serious cases: Third generation cephalosporin along with a macrolide

### **Aspiration Pneumonia**

**Q. Write short note on aspiration pneumonia.**

- It develops due to abnormal entry of fluid, particulate exogenous substances or endogenous secretions into the lower airways.
- Types: (i) Chemical aspiration pneumonia, and (ii) bacterial aspiration pneumonia.

### ***Predisposing Factors***

- Acute aspiration of gastric contents into the lungs: Reduced consciousness, as a complication of anesthesia.
- Mechanical disruption of the glottis closure or cardiac sphincter due to tracheostomy, endotracheal intubation, bronchoscopy, upper endoscopy and nasogastric feeding.
- Disorders of the upper gastrointestinal tract: Esophageal disease, surgery involving the upper airways or esophagus, and gastric reflux.
- Dysphagia from neurologic deficits
- Miscellaneous conditions: Protracted vomiting, large volume tube feedings and feeding gastrostomy.

### **Chemical Aspiration Pneumonia**

- Develops due to the aspiration of substances that are toxic to the lower airways, independent of bacterial infection.
- Chemical pneumonitis associated with the aspiration of gastric acid as a complication of anesthesia particularly during pregnancy (**Mendelson's syndrome**). It can produce an extremely severe and sometimes fatal illness because of the intense destructiveness of gastric acid.

### ***Clinical Features***

- Abrupt onset of low-grade fever and dyspnea.
- Physical examination reveals cyanosis and diffuse crepitations.
- Chest radiograph: Infiltrates involving dependent pulmonary segments that usually develop within 2 hours of aspiration.

#### **Treatment**

- **Tracheal suction:** To clear fluids and particulate matter.
- **Support of respiration:** Mechanical ventilation may be needed.
- **Corticosteroids:** Use controversial.
- **Antibiotics:** In acute events.

## Bacterial Aspiration Pneumonia

- Most common type of aspiration pneumonia caused by bacteria that normally reside in the upper airways or stomach.
- **Predisposing factors:** Hospitalized patients with depressed gag reflex, impaired swallowing, or nasogastric or endotracheal tube. Elderly individuals and patients with impaired consciousness (e.g. drug, alcohol, stroke).

### *Clinical Features*

- Highly variable and depend upon the bacteria involved and status of the host.
- Most cases are due to anaerobic bacteria that normally reside in the gingival crevices.
- **Usual features** of pneumonia such as cough, fever, purulent sputum and dyspnea. The process evolves over a period of several days or weeks instead of hours in usual pneumonia.
- **Other features:** Weight loss and anemia.
- **Oral examination:** May reveal periodontal disease.

### *Diagnosis*

- **Sputum:** Putrid discharge is considered as diagnostic of anaerobic infection
- **Chest radiograph:** Involvement of dependent pulmonary segments by aspiration. Lower lobes are involved when aspiration occurs in upright position and the superior segments of the lower lobes or posterior segment of the upper lobes when aspiration occurs in recumbent position.

#### **Treatment**

- Penicillin. However, about 25% of cases are caused by penicillinase-producing anaerobic bacteria.
- Clindamycin (600 mg 8 hourly IV followed by 300 mg 6 hourly orally) is the drug of choice for anaerobic infections above the diaphragm (e.g. pulmonary infections).
- Other drugs include amoxicillin-clavulanate or newer fluoroquinolones (levofloxacin and gemifloxacin).
- Metronidazole alone should not be used as a monotherapy because of failure rate of about 50%.

## Hospital-Acquired Pneumonia (Nosocomial Pneumonia)

**Q. Write short essay on hospital-acquired pneumonia (nosocomial pneumonia) and its management.**

- Hospital-acquired pneumonia (HAP) or nosocomial pneumonia is a new episode of pneumonia developing in hospital in a patient who is beyond 2 days (more than 48 hours) of their initial admission to hospital, which was not incubating at the time of admission. Most common resistant organism causing HAP is *Staphylococcus aureus*.
- Second most common (urinary infection being first) hospital-acquired infection (HAI) and the leading cause of HAI-associated death. The hospital-acquired pneumonias are serious and may be life threatening.
- Ventilator-associated pneumonia (VAP): It is a subcategory of nosocomial pneumonia that occurs in patients who have been on ventilator support for any reason. Pneumonia is termed as VAP if it occurs after 48 hours after endotracheal intubation for mechanical ventilation, but within 72 hours of start of ventilation. Most common mechanism of nosocomial pneumonia is aspiration and most common organism is *Staphylococcus aureus*. The most common multidrug-resistant Gram-negative bacilli (MDR-GNB) causing HAP/VAP: *P. aeruginosa*.
- Early onset HAP and VAP: Occurring within the first 4 days of hospitalization, usually carry a better prognosis, and are more likely to be caused by antibiotic sensitive bacteria.
- Late-onset HAP and VAP (5 days or more) are more likely to be caused by multidrug-resistant (MDR) pathogens, and are associated with increased patient mortality and morbidity.

**Criteria**

- At least two of three clinical features (fever greater than 38°C, leukocytosis or leukopenia, and purulent secretions), a positive culture of sputum or tracheal aspirate, and a new lung infiltrate.
- *When fever, leukocytosis, purulent sputum, and a positive culture of a sputum or tracheal aspirate are present without a new lung infiltrate, the diagnosis of nosocomial tracheobronchitis should be considered.*

## ***Etiology (Table 6.82)***

The organisms causing hospital-acquired pneumonias are different from those causing CAP.

**Risk factors for nosocomial pneumonia:** Severe underlying disease, malnutrition, uremia, alcoholism, cigarette smoking, immunosuppression, increasing age, nasogastric tube (Lesser risk with orogastric tube), endotracheal tube, decreased level of consciousness, prior AMA use, decreased gastric acidity, upper abdominal surgery.

**Risk factors for VAP:** Re-intubation, supine positioning, enteral nutrition, heavy sedation, paralytic agents, H<sub>2</sub> antagonists and antacids.

**Table 6.82:** Various etiological agents causing hospital-acquired pneumonia.

- **Early onset:** (within 4 days of hospitalization): Staph. aureus, EGNB, *S. pneumoniae* and *H. influenzae*
- **Late onset:** *S. aureus*, *Pseudomonas*, *Enterobacter*, *Klebsiella*, *Acinetobacter*

## ***Clinical Features***

The diagnosis should be considered in any hospitalized or ventilated patient who develops:

- Purulent sputum (or endotracheal secretions)
- New infiltrate on chest radiograph
- Unexplained increase in oxygen requirement
- Core temperature of more than 38.3°C
- Leukocytosis or leukopenia.

## ***Investigations***

- Patients with hospital-acquired pneumonia should have blood cultures, and microbiological confirmation should be sought whenever possible. Vigorous attempts must be made to obtain respiratory secretions for identification of the organism and determining its sensitivity to antibiotics. In mechanically ventilated patients, bronchoscopy-directed protected brush specimens, bronchoalveolar lavage (BAL) or endotracheal aspirates may be obtained.

- Full blood count (FBC), urea and electrolytes (U&E), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), and arterial blood gas analysis and a chest X-ray performed.

#### Management/Treatment

- The principles of management are similar to those for CAP. These include adequate oxygenation, appropriate fluid balance and antibiotics.
- In early-onset HAP:
  - Patients who have not received previous antibiotics can be treated with co-amoxiclav or cefuroxime.
  - If the patient has received a course of recent antibiotics are treated with piperacillin/tazobactam or a third generation cephalosporin.
- In late-onset HAP:
  - The choice of antibiotics must cover the gram-negative bacteria, *Staph. aureus* (including MRSA) and anaerobes.
  - Antipseudomonal cover by a carbapenem (meropenem) or a third-generation cephalosporin combined with an aminoglycoside. MRSA cover may be provided by glycopeptides (vancomycin or linezolid).
  - *Acinetobacter baumannii* is usually sensitive to carbapenems but resistant cases may require the prolonged administration of nebulized colistin.

### ***Prevention of Ventilator-associated Pneumonia (Table 6.83)***

**Table 6.83:** Prevention of ventilator-associated pneumonia.

- Good hygiene: Rigorous handwashing by caregivers and sterility of any equipment used
- Minimize the risk of aspiration
- Semi recumbent positioning of the patient to prevent aspiration
- Avoidance of gastric distention
- Continuous subglottic suctioning
- Adequate nutritional support
- Early removal of endotracheal and nasogastric tubes
- Oral antiseptic (chlorhexidine 2%) may be used to decontaminate the upper airway
- Use of sucralfate (for stress-ulcer prophylaxis)
- Avoidance of prophylactic antibiotic

## **Influenza**

**Q. Discuss the etiology, clinical features, investigations, complications and management of influenza.**

### ***Definition***

Influenza is an acute systemic viral infection caused by influenza viruses that primarily affects the upper and/or lower respiratory tract.

### ***Etiology***

The influenza virus is a spherical or filamentous enveloped RNA virus.

### **Influenza A Virus**

- It is responsible for pandemics and epidemics.
- **Antigenic variation and influenza outbreaks and pandemics:** The most extensive and severe outbreaks of influenza are due to influenza A viruses. This may be because H and N antigens of these viruses undergo periodic antigenic variation. Immunity following viral infection is type-specific and of short duration.
- **Antigenic/genetic shift:** Major antigenic variations (switch in the hemagglutinin or neuraminidase antigen generates new influenza A subtypes) is called antigenic/genetic shift. Antigenic shift results in a virus of different antigenic character to which most or all of the population is susceptible and is the basis for influenza pandemics. For example, an antigenic shift involving both the hemagglutinin and the neuraminidase occurred in 1957 resulting in severe pandemic. It was due to shift of predominant influenza A virus subtype from H1N1 to H2N2.
- **Antigenic/genetic drifts:** These are due to minor antigenic variations. Minor antigenic may periodically involve the hemagglutinin or the neuraminidase component or both. Antigenic drift result viruses that are different enough from preceding strains and enables the virus to evade previously acquired immunity and contributes to yearly seasonal epidemics.

Influenza viruses also infect other species (e.g. birds and pigs) and these animal strains may infect humans and spread from person to person.

### ***Clinical Features***

- Incubation period: 1–3 days.
- **Clinical manifestations:** Influenza is respiratory illness characterized by systemic symptoms such as sudden onset of headache, fever, chills, myalgia, nausea, vomiting and malaise. The respiratory signs and symptoms include harsh unproductive cough and sore throat cough.

- **Physical findings:** Usually minimal in uncomplicated cases. Pharynx may be unremarkable despite a severe sore throat and chest is usually clear.
- In uncomplicated cases, the symptoms usually subside within 3–5 days.

### ***Investigations***

- Blood: Leukopenia.
- Throat swab or nasopharyngeal aspirate or sputum: Virus may be detected in throat swabs or nasopharyngeal aspirate or sputum.
- Reverse-transcriptase polymerase chain reaction (RT-PCR): Most sensitive and specific technique for detection of influenza viruses.
- Rapid influenza diagnostic tests (RIDTs): Detect influenza virus antigens by immunologic or enzymatic techniques.

### ***Complications***

- **Pulmonary complications:** Primary influenza viral pneumonia, secondary bacterial pneumonia (most often due to superinfection with *Strep. pneumoniae*, *Staph. aureus* or other bacteria), mixed viral and bacterial pneumonia, exacerbation of underlying asthma and COPD.
- **Extrapulmonary complications:**
  - Myositis, myocarditis, pericarditis, worsening of underlying congestive heart failure and coronary artery disease.
  - Neurological complications: Reye’s syndrome in children, encephalitis or transverse myelitis.
  - Post-influenzal asthenia and depression.

### **Management**

- Bed rest till fever subsides.
- Paracetamol 0.5–1 g every 4–6 hourly.
- Avoid aspirin, particularly in adolescents and children, because of its association with the Reye’s syndrome.
- **Specific antiviral therapy-administration of neuraminidase inhibitor:** Oral oseltamivir (75 mg twice daily) or inhaled zanamivir (10 mg twice daily) for 5 days reduces the severity of symptoms and duration of illness if given within 48 hours of onset of symptom onset of both influenza A and B. Amantadine (100 mg twice a day) and rimantadine (100 mg twice a day) which are useful only for influenza A.
- Specific treatment of complications.

## ***Prevention***

### *Vaccination*

- **Indications:** Prevention annual seasonal vaccination is advised to elderly, individuals with chronic medical illnesses (which increases the risk of the complications of influenza), such as chronic cardiopulmonary diseases or immunocompromised or renal disease and their health-care workers. Specific vaccination gives about 70% protection.
- **Types of vaccine:** Two types of vaccines against seasonal influenza are available namely inactivated (killed-injectable) and live attenuated vaccines (nasal spray). Both vaccines contain three strains of influenza: an H3N2 virus, an H1N1 (seasonal) virus and an influenza B virus. Vaccine composition is changed yearly to cover the 'predicted' seasonal strains, but vaccination may fail when a new pandemic strain of virus emerges.

**Chemoprophylaxis:** Antiviral drugs may be used as chemoprophylaxis against influenza. However, they may lead to development of resistance.

- Chemoprophylaxis with oseltamivir or zanamivir are helpful against influenza A and B; amantadine and rimantadine are useful for influenza A.

## **Swine Flu (H1N1 Influenza)**

(refer pages 166-7)

## **Avian Influenza**

### **Q. Write short essay on avian influenza.**

- Avian influenza is caused by **avian influenza A viruses** and is primary public health concern of the 21st century.
- Avian influenza A viruses caused sporadic avian influenza and small outbreaks in humans, usually after **direct contact with birds** (most commonly poultry). There is no sustained person-to-person transmission.

### ***Clinical Features***

- **History of exposure** to infected birds.
- **Incubation period:** Usually 2–5 days after exposure (longer than with human influenza infection).
- **Symptoms:** Fever (at least 100.4°F), cough and myalgias. Watery diarrhea is fairly common. Usually complicated by viral pneumonia causing increasing respiratory distress and cyanosis. Ventilatory support is often necessary and mortality rate may be as high as 50%.

### ***Investigations***

- **Blood:** Leukopenia.

- **Liver function tests:** Raised hepatic aminotransferase, lactate dehydrogenase and creatine kinase.
- **Chest X-ray:** Infiltrates seen 7 days after the onset of fever.
- **Diagnosis:**
  - Isolation of virus or detection of H5 specific RNA. Pharyngeal swabs are preferred than nasal swabs, because of greater titers in the throat and lower respiratory tract.
  - Reverse transcriptase polymerase chain reaction (PCR) assays are more sensitive than commercial rapid antigen tests.

**Prevention:** Whenever there is an outbreak of avian influenza, avoid live animal markets and poultry farms.

#### Treatment

**Drug treatment:** Same as H1N1 influenza (refer page 167).

#### *Non-pharmacologic approaches*

- Influenza surveillance: For early warning, travel restrictions, quarantine, use of N 95 particulate respiratory masks, communication networking.
- Proper poultry-handling and personal hygiene (such as handwashing) and minimizing contact with birds during an outbreak.

## Severe Acute Respiratory Syndrome

**Q. Write a short essay/note on severe acute respiratory syndrome (SARS) and its laboratory findings.**

- An extraordinary outbreak of the coronavirus-associated disease known as severe acute respiratory syndrome (SARS) was described for the first time in 2002–2003 from Southern China and quickly spread to several countries within less than a year. A death rate of nearly 10% was reported. Though, presently it has not been reported from any country, there is possibility of either human or animal reservoirs of the virus and this may lead to return of SARS.

### *Etiology*

- SARS is caused by a previously unknown novel coronavirus (SARSCoV). It is not closely related to any of the previously described coronaviruses.

**Mode of spread:** By close person-to-person contact via droplet transmission or fomite.

## ***Clinical Features***

- **Incubation period:** 2–7 days (range 1–14 days).
- **Symptoms:** Begins as a systemic disease with persistent fever, chills/rigor, myalgia, malaise, headache, and myalgias followed in 1–2 days by a nonproductive/dry cough and dyspnea. About 25 % have diarrhea and about 20% develop ARDS over a period of 3 weeks.
- Older individuals may present with decrease in general well-being, poor feeding, fall without the typical febrile response.

## ***Laboratory Findings***

### *Blood*

- Lymphopenia due to the destruction of both CD4+ and CD8+ T-cells. Thrombocytopenia may occur as the disease progresses.
- Raised serum levels of aminotransferases, creatine kinase, and lactate dehydrogenase.
- Laboratory features of low-grade disseminated intravascular coagulation (DIC): Thrombocytopenia, prolonged activated partial thromboplastin time and raised D-dimer.

### *Chest X-ray*

- Most frequently peripheral and lower zone or interstitial infiltrates show patchy areas of consolidation. There will no cavitation, hilar lymphadenopathy or pleural effusion.
- Patchy areas may progress to diffuse involvement.
- Spontaneous pneumomediastinum may occur in few.
- Chest X-ray may be normal in about 25%.

## ***Diagnosis***

- **Detection of SARS CoV:** A rapid diagnosis of SARS-CoV infection by reverse transcription PCR (RT-PCR). The samples use includes:
  - **During early phase:** Respiratory tract (e.g. nasopharyngeal aspirate) samples and plasma
  - **During later phase:** Urine and stool specimen.
- Quantitative measurement of SARS-CoV RNA in blood with RT-PCR technique

- Viral culture of respiratory tract samples.

#### **Treatment**

- No specific therapy.
- **Supportive care:** It is the mainstay in therapy and includes maintenance of fluid and electrolyte balance, oxygenation and, if necessary ventilation with proper protection of health care workers.
- High dose methylprednisolone (0.5 g daily) is given if pneumonia or hypoxemia develops. However, its benefit remains to be established.

## Middle East Respiratory Syndrome

### **Q. Write short note on Middle East respiratory syndrome (MERS).**

- Caused by novel coronavirus namely MERS-CoV.
- Most cases have been reported in Arab Peninsula and neighboring countries with more than 70% from Saudi Arabia.
- **Mode of transmission:** Human to human transmission can occur although spread may not be efficient. Unlike SARS coronavirus, MERS-CoV does not preferentially infect health care workers.

**Source of infection:** Camels are major reservoir host for MERS-CoV and an animal source of infection in humans.

**Incubation period:** 2–14 days (mean 5.2 days)

- The virus causes more severe disease in individuals who are old, with weakened immune systems, with chronic diseases (e.g. cancer, chronic lung disease and diabetes).

**Clinical features:** Typical MERS symptoms include fever, cough and shortness of breath. Pneumonia is common, but not always present. Gastrointestinal symptoms, including diarrhea, have also been reported.

- About 36% of reported patients with MERS died mostly due to ARDS. Renal failure also can develop.
- Investigations: Leukopenia, thrombocytopenia, raised elevated liver enzymes, LDH and creatinine kinase.

**Treatment:** Neither vaccine nor specific treatment is currently available. Treatment is supportive and based on the patient's clinical condition.

## DIFFUSE PARENCHYMAL LUNG

# DISEASE/INTERSTITIAL LUNG DISEASE

**Q. Discuss the etiology and approach to diffuse parenchymal lung disease/interstitial lung diseases.**

**Definition:** Diffuse parenchymal lung diseases [DPLD, also referred to as **interstitial lung diseases-(ILDs)**] are a **heterogeneous group of conditions affecting the parenchyma of lung and alveoli.**

- **Diffuse:** Refers to the nonspecific **radiological patterns**
- **Lung parenchyma** includes the alveoli, the alveolar epithelium, the capillary endothelium, the spaces between those structures (interstitium) as well as the perivascular and lymphatic tissues. **However, the term is often used loosely to refer to any form of lung tissue.** Many of these diseases involve the alveoli air space as well.

- **Interstitium of the lung:** It is defined as continuum of loose connective tissue throughout the lung and composed of three subdivisions:
  1. **Bronchovascular** (axial), surrounding the bronchi, arteries, and veins from the lung root to the level of the respiratory bronchiole.
  2. **Parenchymal** (acinar), situated between the alveolar and capillary basement membranes.
  3. **Subpleural**, situated beneath the pleura, as well as in the interlobular septae.
    - Interstitium of the lung is not normally visible radiographically. It becomes visible only when its volume increases.
    - They are non-infectious and non-malignant and usually chronic diseases that diffusely involve the lungs.
    - Diffuse parenchymal lung diseases can progress fibrosis in the interstitium (interstitial pulmonary fibrosis) of the lung.

## Etiology (Table 6.84)

**Q. Write short essay/note on causes/etiology of interstitial lung disease.**

Many diseases can produce interstitial lung disease. Based on the major underlying histopathology, ILDs can be divided into two groups: (1) those associated with predominant inflammation and fibrosis and (2) those with a predominantly granulomatous reaction in interstitial or vascular.

**Table 6.84:** Major causes of interstitial lung disease (ILD)/diffuse parenchymal lung diseases (DPLD).

<i>ILD/DPLD due to known causes</i>	<i>ILD/DPLD due to unknown causes</i>
<b>Non-granulomatous interstitial inflammation (predominant inflammation and fibrosis)</b>	

- Drugs: Antibiotics, gold, amiodarone, D-penicillamine, nitrofurantoin, Chemotherapeutic (e.g. busulphan, bleomycin, methotrexate, CCNU)
- Asbestos
- Fumes and gases
- Radiation
- Aspiration pneumonitis
- Residual of acute respiratory distress syndrome
- Smoking related: Pulmonary Langerhans cell histiocytosis, respiratory bronchiolitis interstitial lung disease and desquamative interstitial pneumonia
- Acute eosinophilic pneumonia
- Idiopathic interstitial pneumonias (IIPs)
- Idiopathic pulmonary fibrosis
- Pulmonary autoimmune rheumatic diseases (e.g. systemic lupus erythematosus, rheumatoid arthritis)
- Pulmonary alveolar proteinosis
- Eosinophilic pneumonias
- Lymphangiomyomatosis (LAM)
- Diffuse pulmonary hemorrhage
- Goodpasture's syndrome
- Idiopathic pulmonary hemosiderosis
- Lymphocytic interstitial pneumonia (seen in HIV)

#### Granulomatous interstitial inflammation

- Hypersensitivity pneumonitis (organic dusts)
- Inorganic dusts: For example, silicosis, berylliosis
- Sarcoidosis
- Pulmonary Langerhans' cell histiocytosis
- Granulomatous lung disease with vasculitis (e.g. Wegener, Churg–Strauss)

## Clinical Features

### **Q. Write short essay/note on clinical features of diffuse parenchymal lung disease/ interstitial lung diseases.**

Depending on the duration of illness and clinical presentation, ILDs is divided into acute, subacute and chronic.

- **Acute presentation** (days to weeks)
  - This presentation is **uncommon** but may develop with drugs, acute idiopathic interstitial pneumonia and hypersensitivity pneumonitis.
  - **Chief symptoms** are cough, dyspnea and occasionally fever.
  - **Chest X-ray** shows diffuse alveolar opacities which can be confused with 'atypical' pneumonia.
- **Subacute presentation** (weeks to months)
  - **Symptoms:** Gradually increasing cough and dyspnea over weeks to months.
  - This type of presentation can occur especially with sarcoidosis, and drug-induced ILDs.
- **Chronic presentation (months to years)**

- Most common presentation in which symptoms are present for months to years.
- **Common symptoms:** Shortness of breath, dry cough, fatigue, weakness, loss of appetite and weight.

### ***Physical Examination***

- The findings include tachypnea, grossly decreased chest expansion and bibasilar fine **end-inspiratory dry crackles (Velcro)** which are common in ILD associated with inflammation. **Clubbing, cyanosis** and features of right-sided heart failure occurs in advanced disease.
- Signs of underlying cause.

### **Investigations**

#### ***Laboratory Investigation***

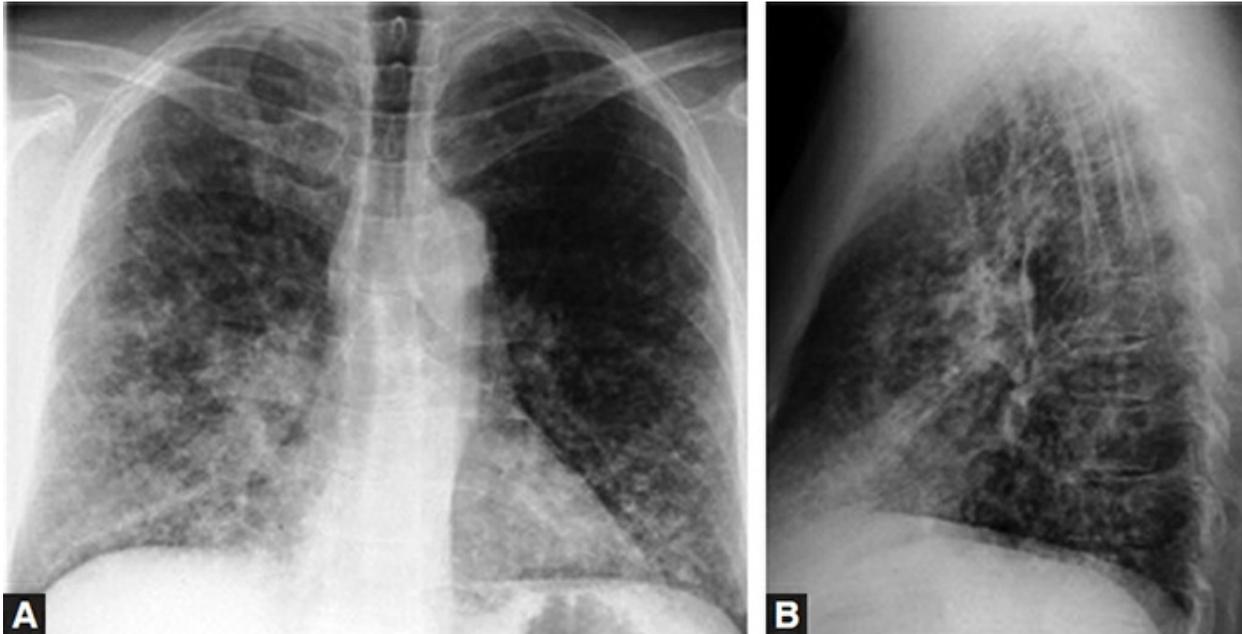

- **Blood:** Total leukocyte count, ESR, renal and liver functions, antinuclear antibodies, rheumatoid factor and circulating immune complexes.
- **Serum precipitins:** Confirm exposure when hypersensitivity pneumonitis is suspected.
- **Angiotensin converting enzyme levels:** Elevated in ILDs (e.g. sarcoidosis).
- **Antibodies:** Antineutrophil cytoplasmic antibodies and anti-basement membrane antibodies are useful if vasculitis is suspected (e.g. Wegener's granulomatosis, Goodpasture's syndrome).

#### ***Chest Imaging Studies***

- **Chest X-ray (Figs. 6.34A and B):** Often shows a bibasilar reticular or linear pattern or ground glass appearance. Nodular or mixed pattern of alveolar filling and reticular pattern may also be observed. Nodular opacities in the upper lung zones seen in sarcoidosis, chronic hypersensitivity pneumonitis, silicosis, rheumatoid arthritis. Honeycombing (due to small thick-walled cystic spaces and fibrosis) in long-standing conditions. It indicates poor prognosis. Basal fibrosis, pleural thickening and pleural plaques suggest asbestosis.
- **Computed tomography:** High-resolution CT (HRCT) of chest is superior to chest radiography for (i) early detection and confirmation of suspected

interstitial lung disease, (ii) demonstrates the extent and distribution of disease, (iii) detection of co-existing disease (e.g. lymphadenopathy, emphysema, carcinoma) and (iv) to determining the most appropriate area for biopsy (if necessary).

- **Pulmonary function tests:** It shows following findings:

**Figs. 6.34A and B:** Chest x ray of bilateral interstitial lung disease (A) AP view; (B) lateral view.

**Q. Write short note on pulmonary function tests in interstitial lung disease.**

- Restrictive ventilatory defect in the presence of reduced lung volumes and impaired gas transfer.
  - ◆ Restrictive defect is characterized by reduced FVC, reduced  $FEV_1$ , normal or elevated  $FEV_1$ : FVC ratio, total lung capacity, reduced diffusion capacity.
  - ◆ Obstructive pattern is seen in sarcoidosis, hypersensitivity pneumonitis, Lymphangioleiomyomatosis, tuberous sclerosis and neurofibromatosis.
- **Exercise tests:** Help in the evaluation of severity of the disease. The six-minute walk test records oxygen saturation before, during and after exercise and measures the total distance walked.
- **Arterial blood gas:** It may reveal hypoxemia and respiratory alkalosis. Hypercapnia is rare and may develop in the end-stage. Increased alveolar-

arterial oxygen gradient  $[P(A-a)O_2]$ .

- **Fiberoptic bronchoscopy and bronchoalveolar lavage (BAL):** In selected cases (e.g. sarcoidosis, hypersensitivity pneumonitis, cancer), cellular analysis of BAL may be useful in narrowing the differential diagnosis. Transbronchial biopsy may aid in diagnosis.
  - Sarcoidosis and hypersensitivity pneumonitis: It fluid shows T cell lymphocytosis (increased CD4 cells in sarcoidosis and CD8 cells in hypersensitivity pneumonitis).
  - Idiopathic pulmonary fibrosis (IPF): It shows predominant neutrophils and eosinophils.
  - Pulmonary alveolar proteinosis: It is milky and microscopically contains foamy macrophages with PAS positive material.
- Diffuse pulmonary hemorrhage: It shows RBCs and hemosiderin-laden macrophages.
- **Biopsy: Open or video assisted lung biopsy is used for confirmation of diagnosis and assessment of activity.**

## Treatment

### Major Goals

- Treat the underlying cause if possible.
- Permanent removal of the offending agent if known.
- General
  - Oxygen therapy: For patients with documented hypoxia,  $SpO_2 < 89\%$ ,  $-PaO_2 < 55$  mm Hg. Improves exercise tolerance.
  - Adequate nutrition, immunizations (pneumococcal, influenza).
  - Pulmonary rehabilitation: Treatment of pulmonary hypertension, single-lung transplantation.

Early identification and aggressive suppression of the acute and chronic inflammatory process, thereby reducing further damage to the lung.

### Drugs

- **Corticosteroids** are the mainstay for the suppression of the inflammation present in ILD, though they are not effective in majority, particularly those with significant fibrosis. Prednisone in the dose is 0.5–1 mg/kg once daily for 4–12 weeks. If the patient improves it is then tapered to maintenance dose of 0.25–0.5 mg/kg level for an additional 4–12 weeks.
- **N-Acetylcysteine:** 600 mg thrice daily. Has been found promising in the management of DPLD.
- **Other immunosuppressants:** If the patient does not respond to steroids, another immunosuppressant such as cyclophosphamide or azathioprine (1–2 mg/kg lean body weight per day) mycophenolate mofetil, rituximab with or without glucocorticoids may be tried.
- **Other drugs:** Include colchicine, cyclosporine and N-acetylcysteine (a precursor to the naturally occurring antioxidant glutathione).
- **Pirfenidone** is an anti-fibrotic drug used for idiopathic pulmonary fibrosis (IPF). Mechanism of

action is via the down regulation of the production of growth factors and procollagens I and II leading to decrease fibroblast proliferation.

## Idiopathic Interstitial Pneumonias

- Idiopathic interstitial pneumonias (IIPs) are characterized by diffuse inflammation and fibrosis in the lung parenchyma in which the etiology is not known. They form a major subgroup of interstitial lung diseases or diffuse parenchymal lung diseases. The lung parenchyma shows varying combinations of fibrosis and inflammation.

**Classification of idiopathic interstitial pneumonias (ATS/ERS joint consensus statement-2002).** Based on mainly histological patterns/in order of relative frequency is presented in Table 6.85.

**Table 6.85:** Classification of idiopathic interstitial pneumonias based mainly on histological patterns/in order of relative frequency.

- Idiopathic pulmonary fibrosis (IPF)/usual interstitial pneumonia (UIP)
- Non-specific interstitial pneumonia (NSIP)
- Cryptogenic organizing pneumonia (COP)/bronchiolitis obliterans organizing pneumonia (BOOP)
- Acute interstitial pneumonia (AIP)/(Hamman-Rich syndrome) rapidly fatal
  - Respiratory bronchiolitis associated interstitial lung disease (RBILD)
  - Desquamative interstitial pneumonia (DIP)
  - Lymphoid interstitial pneumonia (LIP)

## Idiopathic Pulmonary Fibrosis

**Q. Write short essay/note on clinical features, investigations and treatment of idiopathic pulmonary fibrosis.**

Also known as usual interstitial pneumonia (UIP) and was previously called as cryptogenic fibrosing alveolitis (CFA).

**Definition:** It is a progressive fibrosing interstitial pneumonia of unknown cause.

Contributory factors: Cigarette smoking, chronic aspiration, antidepressants, infections (e.g. Epstein–Barr virus), exposure to occupational dusts (e.g. wood, metal dusts) and chronic gastroesophageal reflux.

Clinical features and investigations are discussed under ILD (refer pages 343-5).

### Treatment

- Refer treatment of ‘interstitial lung disease’ as discussed above.
- Corticosteroids: Response is poor.

## OCCUPATIONAL LUNG DISEASES

### Q. Write short essay/note on common occupational lung diseases and their etiology/common causes of pneumoconiosis.

- Exposure to dusts, gases, vapors and fumes at work can cause many types of lung disease. It is difficult to distinguish occupational and environmental lung diseases from those of non-environmental origin.
- **Pneumoconioses** are defined as **lung diseases produced by organic as well as inorganic particulates and chemical fumes and vapors.** However, sometimes the term occupational lung diseases and pneumoconiosis are used interchangeably.
- **Common** pneumoconiosis are those due to inorganic (mineral) dusts. Occupational exposure and associated lung diseases are listed in Table 6.86.

**Table 6.86:** Occupational exposure and associated lung diseases.

<i>Occupational exposure</i>	<i>Disease associated with chronic exposure</i>
<b>Diseases due to inorganic (mineral) dusts: Common pneumoconiosis</b>	
<ul style="list-style-type: none"><li>• Coal</li><li>• Silica</li><li>• Asbestos</li><li>• Beryllium</li><li>• Iron oxide</li><li>• Tin dioxide</li></ul>	Coal-worker’s pneumoconiosis (CWP) Silicosis Asbestos-related diseases Berylliosis Siderosis Stannosis
<b>Diseases due to organic dusts</b>	
<ul style="list-style-type: none"><li>• Cotton, flax or hemp dust</li><li>• Mouldy hay, grain, straw</li><li>• Mould malting</li><li>• Contaminated bagasse (sugar cane)</li></ul>	Byssinosis Farmer’s lung Malt worker’s lung Bagassosis
<b>Diseases due to gases and fumes</b>	
<ul style="list-style-type: none"><li>• Irritant gases, isocyanates cadmium</li><li>• Platinum salts</li></ul>	Occupational asthma, bronchitis, ARDS Occupational asthma

### Diseases due to biological substances

- Proteolytic enzymes, allergens from animals and insects (excreta), contaminated grain dust

Occupational asthma, bronchitis

### Diseases due to chemicals and radioactive substances

- Polycyclic hydrocarbons, radon

Bronchial carcinoma

## Coal-workers' Pneumoconiosis

### **Q.** Write a short essay/note on coal-worker's pneumoconiosis (CWP).

- **Definition:** Coal-workers' pneumoconiosis (CWP) is the **parenchymal lung disease caused by prolonged inhalation of carbon particles** (coal mine dust).
- Coal-worker's pneumoconiosis develops in coal miners with a prolonged history of inhalation of coal dust. The coal mine dust particles about 2–5  $\mu\text{m}$  in diameter are retained in the small airways and alveoli of the lung. The incidence of the disease depends on the total dust exposure, and availability of ventilation and dust suppression. The risk of this disease is reduced due to improved ventilation and working conditions.
- Incidence is more in anthracite coal miners compared to bituminous miners.

**Classification:** Based on the size and extent of radiographic nodularity, CWP is subdivided into:

- Simple coal-worker's pneumoconiosis (SCWP)
- Progressive massive fibrosis (PMF).

### ***Simple Coal-worker's Pneumoconiosis***

- Simple coal-worker's pneumoconiosis (SCWP) refers to the deposition of coal dust in the lung and produces small radiographic (micronodular) shadows/nodules on the chest X-ray in an otherwise asymptomatic individual. It is the most common type of pneumoconiosis.
- Develops after prolonged exposure (15–20 years) to coal dust.
- SCWP does not impair lung function and does not progress if the miner leaves the industry/exposure ceases.
- Grading of simple coal-workers pneumoconiosis: Depending on the chest X-ray appearance, simple CWP is divided into three categories (Table 6.87).

- Simple pneumoconiosis (categories 2 and 3) can progress to progressive massive fibrosis (PMF).

**Table 6.87:** Grading of simple coal-worker's pneumoconiosis.

Category	Chest X-ray appearance
1	Few small round opacities
2	Numerous small round opacities but normal lung markings still visible
3	Very numerous small round opacities and normal lung markings partly or totally obscured

### ***Progressive Massive Fibrosis***

**Q. Write a short essay/note on progressive massive fibrosis (PMF).**

- PMF progresses even after the miner leaves the industry/exposure ceases.
- Chest X-ray: Characterized by single or multiple round fibrotic nodules/masses several centimeters in diameter (>1 cm in size to large dense masses), invariably in the upper lobes. Sometimes these nodules show central necrotic cavities.
- Lung function tests: Mixed restrictive and obstructive ventilatory defect with loss of lung volume, irreversible airflow limitation and reduced gas transfer.
- Clinical features: Progressive breathlessness/dyspnea and cough with blackish sputum (melanoptysis).
- Complications: Respiratory failure, right ventricular failure and Caplan's syndrome.

### **Caplan's syndrome**

**Q. Write a short essay/note on Caplan's syndrome (rheumatoid pneumoconiosis).**

- Caplan's syndrome is the combination of pneumoconiotic nodules with sero-positive rheumatoid arthritis.
- Pneumoconiotic nodules are round, fibrotic and measure 0.5–5 cm diameter and are found mainly in the periphery of the lung fields.
- Rheumatoid factor is positive and pathological features are similar to a rheumatoid nodule.
- This syndrome can also be seen in pneumoconiosis (e.g. silicosis) other than

CWP.

## Asbestos-Related Lung and Pleural Diseases

**Q. Write a short essay/note on the asbestos-related diseases of lungs and pleura.**

- **Asbestos types:** Asbestos has the unique property of occurring naturally as a fiber. It is remarkably resistant to heat, acid and alkali. Major types are: **chrysotile** (white asbestos), **crocidolite (blue asbestos)** and **amosite (brown asbestos)**. All of these types are **fibrogenic** and have the potential to cause asbestos-related diseases. It is widely used for roofing, insulation and fireproofing.
- **Occupational exposure:** It is highest with workers involved in the production of asbestos products (mining, milling and manufacturing), shipyard and construction industries. Exposure can also occur in automobile and railroad workers and those involved in thermal and electrical wire insulation.

### *Asbestos Related Diseases*

1. Asbestosis (progressive pulmonary fibrosis)—highest dose is required to cause asbestosis
2. Benign localized pleural fibrous plaques—calcification of parietal pleura more pronounced on the diaphragm and mediastinum.
3. Benign pleural effusions
4. Carcinoma of lung
5. Malignant mesotheliomas of pleura and mesothelioma of peritoneum (rare)
5. Laryngeal carcinomas.

### *Asbestosis*

- **Definition:** Asbestosis is defined as interstitial fibrosis of the lung caused by exposure to **asbestos dust**. It does not include asbestos-induced pleural diseases and carcinoma of lung that are found in asbestos-exposed workers.
- **Duration of exposure:** Development of asbestosis is directly related to the intensity and duration of exposure. It develops after moderate to severe exposure for at least 10 years.

- **Clinical features:** Progressive exertional breathlessness, finger clubbing and late-inspiratory crepitations/crackles over the lower zones of lung.
- **Investigations:**
  - Radiography:
    - ◆ Chest radiographic hallmark of asbestosis is presence of irregular or linear opacities in the lower lung fields. An indistinct heart border or a 'ground-glass' appearance in the lung fields may be observed.
    - ◆ HRCT: May show subpleural curvilinear lines 5–10 mm in length which appear to be parallel to the pleural surface. Plain chest X-ray may not show pleural disease; however, CT can demonstrate pleural disease in more than 90% cases. Honeycomb lung may also be seen.
  - **Pulmonary function tests:** Restrictive pattern with a decreased both lung volumes and diffusing capacity.
  - **Lung biopsy:** May show asbestos bodies and fibrosis.
- **Complications:** Respiratory failure, right ventricular failure and bronchial carcinoma.

## ***Lung Cancer***

- Most common cancer associated with asbestos exposure. Minimum latent period range from 15 to 20 years between first exposure and development of cancer.
- Histological, it may be squamous cell carcinoma or adenocarcinoma.

## ***Mesothelioma***

- Mesothelioma is a primary malignant tumor of mesothelial lining of pleura and/or peritoneum and both can develop with asbestos exposure and is most commonly caused by blue asbestos.
- In contrast to lung cancer, development of mesothelioma has not association with smoking.
- Relatively short period of exposure (even 1–2 years) that occurred more than 20–40 years ago is associated with development of mesothelium.
- **Clinical presentation:** Persistent chest pain (due to involvement of chest wall), breathlessness (due to pleural effusion) and usually unilateral hemorrhagic pleural effusion. As the tumor advances, it encases the

underlying lung, may invade into the lung parenchyma, the mediastinum and the pericardium.

- Diagnosis is confirmed by video-assisted thoracoscopic biopsy of pleura.
- Mesothelioma is almost invariably fatal.

## Silicosis

**Q. Write a short essay/note on silicosis.**

**Definition:** Silicosis is a **parenchymal lung disease** associated with **inhalation of crystalline silicon dioxide** (silica).

- **Occupational exposure:** High-risk occupations include mining, stone cutting, sand blasting, and quarrying (e.g. granite), pottery and ceramics industry, foundry work, boiler scaling, glass and cement manufacturing, etc.
- Silica is highly fibrogenic and causes the development of hard nodules that coalesce as the disease advances. Pulmonary fibrosis depends on dose and develops after many years of exposure.
- **Associated risk:** Silicosis is associated with increased risk of tuberculosis (silicotuberculosis), lung cancer and COPD. The increased risk is lifelong even if exposure ceases. Chemoprophylaxis using INH for 9 months is recommended if latent tuberculosis is diagnosed with a positive tuberculin test. Other diseases that can develop in silicosis include chronic renal insufficiency and autoimmune diseases (e.g. scleroderma, rheumatoid arthritis and Wegener's granulomatosis).

Forms of silicosis (silica-induced lung disease): Chronic, acute or accelerated.

- **Chronic or simple silicosis**
  - Most common form of silicosis. It occurs after many decades (10 to 20 years) of exposure to relatively low levels of silica.
  - Clinically characterized by gradually progressive dyspnea and dry cough. It is often compatible with normal life.
  - **Radiological features:** Variable and similar to those of coal-worker's pneumoconiosis. It may show multiple well circumscribed 3 to 5 mm nodular opacities mainly in the mid- and upper-zones. As the disease progresses extensive fibrosis develops and resembles PMF. The involvement of hilar lymph nodes by chronic silicosis is characteristic

(but is uncommon and non-specific), with a tendency towards peripheral calcification, which produces the so-called **egg-shell calcification**.

- **Pulmonary function tests:** Mixed pattern of obstruction and restriction with a reduced diffusion capacity.
- No specific treatment.
- **Acute silicosis**
  - It occurs after intense exposure (very high concentration of dust) to very fine crystalline silica dust over a few months (about less than 10 months of exposure) and is usually rapidly fatal within years.
  - Characterized by pulmonary edema, interstitial inflammation and accumulation of proteinaceous fluid rich in surfactant within the alveoli.
  - Chest radiograph: May show miliary infiltration or areas of consolidation. HRCT chest may show pattern known as ‘crazy paving’.
- **Accelerated silicosis**
  - It occurs after a few years (typically 5–10 years) of exposure to silica.
  - More aggressive course associated with rapidly progressive features of dyspnea and pulmonary fibrosis.
  - Involves mainly middle and lower zones of the lungs as compared to chronic silicosis.

## **Pulmonary Fibrosis**

A wide variety of lung disorders heal by producing fibrous tissue and results in fibrosis of the lung.

### ***Types of Pulmonary Fibrosis***

**Q. Write a short essay/note on types of pulmonary fibrosis and causes of interstitial fibrosis.**

1. **Replacement fibrosis:** In this the damaged lung parenchyma (e.g. suppuration, infarction) replaced by fibrous tissue.
  - **Common causes:** Pulmonary tuberculosis, bronchiectasis, lung abscess, pulmonary infarcts and necrotizing pneumonias
2. **Focal fibrosis:** In focal fibrosis, the extent of fibrosis varies from small nodular lesions to extensive areas.

- **Common causes:** Coal-worker's pneumoconiosis (CWP), asbestosis and silicosis.
3. **Interstitial fibrosis:** In this fibrosis is diffuse and represents the end result of interstitial lung diseases.
- **Common causes** of interstitial lung disease (refer Table 6.84).

### ***Clinical Features of Replacement Fibrosis***

**Q. Write a short essay/note on clinical features, radiological features and management of replacement fibrosis.**

- History of cough with or without expectoration and dyspnea. Sputum may be blood-tinged.

#### *Physical findings in the chest*

- **Inspection and palpation:**
  - **Features on the affected side:** Shifting of the trachea and mediastinum towards the affected side. Drooping of the shoulder, flattening, hollowing, and crowding of the ribs, diminished movements of the chest wall and scoliosis of the spine. The hemithorax is smaller, its expansion and spinoscapular distance are diminished and spinoacromial distance is increased. Vocal fremitus is usually decreased.
  - Chest expansion is reduced.
- **Percussion: On the affected side** there is impaired note.
- **Auscultation**
  - When fibrosis is extensive, the intensity of breath sound is reduced and vesicular in character with prolonged expiration.
  - Vocal resonance is reduced. Crepitations are heard.
  - Sometimes if trachea or major bronchus is pulled up due to fibrosis, tubular bronchial breathing can be heard.

### **Fibrothorax**

- **Causes of fibrothorax:** Empyema, pleural effusion, traumatic hemothorax, tuberculosis, benign asbestos pleural effusion, connective and collagen vascular disorders, uremia, paragonimiasis, and drug induced (e.g. ergot alkaloids, bromocriptine, pergoline, methysergide, and

methotrexate).

- **Clinical features** of fibrothorax: (1) marked limitation of chest movements, (2) mediastinal shift to same side, trachea may be central or shifted to affected side, (3) decrease in size of hemithorax and (4) crowding of ribs.

*Radiological findings on the affected side: Shift of the mediastinum towards the affected side. Smaller hemithorax than the other unaffected hemithorax. Crowding of the ribs, pulling of hilum upwards, raised diaphragm (tenting) and lung fields show fibrous bands.*

#### Management/Treatment of Replacement Fibrosis

- **Symptomatic measures:** For example, breathing exercises, expectorants.
- **Treatment of infections:** Antibiotics.
- **Treatment of the underlying disease/cause:** For example, tuberculosis.
- **Surgery:** Resection in selected cases.

## Primary Bronchial Tumors

**Q. Write a short essay/note on classification of primary bronchial tumors.**

**Classification of primary tumors of the lung (Table 6.88)**

**Table 6.88: Classification of tumors of the lung.**

<i>Benign tumors (5%)</i>	<i>Malignant tumors (95%)</i>
<p><b>Benign epithelial tumors</b></p> <ul style="list-style-type: none"> <li>• Papillomas</li> <li>• Adenomas</li> </ul> <p>Mesenchymal tumors</p> <ul style="list-style-type: none"> <li>• Chondroma</li> <li>• Lipoma</li> </ul> <p><b>Miscellaneous tumors</b></p> <ul style="list-style-type: none"> <li>• Pulmonary hamartoma</li> <li>• Sclerosing hemangioma</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Non-small cell carcinoma (75%)</b> <ul style="list-style-type: none"> <li>– Squamous or epidermoid carcinoma</li> <li>– Large-cell carcinoma</li> <li>– Adenocarcinoma                             <ul style="list-style-type: none"> <li>◆Bronchioloalveolar cell carcinoma (presently termed adenocarcinoma in situ)</li> </ul> </li> </ul> </li> <li>• <b>Small-cell carcinoma (oat cell carcinoma) (25%)</b></li> <li>• <b>Adenosquamous carcinoma/Sarcomatoid carcinoma</b></li> <li>• <b>Salivary gland tumor:</b> Mucoepidermoid carcinoma, adenoid cystic carcinoma</li> <li>• <b>Carcinoid tumor:</b> Typical carcinoid, atypical carcinoid</li> </ul>

# LUNG CANCER (BRONCHIAL CARCINOMA)

**Q. Discuss the etiology/risk factors, clinical features, investigations, diagnosis, metastatic and non-metastatic complications, and management of bronchial carcinoma (bronchogenic carcinoma, lung cancer).**

- Carcinoma of the lung is the **most common cause of cancer death**. This is mainly due to the carcinogenic effects of **cigarette smoke**.
- In the past, the term bronchogenic carcinoma was used for primary lung cancer, to indicate the origin from the bronchi. Now it is known that about 5% of primary lung cancers do not arise from bronchus. Hence, the term lung cancer is used.
- Bronchial carcinoma is the most common primary malignant tumor of the lung and arises from the bronchial epithelium or mucous glands.

## Incidence

- **Age and gender:** Mostly found between **50 and 80 years** of age. More common in males, but there is a recent increase in females due to increased smoking among females.
- More in urban than rural dwellers and more in smokers than non-smokers.

## Etiology

- **Cigarette (tobacco) smoking**
  - There is strong evidence that tobacco smoking is the most important cause of cancer of lung. Smoking also multiplies the risk of other carcinogenic influences such as asbestos and uranium. The **strongest association** of smoking is with **squamous cell and small cell carcinoma**. The risk of cancer is directly proportional to the amount of daily smoking, tendency to inhale and duration of the smoking habit. Compared to nonsmokers, the smokers have a 10 times and heavy smokers (more than 40 cigarettes per day for several years) 60 times more risk of lung cancer. Females are more susceptible to tobacco carcinogens than males. Cessation of smoking for 10 years reduces risk but not to the level in nonsmokers. However, only 11% of heavy smokers develop lung cancer, which indicates that genetic factors are involved. **Pipe and cigar smokers have lower incidence than cigarette smokers**. Bidi smoking may be associated with more risk of

lung cancer than cigarette smoking. Second-hand smoke exposure (passive smoking) is also a risk factor. Adenocarcinoma is usually not related to smoking.

- More than 60% of new lung cancers occur in never smokers (smoked <100 cigarettes per lifetime) or former smoker (smoked 100 cigarettes per lifetime, quit 1 year), 1 in 5 women and 1 in 12 men diagnosed with lung cancer have never smoked.
- **Major carcinogens in tobacco smoke** include both initiators and promoters (such as phenol derivatives). These include **polycyclic aromatic hydrocarbons (e.g. Benzo[*a*]pyrene, dibenzanthracene)** and **radioactive elements and other contaminants (e.g. arsenic, nickel, cadmium, molds, and vinyl chloride)**.
- **Environmental tobacco smoke = Main stream smoke + Side stream smoke**

*Main stream smoke refers to the smoke inhaled by smoking directly while side stream smoke refers to the smoke emitted by the burning cigarette. Both contain carcinogens*

- **In Indians** with lung cancer, history of active tobacco smoking was found in 87% of males and 85% of females. History of passive tobacco exposure is found in 3%. Thus, 90% of all cases in India resulted from tobacco exposure.
- The relative risk of developing lung cancer is: 2.64 for beedi smokers, 2.23 for cigarette smokers and 2.45 as the overall relative risk (RR).
- **Industrial and occupational hazards**
  - **Ionizing radiation:** High-dose of ionizing radiation is carcinogenic (uranium mining-oat cell carcinoma is the most common type).
  - **Uranium:** It is weakly radioactive and uranium miners (both nonsmokers and smokers) have higher incidence of lung cancer than in the general population.
  - **Asbestos:** Exposure increases the risk and risk increases when associated with smoking. It develops after a latent period of about 10 to 30 years. Insulation and shipyard workers, increase in risk of lung cancer after 10 years of exposure, with concurrent smoking increases risk 90 fold.
  - **Other carcinogens:** Chloromethyl, ethers and mustard gas (squamous

and undifferentiated are most common types), chromium, nickel, vinyl chloride, polyaromatic hydrocarbons, cadmium, formaldehyde and dioxin.

- **Atmospheric pollution:** The risk of **lung cancers is higher in urban areas** than rural areas, suggesting role of air pollution. Major air pollutants include polycyclic hydrocarbons from fossil fuels and motor vehicle exhaust especially diesel smoke. Studies from China have shown coal burning at home is a significant risk factor for development of lung cancer in nonsmoking females. Coal smoke contains potential carcinogens SO<sub>2</sub>, CO, TSP, B (a) P, radon, thorn.
- **Diet: Vitamin A deficiency** → leads to squamous metaplasia → increased **susceptibility to cancer**. Folate, carotenoid rich fruits and vegetables, vitamin E and beta-carotene are associated with reduced risk of lung cancer.
- **Idiopathic pulmonary fibrosis:** It is associated with increased risk of lung cancer.
- **Prior lung diseases such as** chronic bronchitis, emphysema, and **tuberculosis**
- **Genetic predisposition:** Genetic polymorphisms involving cytochrome P-450 gene CYP1A1 → increased capacity to metabolize procarcinogens present in the cigarette smoke → increased risk of lung cancer.
  - First-degree relatives of lung cancer probands have a two-to threefold excess risk of lung cancer and other cancers, many of which are not smoking-related.
  - Individuals with inherited mutations in *RB* (retinoblastoma) and *p53* (Li-Fraumeni syndrome) genes may develop lung cancer.
- A rare germline mutation (T790M) involving the epidermal growth factor receptor (EGFR) maybe linked to lung cancer susceptibility in never smokers.

Examples of the oncogenes and tumor suppressor genes involved in lung cancer are presented in Table 6.89.

**Table 6.89:** Examples of the oncogenes and tumor suppressor genes involved in lung cancer.

<i>Histology</i>	<i>Oncogene</i>	<i>Tumor-suppressor genes</i>
------------------	-----------------	-------------------------------

Adenocarcinoma	EGFR, KRAS, ALK	TP53, CDKN2A/B(p16, p14), LKB1
Squamous cell carcinoma	EGFR, PIK3CA, IGF-1R	TP53, TP63
Small cell carcinoma	MYC, BCL-2	TP53, RB1, FHIT
Large cell carcinoma	(not well studied)	

## Pathology

**Clinical subgroups of lung cancer** (Table 6.90): Lung carcinomas can be divided into two clinical subgroups on the basis of likelihood of metastases and response to therapies.

- Small cell lung cancer (SCLC), non-small cell lung cancer (NSCLC) (includes adenocarcinoma, squamous cell carcinoma and large cell carcinoma) account for approximately 90% of all epithelial lung cancers.
- Among women and young adults (< 60 years), adenocarcinoma tends also to be the most common form of lung cancer.
- Neuroendocrine tumors of the lung arise from Kulchitsky cells of the bronchial mucosa and consist of typical carcinoid, atypical carcinoid and small-cell lung cancer.

**Table 6.90:** Clinical subgroups of lung cancer.

<i>Small cell lung carcinomas (SCLC) -highly metastatic, high response to chemotherapy</i>	<i>Non-small cell lung carcinomas (NSCLC) -less metastatic, less responsive</i>
<ul style="list-style-type: none"> <li>• Small-cell (oat cell) carcinoma</li> </ul>	<ul style="list-style-type: none"> <li>• Squamous (epidermoid) carcinoma</li> <li>• Adenocarcinoma (including bronchioloalveolar carcinoma)</li> <li>• Large cell carcinoma</li> </ul>

## Lung Cancer in India

- Non-small-cell lung cancer constitutes 75–80% of lung cancers. More than 70% of them are detected in stages III and IV. Thus, curative surgery cannot be done in these cases. In many Western countries adenocarcinoma has become the most common lung cancer. However, in India it is still most common is squamous cell carcinoma in both males and females.
- Small-cell lung carcinoma constitutes 20% of all lung cancers. It is detected at an extensive stage in 70% of patients at the time of diagnosis.

**Site:** Depending on the site, the lung cancers are divided into:

- **Central (hilar):** Lung cancers arise in and around the **hilus** of the lung are

the **most common**. About 75% arise from first, second, and third-order bronchi. Squamous cell and small-cell carcinomas are generally centrally placed.

- **Peripheral:** Lung cancers may also arise in the periphery of the lung from the alveolar septal cells or terminal bronchioles. They are **usually adenocarcinomas, including bronchioloalveolar type**.

**Bronchioloalveolar carcinoma (BAC)** is a subtype of adenocarcinoma that grows along the alveoli without invasion. It can present with profuse, mucoid sputum (bronchorrhea).

### Clinical Features

More than 50% of patients present with locally advanced or metastatic disease at the time of diagnosis. Majority patients present with signs, symptoms, or laboratory abnormalities that may be due to the (i) primary lesion, (ii) local tumor growth, (iii) invasion or obstruction of adjacent structures, (iv) metastatic tumor, or as a (v) paraneoplastic syndrome. Clinical manifestations of bronchial carcinoma can be studied under the following headings:

1. **Manifestation due to the location of the primary tumor/growth** (Table 6.91)

**Table 6.91:** Manifestation due to the location of the primary tumor.

<i>Due to a central or endobronchial growth</i>	<i>Due to a peripheral growth</i>
<ul style="list-style-type: none"> <li>• Cough</li> <li>• Hemoptysis</li> <li>• Wheeze and stridor</li> <li>• Breathlessness/dyspnea</li> <li>• Postobstructive pneumonitis presenting with fever and productive cough</li> </ul>	<ul style="list-style-type: none"> <li>• Chest pain from pleural or chest wall involvement</li> <li>• Dyspnea on a restrictive basis</li> <li>• Symptoms of lung abscess due to cavitation of tumor</li> </ul>

2. **Manifestation due to the regional spread of tumor in the thorax** (Table 6.92)

**Table 6.92:** Manifestations of lung cancer due to regional spread of tumor in the thorax.

<i>Pathological basis</i>	<i>Local effects</i>
<ul style="list-style-type: none"> <li>• Obstruction of airway by tumor</li> </ul>	Pneumonia, abscess, atelectasis, focal

	emphysema
• Tracheal obstruction	Stridor (a harsh inspiratory noise) and dyspnea
• Local spread into pleura	Pleuritis and malignant effusion
• Local spread to pericardium	Pericarditis, effusion, tamponade
• Compression of SVC by tumor	Superior vena cava syndrome
<b><i>Invasion of structure</i></b>	<b><i>Its effects</i></b>
• Recurrent laryngeal nerve	Hoarseness of voice and ‘bovine’ cough
• Phrenic nerve	Diaphragm paralysis and dyspnea
• Sympathetic ganglia	Horner syndrome
• Esophagus	Dysphagia
• Chest wall (direct extension)	Destruction of rib producing rib pain, pathological fractures and intercostal neuralgia
• Superior sulcus tumor (destruction of the T1 and C8 roots in the lower part of the brachial plexus by an apical lung tumor)	Pancoast’s syndrome ((pain in the inner aspect of the arm, sometimes with small muscle wasting in the hand)
• Lymphatic obstruction	Pleural effusion
• Vascular obstruction	Superior vena cava (SVC) syndrome
• Pericardial and cardiac extension	Pericardial effusion, cardiac tamponade, arrhythmias or cardiac failure

### 3. Manifestations of extrathoracic metastasis (Table 6.93)

**Table 6.93:** Manifestations of extrathoracic metastasis.

<b><i>Site of metastasis</i></b>	<b><i>Manifestations</i></b>
<b>Adrenal glands (~50%)</b>	Usually asymptomatic, Addison’s disease
Liver (30–50%)	Anorexia, nausea, biliary obstruction, weight loss, right upper quadrant pain and pain
Brain (20%)	Headache, vomiting, focal neurologic deficits, epileptic seizures confusion, and raised intracranial pressure
Bone (20%)	Bony pain, pathologic fractures or raised alkaline phosphatase
Bone marrow	Cytopenias or leukoerythroblastosis
Lymph node	Lymphadenopathy—commonly to mediastinal, cervical, supraclavicular region (scalene node), and even axillary or intra-abdominal nodes
Epidural and bone metastases	Spinal cord compression (if spine is involved) syndromes

### Paraneoplastic Syndromes (Table 6.94)

**Q. Write short essay/note on:**

- **Paraneoplastic syndromes/manifestations associated with bronchogenic carcinoma.**
  - **Mention the non-metastatic manifestations/complications of bronchial carcinoma.**
- Paraneoplastic syndromes are **symptom complexes in cancer patients** which are **not directly related to mass effects or invasion or metastasis or by the secretion of hormones indigenous to the tissue of origin.**
  - Lung cancer may occasionally be associated with paraneoplastic syndromes. They are summarized in Table 6.94.
  - Paraneoplastic syndromes manifest due to the peptide hormone secreted by the tumor and may be in the first manifestations of lung cancers. They are often relieved by successful treatment of the primary lung cancer. They are common with small-cell carcinoma.

**Table 6.94: Paraneoplastic syndromes in lung cancer.**

<i>System involved</i>	<i>Manifestations</i>
Systemic	<ul style="list-style-type: none"> <li>• Anorexia, cachexia, weight loss, fever</li> </ul>
Endocrine	<ul style="list-style-type: none"> <li>• Syndrome of inappropriate secretion of antidiuretic hormone causing hyponatremia (small-cell carcinoma)</li> <li>• Ectopic ACTH secretion resulting in hypokalemia, rather than full-blown Cushing's syndrome (small cell carcinoma)</li> <li>• Hypercalcemia due to ectopic production of parathyroid hormone or parathyroid hormone related peptide (squamous cell carcinoma)</li> <li>• Carcinoid syndrome, acromegaly, hypoglycemia, hyperthyroidism</li> <li>• Gynecomastia</li> </ul>
Skeletal	<ul style="list-style-type: none"> <li>• Clubbing of fingers (usually NSCLC) non-small cell carcinoma</li> <li>• Hypertrophic pulmonary osteoarthropathy (usually adenocarcinoma)-HPOA</li> </ul>
Neuromyopathic	<ul style="list-style-type: none"> <li>• Polyneuropathy</li> <li>• Myelopathy encephalomyelitis, opsoclonus-myoclonus, limbic encephalitis</li> <li>• Cerebellar degeneration</li> <li>• Myasthenia (Lambert–Eaton syndrome) and retinal blindness (small-cell carcinoma)</li> </ul>
Hematological	<ul style="list-style-type: none"> <li>• Migratory venous thrombophlebitis (Trousseau's syndrome)</li> <li>• Marantic endocarditis</li> <li>• Disseminated intravascular coagulation (DIC)</li> <li>• Anemia, granulocytosis, leukoerythroblastosis</li> </ul>

Cutaneous	<ul style="list-style-type: none"> <li>• Dermatomyositis</li> <li>• Acanthosis nigricans</li> </ul>
Renal	<ul style="list-style-type: none"> <li>• Nephrotic syndrome</li> <li>• Glomerulonephritis</li> </ul>

### ***Lambert-Eaton Myasthenic Syndrome (LMS)***

- Autoimmune disorders of neuromuscular junction due to anti-voltage-gated calcium channel antibodies.
- Proximal muscle weakness, usually in lower extremities
- Occasionally autonomic dysfunction and rarely cranial nerve symptoms.
- Frequently depressed deep tendon reflexes.
- In contrast to patients with myasthenia gravis, strength improves with serial effort.

#### **Treatment of LMS**

- Chemotherapy is the initial treatment of choice.
- 3, 4-diaminopyridine: It increases duration of presynaptic action potential by blocking potassium efflux, prolonging the activation of VGCC and increasing calcium entry into nerve terminals.

**Table 6.95: Causes of large bronchus obstruction.**

#### ***Common***

- Neoplasm (bronchial carcinoma or adenoma)
- Enlargement of tracheobronchial lymph nodes (malignant or tuberculous)
- Inhaled foreign bodies (more common in the right lung)
- Bronchial casts or plugs composed of inspissated mucus or blood clot (especially asthma, cystic fibrosis, hemoptysis, and debility)
- Collections of mucus or mucopus retained in the bronchi as a result of ineffective expectoration (especially postoperative following abdominal surgery)

#### ***Rare***

- Aneurysm of aorta
- Giant left atrium
- Pericardial effusion
- Congenital bronchial atresia
- Bronchial stricture (e.g. following tuberculosis or bronchial surgery/lung transplant)

## **Differential Diagnosis of Large Bronchus Obstruction (Table 6.95)**

## Investigations

Main aims of investigation: (1) to confirm the diagnosis, (2) establish the histological cell type, (3) to stage the extent of the disease and (4) to assess fitness to undergo treatment.

- **Imaging:**
  - **Chest X-ray**
    - Plain chest radiographs may show evidence of lung cancer or nonspecific appearances (Table 6.96).
    - **Evidence of lung cancer:** A normal finding does not rule out the presence of an underlying tumor. Tumor is visible if greater than 1 cm diameter.
- **Computed tomography (CT) of chest and abdomen:** It is an important for diagnosis and staging of carcinoma. Its uses are:
  - To know the tumor size and extent of disease [pleural extension, detect occult abdominal disease (e.g. liver and adrenals)].
  - To evaluate mediastinal or hilar lymph node involvement. If nodal involvement is observed it should be confirmed by histopathology.
  - To plan biopsy procedures: Use for guided biopsy of suspected lesions to know whether a tumor is accessible by bronchoscopy or percutaneous CT-guided biopsy.
  - To assess the response to treatment.

**Table 6.96: Common radiological presentations of bronchial carcinoma.**

<b>Finding</b>	<b>Interpretation</b>
Unilateral enlargement at hilum	Central tumor or enlargement of hilar lymphnode or a peripheral tumor in the apical segment of the lower lobe
Peripheral lung opacity with or without cavitation, solitary pulmonary nodule	Usually irregular but well circumscribed, and may contain irregular cavitation (squamous cell carcinoma may cavitate)
Collapse of the whole lung, lobe or segment	Endoluminal (tumor within the bronchus) tumor or compression of the main bronchus by enlarged lymph glands may produce occlusion leading to complete collapse
Broadening of mediastinum, enlarged cardiac shadow, elevation of a hemidiaphragm	Paratracheal lymphadenopathy (widening of the upper mediastinum). Malignant pericardial effusion (enlargement of the cardiac shadow). Raised hemidiaphragm (phrenic nerve palsy). Mediastinal widening due to mediastinal invasion
Pleural effusion	Usually indicates tumor invasion of pleural cavity/space distal to a

	bronchial carcinoma. Usually erosion is unilateral and large and may mask an underlying mass or pleural tumor (D/D mesothelioma)
Destruction of rib (osteolytic lesions)	Direct extension of tumor or blood-borne metastasis
Single mass/diffuse, multinodular lesion/fluffy	Bronchoalveolar carcinoma

- **Cytological examination:** Specimens that may be obtained for examining for malignant cells include: sputum, bronchial brushings and washings, percutaneous (CT guided) needle aspiration biopsy from a peripheral tumor and fine needle aspiration of lymph node, skin or liver in patients with metastasis.
- **Fibreoptic bronchoscopy:**
  - It permits visualization and biopsy of an intrabronchial tumor.
  - Useful for collecting bronchial washings from the suspicious segments for cytological study.
  - It helps in assessment of operability and the proximity of central tumors to the main carina
- **Percutaneous aspiration and biopsy:** Peripheral lung tumors cannot be seen by fibreoptic bronchoscopy. Hence, samples are obtained by aspiration or biopsy through the chest wall under CT guidance.
  - Diagnosis of lung cancer rests on the morphologic or cytological features correlated with clinical and radiographic findings.
- Use of **immunohistochemistry:**
  - To verify neuroendocrine differentiation within a tumor, with markers such as neuron-specific enolase (NSE), CD56 or neural cell adhesion molecule (NCAM), synaptophysin, chromogranin, and Leu7.
  - Helps in differentiating primary from metastatic adenocarcinomas. For example: thyroid transcription factor 1 (TTF-1), is positive in more than 70% of pulmonary adenocarcinomas and is a reliable indicator of primary lung cancer, provided a thyroid primary has been excluded.
  - To narrow the differential diagnosis: For example, cytokeratins 7 and 20.
- **Investigations for staging to guide treatment:**
  - Fine needle aspiration: (1) endoscopic ultrasound-guided fine needle aspiration (FNA) of tumor or lymph node,(2) endobronchial

ultrasound–guided fine needle aspiration and (3) endoscopic ultrasound via the esophagus.

- Scalene node biopsy, mediastinoscopy, pleural aspiration and biopsy and barium swallow.
- Ultrasonography examination of liver and adrenal glands.
- **If metastasis is suspected:** Bone scans, bone marrow trephine biopsies and brain CT.
- **Positron emission tomography (PET) imaging/CT:** It helps in detecting the intrathoracic tumor, assessing the extent of mediastinal nodal involvement and detection of distant metastases. PET images combined with CT are better than CT or PET alone.
- **Other investigations:** Complete blood count for the detection of anemia, and biochemistry for liver involvement, hypercalcemia and hyponatremia.
- **Molecular testing for guiding treatment:** Test for EGFR mutations and ALK fusion.

## Staging

- **Staging of non-small-cell carcinoma** (Table 6.97): Staged into stages I to IV depending on the size and location of primary tumor, involvement of lymph nodes and distant metastasis (TNM International Staging System).
- **Staging of small-cell carcinoma:** It is staged into limited-stage and extensive-stage disease depending on whether the tumor can be encompassed within a tolerable radiation therapy port.

**Table 6.97: TNM staging of non-small-cell carcinoma.**

<i>TNM</i>	<i>Description</i>
Tx	Main tumor cannot be assessed, or cancer cells seen on sputum cytology or bronchial washing but no tumor can be found
T1	Tumor <3 cm in diameter; surrounded by lung or pleura; does not invade main bronchus
T1a	Tumor 2 cm or less in greatest dimension
T1b	Tumor >2 cm but <3 cm
T2	Tumor >3 cm in diameter; may invade pleura; may extend into main bronchus but remains 2 cm or more distal to carina
T2a	Tumor >3 cm but <5 cm
T2b	Tumor >5 cm but <7 cm
T3	Tumor >7 cm, invasion of chest wall, diaphragm, pleura or pericardium; main

	bronchus <2 cm distal to carina; atelectasis of entire lung
T4	Invasion of mediastinum, heart, great vessels, trachea, esophagus, vertebral body or carina; separate tumor nodules; malignant pleural effusion
N0	No nodal metastasis
N1	Involvement of ipsilateral peribronchial or hilar nodes and intrapulmonary nodes
N2	Involvement of ipsilateral mediastinal or subcarinal nodes
N3	Involvement of contralateral nodes or any supraclavicular nodes
M0	No distant metastasis
M1	Distant metastasis

### Staging of the small cell and non-small-cell carcinoma (Table 6.98)

**Q. Discuss the staging, diagnosis and treatment of small cell carcinoma.**

**Table 6.98: Staging of carcinoma of lung.**

<i>Stages of non-small-cell carcinoma based on TNM classification</i>	
Occult carcinoma	TX, N0, M0
IA	T1a,bN0M0
IB	T2aN0M0
IIA	T2bN0M0; T1a, bN1M0; T1a,bN1M1
IIB	T2bN1M0; T3N0M0
IIIA	T1a, b, T2a, b, N2M0; T3N1, N2M0; T4N0, N1M0
IIIB	T4N2M0; any T N3M0
IV	Any T any N M1
<i>Stage of small-cell carcinoma</i>	<i>Description</i>
Limited stage	<ul style="list-style-type: none"> <li>• 30–40% of small cell lung cancers</li> <li>• Confined to the hemithorax, mediastinum, and ipsilateral supraclavicular lymph node</li> <li>• Within the confines of radiation port</li> </ul>
Extensive stage	<ul style="list-style-type: none"> <li>• 60–70% of small cell lung cancers</li> <li>• Any distant spread</li> </ul>

- **Assessing fitness for treatment:** Before radical treatment, an assessment of fitness for treatment should be done. These include:
  - Evaluation of performance (Karnofsky performance status: Eastern cooperative Oncology Group Performance Status).
  - Full lung function test: Specifically FEV<sub>1</sub> and diffusion capacity

- Tests for any cardiovascular disease if there is evidence of disease (e.g. cardiopulmonary exercise testing, stress echo or occasionally preoperative angiography).

**Table 6.99: Treatment of non-small cell lung cancer.**

**Stage IA:**

- Lobectomy is treatment of choice. T1N0, lobectomy has 70% 5 year recurrence free survival.
- If inoperable:
  - 30% cure rate with XRT alone.
  - Stereotactic radiosurgery (Cyber Knife).
  - Radiofrequency ablation.

**Stage 1B:**

- Lobectomy.
- Adjuvant chemotherapy adds a 4–12% survival benefit. Best in tumors > 4 cm.

**Stage II:**

- Lobectomy is treatment of choice.
- Adjuvant chemotherapy now standard.
- Consider adjuvant XRT to mediastinum

**Stage III:**

- Combination chemotherapy with XRT is treatment of choice.
- Surgery has yet to be established consistently as benefit in randomized trials.
- Neoadjuvant therapy followed by surgical resection is option in IIIA.

**Stage IV:**

- Chemotherapy

**Treatment**

**1. Non-small-cell carcinoma**

- Surgical treatment:** Surgical resection of the tumor is done in early stage (1a, 1b, IIA, IIB and selected IIIa) of non-small cell lung cancer.
  - **Postoperative chemotherapy** (adjuvant therapy): Where surgical staging of resected lung cancer has lymph node involvement, patients need adjuvant chemotherapy.
  - **Preoperative chemotherapy** (neoadjuvant chemotherapy): May improve survival in stage IIIB patients and can effectively ‘down-stage’ disease. Commonly used drugs are carboplatin, paclitaxel ± bevacizumab (an antiangiogenesis drug).

**Contraindications to surgical resection**

- Stage IIIB or IV.
- Extensive invasion into surrounding structures: Involvement of vena cava, atrium, recurrent laryngeal or phrenic nerve and contralateral lymph nodes. Others include SVC obstruction, malignant effusion, and pericardial tamponade.
- Medically unfit: Poor cardiac or pulmonary status, predicted postoperative FEV1% <40%, predicted postoperative DLCO% < 40% and exercise studies for marginal candidates.

## b. Radiotherapy

**Radiotherapy for cure:** Radiotherapy is much less effective than surgical therapy. In selected cases with adequate lung function and early stage NSCLC, high dose radiotherapy or continuous hyperfractionated accelerated regimens (CHART) is a good alternative to surgical resection. It is the treatment of choice if surgery is contraindicated due to comorbidities.

**Radiation treatment for symptoms:** Radiation can be used as palliative for distressing symptoms/complications in lung cancer. Indications for palliative radiotherapy are: bone and chest wall pain from metastases or direct invasion, recurrent hemoptysis and occluded trachea, bronchi and superior vena cava obstruction.

## c. Chemotherapy

Adjuvant chemotherapy with radiotherapy improves response rate and extends median survival.

- **First-line drugs:** Two drug regimen namely cisplatin/carboplatin + 1 other (Paclitaxel/Docetaxel/Gemcitabine). Common side effects are nausea and vomiting and are best treated with 5-HT<sub>3</sub> receptor antagonists.
- **Second line therapy:** Newer targeted agents against epidermal growth factor receptors and tyrosine kinases in NSCLC (in particular adenocarcinoma) in selected patients and can also be used where intravenous chemotherapy produces severe toxicity or as second line chemotherapy. These include gefitinib, erlotinib, cetuximab, tirapazamine, thalidomide, vandetanib antiangiogenesis (e.g. bevacizumab) and ALK tyrosine kinase inhibitors (e.g. Crizotinib).

Treatment of non-small cell lung cancer is summarized in Table 6.99.

## 2. Small-cell carcinoma

General treatment plan for small-cell carcinoma (Table 6.100).

- If the patient responds to treatment plan, prophylactic radiotherapy to brain is advised. High-dose radiotherapy to the entire brain is also advised to patients with documented brain metastasis.
- **Chemotherapeutic regimens for small-cell carcinoma**
  - Commonly used combination Cisplatin/carboplatin + etoposide, ifosfamide, irinotecan plus cisplatin, carboplatin and etoposide with or without vincristine

### Laser therapy and tracheobronchial stents

- In selected patients with inoperable lung cancer, palliation of symptoms due to tracheobronchial narrowing from intraluminal tumor or extrinsic compression can be achieved by bronchoscopic laser treatment.
- It helps to clear tumor tissue and allow re-aeration of collapsed lung. It is useful mainly when the tumor is the main bronchi.
- In case of extrinsic compression by malignant nodes, endobronchial stents can be used to maintain airway patency.

**Table 6.100:** General plan of treatment small-cell carcinoma.

<b>Stage</b>	<b>Status of patient</b>	<b>Treatment</b>
<b>Limited stage</b>	With good performance status of patient	Chemotherapy + radiotherapy
	With poor performance status of patient	Modified chemotherapy and/or palliative radiotherapy

<b>Extensive stage</b>	With good performance status of patient	Chemotherapy ± local radiotherapy
	With poor performance status of patient	Modified chemotherapy and/or palliative radiotherapy

## Neurological Manifestations of Bronchial Carcinoma (Table 6.101)

**Table 6.101:** Neurological manifestations of bronchial carcinoma.

<i>Regional effects</i>	<i>Remote effects (Paraneoplastic)</i>
<ul style="list-style-type: none"> <li>• Nerve paralysis <ul style="list-style-type: none"> <li>– Recurrent laryngeal nerve</li> <li>– Phrenic nerve</li> </ul> </li> <li>• Intercostal neuralgia</li> <li>• Horner's syndrome</li> <li>• Pancoast's syndrome</li> </ul>	<ul style="list-style-type: none"> <li>• Polyneuropathy</li> <li>• Myelopathy</li> <li>• Polymyositis and dermatomyositis</li> <li>• Eaton-Lambert syndrome</li> <li>• Cerebellar degeneration</li> <li>• Cortical degeneration</li> <li>• Limbic encephalitis</li> </ul>
<b>Metastatic effects:</b> Brain and spine	

**Q. Write short note on the neurological manifestations of bronchial carcinoma.**

## Hypertrophic Osteoarthropathy (Hypertrophic Pulmonary Osteoarthropathy)

**Q. Write short note on pulmonary hypertrophic osteoarthropathy (hypertrophic pulmonary osteoarthropathy).**

- Hypertrophic osteoarthropathy (HOA) is characterized by clubbing of digits and in more advanced stages, by periosteal new-bone formation and synovial effusions.
- Clubbing is almost always found in HOA but can occur as an isolated manifestation.
- Primary HOA is also called Pierre-Marie-Bamberger syndrome.

### *Clinical features*

- **Sites involved:** Most common are the distal parts of the long bones of wrists (radius and ulna) and ankles (tibia and fibula).
- **Symptoms:** Pain and swelling of the wrists and ankles, to a lesser extent

in knees and shin. Pain is aggravated by dependency and relieved by elevation of the affected limb.

- **Physical examination:** Digital clubbing, swollen and tender joints, and pitting edema of the anterior aspect of shin.
- **Investigations**
  - **X-ray (Fig. 6.35):** Periosteal thickening and subperiosteal new bone formation along the shaft of distal ends of long bones. The ends of distal phalanges may show osseous resorption.
  - **Radionuclide studies of bones:** It shows pericortical linear uptake along the cortical margins of long bones. These changes may be detected even before any radiographic changes.

**Fig. 6.35:** X-ray of the wrist showing subperiosteal new bone formation—HPOA.

#### **Treatment**

- Identify and treat the associated disease.
- Vagotomy or percutaneous blocking of the vagus nerve: It may give relief in few patients.
- Analgesics: Aspirin or other non-steroidal anti-inflammatory drugs.

## **Pancoast's Syndrome (Pancoast's Tumor; Superior Sulcus Tumor Syndrome)**

**Q. Write short essay/note on clinical features of Pancoast (superior pulmonary sulcus) tumor.**

**Q. Write short note on Horner's syndrome.**

- Pancoast's tumor also known as Pancoast-Tobias tumor or superior sulcus tumor.
- Pancoast tumor is a tumor at the apex of lung which may invade the neural structures around the first rib, subclavian vessels and the cervical sympathetic plexus. Chest X-ray appearance is shown in Figure 6.36.
- Local extension of the tumor can involve the eighth cervical (C<sub>8</sub>) and first thoracic (T<sub>1</sub>) nerves.
- **Features of Pancoast's syndrome**
  - Shoulder pain which radiates in the distribution of ulnar nerve of the arm (i.e. along the C<sub>8</sub>, T<sub>1</sub> distribution).
  - Wasting of the small muscles of the hand from due to C<sub>8</sub>, T<sub>1</sub> nerve involvement.
  - Pain and tenderness over the first and second ribs and radiological evidence of rib destruction due to local invasion by tumor.
  - **Horner's syndrome** (enophthalmos, ptosis, miosis, and anhidrosis) on the same side as the tumor due to involvement of the sympathetic pathway as it passes through the T<sub>1</sub> root.
- **Investigations:** CT scan, fine needle aspiration and MRI.

**Fig. 6.36:** X-ray showing mass lesion in the right upper zone with erosion of ribs—Pancoast’s tumor.

**Treatment:** Combined chemoradiotherapy and surgery. Preoperative radiotherapy along with chemotherapy (cisplatin and etoposide) is given followed by en-bloc resection of the tumor.

## Superior Vena Cava Syndrome

### Q. Write short essay/note on:

- Causes, clinical features and management of superior vena cava (SVC) syndrome.
- Superior vena caval obstruction.

It develops due to the obstruction of SVC secondary to compression and/or invasion by tumors or other lesions in the superior mediastinum (Table 6.102).

Bronchial carcinoma and lymphoma are the most common causes and others are very rare causes of SVC obstruction.

**Table 6.102:** Causes of superior vena cava obstruction.

<i>Neoplastic</i>	<i>Non-neoplastic</i>
<ul style="list-style-type: none"><li>• Primary<ul style="list-style-type: none"><li>– Bronchial carcinoma (75%)</li><li>– Lymphomas (20%)</li><li>– Thymoma</li><li>– Parathyroid tumor</li></ul></li><li>• Metastatic tumors</li></ul>	<ul style="list-style-type: none"><li>• Tuberculosis</li><li>• Fibrosing mediastinitis</li><li>• Retrosternal goiter</li><li>• Central venous catheter, causing thrombosis</li><li>• Aortic arch aneurysm</li></ul>

### *Clinical Features*

- Due to involvement of other structures of mediastinum (refer mediastinal tumors, page 359.)
- Due to involvement of SVC: Headache, visual disturbances change in the state of consciousness and orthopnea.
- **Physical signs:**
  - Distended, **non-pulsatile neck veins**, dilated veins on the upper thorax and upper limbs.
  - Conjunctival edema, suffusion and subconjunctival hemorrhage.
- **Features based on location of SVC obstruction**

- **Preazygos or supra-azygos:** Obstruction to the return of blood above the entry of azygos vein into the SVC produces distension of veins and edema of the face, neck and upper extremities.
- **Postazygos or infra-azygos:** Obstruction below the entry of azygos vein into the SVC causes retrograde flow of blood through the azygos via collaterals to the inferior vena cava. This leads to the symptoms and signs of preazygos disease and dilation of the veins over the abdomen. This is usually more severe and poorly tolerated than preazygos obstruction.

### ***Investigation and Diagnosis***

- Based on **clinical features**.
- **Chest radiograph:** Widening of the superior mediastinum (mostly on the right side). Pleural effusion may be found in about 25% patients.
- **CT of the chest:** Most useful.
- **Invasive procedures:** Bronchoscopy, percutaneous needle biopsy, mediastinoscopy and thoracoscopy.

#### **Management**

- Diuretics, head elevation and oxygen for temporary symptomatic relief in few patients.
- If there is tracheal obstruction: Emergency radiotherapy.
- Radiotherapy (elective): It is the treatment of choice for non-small-cell tumors of lung and metastatic tumors producing SVC syndrome.
- Chemotherapy: For example, small-cell carcinoma of lung or lymphoma.
- Seriously ill patients may be given empiric corticosteroids and cyclophosphamide intravenously for temporary relief.
- Endovascular stent placement.

## **Mediastinum**

### **Q. Define mediastinum. What are its various compartments?**

Mediastinum is the region of the thoracic cavity located between the pleural cavities (sacs) in the chest. It extends antero-posteriorly from the sternum to the spine (paravertebral gutter and ribs) and sagittally from the thoracic inlet (above) to the diaphragm (below) and laterally mediastinal pleura. It has numerous organs and structures and makes it a veritable Pandora's box, within which congenital cysts, benign tumors, and primary and malignant neoplasms may develop.

## Compartments

Mediastinum is divided into four compartments based on the lateral chest radiograph (Table 6.103).

**Table 6.103:** Various compartments of mediastinum and their normal contents..

### Superior mediastinum

- Trachea, upper esophagus, thymus gland, thoracic duct, lymph nodes
- Vessels: Superior vena cava (SVC), arch of aorta and its branches
- Nerves: Phrenic nerve, vagus nerve, left recurrent laryngeal nerve

### Anterior mediastinum

- Thymus gland
- Anterior mediastinal lymph nodes, internal mammary artery and vein
- Adipose tissue

### Posterior mediastinum

- Esophagus, lymph nodes
- Vessels: Descending aorta, azygos vein
- Thoracic duct, sympathetic chain

### Middle mediastinum

- Heart, ascending aorta, arch of aorta, vena cavae, brachiocephalic arteries and veins, pulmonary arteries and veins
- Trachea, main bronchi, hilar lymph nodes
- Phrenic nerves

## Common Mediastinal Tumors, Cysts and Masses (Fig. 6.37)

**Q.** Write short essay/note on causes of mediastinal mass.

### *Clinical Features*

**Q.** Write short essay/note on clinical features, investigations and management of mediastinal tumors.

- **Age group:** Germ-cell tumors and lymphoma/leukemias are more common between 20 and 40 years of age.
- Clinical features are due to the compression and/or invasion (infiltration) of the structures of mediastinum (Table 6.104). Benign tumors cause compression without invasion, whereas malignant tumors compress and invade the vital structures of mediastinum.

## Table 6.104: Structures involved and clinical features of malignant mediastinal invasion.

<b>Trachea and main bronchi:</b> Stridor, breathlessness, cough, collapse of lung
<b>Esophagus:</b> Dysphagia, esophageal displacement or obstruction on barium swallow examination
<b>Phrenic nerve:</b> Diaphragmatic paralysis and dyspnea
<b>Left recurrent laryngeal nerve:</b> Paralysis of left vocal cord producing hoarseness and 'bovine' cough
<b>Sympathetic trunk:</b> Horner's syndrome
<b>Superior vena cava (SVC):</b> SVC syndrome: Non-pulsatile distension of neck veins, subconjunctival edema, and edema and cyanosis of head, neck, hands and arms. Dilated anastomotic veins on chest wall.
<b>Pericardium:</b> Pericarditis and/or pericardial effusion, cardiac tamponade

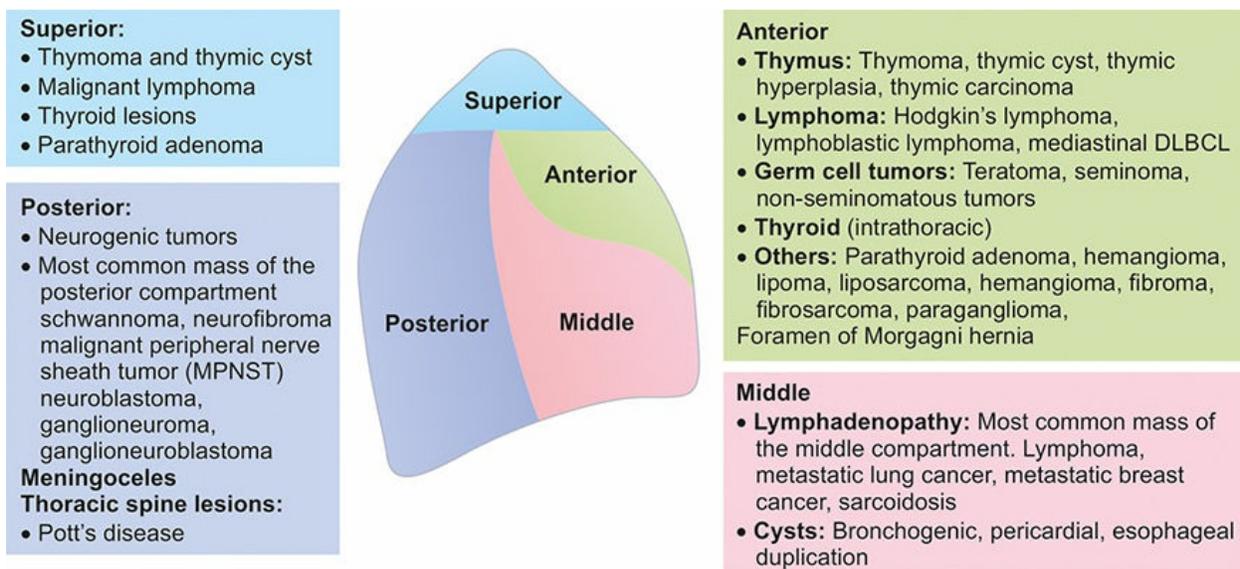

Fig. 6.37: Location of most common lesions of mediastinum.

## Investigations

- **Cytological examination of sputum** for malignant cells.
- **$\alpha$ -fetoprotein and  $\beta$ -human chorionic gonadotropin levels:** Elevated in non-seminomatous germ cell tumors of anterior or superior mediastinum in male.
- **Radiological investigations:**
  - **Plain radiograph of chest:**
    - ♦ **Benign tumor** appears as a sharply circumscribed opacity in the mediastinum which may encroach on one or both lung fields.

- ◆ **Malignant tumor** appears as a lesion with ill-defined margins and often causes a generalized widening of the mediastinal shadow.
- **Fluoroscopic examination:** For diaphragm analysis.
- **Barium swallow:** For identifying esophageal involvement.
- **CT scan of thorax**
- **Magnetic resonance imaging (MRI):** Useful for evaluating cystic lesions.
- **Positron emission tomography (PET)**
- **Bronchoscopy** if there is suspicion of lung cancer.
- **Mediastinoscopy:** To remove lymph node from anterior mediastinum.
- **Exploratory thoracotomy:** For removal of part or entire tumor for histopathological examination.

**Table 6.105: Differential diagnosis of solitary pulmonary nodules.**

<p><b>Malignant tumors</b></p> <ul style="list-style-type: none"> <li>• Bronchogenic carcinoma (adenocarcinoma, large cell, squamous, small cell)</li> <li>• Carcinoid</li> <li>• Pulmonary lymphoma</li> </ul>	<p><b>Non-infectious granulomas</b></p> <ul style="list-style-type: none"> <li>• Rheumatoid arthritis</li> <li>• Wegener’s granulomatosis</li> <li>• Sarcoidosis</li> <li>• Paraffinoma</li> </ul>
<p><b>Benign tumors</b></p> <ul style="list-style-type: none"> <li>• Hamartoma</li> <li>• Adenoma</li> <li>• Lipoma</li> </ul>	<p><b>Others</b></p> <ul style="list-style-type: none"> <li>• Miscellaneous</li> <li>• Bronchiolitis obliterans organizing pneumonia (BOOP)</li> <li>• Abscess</li> </ul>
<p><b>Infectious granulomas</b></p> <ul style="list-style-type: none"> <li>• Tuberculosis</li> <li>• Histoplasmosis</li> <li>• Coccidioidomycosis</li> </ul>	<p><b>Pseudotumor</b></p> <ul style="list-style-type: none"> <li>• Spherical pneumonia</li> <li>• Pulmonary infarction</li> <li>• Arteriovenous malformation</li> <li>• Bronchogenic cyst</li> <li>• Amyloidoma</li> </ul>

**Fig. 6.38:** Chest X-ray of solitary pulmonary nodule.

### **Management**

- Benign mediastinal tumors: Surgical removal.
- SVC obstruction: Refer SVC syndrome, page 358.
- Lung cancer with lymph nodal metastases: Radiotherapy and/or chemotherapy.
- Treatments of lymphomas and leukemias (refer relevant chapters).

### **Solitary Pulmonary Nodule**

- **Criteria:** A single discrete pulmonary opacity surrounded by normal lung tissue. Not associated with adenopathy or atelectasis.
- **Size and nature:** Solitary pulmonary nodule must be 3 cm or less in diameter. Lesions larger than 3 cm are almost always malignant. Malignant nodules have a tumor doubling time between 30–300 days, whereas benign nodules it is either less than 30 days or more than 300 days.
- Prompt diagnosis and resection are usually advisable. Chest X-ray appearance of solitary pulmonary nodule is shown in Figure 6.38.
- Differential diagnosis of solitary pulmonary nodules (Table 6.105).

# RESPIRATORY FAILURE

- Q. Define respiratory failure. Describe in detail the causes and management of various types of respiratory failures.**
- Q. Discuss the role of oxygen therapy in chronic type II respiratory failure complicating chronic bronchitis.**
- Q. Write short essay/note on:**
  - **Acute respiratory failure**
  - **Clinical features of type I and type II respiratory failure.**

## Definition

- Respiratory failure is the term used when pulmonary gas exchange fails to maintain normal arterial oxygen and carbon dioxide levels.
- Respiratory failure is a syndrome of inadequate gas exchange due to dysfunction of one or more essential components of the respiratory system:
  - Chest wall (including pleura and diaphragm)
  - Airways
  - Alveolar–capillary units
  - Pulmonary circulation
  - Nerves
  - CNS or brainstem
- **Criteria:** Respiratory failure is present when **PaO<sub>2</sub> is 60 mm Hg (8.0 kPa) and/or PaCO<sub>2</sub> is 50 mm Hg (6.5 kPa).**
- **Features of respiratory failure:** (1) breathlessness at rest, (2) central cyanosis, (3) raised respiratory rate and (4) drowsiness, confusion or unconsciousness. In such patients arterial blood gas analysis to be done.

## Classification

It can be classified in different ways: (1) type I, II, III and IV, (2) acute and chronic type I respiratory failure; acute and chronic type II respiratory failure and (3) type I (hypoxemic) respiratory failure and type II (hypercapnic) respiratory failure.

***Type I or Hypoxemic ( $PaO_2 < 60$  at sea level): Failure of oxygen exchange***

- Increased shunt fraction ( $Q_S/Q_T$ )
  - Due to alveolar flooding.
  - Hypoxemia refractory to supplemental oxygen.

***Type II or Hypercapnic ( $PaCO_2 > 45$ ): Failure to exchange or remove carbon dioxide***

- Decreased alveolar minute ventilation ( $V_A$ ).
- Often accompanied by hypoxemia that corrects with supplemental oxygen.

***Type III Respiratory Failure: Perioperative respiratory failure***

- Increased atelectasis due to low functional residual capacity (FRC) in the setting of abnormal abdominal wall mechanics.
- Often results in type I or type II respiratory failure.
- Can be ameliorated by anesthetic or operative technique, posture, incentive spirometry, postoperative analgesia, and attempts to lower intra-abdominal pressure.

***Type IV Respiratory Failure: Shock***

- Type IV describes patients who are intubated and ventilated in the process of resuscitation for shock.

Goal of ventilation is to stabilize gas exchange and to unload the respiratory muscles, lowering their oxygen consumption.

**Rate of development:** Respiratory failure may

- Acute: In which pH of blood may drop to below 7.2.
- Chronic: In which pH is normal or slightly reduced and bicarbonate is elevated due to renal compensation. Due to associated hypoxemia, patient may develop polycythemia, pulmonary hypertension and cor pulmonale.
- Acute on chronic (e.g. acute exacerbation of advanced COPD)

It may be **transient or persistent**.

Various mechanisms of producing respiratory failure is listed in Table 6.106.

---

**Table 6.106: Mechanisms of producing respiratory failure.**

**Decreased inspired oxygen concentration**

- High altitude: Acute mountain sickness, chronic mountain sickness

**Hypoventilation**

- Diminished ventilatory drive, e.g. drug overdose, primary alveolar hypoventilation, stroke
- Impaired neuromuscular transmission, e.g. Guillain-Barre syndrome, myasthenia gravis, phrenic nerve injury, spinal cord lesion, amyotrophic lateral sclerosis
- Weakness of muscle, e.g. myasthenia gravis, muscular dystrophies, electrolyte disturbances
- Disorders of chest wall, e.g. kyphoscoliosis, ankylosing spondylitis, severe obesity
- Disorders of pleura, e.g. pneumothorax, pleural effusion
- Parenchymal lung disease
- Airway obstruction, e.g. COPD, acute severe asthma, foreign body, vocal cord palsy

**Ventilation-perfusion (V/Q) mismatch**

- Interstitial lung disease
- Obstructive airway disease, e.g. chronic bronchitis, emphysema, bronchiectasis, bronchial asthma
- Alveolar diseases, e.g. pneumonia, acute respiratory distress syndrome (ARDS)
- Pulmonary vascular diseases, e.g. pulmonary embolism, pulmonary hypertension
- Decreased cardiac output

**Shunt**

- Intracardiac right to left shunts, e.g. tetralogy of Fallot.
- Intrapulmonary shunts, e.g. pulmonary arteriovenous shunts, alveolar collapse, pneumonia, pulmonary edema, pulmonary hemorrhage

**Diffusion abnormality**

- Interstitial lung disease, ARDS, interstitial pneumonias

- **Hypoventilation:** It may be due to (1) low tidal volume, (2) increased dead space or (3) reduced respiratory rate. In hypoventilation PaCO<sub>2</sub> increases, PaO<sub>2</sub> decreases and alveolar arterial oxygen gradient is normal.
- **Ventilation-perfusion (V/Q) mismatch:** Are the **most common cause of hypoxemia** and administration of 100% O<sub>2</sub> will markedly improve hypoxemia. There is elevation of alveolar-arterial oxygen gradient.
- **Shunt:** If there is a shunt, deoxygenated blood bypasses ventilated alveoli and mixes with oxygenated blood and produce hypoxemia. In these patients, hypoxemia will persist even if patient is given 100% oxygen. Hypercapnia will not develop when shunt fraction is more than 60%. There is elevation of alveolar-arterial oxygen gradient.
- **Diffusion abnormality** is an uncommon cause of hypoxemia.

## ***Acute Type I and Chronic Type I Respiratory Failure***

**Q. Write short essay/note on the causes of acute type I respiratory failure.**

Acute type I respiratory failure usually develops abruptly, often in patients with previously normal lungs. Common causes of acute and chronic type I failure are listed in Table 6.107.

**Table 6.107: Causes of acute and chronic type I respiratory failure.**

<b><i>Acute type I respiratory failure</i></b>	<b><i>Chronic type I respiratory failure</i></b>
<ul style="list-style-type: none"><li>• Pneumonia</li><li>• Pulmonary edema</li><li>• Acute asthma</li><li>• Pulmonary embolism</li><li>• Acute respiratory distress syndrome (ARDS)</li><li>• Pneumothorax</li></ul>	<ul style="list-style-type: none"><li>• Diseases with widespread pulmonary fibrosis</li><li>• Chronic pulmonary edema</li><li>• Chronic disorders of chest wall or neuromuscular diseases</li><li>• Chronic pulmonary thromboembolism</li></ul>

## ***Acute Type II and Chronic Type II Respiratory Failure***

Common causes of acute and chronic type II failure are listed in Table 6.108.

**Q. Write short essay/note on management of type I and type II respiratory failure.**

### **Management of Respiratory Failure**

Flowchart 6.7 shows an approach to identify the mechanism of respiratory failure.

#### **1. Secure airway by:**

- Endotracheal intubation or tracheostomy
- Invasive mechanical ventilation
- Non-invasive ventilation

#### **Indications for mechanical ventilation**

- Cardiac or respiratory arrest
- Tachypnea or bradypnea with respiratory fatigue or impending arrest
- Acute respiratory acidosis
- Inability to protect the airway associated with depressed levels of consciousness
- Refractory hypoxemia [when the PaO<sub>2</sub> could not be maintained above 60 mm Hg with inspired O<sub>2</sub> fraction (FIO<sub>2</sub>)>1.0]
- Shock associated with excessive respiratory work
- Inability to clear secretions with impaired gas exchange or excessive respiratory work
- Newly diagnosed neuromuscular disease with a vital capacity <10–15 mL/kg
- Short-term adjunct in management of acutely increased intracranial pressure (ICP).

### Indications for noninvasive ventilation:

- COPD exacerbation
- Cardiogenic pulmonary edema
- Obesity hypoventilation syndrome
- Noninvasive ventilation may be tried in selected patients with asthma or noncardiogenic hypoxemic respiratory failure

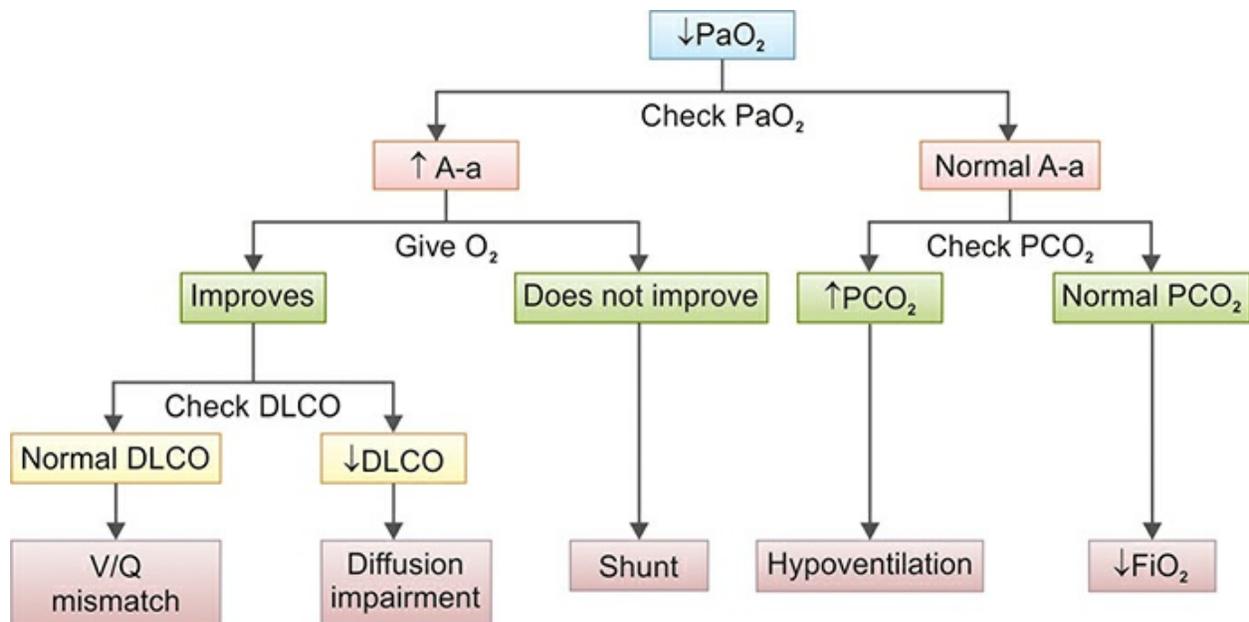

### 2. Supplemental oxygen as needed

### 3. Treat underlying condition

- **Infection:** Antimicrobials and source control
- **Airway obstruction:** Bronchodilators, glucocorticoids
- **Improve cardiac function:** Positive airway pressure, diuretics, vasodilators, morphine, inotropy, and revascularization.

### 4. Respiratory stimulants like doxapram hydrochloride, nikethamide, progesterone, modafanil, acetazolamide can increase or maintain ventilation for a short time, at most 24 hours. However, its role is controversial.

**Flowchart 6.7:** shows step-by-step approach to respiratory failure.

**Table 6.108:** Causes of acute and chronic type II respiratory failure.

#### Acute type II respiratory failure

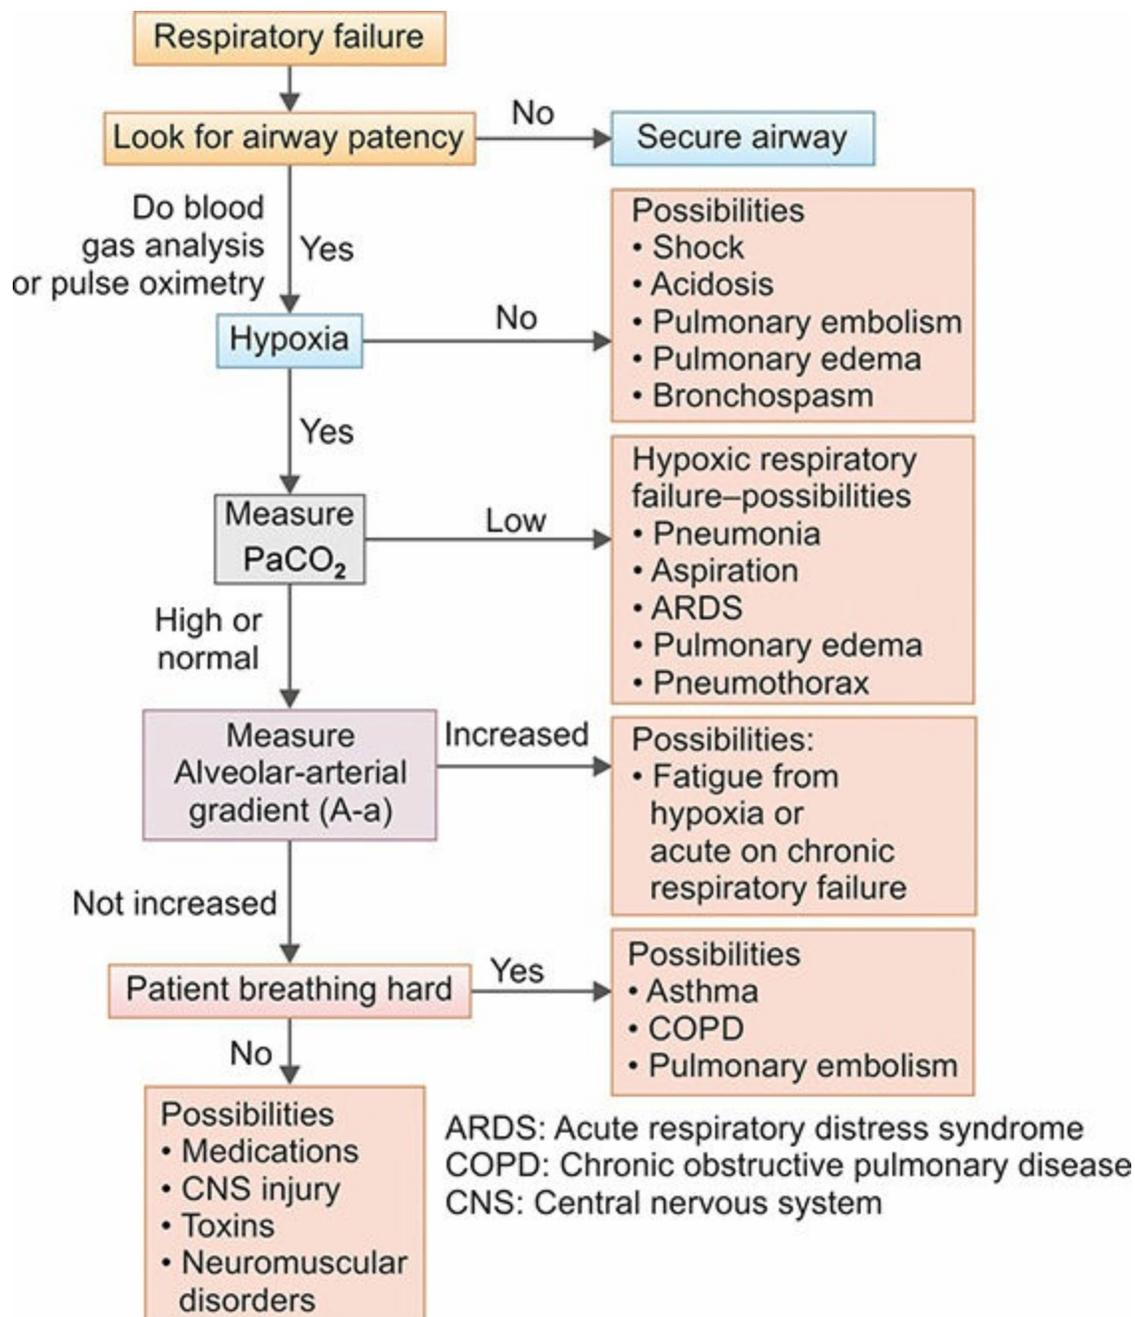

- **Respiratory depressant drugs**, e.g. diazepam, opiates, alcohol
- **Severe obstruction to the airflow**, e.g. severe acute asthma, laryngeal and tracheal obstruction, acute exacerbation of chronic obstructive pulmonary disease (COPD)
- **Disorders of respiratory muscles**, e.g. acute polymyositis
- **Injuries to chest**, e.g. tension pneumothorax, massive hemothorax and flail chest
- **Brainstem damage**, e.g. stroke, encephalitis, trauma

- **Disorders of spinal cord, nerves and neuromuscular transmission**, e.g. spinal trauma, transverse myelitis, acute GB syndrome, poliomyelitis, myasthenia gravis and botulism

### Chronic type II respiratory failure

- **COPD** (most common)
- **Chest wall abnormalities**, e.g. marked kyphoscoliosis, marked obesity
- Amyotrophic lateral sclerosis, muscular dystrophy
- Central hypoventilation

**Flowchart 6.8:** shows step-by-step approach to respiratory failure.

# SLEEP APNEA/HYPOPNEA SYNDROME

## Q. Write short note on sleep apnea syndromes.

- Sleep apnea is defined as an intermittent recurrent reduction or cessation of breathing (upper airway obstruction) during sleep.
- **Apnea:** Defined by the American Academy of Sleep Medicine (AASM) as the cessation of airflow for at least 10 seconds.
- **Hypopnea:** Defined as a recognizable transient reduction (but not complete cessation) of breathing for 10 seconds or longer, a decrease of greater than 50% in the amplitude of a validated measure of breathing, or a reduction in amplitude of less than 50% associated with oxygen desaturation of 4% or more.
- **Respiratory effort-related arousal (RERA):** It is an event characterized by increasing respiratory effort for 10 seconds or longer leading to an arousal from sleep. It does not fulfil the criteria for a hypopnea or apnea.

**Types of Sleep Apnea:** (1) Obstructive sleep apnea (OSA), (2) central sleep apnea and (3) mixed sleep apnea (combination of factors).

- **Obstructive** sleep apnea are characterized by continued thoracoabdominal effort in the setting of partial or complete airflow cessation.
- **Central** sleep apnea is characterized by the lack of thoracoabdominal effort in the setting of partial or complete airflow cessation.
- **Mixed** sleep apnea has both obstructive and central features. They generally begin without thoracoabdominal effort and end with several thoracoabdominal efforts in breathing.

## Obstructive Sleep Apnea (OSA)

### Risk Factors (Table 6.109)

**Table 6.109:** Risk factors for obstructive sleep apnea.

Obesity (major)	Mandibular retrognathia and micrognathia
Male sex (major)	Family history
Enlarged tonsils (especially in Children)	Endocrine diseases (e.g. acromegaly, hypothyroidism)
Menopause	Advancing age
Nasal obstruction (e.g. nasal deformities, rhinitis, polyps, adenoids)	Respiratory depressant drugs (e.g. alcohol, sedatives, strong analgesics)
Smoking	

## ***Clinical Features (Table 6.110)***

**364Pickwickian syndrome** (obesity-hypoventilation syndrome): It is characterized by morbid obesity (body mass index greater than 40 kg/m<sup>2</sup>), chronic sleep-induced central hypoventilation with hypercapnia (PaCO<sub>2</sub> greater than 45 mm Hg) during wakefulness. Awake resting hypoxemia, hypersomnolence, signs of cor pulmonale (right-sided heart failure and lower extremity edema), and nocturnal hypoventilation.

**Table 6.110:** Clinical features of obstructive sleep apnea.

<b><i>Nocturnal features</i></b>	<b><i>Daytime features</i></b>
<ul style="list-style-type: none"><li>• Snoring, usually loud, habitual</li><li>• Witnessed apnea, which often interrupt the snoring and end with a snort</li><li>• Nocturnal gasping and choking sensations</li><li>• Nocturia</li><li>• Insomnia</li><li>• Restless sleep</li></ul>	<ul style="list-style-type: none"><li>• Nonrestorative sleep (i.e. waking up as tired as when they went to bed)</li><li>• Morning headache, dry or sore throat</li><li>• Excessive daytime sleepiness (EDS)</li><li>• Daytime fatigue/tiredness</li><li>• Cognitive deficits; memory and intellectual impairment (short-term memory, concentration) and impaired work performance</li><li>• Decreased vigilance</li><li>• Morning confusion</li><li>• Personality and mood changes, including depression, anxiety and irritability</li></ul>

## ***Physical Examination***

- Obesity: Body mass index (BMI) greater than 30 kg/m<sup>2</sup>
- Large neck circumference: Greater than 17 inches in men and 15 inches in women
- Abnormal (increased) Mallampati score
- Narrowing of the lateral airway walls
- Other risk factors mentioned in Table 6.109 may be found.

## ***Diagnosis***

- Diagnosis can be made on the basis of history and pulse oximetry demonstration of at least a 10 mm Hg increment in PaCO<sub>2</sub> during sleep.
- **Polysomnography**
  - Sleep stages are recorded via an EEG, electrooculogram, and chin

electromyogram (EMG).

- Heart rhythm is monitored with a single-lead ECG.
- Leg movements are recorded via an anterior tibialis EMG.
- Breathing is monitored, including airflow at the nose and mouth (using both a thermal sensors and a nasal pressure transducer), effort (using inductance plethysmography), and oxygen saturation.
- The breathing pattern is analyzed for the presence of apnea and hypopneas
- Apnea-hypopnea index (AHI): AHI is defined as the average number of episodes of apnea and hypopnea per hour. Diagnosis of sleep apnea is confirmed if  $AHI \geq 5$  (Table 6.111).
- Excessive daytime sleepiness (EDS) assessed by **Epworth Sleepiness Scale (ESS)**.
- Respiratory disturbance index (RDI): It is the average number of respiratory disturbances (obstructive apneas, hypopneas, and respiratory event-related arousals [RERAs]) per hour.

**Table 6.111: Degree of obstructive sleep apnea and apnea-hypopnea index.**

<i>Degree of obstructive sleep apnea</i>	<i>Apnea-hypopnea index (AHI)</i>
Mild	5–15
Moderate	16–30
Severe	>30

### **Treatment**

- Mild apnea: Wider variety of options
- Moderate-to-severe apnea: Should be treated with nasal continuous positive airway pressure (CPAP).
  1. **Conservative nonsurgical treatment**
    - Weight reduction in obese individuals
    - Avoidance of alcohol for 4–6 hours prior to bedtime.
    - Sleeping on one’s side rather than on the stomach or back.
  2. **Nasal CPAP therapy**
    - Most effective for OSA. Increases the calibre of the airway in the retropalatal and retroglossal regions. It increases the lateral dimensions of the upper airways and thins the lateral pharyngeal walls. Maintain upper airways patency during sleep, preventing the soft tissues from collapsing.
    - **Indications:** (1) Patients with an apnea-hypopnea index (AHI) greater than 15 regardless of symptomatology. (2) For patients with an AHI of 5–14.9, if the patient has one of the following: excessive daytime sleepiness (EDS), hypertension, or cardiovascular disease.

3. **Other modalities:** BiPAP therapy and oral appliance therapy.
4. **Surgery for obstructive sleep apnea**, e.g. nasal surgery (septoplasty, sinus surgery, and others), tonsillectomy ± adenoidectomy, uvulopalatopharyngoplasty (UPPP), etc.
5. **Pharmacotherapy:**
  - Many drugs (e.g. mirtazapine, protriptyline, theophylline, naloxone, doxapram, oxymetazoline nasal application, inhaled nasal corticosteroids, and acetazolamide) have been tried without much benefit in OSA.
  - Modafinil is used in patients who have residual daytime sleepiness despite optimal use of CPAP.
  - Selective serotonin reuptake inhibitor agents such as paroxetine and fluoxetine have been shown to increase genioglossus muscle activity and decrease REM sleep (apneas are more common in REM).

## Central Sleep Apnea

- It occurs without obstruction of the airway.
- *Causes:* Congenital central sleep apnea (Ondine's curse) and a many neurological lesions.
- *Mechanisms:*
  - Primary central alveolar hypoventilation syndrome.
    - ◆ Etiology not known. Probably due to high chemoresponsiveness of the respiratory system. Apnea is terminated with an abrupt, large breath.
    - ◆ Daytime somnolence is less common
  - *Others:* High altitude, stroke, neurodegenerative diseases (e.g. Parkinson's disease), left ventricular failure with Cheyne-Stokes breathing.

### Treatment

- Administration of oxygen during sleep.
- Nasal CPAP.
- Noninvasive positive-pressure ventilation (bilevel nasal positive pressure).
- Acetazolamide and theophylline may be tried though effect is modest.
- Treatment of underlying cause:  $\beta$ -blockers in congestive heart failure).

## Oxygen Therapy

**Q. Write short essay/note on different types of oxygen therapy.**

***Therapeutic Indications for Oxygen Therapy (Table 6.112)***

**Q. Write short essay/note on common therapeutic indications of oxygen therapy in clinical practice.**

**Table 6.112:** Therapeutic indications for oxygen therapy.

<ul style="list-style-type: none"><li>• Pulmonary edema</li><li>• Acute attack of bronchial asthma</li><li>• Chronic obstructive pulmonary disease (COPD)</li><li>• Acute respiratory distress syndrome (ARDS)</li></ul>	<ul style="list-style-type: none"><li>• Respiratory paralysis</li><li>• Anaerobic infections</li><li>• High altitude</li><li>• Prevent development of severe pulmonary hypertension</li></ul>
--	---

### ***Hazards of Oxygen Therapy***

**Q. Write short essay/note on hazards of oxygen therapy.**

- CO<sub>2</sub> narcosis
- Pulmonary complications: Irritation of respiratory tract, pulmonary edema, ARDS, consolidation, reduction in lung compliance → fibrosis.
- In premature infants and neonates: Retrolental fibroplasias, blindness, bronchopulmonary dysplasia.
- Idiopathic epilepsy.

### ***Technique of Administration***

- Fraction of inspired oxygen (FiO<sub>2</sub>) while inhaling 100% oxygen depends upon rate of oxygen flow and minute ventilation of patient. Merits and demerits of various techniques of oxygen administration are presented in Table 6.113.
- Oxygen delivery system can be divided into:
  - Low flow systems
  - High flow systems

### ***Hyperbaric Oxygen Therapy***

Hyperbaric oxygen (HBO) exposure (breathing oxygen at increased ambient pressure), usually 2 to 3 atmospheres absolute (ATA) causes an increase in PaO<sub>2</sub>.

#### 1. Indication for HBOT

- Poisoning: Carbon monoxide
- Infections: Clostridial myonecrosis

- Acute ischemia: Crush injury
- Chronic ischemia: Radiation necrosis
- Ischemic ulcers: Diabetic ulcers.

**Table 6.113: Merits and demerits of various techniques of oxygen administration.**

<i>Merits</i>	<i>Demerits</i>
<b>Nasal catheter, nasal cannula</b> (Simple plastic tubing + prongs)	
<ul style="list-style-type: none"> <li>• Easy to fix</li> <li>• Keep hands free</li> <li>• Not much interference with further airway care</li> <li>• Useful in both spontaneous breathing and apneic</li> </ul>	<ul style="list-style-type: none"> <li>• Mucosal irritation (uncomfortable)</li> <li>• Gastric dilatation (especially with high flows)</li> </ul>
<b>Simple face mask</b>	
<ul style="list-style-type: none"> <li>• Simple</li> <li>• Lightweight</li> <li>• FiO<sub>2</sub> up to 0.60</li> </ul>	<ul style="list-style-type: none"> <li>• Need to remove when speak, eat, drink, vomiting, expectoration of secretions</li> <li>• Drying/irritation of eyes</li> <li>• Uncomfortable when facial burns/trauma</li> <li>• Application problem when Ryle's tube in situ</li> </ul>
<b>Partial rebreathing mask (polymask)</b>	
<ul style="list-style-type: none"> <li>• FiO<sub>2</sub> delivered &gt;0.60 is delivered in moderate to severe hypoxia</li> <li>• Exhaled oxygen from anatomic dead space is conserved</li> </ul>	<ul style="list-style-type: none"> <li>• Insufficient flow rate may lead to rebreathing of CO<sub>2</sub></li> <li>• Claustrophobia</li> <li>• Drying and irritation of eyes</li> </ul>
<b>Non-rebreathing mask</b>	
<ul style="list-style-type: none"> <li>• Higher oxygen concentration</li> </ul>	<ul style="list-style-type: none"> <li>• Air dilution (if not fitting properly)</li> <li>• Rebreathing (if O<sub>2</sub> flow is inadequate)</li> <li>• Interfere with further airway care</li> <li>• Uncomfortable (sweating, spitting)</li> </ul>
<ul style="list-style-type: none"> <li>• Fixed performance device <b>Venturimask</b> (color coded fixed FiO<sub>2</sub> and oxygen flow)</li> </ul>	
<ul style="list-style-type: none"> <li>• Endotracheal tube-oxygen can be directly delivered</li> </ul>	

## Mechanical Ventilation

**Q. Write short essay on noninvasive ventilation.**

**Types of mechanical ventilation:** (1) invasive and (2) non-invasive. Indications for mechanical ventilation are mentioned in Box 6.16.

### **General Principles of Ventilation**

- Endotracheal tube should be inserted to an average depth of 23 cm in men and 21 cm in women (measured at the incisor).
- Pressure in the cuff generally should not exceed 25 mm Hg.
- Tracheostomy should be done if anticipating ventilator setting for more than 3 days.
- Routine suctioning is not recommended because it may be associated with complications (e.g. desaturation, arrhythmias, bronchospasm, severe coughing and introduction of secretions into the lower respiratory tract).

### **Box 6.16: Indications of mechanical ventilation.**

- Apnea with respiratory arrest
- Acute lung injury
- Respiratory rate >35 breaths per minute
- Vital capacity <15 mL/kg
- PO<sub>2</sub> <60 at FiO<sub>2</sub>0.6
- Respiratory muscle fatigue
- Obtundation or coma
- Bradypnea
- PCO<sub>2</sub> of >50 mm Hg with pH <7.25

**Modes of ventilatory support:** Controlled mode ventilation (CMV), assist control mode ventilation (ACMV), synchronized intermittent mandatory ventilation (SIMV) and continuous positive airway pressure/positive end-expiratory pressure (CPAP/PEEP).

- **Controlled mode ventilation**
  - Used for initiation of the ventilation
  - No patient contribution
  - All variables are independent (FiO<sub>2</sub>, TV, RR, I/E)
- **Assist control mode ventilation**
  - Inspiratory cycle is initiated either by the patient or if no patient effort is present then by a timer signal within the ventilator.
  - Also commonly used for initiation.
  - Synchronization of ventilator cycle with patient's inspiratory effort.
  - Drawbacks: Respiratory alkalosis, myoclonus and seizures.
- **Synchronized intermittent mandatory ventilation (SIMV)**

- Patient is allowed to breathe spontaneously without ventilator assist in between the ventilator breaths.
- Ventilator breath is delivered in synchrony.
- Mandatory are the number of present breaths.
- Intermediate mode.
- Helpful in weaning.
- **Continuous positive airway pressure (CPAP)**
  - Not a true mode of ventilation.
  - All ventilation occurs because of patients spontaneous efforts ventilator just gives fresh gas to the breathing circuit with operator depended positive pressure.
  - Used to assess the extubation potential in the patient who require very little ventilator support or in patient with intact respiratory system function who require an ET tube for airway protection.

## ***Weaning***

- Arterial pH: 7.35–7.40
- $SO_2 >90\%$  with  $FiO_2 0.5$
- PEEP <5 mm Hg
- Intact cough reflex (assessed during suctioning)
- Weaning index: RR/TV <105
- Patient off inotropes.

## ***Complications of Ventilation***

- **Pulmonary:** Barotrauma (>50 mm Hg), interstitial emphysema, pneumomediastinum, subcutaneous emphysema, pneumothorax, **ventilator-associated pneumonia (VAP)**, tracheal stenosis.
- **Hypotension:** Resulting from elevated intrathoracic pressure and decreased venous return and it responds to volume repletion.
- **Gastrointestinal:** Stress ulcers and cholestasis.
  - Neuromuscular weakness
  - Pressure sores
  - Raised intracranial pressure
  - Sinusitis, oral ulcers.

## **Acute Lung Injury and the Acute Respiratory Distress Syndrome**

**Q. Describe acute respiratory distress syndrome (ARDS), non-**

## cardiogenic pulmonary edema and acute lung injury (ALI).

**Definition:** Acute respiratory distress syndrome (ARDS) is a sudden and progressive form of acute respiratory failure in which the alveolar capillary membrane becomes damaged and more permeable to intravascular fluid resulting in severe dyspnea, hypoxemia and diffuse pulmonary infiltrates.

The Berlin definition of ARDS (Table 6.114): An acute, diffuse, inflammatory lung injury that leads to increased pulmonary vascular permeability, increased lung weight, and a loss of aerated tissue.

ARDS and ALI are serious diseases characterized by damage to alveolar epithelium and pulmonary capillary endothelium. Alveoli become filled with edema fluid of high protein content and inflammatory cells.

**Table 6.114:** The Berlin definition of acute respiratory distress syndrome (ARDS).

<i>The Berlin definition of acute respiratory distress syndrome (ARDS)</i>	
Timing	Within 1 week of a known clinical insult/new/worsening respiratory symptoms
Chest X-ray	Bilateral opacities-not fully explained by effusions, lobar/lung collapse or nodules
Origin of edema	<ul style="list-style-type: none"><li>• Respiratory failure not fully explained by cardiac failure or fluid overload</li><li>• Need objective assessment (e.g. echocardiography) to exclude hydrostatic edema if no risk factor is present.</li></ul>
Oxygenation	
Mild	200 mm Hg $<PaO_2/FiO_2 \leq 300$ mm Hg with PEEP or CPAP $>5$ cm H <sub>2</sub> O
Moderate	100 mm Hg $<PaO_2/FiO_2 \leq 200$ mm Hg with PEEP $>5$ cm H <sub>2</sub> O
Severe	$PaO_2/FiO_2 \leq 100$ mm Hg with PEEP $>5$ cm H <sub>2</sub> O

### ***Etiology of ARDS and ALI (Table 6.115)***

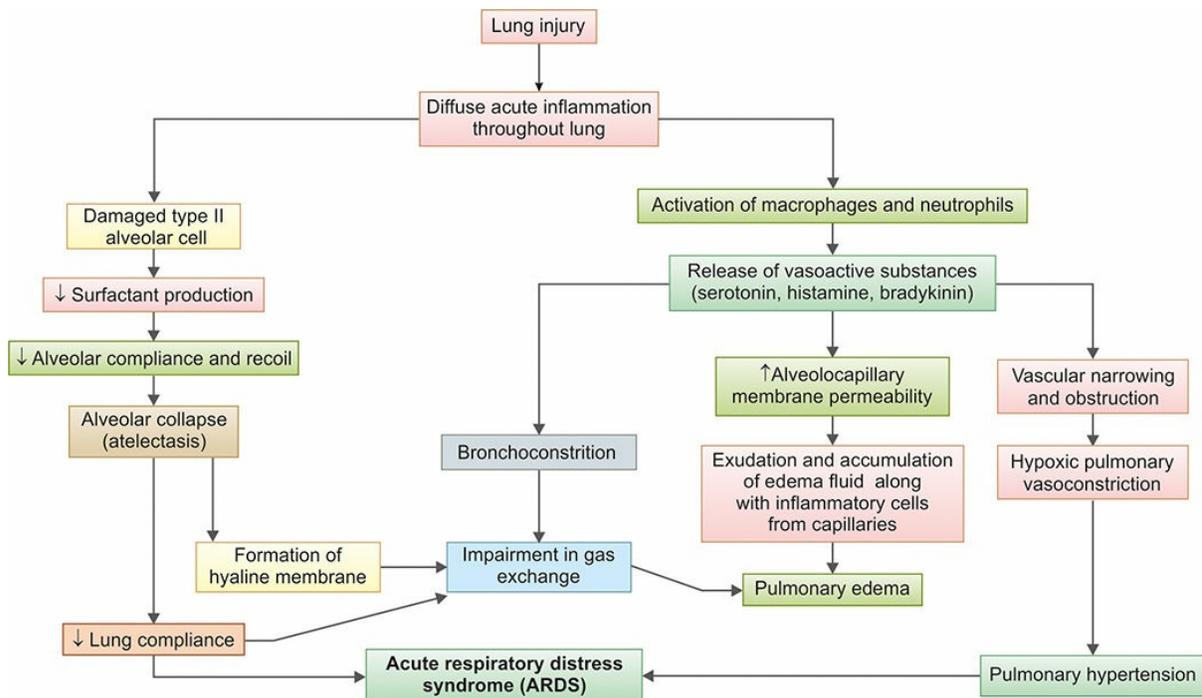

ARDS may develop due diffuse lung injury from many medical and surgical disorders. The lung injury may be direct (e.g. toxic inhalation) or indirect (e.g. in septicemia).

### ***Pathophysiology (Flowchart 6.9)***

Natural history of ARDS can be divided into three: Exudative, proliferative and fibrotic.

1. **Exudative phase (1–7 days):** Diffuse acute inflammation (e.g. neutrophils) occurs throughout the lungs, involving both endothelial and epithelial surfaces. Activated neutrophils are sequestered into the lungs and increase the capillary permeability as well as damages type I and II alveolar cells. The leaked proteins aggregate in the air spaces with cellular debris and dysfunctional pulmonary surfactant to form the characteristic hyaline membranes. Activated macrophages and neutrophils release cytokines and chemokines which progressively recruit more inflammatory cells and amplify the inflammatory response. There is loss of surfactant and impaired surfactant production as a secondary event. The net effect is alveolar collapse (most marked in dependent regions of the lung) and results in hypoxemia due to ventilation-perfusion mismatch and increased pulmonary shunt.

**Flowchart 6.9:** Pathophysiology of acute respiratory distress syndrome (ARDS).

2. **Proliferative phase (3–7 days):** Resolution often starts at this phase along with the initiation of repair process. The alveolar exudate undergoes organization and neutrophils disappear with appearance of lymphocytes. Type II pneumocytes start proliferating. Connective tissue and other structural elements in the lungs proliferate in response to the initial injury, including development of fibroblasts. The terms ‘stiff lung’ and ‘shock lung’ frequently used to characterize this stage.

3. **Fibrotic phase (>10–14 days):** It occurs in some cases and is characterized by proliferation of fibroblasts resulting in interstitial fibrosis. Lung function may continue to improve for as long as 6 to 12 months after onset of respiratory failure, depending on the precipitating condition and severity of the initial injury.

**Table 6.115:** Disorders commonly associated with ARDS.

<b>Direct lung injury</b>	
Pulmonary infections	Pneumonia (Viral, bacterial, fungal <i>pneumocystis jirovecii</i> , Mycoplasma)
Aspiration	Aspiration of gastric contents (vomitus)
Inhalation of toxic gas	Ammonia, chlorine, nitrogen dioxide, ozone, oxygen, smoke
Blunt chest trauma	Pulmonary contusion
Near drowning	
<b>Indirect lung injury</b>	
Systemic disorders	Shock, septicemia, uremia, eclampsia
Severe trauma	Multiple bone fractures (fat embolism), flail chest, head trauma, burns
Blood	Multiple transfusions
Drug overdose	
• Narcotic overdose	Heroin, methadone, morphine, dextropropoxyphene
• Non-narcotic drugs	Barbiturates, thiazides, nitrofurantoin
Others	Acute pancreatitis, cardiopulmonary bypass, trauma, Goodpasture's syndrome, SLE

## **Results**

- Hypoxemia (V/Q mismatch, impaired hypoxic pulmonary vasoconstriction)
- Increase in dependent densities (surfactant dysfunction, alveolar instabilities)
- Decreased compliance (surfactant dysfunction, decreased lung volume, fibrosis)
- Collapse/consolidation (increased compression of dependent lung)
- Increased minute ventilation (increased in alveolar dead space)
- Increased work of breathing-WOB (increased elastase, increased minute volume requirement)

- Pulmonary hypertension (vasoconstriction, microvascular thrombi, fibrosis, PEEP (positive end expiratory pressure)).

### ***Clinical Features***

- Development of **acute dyspnea and hypoxemia within hours to days** of an inciting event.
- **Tachypnea, tachycardia**, cyanosis and the need for a high fraction of inspired oxygen ( $\text{FiO}_2$ ) to maintain oxygen saturation.
- Febrile or hypothermic.
- Sepsis-hypotension and peripheral vasoconstriction with cold extremities.
- Bilateral rales/crepitations.
- Manifestations of the underlying cause.
- *Because cardiogenic pulmonary edema must be distinguished from ARDS, carefully look for signs of congestive heart failure or intravascular volume overload, including jugular venous distension, cardiac murmurs and gallops, hepatomegaly, and edema.*

**Fig. 6.39:** Bilateral alveolar shadows in ARDS on Chest X-ray.

### ***Investigation***

- **Chest radiograph (Fig. 6.39):** Diffuse, bilateral alveolar infiltrates consistent with pulmonary edema

- Early stage: Infiltrates associated with ARDS **may be variable**: mild or dense, interstitial or alveolar, patchy or confluent.
- Initially, the **infiltrates** may have a **patchy peripheral distribution**, but soon they progress to **diffuse bilateral involvement with ground glass changes** or **frank alveolar infiltrates**.
- **Cardiogenic edema**: Increased heart size, increased width of the vascular pedicle, vascular redistribution toward upper lobes, the presence of septal lines, or a perihilar (‘bat’s wing’) distribution of the edema. Lack of these findings, in conjunction with patchy peripheral infiltrates that extend to the lateral lung margins, suggests ARDS.
- **Arterial blood gas analysis:**
  - PaO<sub>2</sub>/FiO<sub>2</sub> ratio and severity (Table 6.116)
  - In addition to hypoxemia, arterial blood gases often initially show a respiratory alkalosis.
  - However, in ARDS occurring in the context of sepsis, a metabolic acidosis with or without respiratory compensation may be present.
  - As the condition progresses and the work of breathing increases, the partial pressure of carbon dioxide (PCO<sub>2</sub>) begins to rise and respiratory alkalosis gives way to respiratory acidosis.
- **To exclude cardiogenic pulmonary edema**
  - Echocardiogram: Left ventricular ejection fraction, wall motion, and valvular abnormalities.
  - Plasma B-type natriuretic peptide (BNP) value.
- **CT scan:**
  - Diffuse consolidation with air bronchograms, bullae, pleural effusions, pneumomediastinum and pneumothorax. Later may show lung cysts.

**Table 6.116: ARDS severity and PaO<sub>2</sub>/FiO<sub>2</sub>.**

<i>ARDS severity</i>	<i>PaO<sub>2</sub>/FiO<sub>2</sub></i>
Mild	200–300
Moderate	100–200
Severe	<100

## Management

### ***Goals of Management of patients with ARDS***

- Treatment of respiratory system abnormalities.
- Diagnose and treat the precipitating/initiating cause of ARDS. Support or treat other organ system dysfunction or failure.
- Maintain oxygenation.
- General critical care, adequate early nutritional support, prophylaxis against deep vein thrombosis (DVT) and gastrointestinal (GI) bleeding.

### ***Maintaining adequate oxygenation***

- Positive end-expiratory pressure (PEEP) is employed.
- When utilized in sufficient amounts PEEP allows FiO<sub>2</sub> to be lowered from high potentially toxic concentrations.
- **Lung-protective mechanical ventilation**
  - Mechanical ventilation using limited tidal volumes.
  - The goals of lung-protective ventilation are to avoid injury due to overexpansion of alveoli during inspiration ('volutrauma') and injury due to repetitive opening and closing of alveoli during inspiration and expiration ('atelectrauma').
- **Low tidal volume ventilation (LTVV)**
  - Set initial tidal volume to 8 mL/kg IBW.
  - Reduce tidal volume to 7 mL/kg IBW then 6 mL/kg IBW over the next 1–3 hours.
  - Set respiratory rate to < 30 bpm to match baseline minute ventilation.
- **Permissive hypercapnia** is defined as clinician-allowed hypercapnia during assisted ventilation, despite an ability to achieve a level of minute ventilation sufficient to maintain a normal.

### ***Fluid management***

- Primary ARDS due to aspiration, pneumonia, or inhalational injury, usually can be treated with fluid restriction.
- Secondary ARDS due to remote infection or inflammation requires initial fluid and potential vasoactive drug therapy.

### ***Prone positioning ventilation***

About two-thirds of patients with ARDS improve their oxygenation after being placed in a prone position.

### ***Adjuncts to lung protective mechanical ventilation***

Inhaled nitric oxide, inhaled prostacyclin, tracheal gas insufflation, extracorporeal membrane oxygenation (ECMO) or extracorporeal CO<sub>2</sub> removal (ECCO<sub>2</sub>R)

### ***Corticosteroids***

- Corticosteroids have little or no role in acute phase of ALI or ARDS. However, the role of corticosteroids in later phases of ALI or ARDS has been controversial.

### ***Experimental therapies***

- Surfactant replacement therapy: Improves oxygenation but no improvement in mortality.
- Ketoconazole: Antifungal that inhibits thromboxane synthase and 5-lipoxygenase.

### ***Future nonventilatory therapeutic options***

- Gene therapy for ALI/ARDS
- Mesenchymal stem cells (MSC).

## **Sarcoidosis**

**Q. Discuss the clinical features, investigations and management of sarcoidosis.**

**Definition:** Sarcoidosis is a multisystem disorder of unknown etiology characterized by noncaseating granuloma which affects mainly lung but can also any other organs.

### ***Etiology***

- Etiology of sarcoidosis is **remains unknown**, but several lines of evidence suggest that it is a disease of disordered immune regulation in genetically predispose individual.
- Factors that play a role in its pathogenesis are: 1) **environmental agents** (infectious and noninfectious), 2) **genetic** (e.g. HLA-A1 and HLA-B8) and 3) **immunological** (cell-mediated immune response).
- The granuloma is the pathologic hallmark of sarcoidosis. The sarcoid granulomas develop as an exaggerated cell-mediated immune response to an unidentified environmental antigen. (Infectious or noninfectious) agent in a genetically susceptible individual. Probable infectious inciting agent includes: mycobacteria (both *Mycobacterium tuberculosis* and nontuberculous mycobacteria), *Propionibacterium acnes*, *Borrelia burgdorferi*, viruses, fungi, spirochetes, and *Rickettsia*.

### ***Pathology***

- **Noncaseating granulomas** are composed of an **aggregate of epithelioid cells and lymphocytes** (mainly CD4+ T-cell). Epithelioid cells are modified macrophages and characteristically have abundant eosinophilic cytoplasm and vesicular nuclei. Schumann bodies and stellate inclusion as asteroid bodies enclosed with in giant cells are formed in approximately 60% of granulomas.
- **Organs involved:** Sarcoidosis can affect every organ of the body. **It most commonly** affects the **lung** and the **lymph nodes** in the **mediastinum and hilar regions**. Other organs commonly affected are the liver, spleen, skin, parotid glands and eye.

### ***Clinical Features***

- **Age and gender:** It occurs mainly in 3rd or 4th decade of life. More predominant in women.

- **More prevalent** in Swedes, Danes, and US blacks.
- **Systems involved:** Pulmonary (90%), lymph nodes (70%), hepatic (50–80%), cardiac (30%), cutaneous (25%), and ocular (20%).

### ***Manifestations of sarcoidosis***

- **Asymptomatic form** (30–45%): It is usually detected incidentally on a routine chest X-ray (~30%) or abnormal liver function tests.
- Acute or subacute form (10–15%)
- Chronic form (40–60%).

#### *Pulmonary manifestations*

- First site of involvement. Begins with alveolitis involving small bronchi and small blood vessels. Alveolitis either clear-up spontaneously or lead to granuloma or fibrosis.
- Other features: Interstitial lung diseases, atelectasis, cavitation, unilateral pleural effusion, pulmonary nodules, miliary mottling, lymphadenopathy.
- Most patients have the pulmonary manifestations, most commonly presenting with incidental findings on CXR as an interstitial disease.
- Symptoms include dry cough, dyspnea, and chest discomfort.
- Unpredictable course.

#### *Extrapulmonary involvement*

1. Lymph nodes: Lymph nodes are involved in almost all cases (mainly hilar and mediastinal nodes), but any nodes may be involved. Involved nodes are characteristically enlarged discrete and sometimes calcified.
  - **Typical**
    - Bilateral hilar and right paratracheal lymph nodes.
    - Middle mediastinal lymph node (**50%** of cases).
    - Left paratracheal, aorto-pulmonary and subcarinal lymph nodes.**1-2-3 sign present in 95% of cases. This is called **Garland triad.****
  - **Atypical**
    - Unilateral hilar lymph node.
    - Anterior or posterior mediastinal lymph nodes.
    - Lymph node calcification (amorphous, punctate, popcorn or eggshell calcification).

- Tonsil may be affected in about quarter to one-third of the cases.
2. Skin (33%): Erythema nodosum, plaques, maculopapular eruptions, subcutaneous nodules, lupus pernio, keloid, infiltration of previous scars by granuloma.
  3. Eyes (25%): Anterior uveitis, iridocyclitis, retinitis, phlyctenular conjunctivitis, lacrimal gland involvement-keratoconjunctivitis sicca (dry eyes).
  4. Salivary glands: Parotid gland enlargement.

**Q. Write short note on Heerfordt-Waldenström syndrome.**

- Heerfordt's syndrome/uveoparotid fever/Heerfordt-Mylius syndrome/Waldenström's uveoparotitis is a rare manifestation of sarcoidosis. It is characterized by uveitis, swelling of the parotid gland, chronic fever, and facial nerve palsy (in some cases).
5. Heart: Cardiac arrhythmias, heart block, sudden death, CHF.
  6. Liver and spleen: Granulomatous liver disease, hepatosplenomegaly, Budd-Chiari syndrome.
  7. Nervous system: Cranial nerve palsy, pachymeningitis, space occupying lesion, diabetes insipidus due to hypothalamic involvement, mononeuritis multiplex, peripheral neuropathy
  8. Kidneys: Nephrocalcinosis, hypercalciuria, renal stones.
  9. Musculoskeletal
    - Arthropathies, osteoporosis, phalangeal bone cysts, polymyositis, chronic myopathy
    - Endocrine
    - Diabetes insipidus, anterior pituitary dysfunction, Addison's syndrome.
  10. Lupus pernio
    - It is a specific complex involvement of skin around nose, eye and cheeks.
    - These chilblains like lesions often cause disfiguration by eroding the cartilage and bone, especially around the nose.
    - It is diagnostic for chronic form of sarcoidosis and is associated with more severe pulmonary disease.
    - Associated with poor prognosis of sarcoidosis.
-

**Table 6.117: Staging of pulmonary sarcoidosis according to radiographic patterns and corresponding clinical features.**

<i>Stage</i>	<i>X-ray finding</i>	<i>Clinical features</i>
I	Bilateral hilar lymphadenopathy (BHL) without any parenchymal abnormalities (50% cases)	Often asymptomatic, but may be associated with erythema nodosum and arthralgia. Majority resolve spontaneously within 1 year
II	BHL with diffuse pulmonary infiltrates (30% cases)	May present with breathlessness or cough. Majority resolve spontaneously
III	Diffuse pulmonary infiltrates without BHL (10% cases)	Disease is less likely to resolve spontaneously
IV	Evidence of diffuse pulmonary fibrosis	Can progress to ventilatory failure, pulmonary hypertension and cor pulmonale

**Q. Write short note on Löfgren’s syndrome.**

**Löfgren’s syndrome:** It is an acute triad of erythema nodosum, joint pains, and radiographic evidence of bilateral hilar adenopathy. It is often seen in young women and resolves over 6 months—2 years with NSAIDs.

### *Investigations*

**Q. Write short note on radiological/X-ray findings in sarcoidosis.**

- **Radiological investigations**

- **Classic radiographic patterns of pulmonary sarcoidosis (Table 6.117):** The chest X-ray is the most commonly used tool to assess the lung involvement in sarcoidosis. According to the pattern of involvement on X-ray findings, sarcoidosis is classified into four stages.
- **Computed tomography of the chest (contrast-enhanced):** Helps in better delineation of the hilar and mediastinal lymph nodes.
- **HRCT:** Characteristic appearance is presence of reticulonodular opacities that follow a perilymphatic distribution, centred on bronchovascular bundles and the subpleural areas. Confluence of many interstitial granulomas can produce large, irregular, mass-like opacities (alveolar sarcoid). Small satellite nodules are usually found at the periphery of these large nodules termed the ‘galaxy sign’ (a collection of stars). Honeycombing is not common.
- **Gallium 67 scan:** Shows diffuse uptake.

- **PET scan:** Using radiolabeled fluorodeoxyglucose is more useful than gallium-67 scan to detect areas of granulomatous disease in the chest and other sites and select potential area for biopsy.
- **MRI:** May be useful in the assessment of extrapulmonary sites (e.g. brain, heart and bone).
- **Complete blood count:** There may be a mild normochromic, normocytic anemia, lymphocytopenia (characteristic), eosinophilia, raised ESR, hyperglobulinemia, elevated serum alkaline phosphatase.
- **Serum biochemistry:** Serum calcium is often raised (hypercalcemia due to increased production of 1, 25-dihydroxyvitamin D by the granuloma) and there is hypergammaglobulinemia.
- **Serum angiotensin converting enzyme (ACE) level** is elevated in more than 75% of patients with untreated sarcoidosis. Elevated levels are not of diagnostic value because it may also be elevated in lymphoma, pulmonary tuberculosis, asbestosis and silicosis. However, it is useful in assessing disease activity and response to treatment.
- **Mantoux test:** Skin sensitivity to tuberculin is reduced or absent. So, Mantoux test is a useful screening test and a strongly positive reaction virtually rules out sarcoidosis.
- **Lung function tests:** They show a typical restrictive lung defect in patients with pulmonary infiltration or fibrosis. There is a decrease in TLC, FEV and FVC, and gas transfer. Lung function is usually normal in patients with extrapulmonary disease or those with only hilar lymphadenopathy on chest X-ray.
- **Bronchoscopy:** May show a ‘cobblestone’ appearance of the mucosa.
- **Bronchial and transbronchial biopsy:** Most useful investigation. It usually shows noncaseating granulomas composed of epithelioid cells and multinucleate giant cells.
- **Bronchoalveolar lavage (BAL):** Shows increased proportion of lymphocytes, mostly activated Th1 (subset of Cd4+ cells) cells. BAL fluid also shows an increased CD4:CD8 T-cell ratio.
- **Kveim (or Kveim-Siltzbach) test:** It involves intradermal injection of 0.1 mL of an antigen obtained from sarcoidosis spleen extract. Development of small nodule at the injection site indicates the test as positive. The nodule is biopsied at 4–6 weeks and shows typical non-caseating

epithelioid granuloma. However, this test is obsolete now.

- Mediastinoscopic biopsy of mediastinal or hilar lymph nodes.
- Exercise tests: May show oxygen desaturation.
- Bone marrow examination may show granulomas in about 30% cases

Differential diagnosis of bilateral hilar lymphadenopathy (Table 6.118).

**Table 6.118: Differential diagnosis of bilateral hilar lymphadenopathy.**

1. <b>Lymphoma</b>	Involvement of only the hilar lymph nodes is rare
2. <b>Pulmonary tuberculosis</b>	Symmetrical enlargement of hilar lymph nodes is rare
3. <b>Carcinoma of the bronchus</b>	Malignant spread to the contralateral hilar lymph nodes is rarely symmetrical

Various causes of granuloma are listed in Table 6.119.

**Table 6.119: Causes of granulomas.**

<b><i>Infectious diseases</i></b>	<b><i>Noninfectious diseases</i></b>
<ul style="list-style-type: none"> <li>• Mycobacterial infections</li> <li>• <i>Mycobacterium tuberculosis</i></li> <li>• Nontuberculous mycobacteria (NTM)</li> <li>• Fungal infections: <i>Histoplasma</i>, <i>Cryptococcus</i>, <i>Coccidioides</i>, <i>Blastomyces</i>, <i>Pneumocystis jirovecii</i>, <i>Aspergillus</i></li> <li>• Other infections: Brucella, Chlamydia, Cat scratch disease</li> </ul>	<ul style="list-style-type: none"> <li>• Sarcoidosis, lymphoma, chronic beryllium disease, hypersensitivity pneumonitis, Wegener's granulomatosis, Churg-Strauss syndrome, talc granulomatosis, rheumatoid nodule, foreign body</li> </ul>

### **Treatment**

Treatment should be based on symptoms or presence of organ or life-threatening disease.

#### ***Minimal or no symptoms***

- No treatment is required when there is only hilar lymphadenopathy.
- Persisting infiltration found on the chest X-ray with normal lung function tests requires careful monitoring.

#### ***Symptomatic single organ disease***

Symptoms limited to only one organ: Topical steroid therapy is preferable.

#### ***Symptomatic multiple organ disease***

Multiorgan or disease too extensive for topical therapy requires systemic therapy and are usually immunosuppressive including glucocorticoids, cytotoxics or biologics.

- **Glucocorticoids:** Remain the drugs of choice and given immediately in the presence of hypercalcemia, pulmonary impairment, renal impairment and uveitis. Prednisolone is given 20–40 mg/day for 6 weeks, followed by a maintenance dose of 7.5–10 mg daily for 6–12 months.
- **Steroid-sparing agents:** In patients with severe disease, methotrexate (10–20 mg/week),

azathioprine (50–150 mg/day) and the use of specific tumor necrosis factor (TNF)- $\alpha$  inhibitors is useful in patients developing toxicity with glucocorticoids. Chloroquine, hydroxychloroquine and low-dose thalidomide may be useful for skin, bone and joint involvement.

- Selected patients may be considered for single lung transplantation.

## Bronchopulmonary Aspergillosis

**Q. Write short essay/note on bronchopulmonary aspergillosis and classify bronchopulmonary aspergillosis.**

Bronchopulmonary aspergillosis is the term used for the bronchopulmonary diseases caused by fungus *Aspergillus* species, the most common being *Aspergillus fumigatus*. Others fungus in *Aspergillus* species include *A. clavatus*, *A. niger*, *A. flavus* and *A. terreus*.

### ***Classification of Bronchopulmonary Aspergillosis (Table 6.120)***

**Table 6.120:** Classification of bronchopulmonary aspergillosis.

- Allergic bronchopulmonary aspergillosis (ABPA-asthmatic pulmonary eosinophilia)
- Extrinsic allergic alveolitis (*Aspergillus clavatus*) (hypersensitivity pneumonitis)
- Intracavitary aspergilloma
- Invasive pulmonary aspergillosis
- Chronic and subacute pulmonary aspergillosis

**Q. Write short note on classification of bronchopulmonary aspergillosis.**

### ***Allergic Bronchopulmonary Aspergillosis (ABPA-Asthmatic Pulmonary Eosinophilia)***

**Q. Discuss the clinical features, diagnostic criteria and management of allergic bronchopulmonary aspergillosis (ABPA-asthmatic pulmonary eosinophilia).**

Allergic bronchopulmonary aspergillosis (ABPA) occurs due to hypersensitivity reaction against germinating fungal spores in the wall of the airway. Usually hypersensitivity reaction to *A. fumigatus*, rare cases are due to other *Aspergilli* and other fungi.

- It can complicate bronchial asthma or cystic fibrosis.
- It is one of the causes of pulmonary eosinophilia.

## ***Pathogenesis***

Exact pathogenesis of ABPA is not known but probably occurs as a result of a hypersensitivity reaction to germinating fungal spores in the airway wall. Thus, it may be due to *Aspergillus*-specific IgE-mediated type I hypersensitivity reactions or specific IgG-mediated type III hypersensitivity reactions and abnormal T-lymphocyte cellular immune response.

## ***Clinical features***

- Fever, breathlessness, cough-up of thick sputum casts and worsening of asthmatic symptoms.
- *Aspergillus* may grow in the walls of proximal bronchi and may produce **proximal bronchiectasis**. It may cause repeated episodes of eosinophilic pneumonia which manifest as wheeze, cough, fever and expectoration with sputum containing fungal mycelia.

## ***Investigations***

- Radiological signs on chest X-ray:
  - Radiographically show infiltrates which may be mistaken for pneumonia. Segmental or lobar collapse on chest X-rays in patients where asthma symptoms are stable, suggestive of ABPA.
  - Repeated pneumonic episodes may show fleeting shadows of infiltrates on chest radiographs. Other findings include transient area of opacification (due to mucoid impact in of the airways), band-like opacities with rounded distal margin (gloved finger appearance), and ‘ring sing’ and ‘tram lines’ (due to thickened and inflamed bronchi). Eventually, it may result in central bronchiectasis and progressive pulmonary fibrosis.
- Other relevant investigations and diagnostic features of allergic bronchopulmonary aspergillosis are mentioned in Table 6.121.

**Table 6.121:** Diagnostic features of allergic bronchopulmonary aspergillosis.

<i>Rosenberg-Patterson criteria</i>	
<i>Major criteria (ARTEPICS)</i>	<i>Minor criteria</i>
A = Asthma (bronchial) R = Roentgenographic fleeting pulmonary	<ul style="list-style-type: none"><li>• Sputum</li></ul>

opacities

**T** = Skin test positive (immediate wheal-and-flare response) for *Aspergillus* (type I)

**E** = Eosinophilia-in peripheral blood (>1000/mm<sup>3</sup>)

**P** = Precipitating antibodies (IgG) in serum

**I** = IgE in serum elevated (> 1,000 IU/mL)

**C** = Central/proximal bronchiectasis (inner two-thirds of chest CT field)

**S** = Serum *A. fumigatus*-specific IgG and IgE (more than twice the value of pooled serum samples from patients with asthma who have *Aspergillus* hypersensitivity)

– Fungal hyphae of *A. fumigatus* and eosinophils on microscopic examination of sputum

– Expectoration of brownish black mucus plugs in sputum

– Culture of *A. fumigatus* from sputum

- Delayed skin reaction to *Aspergillus* antigen (type III)

**Presence of 6 of 8 major criteria makes diagnosis almost certain**

### Management

- Corticosteroids: Oral prednisolone 30 mg daily for 7–10 days causes rapid clearing of the pulmonary infiltrate. Prednisolone should be gradually tapered to a maintenance dose of 5–10 mg/day for long term. Asthma responds to inhaled corticosteroids.
- Antifungal agents: Oral itraconazole Dose: 200 mg bid for 16 wk then once a day for 16 wk or voriconazole should be used in patients on high doses of steroids. It reduces exacerbations and requirement of steroids.
- Humanized monoclonal antibody against IgE: Omalizumab is under trial.
- Bronchoscopic extraction of the casts: If there is persistent lobar collapse, bronchoscopic (usually under general anesthesia) removal of impacted mucus and casts may result in re-inflation of the collapsed lobe.

## *Aspergilloma*

**Q. Discuss the etiology, clinical features, diagnosis and management of intracavitary aspergilloma (fungal ball).**

*Aspergilloma* is the growth of *Aspergillus* fungus within previously damaged lung tissue and forms a ball of fungus (mycelium) within lung cavities. Most commonly the fungal ball is produced by *Aspergillus fumigatus* and rarely by other fungi (e.g. *Zygomycetes* and *Fusarium*).

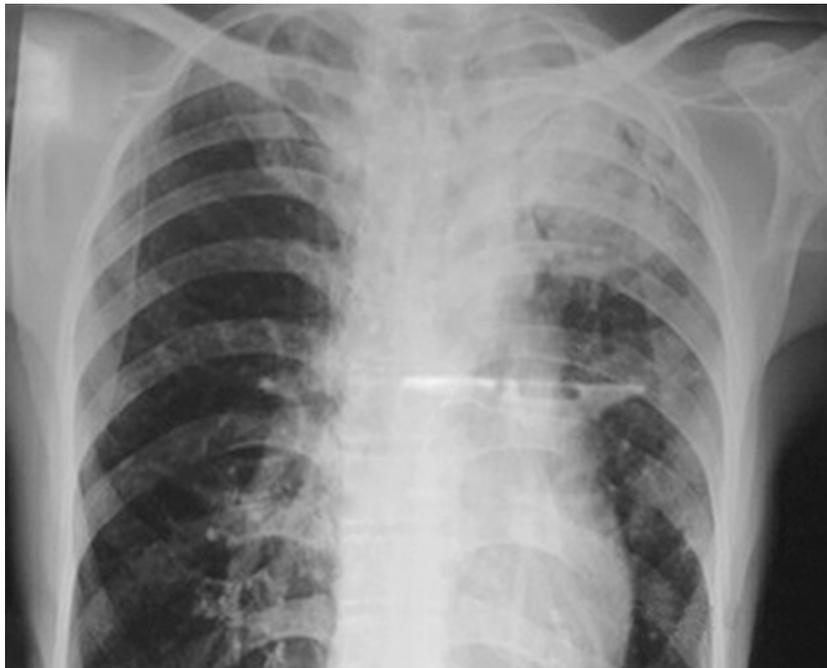

### *Etiology*

- An intracavitary *aspergilloma* may develop in any area of damaged lung with abnormal cavity. Inhaled *Aspergillus* may reach and germinate in this cavity forming ‘*aspergilloma*’.
- **Causes of cavitation associated with aspergillum:** Colonization and proliferation of fungus in a pre-existing lung cavity.

- **Common cause:** Tuberculosis cavity occurs most often in the upper lobes.
- **Less common causes:** Lung abscess, sarcoidosis, Histoplasmosis, Blastomycosis, AIDS pneumonia, bronchiectasis, rheumatoid nodules, pulmonary infarction, lung cancer
- When there are multiple aspergilloma cavities in a diseased area of lung, it is termed a ‘complex aspergilloma’.
- Aspergilloma (fungus ball) consists of fungal hyphae, inflammatory cells, fibrin, mucous and tissue debris.

### ***Clinical features***

- Simple aspergilloma is usually asymptomatic.
- Occasionally it may cause recurrent scanty to **massive hemoptysis**. The source of hemoptysis is usually bronchial blood vessels. It may be due to local invasion of blood vessels lining the cavity, endotoxins released from the fungus or mechanical irritation of the vessels inside the cavity during rolling of the fungus ball.
- Non-specific systemic features like lethargy and weight loss may be present.

**Fig. 6.40:** Chest X-ray shows air crescent sign of aspergilloma in the left upper zone.

## Diagnosis

- Chest X-ray: Shows a round cavity with a tumor-like opacity inside. It is distinguished from a carcinoma by the presence of a crescentic air shadow (halo) between the fungal ball and the upper wall of the cavity. If the radiographs are repeated in a different position, the fungal ball occupies the dependent portion of the cavity. **Crescent sign of Monad (Fig. 6.40).**
- HRCT is more sensitive for demonstration the fungal ball.
- Serum precipitins to *Aspergillus fumigatus* can be detected.
- Sputum:
  - Microscopic examination shows fungal hyphal fragments.
  - Culture usually grows the fungus.
- Positive skin tests (hypersensitivity) to extracts of *Aspergillus fumigatus*.

## Management

- No treatment required for asymptomatic patients.
- Antifungal drugs have not useful and corticosteroids may predispose to invasion.
- **Surgical removal:**
  - Aspergillomas complicated by hemoptysis should be excised surgically in suitable patients.
  - In patient unfit for surgery, palliative procedures such as ultrasound or CT-guided local injection of amphotericin B into the cavity and bronchial artery embolization to control hemoptysis.

## Invasive Pulmonary Aspergillosis

**Q. Discuss the etiology, clinical features, diagnosis and management of invasive pulmonary aspergillosis.**

Invasive pulmonary aspergillosis (IPA) is invasion of previously healthy lung tissue by *Aspergillus fumigatus* and usually develops as a complication in patients who are immunocompromised (with profound neutropenia) either by drugs (especially immunosuppressants) and/or disease.

*Risk factors for invasive aspergillosis (Table 6.122)*

### Table 6.122: Risk factors for invasive aspergillosis.

- Prolonged neutropenia ( $<500$  cells/mm<sup>3</sup> for  $>10$  days) most common and risk is related to duration and degree
- Solid-organ (particularly lung transplantation) or allogeneic stem cell transplantation
- Prolonged ( $>3$  weeks), high dose corticosteroid therapy

- Leukemia and other hematological malignancies
- Cytotoxic chemotherapy
- Advance AIDS
- Severe COPD
- Critically ill patients on intensive care units
- Chronic granulomatous disease

## ***Clinical features***

**Acute IPA ( $\leq 1$  month):** Causes severe necrotising pneumonia. They present with fever, cough (sometimes productive), chest discomfort, mild to massive hemoptysis, and shortness of breath.

### **Subacute (1–3 months):**

- Local invasion of pulmonary vessels causes thrombosis and infarction.
- Epithelial spread: Involvement of tracheobronchial mucosa produces fungal plaques and ulceration.
- Systemic spread through blood may occur to the brain (causes seizures, ring-enhancing lesions, cerebral infarctions, intracranial hemorrhage, meningitis and epidural abscess), heart, kidneys and other organs.

## ***Diagnosis***

- Sputum:
  - Microscopic examination shows fungal hyphal fragments.
  - Culture usually grows the fungus.
- Serum precipitins to *Aspergillus fumigatus* can be detected.
- Chest X-ray: Non-specific and include round densities, pleural based infiltrates (suggestive of pulmonary infarctions) and cavitations.
- HRCT: Very useful for diagnosis particularly in neutropenic patients. Characteristically it shows macronodules (usually  $\geq 1$  cm) surrounded by a 'halo' (low attenuation due to hemorrhage surrounding the pulmonary nodule) during first 5 days.
- Detection of cell-wall components (**galactomannan and  $\beta$ -1, 3-glucan**) in blood or BAL fluid is useful for early confirmation of the diagnosis, and also its serial estimation may be useful in assessing the evolution of infection during treatment.
- PCR to detect *Aspergillus* DNA in BAL fluid and serum.
- Bronchoscopy and BAL transbronchial biopsy is of little value and may

produce complications. However, biopsy may be needed for confirmation.

### Management

Treatment should not be delayed because IPA has a high mortality rate. It requires aggressive antifungal therapy and immunosuppression should be reduced if possible.

**Voriconazole and liposomal amphotericin B** allow a safer and more effective treatment of invasive aspergillosis when compared with amphotericin B-deoxycholate.

First-line agents: The treatment of choice is intravenous voriconazole (6 mg/kg every 12 hours for two doses and then 4 mg/kg twice a day). It is better tolerated and more effective than amphotericin B. Antifungal therapy with amphotericin (1.0–1.5 mg/kg/day) with or without flucytosine is equally effective.

Second-line agents: Intravenous echinocandin derivatives such as caspofungin, micafungin and anidulafungin are used in refractory cases or if the patient cannot tolerate first-line agents.

In less immunosuppressed patients, oral itraconazole (200 mg twice a day) may be given.

## Fungal Infections of Lung (Box 6.17)

### Box 6.17: Fungal infections of the lung.

#### Endemic fungal pneumonia pathogens in healthy and in immunocompromised individuals

- *Histoplasma capsulatum*
- *Coccidioides immitis*
- *Blastomyces dermatitidis*
- *Paracoccidioides brasiliensis*
- *Sporothrix schenckii*
- *Cryptococcus neoformans*

#### Opportunistic fungal infections organisms in patients with congenital or acquired defects in the host immune defenses

- *Candida spp.*
- *Aspergillus spp.*
- *Mucor spp.*
- *Cryptococcus neoformans*

## HEMOPTYSIS

**Q. Write essay on hemoptysis (its definition, causes, clinical features, investigations and management).**

### Definition

- Hemoptysis is defined as coughing of blood originating from below the vocal cords.
- Hemoptysis can range from blood-streaking of sputum to the presence of

gross blood in the absence of any accompanying sputum.

- Life threatening (or) massive hemoptysis is defined as coughing of blood > 150 mL/time (or) > 600 mL/24 hours.
- Only 5% of hemoptysis is massive but mortality is 80%.
- Clinical definition of massive hemoptysis is any bleeding that result in a threat to life because of airway or hemodynamic compromise due to bleeding.

## Causes of Hemoptysis (Tables 6.123 and 6.124)

**Q. Write short essay/note on common causes of hemoptysis.**

**Table 6.123: Causes of hemoptysis.**

<i>Structure involved</i>	<i>Common causes</i>	<i>Uncommon causes</i>
Bronchial disease	Bronchial carcinoma, bronchiectasis, acute and chronic bronchitis	Bronchial adenoma, foreign body
Parenchymal disease of lung	Pulmonary tuberculosis (Rasmussen's aneurysm-dilation of a pulmonary artery in a tuberculous cavity), lung abscess, pneumonia (particularly <i>Klebsiella</i> ), fungal infections (aspergilloma and invasive aspergillosis, pulmonary contusion/laceration (traumatic))	Parasites (e.g. hydatid disease, flukes), trauma, actinomycosis, mycetoma
Vascular diseases of lung	Pulmonary infarction	Goodpasture's syndrome, polyarteritis nodosa, idiopathic, pulmonary hemosiderosis, primary pulmonary hypertension
Cardiovascular disease	Acute left ventricular failure	Mitral stenosis, aortic aneurysm, pulmonary thromboembolism
Hematological disorders		Leukemia, hemophilia, anticoagulants, hemorrhagic diathesis

**Table 6.124: Causes of massive hemoptysis.**

<ul style="list-style-type: none"> <li>• Pulmonary tuberculosis</li> <li>• Pulmonary infarction</li> <li>• Bronchiectasis</li> <li>• Bronchogenic carcinoma</li> </ul>	<ul style="list-style-type: none"> <li>• Cystic fibrosis</li> <li>• Lung abscess</li> <li>• Necrotizing pneumonia</li> </ul>	<ul style="list-style-type: none"> <li>• Mitral stenosis</li> <li>• Pulmonary arteriovenous malformation</li> </ul>
--	--	---

**Clinical clues for the diagnosis of cause of hemoptysis (Table 6.125)**

**Table 6.125: Clinical clues for the diagnosis of cause of hemoptysis.**

<b>Clinical clues</b>	<b>Suggested diagnosis</b>
Anticoagulant use	Medication effect, coagulation disorder
Tobacco use	Acute bronchitis, chronic bronchitis, pneumonia, lung cancer
Dyspnea on exertion, fatigue, orthopnea, paroxysmal nocturnal dyspnea, frothy pink sputum	Congestive heart failure, left ventricular failure, mitral stenosis
Fever, productive cough	Upper respiratory tract infection, acute bronchitis, pneumonia, lung abscess
History of cancer (e.g. Breast, colon, or kidney)	Endobronchial metastasis from carcinoma
History of chronic lung disease, recurrent lower respiratory tract infection, cough with copious purulent sputum	Bronchiectasis, lung abscess
Pleuritic chest pain, calf tenderness	Pulmonary embolism or infarction
Toxic symptoms	Tuberculosis
Weight loss	Emphysema, lung cancer, tuberculosis, bronchiectasis, lung abscess
Melena, alcoholism, chronic use of NSAIDs	Gastritis, gastric or peptic ulcer, esophageal varices
Association with menses	Catamenial hemoptysis
Cachexia, clubbing, hoarseness	Lung cancer, small cell carcinoma
Clubbing	Lung cancer, bronchiectasis, lung abscess
Dullness to percussion, fever, crepitations	Pneumonia

**Differences between true and false hemoptysis (Table 6.126)**

**Table 6.126: Differences between true and false hemoptysis.**

<b>True hemoptysis</b>	<b>False hemoptysis (Spurious)</b>
Below vocal cords	Above vocal cords
Persists as blood tinged sputum	Does not persist
May be mixed with sputum	Not mixed with sputum
History of cardiopulmonary disease	Obvious by ENT examination
Chest X-ray may be abnormal	Normal chest X-ray

**Differences between hemoptysis and hematemesis (Table 6.127)**

**Q. Write short essay/note on differences between hematemesis and hemoptysis.**

**Table 6.127: Differences between hemoptysis and hematemesis.**

<i>Hemoptysis</i>	<i>Hematemesis</i>
Coughing of blood. Cough precedes hemoptysis.	Vomiting of blood. Nausea and vomiting precedes hematemesis
History of cardiopulmonary disease	History of gastrointestinal disease
Bright red in color	Dark brown in color
Sputum remains blood stained after the attack for few days	Usually followed by melena
Mixed with sputum	Mixed with gastric contents
Blood is frothy due to admixture of air	Airless and not frothy
Alkaline	Acidic
Sputum contains hemosiderin laden macrophages	No
Melena absent	Melena present

## Investigations

When a patient comes with massive hemoptysis, initial diagnostic tests (Table 6.128) must begin in concert with efforts to stabilize the patient and control the bleeding.

- Other test includes antineutrophil cytoplasmic antibody, antiglomerular basement membrane antibody, and antinuclear antibody.
- Chest X-ray: Posteroanterior and lateral views may provide important diagnostic clues. It may provide evidence of a localized lesion, including tumor (malignant or benign), pneumonia, mycetoma or tuberculosis.

Chest X-ray may be useful in pulmonary thromboembolism, mitral stenosis, primary pulmonary hypertension, pulmonary hemosiderosis and bronchial adenoma.

- **Computed tomography of the chest:** Useful in delineating lesions that are not seen on a plain chest X-ray and it defines the lesions better than seen on X-ray.
  - It is valuable in selected cases to show the presence of lung cavities, solid masses, and mediastinal and hilar lymphadenopathy.
  - Along with fiberoptic bronchoscopy it gives a greater positive yield of pathology and is useful for excluding malignancy in high-risk patients.

- Allows application of special imaging techniques, for example, HRCT (1–3 mm thickness section) → **bronchiectasis** and spiral CT with pulmonary angiography → **pulmonary embolism**.
- **Electrocardiogram:** It may be useful in unsuspected mitral stenosis, pulmonary thromboembolism and pulmonary hypertension.
- **Bronchoscopy:** Most important diagnostic procedure.
- Angiography
- Isotope lung scans: Useful when pulmonary embolism is suspected in a patient with a normal chest radiograph.

**Q. Write short essay/note on:**

- **Outline the management of a case of hemoptysis.**
- **Management of massive (potentially lethal) hemoptysis.**

**Treatment**

- **Medical**
  - Endotracheal tube (single wide bore (or) double lumen). – Position of the patient in sitting (or) bleeding side down.
  - Large bore IV line for fluids, blood transfusion. – Supplemental oxygen/mechanical ventilation.
  - Avoid cough suppressants (if necessary benzodiazepine). – Vasopressin 0.2–0.4 units/min IV
- **Surgical**
  - Emergency resection for bronchogenic mass. – Resection of bronchogenic mass after patient stabilization.
  - Surgical resection for aspergilloma.
- **Endobronchial**
  - Identify: Source, Rate and to Slow (or) Arrest bleeding.
  - The rigid bronchoscope preferred as it enables blood to be aspirated more easily.
  - The fiberoptic bronchoscopy may be used for cold saline lavage, which may sometimes arrest bleeding. The iced saline is instilled in 50 to 100 mL aliquots followed by suctioning and repeated until there is noticeable improvement.
  - Other techniques used to control bleeding include: Topical thrombin or fibrinogen, topical coagulation with laser photocoagulation (Nd:YAG), argon plasma coagulator, endobronchial brachytherapy in high doses (10–12 Gy/hour for a total of 500–4000 Gy), endobronchial cryotherapy.
  - A balloon catheter passed through the bronchoscope can be inflated proximally in the bleeding bronchus. This will isolate the source of bleeding from the rest of the lung and the contralateral lung, preventing asphyxiation by blood flooding.
- **Endovascular**
  - In most patients the bleeding originates from bronchial arteries rather than pulmonary arteries.
  - Transcatheter embolization is effective in immediate control of massive hemoptysis (73–98%).

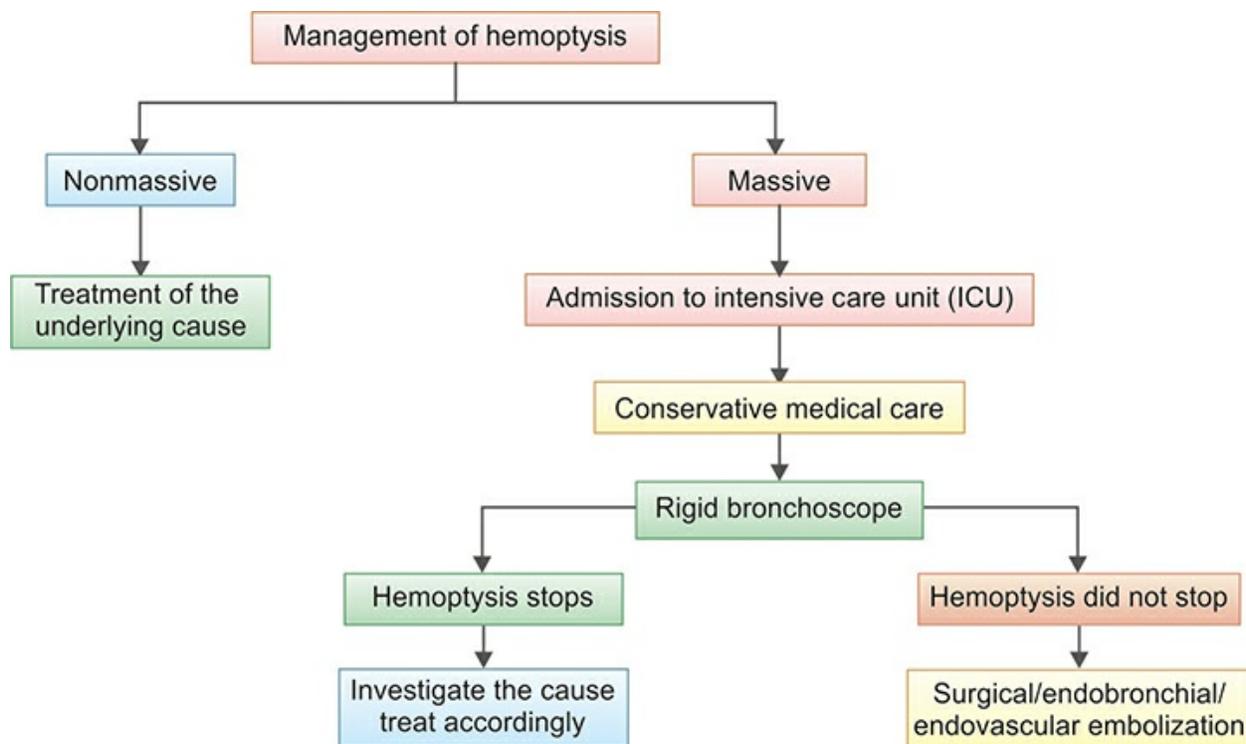

- Causes of recurrence: Incomplete embolization of artery, recanalization of previously embolized artery, revascularization through collateral circulation, progression of basic lung disease.

**Table 6.128:** Common laboratory tests and their interpretation.

<b>Test</b>	<b>Diagnostic findings</b>
Total leukocyte count with differential count	Raised leukocyte count and shift to the left in upper and lower respiratory tract infections
Hemoglobin and hematocrit	Decreased in anemia
Platelet count	Reduced in thrombocytopenia
Prothrombin and partial thromboplastin time	Increased in anticoagulant use, disorders of coagulation
Arterial blood gas	Hypoxia, hypercarbia
d-dimer	Raised in pulmonary embolism
Sputum	
<ul style="list-style-type: none"> <li>• Gram stain, and culture and sensitivity</li> </ul>	Klebsiella pneumoniae, identify organism in acute exacerbations of chronic bronchitis, bronchiectasis and lung abscess
<ul style="list-style-type: none"> <li>• AFB (Ziehl-Neelsen stain) and culture</li> </ul>	Pulmonary tuberculosis
<ul style="list-style-type: none"> <li>• Cytological examination</li> </ul>	Neoplasm (bronchial carcinoma)
Tuberculin test	Positive in TB
ESR	↑ in infection, autoimmune disorders (e.g. Wegener's syndrome, SLE, Goodpasture's syndrome) and malignancy
Urine microscopy	RBCs and red cell casts in hemorrhagic diathesis and Goodpasture's syndrome

Management of hemoptysis is summarized in Flowchart 6.10

**Flowchart 6.10:** Management of hemoptysis.

## DYSPNEA

**Q. Discuss briefly the differential diagnosis of acute onset dyspnea.**

**Q. Write short note on respiratory causes of acute breathlessness (dyspnea).**

Dyspnea or breathlessness is defined as **subjective experience of breathing discomfort** (i.e. uncomfortable need to breathe). It is a sense of awareness of increased respiratory effort that is unpleasant and recognized by the patient as being inappropriate. Patient often complains of tightness in the chest.

**Table 6.129:** Causes of acute and chronic dyspnea.

<i>Acute dyspnea</i>	<i>Chronic dyspnea</i>
<b>Cardiovascular system</b>	
Cardiogenic acute pulmonary edema	Chronic heart failure, myocardial ischemia
<b>Respiratory system</b>	
<ul style="list-style-type: none"> <li>Acute severe bronchial asthma</li> <li>Acute exacerbation of COPD</li> <li>Spontaneous pneumothorax</li> </ul>	<ul style="list-style-type: none"> <li>COPD</li> <li>Chronic bronchial asthma</li> <li>Bronchial carcinoma</li> </ul>

- Pneumonia
- Acute pulmonary embolism
- ARDS
- Inhaled foreign body (especially in children)
- Lobar collapse
- Laryngeal edema (e.g. anaphylaxis) or obstruction
- Metabolic acidosis (e.g. diabetic ketoacidosis, lactic acidosis, uremia, overdose of salicylates, ethylene glycol poisoning)
- Psychogenic hyperventilation (anxiety or panic-related)
- Interstitial lung disease (e.g. sarcoidosis, fibrosing alveolitis, extrinsic allergic alveolitis, pneumoconiosis)
- Chronic pulmonary thromboembolism
- Lymphatic carcinomatosis
- Large pleural effusion(s)
- Severe anemia
- Obesity
- Deconditioning

## Causes of Dyspnea (Table 6.129)

**Acute dyspnea:** Dyspnea arising over the course of a few minutes to 24 to 28 hours is termed acute dyspnea.

## Bronchial Obstruction

**Q. Write short note on the causes, clinical presentation and management of bronchial obstruction.**

## Causes (Table 6.130)

**Table 6.130:** Causes of bronchial obstruction.

<i>Causes</i>	<i>Disease/lesion</i>
Tumors	Bronchial adenoma or carcinoma
Enlarged tracheobronchial lymph nodes	Malignancy, Hodgkin lymphoma, non-Hodgkin lymphoma, tuberculosis
Inhaled foreign bodies	Common foreign bodies nuts, peas, beans, small pieces of toys, articles of food
Bronchial casts or plugs	Inspissated mucus (in asthma or pulmonary eosinophilia) or blood clots (severe hemoptysis)
Ineffective expectoration	Results in collection of mucus or mucopus in the bronchus
Rarely	Congenital bronchial atresia, post-tuberculous bronchial stricture, aortic aneurysm

## Clinical Features

Depends on the following:

- Cause of obstruction

- Degree of obstruction: Complete or partial obstruction.
- Presence or absence of secondary infection
- Effect on function of lung.

#### *Degree of obstruction*

- **Complete obstruction**

- Consequences of complete obstruction: Absorption of air distal to the obstruction, closure of alveolar spaces, collapse and solidification of the affected lung distal to obstruction.
- Physical signs on involved side: Mediastinal shift to the side of collapse, dull percussion note, and absent/diminished breath sounds.
- Radiological features on involved side: Mediastinal shift to the side of collapse, elevation of the diaphragm and a dense pulmonary opacity. When only small portion of the lung is collapsed, there may not be mediastinal displacement and abnormal physical signs, but a characteristic opacity will be seen on the radiograph.

- **Partial obstruction**

- Consequences of partial obstruction: Less resistance to the airflow during inspiration than during expiration and results in trapping of air distal to the obstruction. This leads to over distension of the part of the lung distal to the obstruction (obstructive emphysema).
- Physical signs on involved side: Percussion note is hyper resonant and breath sounds are diminished.
- Radiological features on involved side: Hypertranslucency.

#### *Features of secondary infection*

- Secondary bacterial infection usually develops distal to the obstruction and is usually caused by microorganism of low virulence. Sometimes suppuration can produce lung abscess.
- It may manifest as recurrent pneumonia in the same segment/lobe of the involved lung.

#### *Effect on function of lung*

- Symptoms usually follow if there is obstruction of a main or lobar bronchus.
- Sudden occlusion may produce severe breathlessness and hypoxemia.

### Management

- Identify the cause of obstruction: By chest X-ray, bronchoscopy and biopsy.
- Treat the underlying cause.
- Remove foreign bodies, bronchial casts, plugs and secretions by bronchoscopy.

## PULMONARY EOSINOPHILIC SYNDROMES

### Q. Write short essay/note on:

- **Causes of eosinophilia**
- **Diagnosis, differential diagnosis and management/treatment of tropical pulmonary eosinophilia.**

Heterogenous group of pulmonary disorders characterized by pulmonary parenchymal or peripheral blood eosinophilia.

#### 1. *Loeffler's syndrome (simple pulmonary eosinophilia)*

- It is a clinical syndrome characterized by:
  - Mild respiratory symptoms
  - Peripheral blood eosinophilia, and
  - Transient, migratory pulmonary infiltrates.
- Affects all ages.
- **Immune hypersensitivity to *Ascaris lumbricoides*** is the likely cause. Other parasites like Necator, Ancylostoma, Dirofilaria, etc. can be associated
- Chest X-ray: Transient, migratory, nonsegmental interstitial and alveolar infiltrates (often peripheral or pleural based).
- Pulmonary function tests: Typically reveals mild to moderate restrictive ventilatory defect with a reduced diffusing capacity of the lungs for carbon monoxide (DLCO).

#### 2. *Drug and toxin-induced pulmonary eosinophilic syndromes*

- Onset: Acute or subacute.
- Respiratory symptoms: Vary widely in severity.
  - Mild Loeffler's-like illness with dyspnea, cough, and fever.
  - Severe fulminant respiratory failure.
- Drugs implicated are acetyl salicylate, nitrofurantoin, bleomycin,

methotrexate, minocycline, sulfa drugs, gold salts, INH, etc.

### 3. *Idiopathic acute eosinophilic pneumonia*

- More common in younger men (mean age about 30 years).
- Occurs commonly in previously healthy persons. Also seen in persons with history of chronic myeloid leukemia (CML), HIV infection, recent commencement of smoking, etc.
- Diagnostic criteria:
  - Acute onset of febrile respiratory manifestations ( $\leq 1$  month duration before consultation).
  - Bilateral diffuse infiltrates on chest X-ray.
  - Hypoxemia, with  $\text{PaO}_2$  on room air  $< 60$  mm Hg, and/or  $\text{PaO}_2/\text{FiO}_2 \leq 300$  mm Hg, and/or oxygen saturation on room air  $< 90\%$ .
  - Lung eosinophilia, with  $> 25\%$  eosinophils in BAL (or eosinophilic pneumonia at lung biopsy).
  - Absence of infection, or of other known causes of eosinophilic lung disease (especially exposure to drug known to induce pulmonary eosinophilia).

#### Treatment

- Initial doses of methyl-prednisolone used in the range from 60 to 125 mg every 6 hours.
- After resolution of respiratory failure, oral prednisolone (in doses of 40 to 60 mg per day) may be continued for 2 to 4 weeks with a subsequent slow taper over the next several weeks.
- Idiopathic acute eosinophilic pneumonia (AEP) carries an excellent prognosis.

### 4. *Tropical pulmonary eosinophilia*

**Q. Write short note on tropical pulmonary eosinophilia, its diagnosis and management.**

Tropical pulmonary eosinophilia (TPE) was first described in the early 1940s by Weingarten, in India. It is seen mainly in South and South-east Asia and Africa.

**Definition:** Tropical pulmonary eosinophilia is an occasional atypical host response (hypersensitivity reaction) of an individual to a mosquito-borne filarial infection by tissue-dwelling human nematode (microfilariae) *Wuchereria bancrofti* and *Brugia malayi*.

**Pathogenesis:** When filarial parasites are destroyed, the antigens released

and initiate an immediate IgE-mediated reaction. There is dense inflammatory reaction with eosinophils which over time, progresses to granuloma formation and fibrosis. In children, marked enlargement of lymph nodes and spleen (**Meyers-Kouwenaar syndrome**) may be evident. In adults, symptoms are predominantly due to lung involvement. Microfilariae are trapped in the pulmonary capillaries and produce symptoms of lung involvement.

### **Clinical features:**

- Paroxysmal dry cough, fever, malaise, anorexia weight loss, dyspnea or wheeze/nocturnal bronchospasm (asthma-like symptoms) and miliary pulmonary infiltrates (**Weingarten syndrome or tropical pulmonary eosinophilia**).
- Tropical pulmonary eosinophilia is a complication seen mainly in India. If untreated, it may progress to chronic interstitial lung disease. Spontaneous resolution over several weeks.
- Other features:
  - Presentation can be similar to status asthmaticus
  - Chest pain, muscle tenderness, pericardial and CNS involvement
  - Rarely, patients remain asymptomatic.
- Chest examination: Coarse crackles and rhonchi.
- Generalized lymphadenopathy and hepatosplenomegaly may be present.

### **Diagnosis**

- **History** of long period of residence in an endemic area.
- **Peripheral blood:**
  - Absence of microfilariae in the despite repeated examinations.
  - Marked peripheral blood **eosinophilia** in excess of 3000/mL.
- Chest X-ray—Miliary mottling.
- **Serological findings**
  - High titers of antifilarial antibodies.
  - Elevated levels of total IgE (at least 1000 units/mL).
- **Therapeutic response to DEC** (6 mg/kg/day for 3 weeks) within 7–10 days of initiating therapy.

**Treatment:** Diethylcarbamazine in a dose of 2 mg/kg orally three times a day for 14–21 days or for as long as 4 weeks. It is directly filaricidal to both adult worms and microfilariae.

## 5. ***Chronic eosinophilic pneumonia***

- Typically subacute presentation.
- Symptoms present for several months before diagnosis.
- Common presenting complaints include: Low-grade fevers, drenching night sweats, moderate (10 to 50-pound) weight loss, cough.
- History of atopy, allergic rhinitis, or nasal polyps may be found.
- About 2/3 develop adult-onset asthma: Preceding or concurrent with the occurrence of CEP.
- No major extrapulmonary manifestations
- Chest X-ray: Bilateral opacities in upper and mid zone. Photographic negative of pulmonary edema.
- Corticosteroids are the mainstay of therapy for CEP. Dramatic clinical, radiographic, and physiological improvements.

## 6. ***Allergic bronchopulmonary aspergillosis (discussed on pages 373-4)***

## 7. ***Churg-Strauss Syndrome***

- It is a form of necrotizing vasculitis in several organs, associated with eosinophilic tissue inflammation and extravascular granulomas. It occurs in asthmatics and presents with fever and peripheral hypereosinophilia (discussed on pages 693-4).

## 8. ***Idiopathic hypereosinophilic syndrome***

- Several names: Eosinophilic leukemia, Loeffler's fibroblastic endocarditis, disseminated eosinophilic cardiovascular disease.
- Clinical features: Often nonspecific and include:
  - Weakness, fatigue, low-grade fevers, myalgias, cough, angioedema, rash, retinal lesions, and dyspnea.
  - Can affect every organ system.
  - Cough is nocturnal, either nonproductive or productive of small quantities of non-purulent sputum.
  - Wheezing and dyspnea without evidence of airflow obstruction on spirometry.
  - Pulmonary hypertension, ARDS, and pleural effusions.
  - Progressive chronic heart failure due to eosinophilic myocarditis and endocarditis, intracardiac thrombi and endocardial fibrosis.

- Encephalopathy with neuropsychiatric dysfunction, thromboembolic events, like hemiparesis. Peripheral neuropathy is extremely common in IHS.
- Hepatosplenomegaly, lymphadenopathy
- Investigations:
  - Anemia, thrombocytopenia
  - Elevated vitamin B<sub>12</sub> levels
  - Bone marrow: Universally affected with a striking eosinophilia (up to 25–75% of the differential count).

#### Treatment

- Glucocorticoids are the first line therapy in all patients without FIP1L1/PDGFRA mutation.
- Patients **with** FIP1L1/PDGFRA mutation: Imatinib is the drug of choice with a very good response rate.
- Other drugs include: hydroxyurea, vincristine, interferons, anti-IL-5 monoclonal antibody (e.g. mepolizumab) and an anti-CD52 antibody (alemtuzumab).

## Causes of Calcification in Lung Parenchyma (Box 6.18)

**Q. Write short note on causes of calcification in lung parenchyma.**

### Box 6.18: Calcification in lung parenchyma.

#### Micronodules

- Pulmonary alveolar microlithiasis, occupational lung diseases (e.g. silicosis, coal-worker's pneumoconiosis)

#### Large nodules or masses

- Granulomatous disease (tuberculosis, histoplasmosis)
- Primary lung cancer (5–10%)
- Metastasis to lung (e.g. osteosarcoma, chondrosarcoma)
- Non-malignant metastatic calcification in lung (e.g. renal failure, hyperparathyroidism)
- Multiple pulmonary chondroma (e.g. with Carney triad)
- **Others:** Chickenpox pneumonia, hemosiderosis, pulmonary hemorrhage

## Breath Sounds (Fig. 6.41)

**Q. Write short note on:**

- **Causes of bronchial breathing, tubular and amphoric breathing.**  
**Three components of tubular breathing.**

- **Cavernous breathing.**

Normal breath sounds are produced by vibration of vocal cords due to turbulent flow in the larynx. This sound is harsher anteriorly over the upper lobes (particularly on the right).

- **Vesicular breath sounds:** Healthy lungs filter out most of the high frequency component, and the resulting low-pitched, rustling sounds are called vesicular. Inspiration is longer than expiration and there is no gap in between rustling in character.
  - Conditions with diminished vesicular breath sounds are heard in bronchial asthma, tumors, pleural effusion (small), pleural thickening, collapsed lung with occluded bronchus, and emphysema.
- **Bronchial breath sounds** are produced by the passage of air through the trachea and large bronchi. It is loud and high pitched. Inspiration and expiration are of equal duration, there is a gap between inspiration and expiration, and the quality is guttural or aspirate.
  - Types of bronchial breathing
    - ◆ **Tubular:** High pitched and heard in pneumonia with consolidation, partially collapsed lung or lobe and above the level of pleural effusion (relaxation atelectasis)
    - ◆ **Cavernous:** Low pitched and heard in thick walled cavity with communicating bronchus.
    - ◆ **Amphoric:** Low pitched with high tone and a metallic quality. It is heard in bronchopleural fistula, rarely over a superficial cavity and tension pneumothorax.
- **Bronchovesicular breath sound:** This is classically seen in obstructive lung disease where expiration is prolonged, however there is no gap in between.

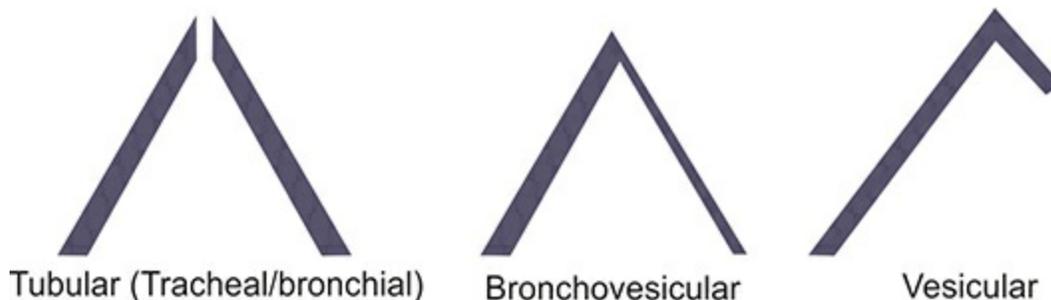

Fig. 6.41: Types of breath sounds.

## Indications of Bronchoscopy (Table 6.131)

**Q.** Write short note on indications for bronchoscopy.

**Table 6.131:** Indications of bronchoscopy.

<i>Diagnostic</i>	<i>Therapeutic</i>
<ul style="list-style-type: none"><li>• Diagnosis of lung cancer</li><li>• Chest radiographic abnormality (lung tumor or changes suggestive of bronchial obstruction, such as appearance of early volume loss or undoubted collapse, unresolved pneumonia or hemi-diaphragmatic paralysis)</li><li>• Evaluation of hemoptysis</li><li>• Evaluation of persistent or recurrent cough</li><li>• Evaluation of paralyzed vocal cord</li><li>• To obtain positive sputum cytology</li><li>• Staging of lung cancer</li><li>• Diagnosis of diffuse lung disease</li><li>• Identification of infecting agents</li></ul>	<ul style="list-style-type: none"><li>• Insertion of an endotracheal tube for general anesthesia in patients in whom extension of neck may be dangerous (atlanto-axial subluxation)</li><li>• Tamponade of endobronchial bleeding, either with end of bronchoscope itself or by using a Fogarty</li><li>• Removal of foreign bodies</li><li>• Aspiration of secretions in acute inflammatory lobar atelectasis where physiotherapy has proved unsuccessful in achieving this end</li><li>• Relief of tracheobronchial narrowing by laser treatment</li><li>• Treatment of lung cancer by placement of stents or delivery of endobronchial radiotherapy (brachytherapy)</li></ul>

# Cardiology

# CHAPTER 7

## INTRODUCTION AND SYMPTOMATOLOGY

### Chest Pain

**Q.** Write a short essay on the differential diagnosis of chest pain. List the non-cardiac causes of chest pain.

Chest pain is a common symptom of cardiac disease. It can be due to non-cardiac causes such as anxiety or diseases involving the respiratory, musculoskeletal or gastrointestinal systems.

### Common Causes of Chest Pain (Fig. 7.1)

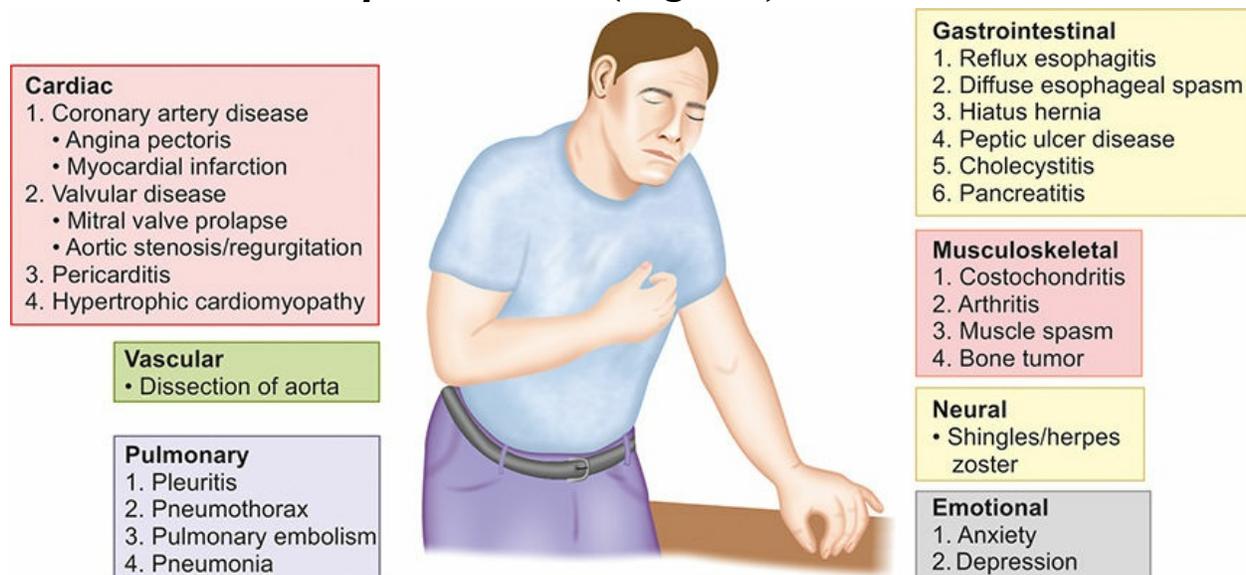

Fig. 7.1: Causes of chest pain.

### Differential Diagnosis of Chest Pain (Table 7.1)

Table 7.1: Differential diagnosis of chest pain.

<b>Potentially life-threatening causes</b>	<b>Common non-life-threatening causes</b>
<ul style="list-style-type: none"> <li>• Acute coronary syndromes: Acute myocardial infarction (MI), ST segment elevation MI, non-ST segment elevation MI</li> <li>• Unstable angina</li> <li>• Pulmonary embolism</li> <li>• Aortic dissection</li> <li>• Myocarditis (most common cause of sudden death in the young)</li> <li>• Tension pneumothorax</li> <li>• Acute chest syndrome/crisis in sickle cell anemia</li> <li>• Pericarditis</li> <li>• Boerhaave's syndrome (perforated esophagus)</li> <li>• Gastrointestinal: Perforated peptic ulcer, acute pancreatitis, acute cholecystitis</li> </ul>	<ul style="list-style-type: none"> <li>• Gastrointestinal <ul style="list-style-type: none"> <li>– Biliary colic</li> <li>– Gastroesophageal reflux disease</li> <li>– Peptic ulcer disease</li> </ul> </li> <li>• Pulmonary <ul style="list-style-type: none"> <li>– Pneumonia</li> <li>– Pleuritis</li> </ul> </li> <li>• Musculoskeletal pain: Costochondritis (Tietze's syndrome), intercostal myalgia/neuralgia, fracture of the ribs (cough, trauma), secondaries in the ribs, Bornholm disease</li> <li>• Thoracic radiculopathy: Texidor's twinge (precordial catch syndrome)</li> <li>• Emotional: Anxiety</li> <li>• Neural: Shingles/herpes zoster</li> </ul>

## ***Differential Features of Ischemic Cardiac and Non-Cardiac Pain (Table 7.2)***

**Table 7.2:** Differential features of ischemic cardiac and non-cardiac pain.

<b>Features</b>	<b>Ischemic cardiac pain</b>	<b>Noncardiac pain</b>
Site	Central, diffuse	Peripheral, localized
Character of pain	Tight, squeezing, dull, constricting, choking or 'heavy'	Sharp, stabbing, catching
Precipitation/provocation	Exertion, emotion	Spontaneous, not related to exertion
Radiation	Jaw/neck/shoulder	Usually no radiation
Relieving factors	Rest (in less than 5 minutes), nitrates	Not relieved by rest or by nitrates
Associated features	Breathlessness, diaphoresis	Depends on the cause

## ***Differentiating Features***

Differentiating features of the common causes of chest pain (Table 7.3).

**Table 7.3:** Differentiating features of the common causes of chest pain.

<b>Disease</b>	<b>Description</b>	<b>Location</b>	<b>Radiation</b>	<b>Associations</b>
Acute coronary	Crushing,	Retrosternal, left	Right (R) or left	Dyspnea,

syndromes	tightening, squeezing, or pressure like	anterior chest or epigastric	(L) shoulder, R or L arm/hand/jaw	diaphoresis, nausea
Pulmonary embolism	Heaviness, tightness	Whole chest (massive) or focal chest (segmental)	None	Dyspnea, unstable vital signs, feeling of impending doom if massive or just tachycardia, tachypnea if segmental
Aortic dissection	Ripping, tearing	Midline, substernal	Intrascapular area of back	Secondary arterial branch occlusion (paraplegia)
Pericarditis/cardiac tamponade	Sharp, constant or pleuritic	Substernal	None	Fever, dyspnea, pericardial friction rub
Pneumothorax	Sudden, sharp, lancinating, pleuritic	One side of chest	Shoulder, back	Dyspnea
Perforated esophagus	Sudden, sharp, after forceful vomiting	Substernal	Back	Dyspnea, diaphoresis, signs of sepsis

## Palpitations

### **Q. Discuss the approach to a patient with palpitations.**

- Palpitation is the term used to describe an uncomfortable increased awareness of one's own heartbeat or the sensation of slow, rapid or irregular heart rhythms.
- Palpitations do not always indicate the presence of arrhythmia and conversely, an arrhythmia can occur without palpitations. Palpitations are usually noted when the patient is quietly resting.
- Palpitation can be either intermittent or sustained and either regular or irregular. **A change in the rate, rhythm or force of contraction can produce palpitations.**

### ***Causes of Palpitations (Table 7.4)***

**Table 7.4:** Causes of palpitations.

Cardiac causes	Drug induced
----------------	--------------

<ul style="list-style-type: none"> <li>• <b>Cardiac arrhythmias</b> <ul style="list-style-type: none"> <li>– Premature atrial and ventricular contractions</li> <li>– Supraventricular and ventricular arrhythmias</li> </ul> </li> <li>• <b>Structural heart diseases</b> <ul style="list-style-type: none"> <li>– Atrial myxoma, valvular heart disease</li> <li>– Congenital heart disease, cardiomyopathy</li> <li>– Mitral valve prolapse, pacemaker</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Alcohol (use or withdrawal)</li> <li>• Atropine</li> <li>• Amphetamines</li> <li>• Caffeine, nicotine</li> <li>• Cocaine</li> <li>• Beta agonists, theophylline</li> </ul>
<p><b>Psychosomatic disorders</b></p> <ul style="list-style-type: none"> <li>• Generalized anxiety, major depression, panic disorder</li> </ul>	<p><b>Endocrine</b></p> <ul style="list-style-type: none"> <li>• Hyperthyroidism, pheochromocytoma</li> <li>hypoglycemia,</li> </ul>
<p><b>High output states</b></p> <ul style="list-style-type: none"> <li>• Anemia, beriberi, fever, pregnancy, thyrotoxicosis</li> </ul>	<p><b>Miscellaneous and idiopathic</b></p> <ul style="list-style-type: none"> <li>• Emotional stress, hyperventilation, premenstrual syndrome, strenuous physical activity</li> </ul>

## ***Evaluation of Palpitation (Box 7.1)***

### ***Clinical Presentation***

#### **Box 7.1:** Evaluation of palpitation.

- Detect and identify any underlying arrhythmia
  - Determine presence of any organic heart disease
  - Determine any precipitating cause
- 
- **Duration and frequency of palpitations**
    - Duration may be either short-lasting or persistent.
    - Note onset and offset of palpitations.
    - Frequency: It may occur daily, weekly, monthly, or yearly.
  - **Types of palpitations:** They are classified according to the rate, rhythm, and intensity of heartbeat as follows:
    - **Extrasystolic palpitations:** Due to ectopic beats, usually produce feelings of ‘missing/skipping a beat’ and/or a ‘sinking of the heart’ interspersed with periods during which the heart beats normally. Patients report that the heart seems to stop and then start again. It can often be seen even in young individuals, usually without any disease of the heart, and generally benign.
    - **Tachycardiac palpitations** is the rapid fluctuation like ‘beating wings’

in the chest. It may be regular (e.g. in atrioventricular tachycardia, atrial flutter, or ventricular tachycardia) or irregular or arrhythmic (e.g. in atrial fibrillation).

- **Anxiety-related palpitations** are perceived as a form of anxiety. They begin and end gradually.

- **Associated symptoms and circumstances**

- Palpitations developing after sudden changes in posture are usually due to intolerance to orthostatic or to episodes of atrioventricular nodal re-entrant tachycardia.
- Occurrence of syncope or other symptoms, such as severe fatigue, dyspnea, or angina, in addition to palpitations, is more common with structural heart disease.
- Hypersecretion of natriuretic hormone results in polyuria/postpalpitation diuresis in atrial fibrillation.
- Palpitations associated with anxiety or during panic attacks are usually due to sinus tachycardia secondary to the mental disturbance.
- Palpitations may be produced by an increase in the sympathetic drive during physical exercise.

- **Typical description**

- **Flip-flopping in the chest:** Palpitations are sensed as the heart seeming to stop and then start again, producing a pounding or flip-flopping sensation. This type of palpitation is generally caused by supraventricular or ventricular premature contractions.
- **Rapid fluttering in the chest:** It is due to a sustained ventricular or supraventricular arrhythmia, including sinus tachycardia.
- **Pounding in the neck:** An irregular pounding feeling in the neck is caused by atrioventricular dissociation, with independent contraction of the atria and ventricles, resulting in occasional atrial contraction against a closed tricuspid and mitral valve. This produces cannon A waves, which are intermittent increases in the “A” wave of the jugular venous pulse. **Cannon A** waves may be seen with ventricular premature contractions, third degree or complete heart block, or ventricular tachycardia (VT).

## ***Physical Examination***

May help to confirm or refute the presence of an arrhythmia as a cause for palpitations:

- Measurement of the vital signs
- Assessment of the jugular venous pressure and pulse
- Auscultation of the chest and precordium.

## ***Investigations***

- **Electrocardiogram**
  - Resting electrocardiogram can be used to diagnose the arrhythmia.
  - If exertion induces the arrhythmia and palpitations, exercise electrocardiography can be used to make the diagnosis.
  - It may reveal bundle branch block, short PR interval, delta waves, prolonged QT interval, ischemia, and enlargement of heart chambers, prior myocardial infarction or other organic diseases of the heart.

If the arrhythmia is not frequent, other methods must be used. These include:

- **Continuous electrocardiographic (Holter) monitoring** or telephonic monitoring.
- **Echocardiography:** To evaluate any structural heart disease and assessment of left ventricular function.
- **Electrophysiology study** is an invasive test of electrical conduction system of heart.
- **Blood tests:** Hemoglobin, serum glucose level, serum electrolytes and thyroid function tests depending on the clinical findings.

### **Management of palpitation**

- Most of the causes do not have serious arrhythmias or underlying structural heart disease.
- In symptomatic patients, occasional benign atrial or ventricular premature contractions can often be treated by beta-blockers.
- Avoid precipitation factor like alcohol, tobacco, or illicit drugs.
- **If caused by pharmacologic agents:** Consider alternative therapies if appropriate or possible.
- **Psychiatric causes:** By cognitive therapy or pharmacotherapy.
- **Reassurance:** After all the serious causes have been excluded.

## **Dyspnea**

**Q. Write short note on causes of acute dyspnea.**

**Definition:** “Dyspnea” is a term used to characterize a subjective experience of breathing discomfort that is comprised of qualitatively distinct sensations that vary in intensity. The experience derives from interactions among multiple physiological, psychological, social, and environmental factors, and may induce secondary physiological and behavioral responses.

Causes of dyspnea (refer Table 6.129).

## ***Mechanisms***

- **Chemoreceptors**

- **Peripheral:** Carotid and aortic bodies (sensitive to changes  $pO_2$ ,  $pCO_2$  and  $H^+$ )
- **Central:** Medulla (sensitive only to changes  $pCO_2$ , not  $pO_2$ , change in pH of CSF).

- **Increased work of breathing**

- **Airflow obstruction:** Bronchial asthma, COPD, tracheal obstruction
- **Decreased pulmonary compliance:** Pulmonary edema, fibrosis, allergic alveolitis
- **Restricted chest expansion:** Ankylosing spondylitis, respiratory paralysis, kyphoscoliosis.

- **Increased ventilatory drive**

- **Increased physiological dead space (V/Q mismatch):** Consolidation, collapse, pleural effusion (PE), pulmonary edema
- Hyperventilation due to receptor stimulation
- **Chemoreceptors:** Acidosis, hypoxia (shock, pneumonia), hypercapnia
- **J receptors at alveolo-capillary junction:** Pulmonary edema, pulmonary embolism, pulmonary congestion (activates Hering-Breuer reflex which terminates inspiratory effort before full inspiration is achieved—rapid and shallow)
- **Muscle spindles in intercostal muscles:** Tension-length disparity
- **Central:** Exertion, anxiety, thyrotoxicosis, pheochromocytoma.

- **Impaired respiratory muscle function:** Poliomyelitis, Guillain-Barré syndrome (GBS), myasthenia gravis.

**Orthopnea:** Dyspnea develops in recumbent position and is relieved by

sitting up or by elevation of the head with pillows.

- Pulmonary congestion during recumbency (cannot be pumped out of LV) seen in congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD) and bronchial asthma.
- Increased venous return.
- Diaphragm elevation leading to decreased vital capacity.

**Basics:** *A normal 70 kg person breathes 12–15/min with a tidal volume of 600 mL. A normal individual is not aware of respiratory effort until ventilation is doubled, and dyspnea is not experienced until ventilation is tripled.*

Causes of dyspnea in COPD are listed in Box 7.2.

**Paroxysmal nocturnal dyspnea (PND):** Attacks of dyspnea occur at night and awaken the patient from sleep.

**Box 7.2:** Dyspnea in COPD.

- **Hypoxia and hypercapnia:** Chemoreceptors
- **Increased airway resistance and hyperinflation**
- **De-conditioning:** Reduced threshold at which respiratory muscles produce lactic acidosis

- It is due to decreased responsiveness of respiratory center in brain during sleep and pulmonary congestion (due to increased sympathetic activity during REM sleep) 2–3 hours after onset of sleep.
- Takes 10–30 minutes for recovery after upright posture.
- Causes: Specific sign of LV dysfunction and includes ischemic heart disease, aortic valve disease, hypertension, cardiomyopathy.

Differences between **orthopnea** and **paroxysmal nocturnal dyspnea** is presented in Table 7.5.

**Table 7.5:** Differences between paroxysmal nocturnal dyspnea and orthopnea.

	<i>Paroxysmal nocturnal dyspnea</i>	<i>Orthopnea</i>
Definition	Episode of sudden onset of dyspnea 2–2.5 hours after sleep	Dyspnea in recumbent posture
Timing	Patient wakes up from rapid eye movement (REM) sleep	Occurs soon after lying down
Method of relief	Sits up with legs hanging down,	Gets up, uses more pillows,

	stands up, air hunger, self ventilates to comfort	sleeps in erect posture
Mechanism	Depressed respiratory center. Sympathetic over activity during REM → catecholamine surge resulting in tachycardia → interstitial pulmonary congestion → respiratory center lags behind → perceived as acute dyspnea. There is sudden transient increase in PCWP	Shifting of venous blood (>400 ml) into pulmonary circulation, V/Q mismatch, compression of diaphragm, postural diastolic dysfunction. There is a slow sustained rise in pulmonary capillary wedge pressure (PCWP)
Associated symptoms	Angina, perspiration, palpitation, rarely hemoptysis	All the symptoms of congestive cardiac failure (CCF)
Oxygen saturation	Transient hypoxia	Normal
Differential diagnosis	Night mares/panic attacks/nocturnal hypoglycemia/obstructive sleep apnea (OSA)	COPD/gross obesity/acute asthma/gross ascites

**Trepopnea:** Aggravation of dyspnea when lying on one side and relieved by lying on opposite side. Its causes are:

- **Unilateral lung disease:** Uninvolved normal lung receives more blood supply due to gravity.
- **Congestive heart failure:** Lying on right side enhances venous return and sympathetic activity.
- **Lung tumor:** Gravity induced compression of blood vessels or lung.

**Platypnea:** Dyspnea on sitting or standing and relieved by supine position. Its causes are:

- Venous to arterial shunting (lung bases)
- Intracardiac shunts (ASD, pneumonectomy)
- Intrapulmonary right to left shunt [hepatopulmonary syndrome, pulmonary embolism (PE), COPD]
- Acute respiratory distress syndrome (ARDS).

### ***Approach to Dyspnea***

- **Onset and duration**
  - **Minutes to hours (rapid onset):** Pneumothorax, acute asthma, PE, pulmonary edema, foreign body.
  - **Hours to days (gradual onset):** Pneumonia, pleural effusion, anemia,

Guillain–Barré syndrome (GBS).

- **Months to years (slow onset):** Pulmonary tuberculosis (PTB), COPD, carcinoma, fibrosing alveolitis.
- **Severity of dyspnea (Table 7.6)**
- **Aggravating and relieving factors**
  - **Improves on weekend/holidays:** Occupational asthma, extrinsic allergic alveolitis
  - **Recumbency/sleep:** Orthopnea/paroxysmal nocturnal dyspnea (PND)

**Q. NYHA functional classification of cardiac disability.**

**Table 7.6: Severity of dyspnea.**

<i>Medical Research Council (MRC) grading of severity of dyspnea</i>	<i>New York Heart Association (NYHA) classification of severity of heart failure (angina, fatigue, palpitation, or dyspnea)</i>
1. Not troubled by breathlessness except on strenuous exertion	Class I: No limitation with ordinary physical activity
2. Short of breath when hurrying on level ground or walking up slight hill	Class II: Mild/slight limitation of ordinary physical activity
3. Walks slower than people of same age or stops after 15 minutes when walking at own pace on level	Class III: Marked limitation of physical activity, symptoms with exertion
4. Stops after 100 yards (90 m) or after few minutes in level ground	Class IV: Symptoms at rest. Unable to carry out physical activity without discomfort
5. Too breathless to leave house, dress or undress	

- **Associated symptoms**
  - **Pleuritic chest pain:** Pneumonia, pulmonary infarction, rib fracture, pneumothorax
  - **Central non-pleuritic chest pain:** Myocardial infarction, massive pulmonary embolism
  - **Cough or wheeze:** Asthma, pulmonary embolism, pneumothorax.

## Arterial Pulses

**Q. Write short essay/note on the clinical value of examination of radial and carotid pulses at bedside.**

**Definition of arterial pulse:** It is a pressure distension wave produced by the

contraction and relaxation of the left ventricle against a partially filled aorta which is transmitted to peripheries and is felt against bony prominences.

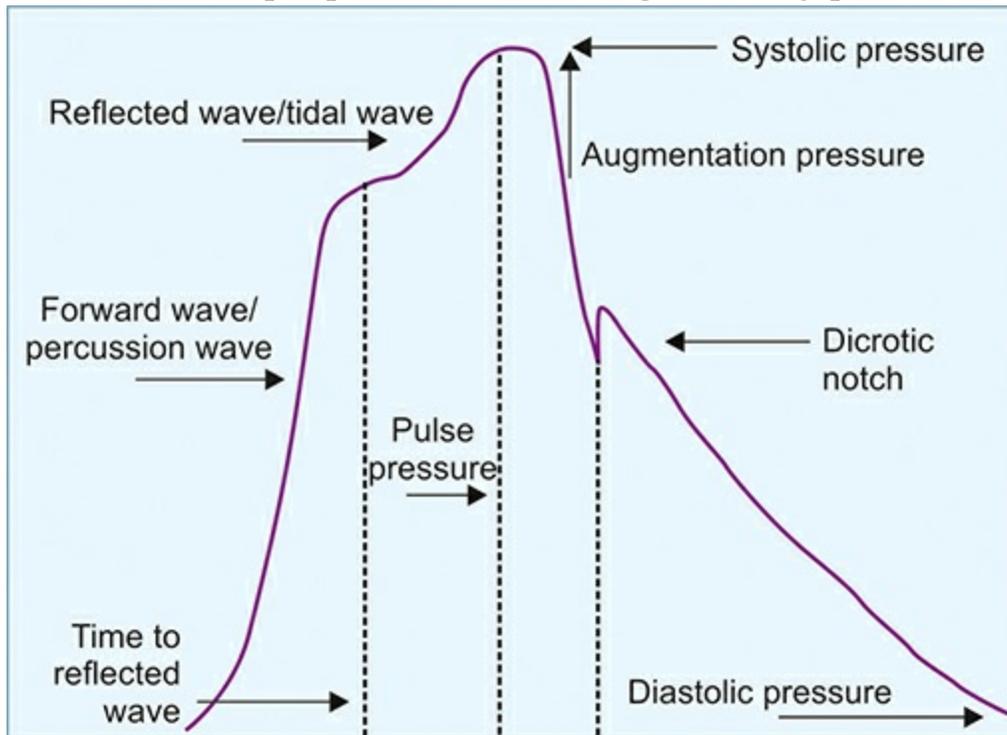

Fig. 7.2: Normal carotid and peripheral pulse wave.

**Table 7.7: Assessment of arterial pulse.**

<i>Characteristics</i>	<i>Best assessed by palpating</i>
• Rate	Radial artery
• Rhythm	
• Volume	Carotid artery
• Character or quality	Carotid artery (except collapsing pulse which is appreciated better at radial artery)
• Radiofemoral delay	
• Whether felt in all peripheral vessels	
• Condition of vessel wall	

**Peripheral arterial pulses:** Include radial, brachial, carotid, femoral, popliteal, posterior tibial and dorsalis pedis pulses. Right radial pulse is the first pulse to be examined during clinical examination. Normal pulse wave is depicted in Figure 7.2.

## Examination of the Arterial Pulse (Table 7.7)

- The character of the pulse is determined by stroke volume and arterial compliance, and is best assessed by palpating a major artery, such as the carotid or brachial artery.
- **Pulse rate**

### Q. Write short note on bradycardia and its causes.

- Normal (resting) pulse rate in an adult is between 60 and 100 beats per minute (bpm).
- Should be counted for 1 full minute by palpating the radial artery.
  - **Sinus bradycardia:** Resting pulse rate is less than 60 beats/minute.
  - **Sinus tachycardia:** Resting pulse rate is more than 100 beats/minute.
- Causes of bradycardia and tachycardia are listed in Table 7.8.

**Table 7.8: Causes of bradycardia and tachycardia.**

<b>Bradycardia</b>	<b>Tachycardia</b>
<b>Physiological:</b> Athletes, sleep <b>Pathological</b> <ul style="list-style-type: none"><li>• Severe hypoxia</li><li>• Hypothyroidism/myxedema</li><li>• Hypothermia</li><li>• Sick sinus syndrome</li><li>• Vasovagal syncope</li><li>• Drugs—<math>\beta</math>-blockers, verapamil, digoxin</li><li>• Heart block</li><li>• Raised intracranial tension</li></ul>	<b>Physiological:</b> Infants, children, emotion, exertion, pregnancy <b>Pathological</b> <ul style="list-style-type: none"><li>• Tachyarrhythmias</li><li>• High output states: Anemia, pyrexia, anxiety, beriberi, thyrotoxicosis, cardiac failure, cardiogenic shock, drugs (e.g. atropine, nifedipine, salbutamol, terbutaline, nicotine, caffeine)</li></ul>

**Pulse deficit (Apex-pulse deficit)** is the difference between the heart rate (counted by auscultation) and pulse rate when counted simultaneously for one full minute.

- Causes: Pulse deficit of more than 10/minute occurs in atrial fibrillation and less than 10/minute may be found with ventricular premature beats or slow/controlled atrial fibrillation (AF).
- **Rhythm**
  - Rhythm is assessed by palpating the radial pulse. The normal rhythm is regular.

- Causes of various types of arterial pulse rhythm abnormalities are listed in Box 7.3.

**Box 7.3:** Causes of various types of arterial pulse rhythm abnormalities.

**Regularly irregular**

- Atrial tachyarrhythmias, sinus arrhythmia, partial AV blocks
- Ventricular bigemini, trigemini

**Irregularly irregular**

- Atrial or ventricular ectopics
- Atrial fibrillation
- Atrial tachyarrhythmia with AV blocks
- Frequent extrasystoles

**Regular with occasional irregularity**

- Extrasystoles

**Q. What are the causes for irregularly irregular pulse?**

- **Ventricular ectopics:** Develop as occasional or repeated irregularities superimposed on a regular pulse rhythm. Intermittent heart block also present with occasional beats dropped from an otherwise regular rhythm.
- **Atrial fibrillation:** Develops an irregularly irregular pulse. This irregular pattern persists when the pulse increases in response to exercise. On the contrary pulse irregularity due to ectopic beats usually disappears with exercise.
- **Pulse volume**
  - Pulse volume is best assessed by palpating the carotid artery. However, the **pulse pressure** (i.e. difference between systolic and diastolic blood pressure) provides an accurate measure of pulse volume.
  - Pulse volume is normal when pulse pressure is between 30 and 60 mm Hg, low when it is less than 30 mm Hg and large volume when more than 60 mm Hg.
- **Pulse character or quality**
  - Causes of hypokinetic and hyperkinetic pulse are listed in Table 7.9. Various types of pulse quality and its causes are mentioned in Table 7.10.
  - **Grading of pulse:** Palpation of pulse is done by the fingertips and intensity of the pulse is graded from 0 to 4 +. 0 = pulse not palpable; 1

+ = faint, but detectable pulse; 2 + = slightly more diminished pulse than normal; 3 + = normal pulse; and 4 + = bounding pulse.

**Table 7.9:** Causes of hypokinetic and hyperkinetic pulse.

<i>Hypokinetic pulse</i>	<i>Hyperkinetic/bounding pulse</i>
<ul style="list-style-type: none"> <li>• Congestive cardiac failure</li> <li>• Hypovolemia</li> <li>• Shock</li> <li>• Mitral stenosis</li> <li>• Aortic stenosis</li> <li>• Constrictive pericarditis</li> </ul>	<p><b>Physiological</b></p> <ul style="list-style-type: none"> <li>• Fever, pregnancy, alcoholism, exercise</li> </ul> <p><b>Pathological</b></p> <ul style="list-style-type: none"> <li>• <b>High output states:</b> Anemia, cor pulmonale, cirrhosis liver, beriberi, thyrotoxicosis, AV fistula, Paget's disease</li> <li>• <b>Cardiac cause:</b> Aortic regurgitation, bradycardia, complete heart block, PDA, systolic HTN, rupture of sinus Valsava into heart chamber, aortopulmonary window</li> </ul>

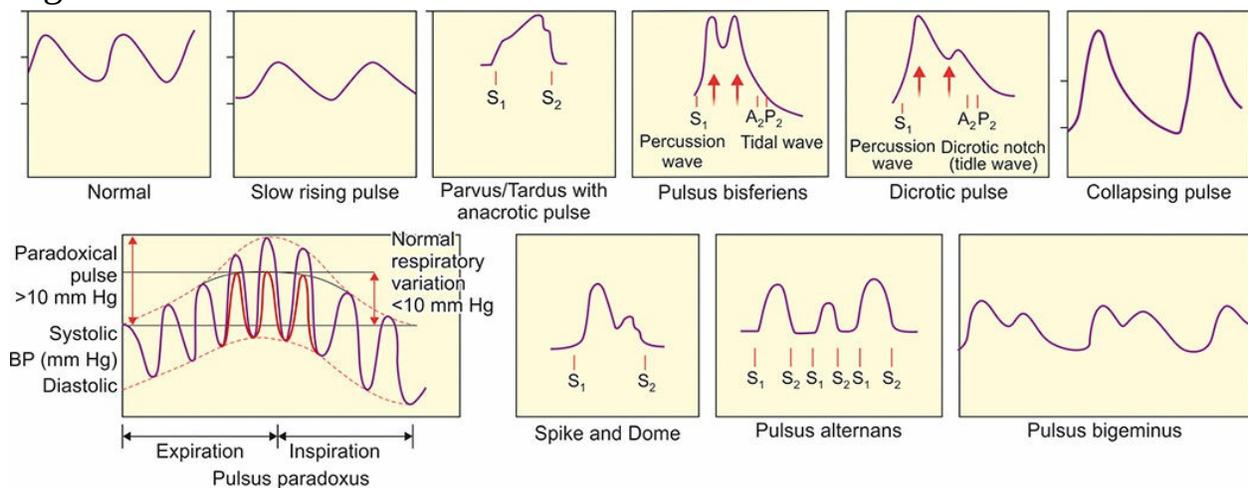

**Q. Write short note on: (1) Corrigan's/water hammer/collapsing pulse and its causes, (2) pulsus paradoxus and its causes and (3) pulsus alterans.**

**Table 7.10:** Various types of pulse quality and its causes.

<i>Types</i>	<i>Wave forms</i>	<i>Causes</i>
Catacrotic pulse	Percussion(p)—ejection of blood Tidal(t) Dicrotic—elastic recoil of vessel (reflected waves)	Normal
Pulsus parvus et tardus	A low amplitude (parvus) with a slow rising and late peak (tardus)	Severe aortic stenosis (AS)
Anacrotic pulse	Single peak low volume	Severe aortic stenosis
Pulsus bisferiens: Single pulse wave with two peaks in systole	Rapid rising, twice beating and both waves felt in systole	Severe aortic regurgitation (AR), moderate AR +AS, hypertrophic obstructive cardiomyopathy (HOCM)
Pulsus dicroticus	Twice beating. First wave in systole, second wave in diastole. Seen when pulse rate and diastolic pressure is low	Typhoid fever, severe left ventricular failure (LVF), dehydration, dilated cardiomyopathy endotoxic shock
Watson's water hammer pulse or collapsing pulse	High (large) volume pulse, sharp rise (systolic pressure is high), ill-sustained, sharp fall (diastolic	Aortic regurgitation, patent ductus arteriosus (PDA), AP window, rupture of sinus

	pressure is low), pulse pressure is at least 60 mm Hg	Valsalva, arteriovenous fistula, hyperdynamic circulation states
Pulsus paradoxus: Exaggerated reduction in the strength of pulse during normal respiration	Systolic blood pressure falls more than 10 mm Hg during inspiration (exaggeration of normal phenomenon)	Constrictive pericarditis, acute severe asthma/COPD, cardiac tamponade, tension pneumothorax, massive pulmonary embolism
Absent pulsus paradoxus in an expected disease		ASD, VSD, AR, pericardial adhesions
Reverse pulsus paradoxus		Positive pressure ventilation, HOCM (hypertrophic obstructive cardiomyopathy)
Pseudo-pulsus paradoxus		Complete heart block with AV dissociation
Jerky pulse—Spike and dome		HOCM
Pulsus alternans	Alternating weaker and stronger volume pulses in regular rhythm, doubling rate of Korotkoff sound on lowering cuff pressures	Left ventricular failure
Plateau pulse		Severe AS
Pulsus bigeminus	Pulse wave with normal beat followed by a premature beat and a compensatory pause, occurring in rapid succession, resulting in alteration of the strength of pulse.	Digoxin toxicity
Sinus arrhythmia	Increase pulse rate with inspiration and decrease with expiration	Absent sinus arrhythmia in CCF and autonomic neuropathy

Diagrammatic appearances of various arterial waveforms are presented in Figure 7.3.

**Fig. 7.3:** Diagrammatic appearances of various arterial waveforms. A<sub>2</sub>, aortic component of the second heart sound; P<sub>2</sub>, pulmonary component of the second heart sound; S<sub>1</sub> first heart sound.

- **Radiofemoral delay**

- A delayed femoral pulsation compared to right radial pulse occurs in coarctation of aorta.
- Demonstrated by simultaneous palpation of right radial artery and one femoral artery.
  - ◆ **Apico-carotid** delay is seen in severe aortic stenosis where there is a delay between apical impulse and the carotid upstroke.

- **Reduced or absent arterial pulses**

- It indicates impaired blood flow.
- Causes: (1) congenital (e.g. coarctation of the aorta), (2) intrinsic disease of artery (e.g. atherosclerosis, thrombosis, arteritis), (3) disorders with vasospasm (e.g. Raynaud's phenomenon), (4) extrinsic compression of blood vessel (e.g. thoracic outlet syndrome, trauma, neoplasms).

## Jugular Venous Pressure

**Q.** Write short essay/note on jugular venous pulse (JVP) and its clinical significance.

**Definition:** Jugular venous pulse (JVP) is defined as the **oscillating top of undulating vertical column of blood in the right internal jugular vein that faithfully reflects the pressure and volumetric changes in the right atrium that varies with all phases of cardiac cycle and respiration.** Jugular venous pressure (JVP) is the vertical height of oscillating column of blood.

### ***Advantages of Internal Jugular Vein (IJV) vs External Jugular Vein (EJV)***

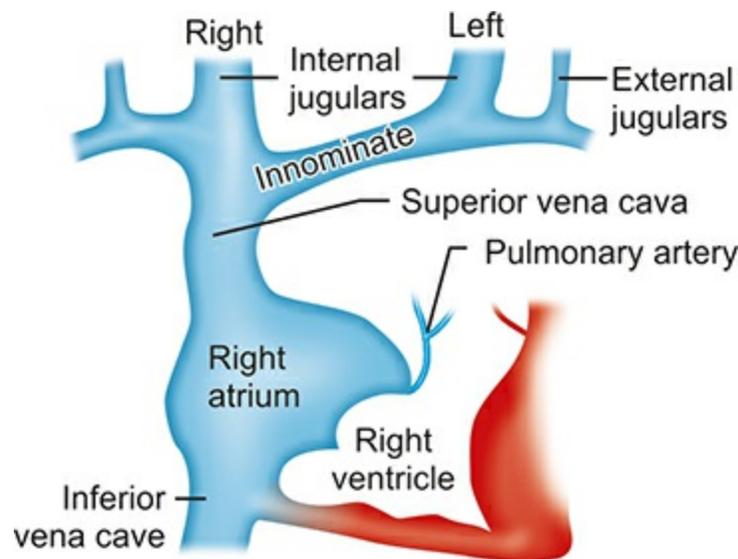

- IJV is **anatomically** (Fig. 7.4) **closer** to and has a **direct course to right atrium** while EJV does not directly drain into superior vena cava.
- IJV is valveless and pulsations can be seen. EJV has valves and pulsations cannot be seen.
- EJV can become small and barely visible when there is vasoconstriction

secondary to hypotension (as in congestive heart failure).

- EJV is superficial and prone to kinking.

### ***Importance of Right Internal Jugular Vein***

- Right internal jugular veins extend in an almost straight line to superior vena cava, thus favoring transmission of the hemodynamic changes from the right atrium.
- The left innominate vein is not in a straight line and may be kinked or compressed between aortic arch and sternum, by a dilated aorta, or by an aneurysm.

**Fig. 7.4:** Diagrammatic appearance of anatomic relations of jugular veins and right atrium.

### ***Technique of Measuring JVP***

- **Position:** Semi-reclining position with 45° angle between the trunk (not the neck) and the bed turn the head slightly towards left shoulder, so that the neck muscles are relaxed (Fig. 7.5). Tangential light source can be put from opposite side.
  - **Not in sitting position:** Because the upper level of venous column is below the clavicle.
  - **Not in supine position:** Because the whole venous column moves beyond the angle of jaw into the intracranial cavity.
- **Identify jugular venous pulsation**
  - Assure good lighting (can use tangential beam of light through torch).

- Look between the two heads of sternocleidomastoid.
- Note the upper level of pulsation, waveform and respiratory variation.
- Do not mistake the carotid pulsations for venous pulsations (Table 7.11).

**Q. Write short essay/note on differentiation of jugular venous pulse from carotid pulse.**

**Table 7.11: Differences between jugular venous pulsations and carotid pulsations.**

<i>Jugular vein</i>	<i>Carotid artery</i>
• Pulsations not palpable	• Pulsations palpable
• Pulsations obliterated by pressure above the clavicle.	• Pulsations not obliterated by pressure above the clavicle
• Pulse wave level of reduced during inspiration and increased on expiration	• No effects of respiration on pulse
• Usually two pulsations per systole (x and y descents)	• One pulsation per systole
• Prominent descents	• Descents not prominent
• Pulsations more prominent with abdominal pressure	• No effect of abdominal pressure on pulsations
• Changes with position	• No change with position
• More lateral in position in the neck	• Medial in the neck
• Has a definite upper level	• No upper level
• More superficial	• Deeper in location
• Wavy and undulant	• Brisk and jerky
• Descents are more prominent	• Only positive waves

- **Measurement of JVP:** Measure the vertical distance (in cm) between the horizontal lines drawn from the upper level of venous pulsation and the sternal angle.
  - This can be done by using two rulers—one placed horizontal to the upper level of pulsation and another taking the vertical distance of that ruler from the sternal angle.

**Q. Method of calculation of central venous pressure from jugular**

**venous pressure.**

- **Calculate the right atrial pressure (RAP) or central venous pressure (CVP)**
  - Normally, the center of right atrium is 5 cm below the sternal angle at any position of the patient. Hence, 5 cm is added to the above value to obtain the right atrial pressure.
  - Conversion: 1.3 cm of H<sub>2</sub>O or blood = 1 mm Hg

**Evaluation/Interpretation of JVP (Box 7.4)**

**Box 7.4:** Evaluation of jugular venous pulse (JVP).

(1) Level, (2) waveform, (3) venous hum, (4) respiratory variation in level and wave pattern, (5) abdomino-jugular reflux, and (6) liver size and pulsations.

*Level*

- Normal level of JVP: **(1) From sternal angle <4 cm, (2) from center of right atrium <9 cm. In mm Hg <7 mm Hg.**
- Causes of elevated and lowered JVP (Table 7.12).

**Table 7.12:** Causes of raised and lowered JVP.

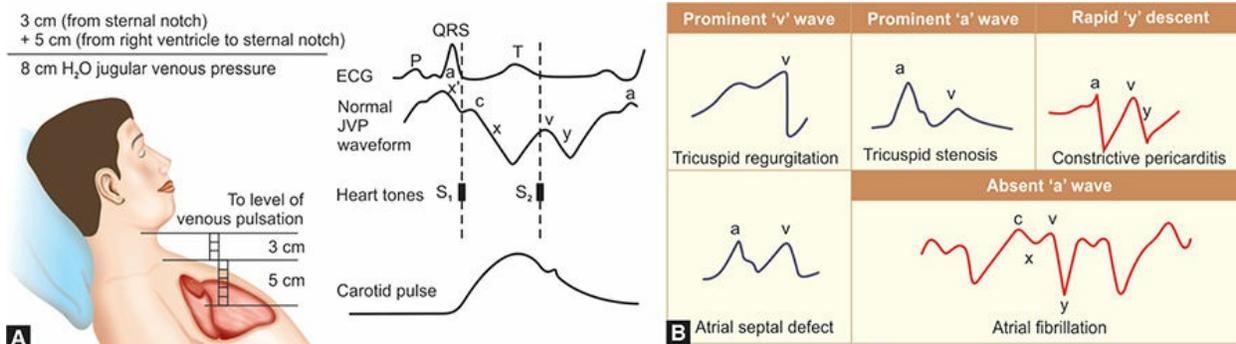

**Causes of elevated JVP (jugular venous distension)**

- |   |  |
|---|--|
| <ul style="list-style-type: none"><li>• Right ventricular failure</li><li>• Pericardial compression (constriction/tamponade): little or no pulsations when severe</li><li>• Tricuspid stenosis</li><li>• Superior vena cava (SVC) obstruction—no pulsations</li></ul> | <ul style="list-style-type: none"><li>• Circulatory overload</li><li>• Renal failure</li><li>• Excessive fluid administration</li><li>• Atrial septal defect with mitral valve disease</li></ul> |
|---|--|

**Causes of lowered JVP:** Dehydration, hypovolemia

**Q. Write short essay/note on normal wave patterns of JVP and their variations.**

*Wave pattern (Figs. 7.5A and B)*

**Figs. 7.5A and B:** (A) Wave patterns in jugular venous pressure (JVP); (B) Abnormalities of JVP.

- The normal JVP consists of three ascents or positive waves (a, c and v) and two descents or negative waves (x, x' and y):
  - **a wave (ascent):** Due to active atrial contraction leading to retrograde blood flow into neck veins.
  - **x wave (descent):** Due to continued atrial relaxation.
  - **c wave:** Due to impact of the carotid artery adjacent to the jugular vein and retrograde transmission of a positive wave in the right atrium. It is produced by the right ventricular systole and the bulging of the tricuspid valve into the right atrium. Not usually seen in humans.
  - **x' wave (descent):** Due to descent of floor of right atrium (tricuspid valve) during right ventricular systole and continued atrial relaxation.
  - **v wave (ascent):** Due to passive atrial filling (venous filling).
  - **y wave (descent):** Due to opening of tricuspid valve and subsequent rapid inflow of blood from right atrium into the right ventricle leading to a sudden fall in right atrial pressure.

Wave patterns in jugular venous pressure are presented in Figure 7.5.

Best way to identify the waves (ascents and descents): Simultaneously auscultate and observe the wave pattern.

- **'a' ascent:** Clinically corresponds to S<sub>1</sub> (though it actually occurs before S<sub>1</sub>); sharper and more prominent than 'v' wave.
- **'x' descent:** Follows S<sub>1</sub>; less prominent than 'y' descent.
- **'c' ascent:** Occurs simultaneously with carotid pulse; but never seen normally.
- **'v' ascent:** Coincides with S<sub>2</sub>; less prominent than 'a' ascent.
- **'y' descent:** Follows S<sub>2</sub>; more prominent than 'x' ascent.

**Note: h wave** —between the bottom of 'y' descent and beginning of 'a' ascent, during the period of diastasis (relatively slow ventricular filling).

Patient with prominent jugular veins is depicted in Figure 7.6.

*Abnormalities of wave patterns of JVP*

**Fig. 7.6:** Prominent jugular veins.

- **Prominent ‘a’ waves (giant a-wave or Venous Corrigan):** Due to resistance to atrial emptying at:
  - **Tricuspid level:** Tricuspid stenosis, right atrial tumors.
  - **Right ventricular level:** Concentric hypertrophy due to severe pulmonary hypertension, right ventricular cardiomyopathy, severe aortic stenosis, acute pulmonary embolism, acute tricuspid regurgitation.
- **Cannon waves:** Very prominent ‘a’ waves due to atrial contraction against closed tricuspid valve.
  - **Regular cannon waves:** Junctional rhythm, ventricular tachycardia 1:1 retrograde conduction, isorhythmic AV dissociation.
  - **Irregular cannon waves:** Complete heart block, ventricular tachycardia, ventricular ectopy, ventricular pacing, and classic AV dissociation.
- Rapid and regular neck pulsations, which are due to prominent and regular A waves, may be seen as a bulging in the neck, sometimes termed as **“frog sign”** and is most typical of re-entrant supraventricular arrhythmias, particularly AVNRT or atrioventricular re-entrant tachycardia due to a pre-excitation syndrome.
- **Absent ‘a’ waves:** Atrial fibrillation (AF), post DC conversion of AF, sinoventricular conduction in hyperkalemia.
- **Single wave**
  - **‘a’ and ‘v’ wave merge:** Heart rate >120/min
  - **Early ‘v’ wave with obliterated ‘x’ wave:** Severe chronic tricuspid regurgitation, acute

tricuspid regurgitation

- **Absent 'x' wave** (failure of atrial pressure to fall): Atrial fibrillation, severe chronic tricuspid regurgitation, acute tricuspid regurgitation, constrictive pericarditis.
- **Prominent 'x' wave:** Cardiac tamponade.
- **Prominent 'v' wave:** Right ventricular failure, tricuspid regurgitation, atrial septal defect with or without mitral regurgitation.
- **Diminished 'v' wave:** Hypovolemia, venodilators.
- **Rapid 'y' descent:** Causes of prominent 'v' wave, constrictive pericarditis (Friedrich's sign).
- **Slow 'y' descent:** Tricuspid stenosis, pericardial tamponade, tension pneumothorax.
- **c-v wave with prominent "y" descent:** Tricuspid regurgitation (lateral ear lobe pulsations—Lancisi's sign).
- **Steeply rising "h" wave:** Restrictive cardiomyopathy, constrictive pericarditis, right ventricular infarction.
- **Equal 'a' and 'v' wave ( M Pattern):** Atrial septal defect.

### **Venous hum (Pontain's murmur)**

- Continuous bruit over neck veins (normally noiseless) due to increased velocity of blood flow or decreased viscosity of blood.
- Best heard with the bell of the stethoscope over the right supraclavicular fossa/root of neck, patient in standing position.
- Causes:
  - **Physiological:** Children, pregnancy
  - **Pathological:** Hyperkinetic states, anemia (indicates **chronic compensated severe anemia**), thyrotoxicosis, beriberi, intracranial AV fistula. Indicates chronic compensated severe anemia.

### *Respiratory variation of JVP*

- Normal: Venous column in IJV rises during expiration and falls during inspiration.
- **Reason:**
  - During inspiration venous return to the right side of the heart increases due to increased negative thoracic pressure. However, this is accommodated by the inspiratory decrease in pulmonary vascular resistance. As a result, pulmonary artery, right ventricle and right atrial pressures fall in spite of increased venous return.
  - During expiration, due to increased positive intrathoracic pressure, pulmonary circulation is compressed by the thoracic cage resulting in increased pulmonary resistance and pressure.

### *Kussmaul's sign*

**Q. Write short essay/note on Kussmaul's sign.**

- Normally, during inspiration there will be decrease in the height of jugular venous pulsation and drop in jugular venous pressure (respirophasic changes).
- Kussmaul's sign is paradoxical rise in JVP during inspiration.
- **Causes:** Constrictive pericarditis, right ventricular infarction, restrictive cardiomyopathy, severe right-sided heart failure, acute severe asthma. Rarely can be seen in cardiac tamponade, tricuspid stenosis, severe tricuspid regurgitation.
- **Reason:** Increased venous return in inspiration cannot be accommodated by the heart in the above-mentioned conditions leading to a translation of the venous blood back through the SVC and presents as distended jugular veins even during inspiration.

### **Abdominojugular/hepatojugular reflux**

**Q. Write a short note on abdominojugular/hepatojugular reflux test and its clinical significance.**

- **Technique:** When pressure is applied over the liver by pressing firmly (40 mm Hg) over the abdomen for around 30 seconds, the venous pressure gets exaggerated initially due to increased venous return. Later the myocardium accommodates the extravenuous return and the level falls. Normally within 2–3 cardiac cycles, i.e. within 3 seconds.
- **Normal response:** Upper level of jugular venous pulsation moves upwards by less than 3 cm and then falls down within 5 seconds even when the pressure is continued.

#### *Significance*

- **Positive test:** Rise in JVP (more than 3 cm) for >10 seconds of firm mid-abdominal compression.
  - **Early cardiac failure:** First sign of right heart failure (RHF).
  - **False positive:** Valsalva (abdominal guarding), fluid overload
- **False negative:** SVC/IVC obstruction, Budd Chiari syndrome where there is no rise in JVP.

This test also helps to differentiate venous pulsation from the arterial pulsation.

## Square root sign

Found in constrictive pericarditis on **cardiac catheterization** to note pressure tracings. A rapid halt of ventricular filling occurs as the ventricular wall is impeded by the abnormal pericardium causing an abrupt rise in LV pressure (Fig. 7.7). This has been described as the square root sign.

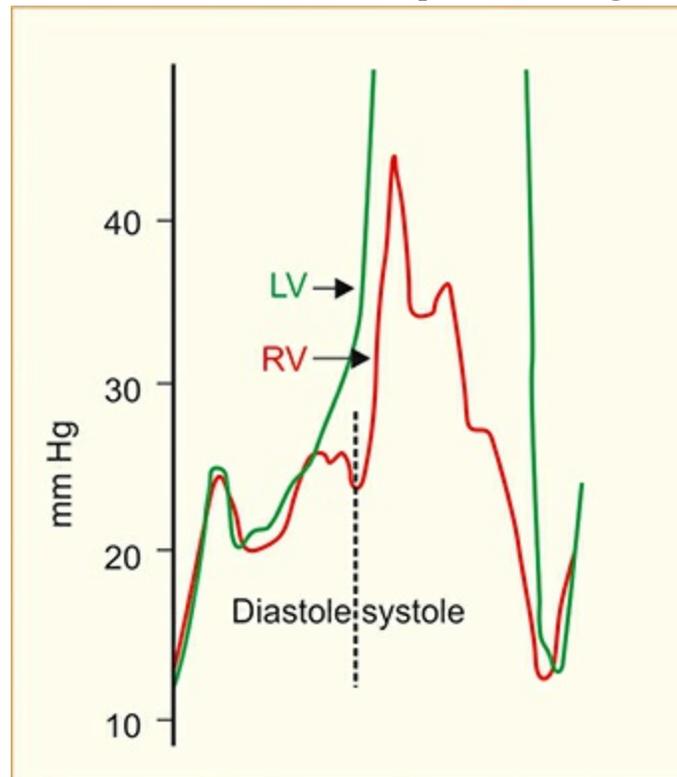

Fig. 7.7: Ventricular pressure curve in constrictive pericarditis.

## APICAL IMPULSE

**Q.** Write a short note on apical impulse.

**Definition:** It is the outermost and lowermost point of maximum impulse (PMI) in early systole, which imparts a perpendicular gentle thrust to a palpating finger, followed by a slight medial retraction in the late systole.

**Cause of normal apical impulse:** Anterior and counter clock-wise rotation of LV due to isovolumic contraction during early systole and medial retraction due to clock-wise rotation of the LV during late systole.

Characteristics of normal apical impulse are listed in Box 7.5.

**Box 7.5:** Characteristics of normal apical impulse.

---

- **Location:** Left 5th ICS at or around half an inch medial to mid-clavicular line and <10 cm from mid-sternal line.
- **Extent:** <2.5 cm in diameter which is one ICS.
- **Duration:** <50% of systole.
- Mildly tapping in character.

## Abnormal Apical Impulse

- **Absent:** Dilated cardiomyopathy, pericardial effusion, behind the rib, dextrocardia, obesity, COPD, left pleural effusion
- **Tapping:** Mitral stenosis (palpable S<sub>1</sub>—closing snap)
- **Hyperdynamic:** Increased in amplitude, duration is >1/3 to <2/3 of systole, occupies more than one intercostal space. Occurs in LV volume overload [AR (aortic regurgitation), MR (mitral regurgitation), VSD (ventricular septal defect), PDA (patent ductus arteriosus), high output states]
- **Heaving:** Increase in amplitude, duration is >2/3 of systole and occupies more than one intercostal space. Occurs in LV pressure overload [AS (aortic stenosis), HTN (hypertension), coarctation of aorta]
- **Diffuse:** Occupying more than 1 ICS. Occurs in LV aneurysm, LV dilatation as in AR
- **Double:** Hypertrophic obstructive cardiomyopathy (HOCM), AS with AR, left dyssynergy (LBBB), LV aneurysm
- **Triple or quadruple:** HOCM
- **Retractile:** Severe TR (tricuspid regurgitation).
- **Medial apical retraction:** Left ventricular enlargement
- **Lateral apical retraction:** Right ventricular enlargement.

## Cheyne-Stokes Breathing

**Q. Write short essay on mechanism, causes, consequences and management of Cheyne-Stokes breathing.**

**Definition:** This is a cyclical pattern of respiration due to impaired responsiveness of the respiratory center to carbon dioxide. It is characterized by gradual increases and decreases in respiration. It has two alternative periods namely (1) rapid deep respiration called hyperpnea and (2) complete stoppage of respiration called apnea.

### ***Mechanism (Fig. 7.8)***

- Spontaneous rhythmic activity of breathing is abolished when there is anoxemia. Consequent apnea causes accumulation of carbon dioxide.
- Hypercapnia stimulates respiratory centers → produces hyperventilation → leads to reduced carbon dioxide → causes depression of the respiratory center → resulting in apnea. The cycle is repeated.

**Fig. 7.8:** Cheyne-Stokes breathing and levels of carbon dioxide (CO<sub>2</sub>).

### ***Conditions Associated with Cheyne-Stokes Breathing***

- **Physiological conditions:** During deep sleep, high altitude, newborn babies
- **Pathological conditions:** Severe heart (left ventricular) failure, uremia, chronic hypoxia, diffuse cerebral atherosclerosis, stroke, head injury and hemorrhage, increased intracranial pressure, severe pneumonia, narcotic drug (e.g. barbiturates, opiates) poisoning.

## **HEART SOUNDS**

Relative, brief, auditory vibrations of variable intensity, frequency and quality.

### **First Heart Sound (S<sub>1</sub>)**

**Q. What is the mechanism of first heart sound? Write short note on the variations in first heart sound.**

#### ***Mechanism***

During systole the atrioventricular (AV), i.e. mitral and tricuspid valves closes and blood tries to enter the atrium and lead to back bulging of the AV valves into the respective atria. But the taut (stretched or pulled tight) chordate tendinae stop the back bulging and causes the blood to flow forward. This will cause vibration of the valves, blood and the walls of the ventricles.

#### ***Timing***

- Just precedes carotid upstroke.
- S<sub>1</sub> will appear to initiate the outward LV thrust of apex beat.

## Characteristics

- Medium to high frequency but lower pitch than  $S_2$
- Q- $M_1$  60 ms, Q- $T_1$  90 ms,  $M_1$ - $T_1$  30 ms.
- First heart sound has two components: (1) Mitral component ( $M_1$ ) due to mitral valve closure followed by (2) tricuspid component ( $T_1$ ) due to tricuspid valve closure.
- $S_1$  is best heard at the apex. It is best heard with the diaphragm of stethoscope.

## Intensity

Determined by structural integrity of mitral valve, **position of AV valves at time of ventricular contraction**, integrity of isovolumetric systole, heart rate, P-R interval, myocardial contractility.

## Abnormalities of $S_1$

Table 7.13 lists the causes of variations in the intensity of first heart sound.

**Table 7.13:** Causes of variations in the intensity of first heart sound.

Loud first heart sound ( $S_1$ )	Soft first heart sound ( $S_1$ )
<ul style="list-style-type: none"> <li>• Mitral stenosis (mild to moderate)</li> <li>• Tachycardia</li> <li>• Hyperdynamic circulation: Exercise, anemia, fever, thyrotoxicosis, Paget's disease, pregnancy, beriberi, increased cardiac output</li> <li>• Short P-R interval</li> <li>• Left atrial myxoma</li> <li>• Tricuspid stenosis</li> <li>• Thin people</li> </ul>	<ul style="list-style-type: none"> <li>• Mitral or tricuspid regurgitation</li> <li>• Obesity</li> <li>• Emphysema</li> <li>• Pericardial effusion</li> <li>• Severe calcified mitral stenosis</li> <li>• Left ventricular failure</li> <li>• Shock</li> <li>• Bradycardia</li> <li>• First degree block</li> <li>• Long P-R interval</li> </ul>

- **Variation in the intensity of first heart sound:** Atrial fibrillation, complete heart block (CHB), ventricular tachycardia, atrial flutter with varying block, atrial tachycardia with varying block, ventricular ectopics.
- **Splitting of  $S_1$ :** Abnormalities in splitting of first heart sound are presented in Table 7.14.

**Table 7.14: Abnormalities in splitting of first heart sound.**

<i>Wide splitting of first heart sound</i>	<i>Reversed splitting of first heart sound</i>
<ul style="list-style-type: none"><li>• Ebstein's anomaly T1 delayed</li><li>• Atrial septal defect (ASD)</li><li>• Complete right bundle branch block (RBBB)</li><li>• Left ventricular pacing</li></ul>	<ul style="list-style-type: none"><li>• Complete left bundle branch block</li><li>• Severe mitral stenosis</li><li>• Myxoma of left atrium</li><li>• Right ventricular pacing</li><li>• Ectopic beats from right ventricle</li></ul>

## Second Heart Sound (S<sub>2</sub>)

**Q. What is the mechanism of second heart sound? Write short note on the variations in second heart sound.**

It is due to the closure of aortic and pulmonary valve.

### *Characteristics*

- It has two components: (1) aortic component (A<sub>2</sub>) due to aortic valve closure, followed by the (2) pulmonary component (P<sub>2</sub>) due to pulmonary valve closure.
- Loudness of A<sub>2</sub> or P<sub>2</sub> is directly proportional to the pressures in aorta or pulmonary artery at the beginning of diastole respectively.
- The 2nd heart sound is **medium to high pitched** (higher frequency) because:
  - The semilunar valves are more taut
  - The great elastic coefficient of the taut arteries provide the principle vibrations of the 2nd heart sound.
- P<sub>2</sub> only heard at second left intercostal space. *Loudest sound in pulmonary area is A<sub>2</sub>.*
- A<sub>2</sub> is audible at region of right second intercostal space, left parasternal space and apex.
- Normal splitting
  - **Splitting during inspiration:** During inspiration, the aortic valve closes early than pulmonary valve and produces a physiological **inspiratory splitting of second heart sound**. Split is audible in second and third intercostal space and amplitude of A<sub>2</sub> > P<sub>2</sub>.

- Normally, during expiration both aortic and pulmonary valves close almost simultaneously and produce a **single expiratory second heart sound**.
- Frequency of both  $A_2$  and  $P_2$  components are same.

Hangout time/interval: The interval between the pressure crossover point and the incisura (the onset of  $A_2$  or  $P_2$ ) has been termed “hangout time”. During inspiration, pulmonary vascular impedance declines with a further increase in the pulmonary hangout time, which is the mechanism for inspiratory splitting of  $S_2$ .

### ***Abnormalities of Second Heart Sound ( $S_2$ )***

- **Absent  $S_2$ :** Old age as in calcific aortic stenosis (due to absence of  $A_2$ ) or chronic emphysema.
- **Single second heart sound ( $S_2$ ):** May be either due to absent  $A_2$  (e.g. severe aortic stenosis or atresia) or absent  $P_2$  (e.g. severe pulmonary stenosis or atresia) and tetralogy of Fallot.
- **Variation in the intensity  $S_2$  (Table 7.15).**

**Table 7.15: Variations in the intensity of second heart sound.**

#### ***Aortic component ( $A_2$ )***

- **Loud  $A_2$ :** Essential hypertension, hyperhemodynamic circulatory states, syphilitic aortic regurgitation, aortic aneurysm
- **Soft  $A_2$ :** Aortic stenosis and regurgitation

#### ***Pulmonary component ( $P_2$ )***

<b>Causes of loud <math>P_2</math></b>	<b>Diminished (soft) <math>P_2</math></b>	<b>Absent <math>P_2</math></b>
<ul style="list-style-type: none"> <li>• Normal in infants and children</li> <li>• Adults with chest deformity or thin chests</li> <li>• Pulmonary arterial hypertension</li> <li>• Left to right shunts</li> <li>• Hyperkinetic circulatory states</li> </ul>	<ul style="list-style-type: none"> <li>• Normal in elderly</li> <li>• Thick chested adults</li> <li>• Pulmonary stenosis</li> <li>• Dysplastic valve</li> </ul>	<ul style="list-style-type: none"> <li>• Tetralogy of Fallot</li> <li>• Transposition of great arteries</li> <li>• Truncus arteriosus</li> <li>• Pulmonary atresia</li> <li>• Absent pulmonary valve</li> </ul>

- **Splitting of S<sub>2</sub>:** Physiological splitting of S<sub>2</sub> is normally found in children and young adults during inspiration. Normal interval is A<sub>2</sub>-P<sub>2</sub> 30 ms and A<sub>2</sub>-OS 30–150 ms.
- **Wide split S<sub>2</sub>:** It may be variable or fixed (Table 7.16).

**Table 7.16:** Causes of wide split of second heart sound.

<i>Wide split S<sub>2</sub></i>		<i>Wide fixed split</i>
<ul style="list-style-type: none"> <li>• <b>Due to early A<sub>2</sub></b> <ul style="list-style-type: none"> <li>– Mitral regurgitation</li> <li>– Ventricular septal defect</li> <li>– Constrictive pericarditis</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>Due to late P<sub>2</sub></b> <ul style="list-style-type: none"> <li>– Right bundle branch block</li> <li>– Ectopic from left ventricle</li> <li>– Left ventricular pacemakers</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Atrial septal defect</li> <li>• Severe right ventricular failure</li> <li>• Massive acute pulmonary embolism</li> </ul>

- **ASD with variable split S<sub>2</sub>:** Sinus venosus type of ASD or ASD with atrial fibrillation.
- **Reversed (paradoxical) splitting S<sub>2</sub>:** May be due to early P<sub>2</sub> or delayed A<sub>2</sub> (Table 7.17).

**Table 7.17:** Causes of reversed or paradoxical split.

<i>Early P<sub>2</sub></i>	<i>Delayed A<sub>2</sub></i>	
<ul style="list-style-type: none"> <li>• Left bundle branch block</li> <li>• Right ventricular pacing</li> <li>• PVCs of right ventricular origin</li> <li>• Wolff-Parkinson-White (WPW) syndrome (type B)</li> </ul>	<ul style="list-style-type: none"> <li>• Severe aortic stenosis</li> <li>• Severe systemic hypertension</li> <li>• Acute myocardial infarction</li> <li>• Hypertrophic cardiomyopathy</li> </ul>	<ul style="list-style-type: none"> <li>• Severe aortic regurgitation</li> <li>• Large patent ductus arteriosus</li> <li>• Aneurysm of ascending aorta</li> <li>• Post-stenotic dilatation in aortic stenosis</li> </ul>

- **Pseudo-paradoxical split:** Normally S<sub>2</sub> split in expiration and inspiration. But during inspiration patients with muffled P<sub>2</sub>, so that single S<sub>2</sub> will be heard in inspiration.
- **Narrow splitting:** Ageing, artifactual muffling of P<sub>2</sub>, severe pulmonary arterial hypertension and murmur obscuration.

### Third Heart Sound

**Q. Write short note on the significance of third heart sound.**

- Third heart sound ( $S_3$ ) is also called as **protodiastolic sound**/ventricular gallop.
- $S_3$  is a low-pitched early diastolic sound produced due to rapid ventricular filling immediately after opening of the atrioventricular valves.
- $S_3$  best heard with the bell of stethoscope at the apex. It coincides with rapid ventricular filling. It occurs 0.12–0.18 seconds after  $S_2$  and has low frequency and low intensity.

***Causes of Third Heart Sound (Table 7.18)***

- A third heart sound is a normal finding in children, in young adults and during pregnancy.
- A third heart sound is usually pathological after the age of 40 years. In heart failure  $S_3$  occurs with a tachycardia and  $S_1$  and  $S_2$  are quiet (lub-da-dub).

**Table 7.18:** Causes of third heart sound.

**Physiological  $S_2$ :** Children, young adults under 40 years, athletes, pregnancy

**Pathological**

- **Hyperdynamic/high output states:** AV fistula, thyrotoxicosis
- **Left-sided  $S_2$**  (arising from the left ventricle): Left ventricular failure (most common cause), aortic regurgitation, mitral regurgitation, ischemic heart disease, hypertrophic cardiomyopathy
- **Right-sided  $S_2$**  (arising from right ventricle): Right ventricular failure, tricuspid regurgitation, pulmonary hypertension

**Fourth Heart Sound**

**Q. Write short note on significance of fourth heart sound.**

- Fourth heart sound ( $S_4$ ) is less common and is also called **presystolic/atrial gallop**. It occurs just before the first sound (da-lub-dub). It occurs 0.11 seconds prior to  $S_1$ .
- It is soft and low-pitched, best heard with the bell of the stethoscope at the apex.
- It is always pathological and is produced by a rapid (forceful) emptying of

the atrium into the non-compliant or stiff ventricle. It cannot occur when there is atrial fibrillation.

- Third and a fourth heart sound causes a ‘triple’ or ‘gallop’ rhythm.  $S_4$  may be confused with split  $S_4$ . Firm pressure by the diaphragm of stethoscope eliminates  $S_4$  but not split  $S_1$ .

## ***Causes of Fourth Heart Sound (Box 7.6)***

**Box 7.6:** Causes of fourth heart sound.

### **Left sided $S_4$**

- Systemic hypertension with left ventricular hypertrophy
- Hypertrophic cardiomyopathy
- Ischemic heart disease (especially acute myocardial infarction)
- Acute mitral regurgitation
- Anemia, thyrotoxicosis and AV fistula

### **Right sided $S_4$**

- Right ventricular hypertrophy due to pulmonary hypertension, pulmonary stenosis

## *Summation gallop*

### **Q. Write short note on summation gallop.**

- Summation is the presence of  $S_1$ ,  $S_2$  merging with  $S_3$  and  $S_4$ . It occurs when both  $S_3$  and  $S_4$  are present in a patient with tachycardia.
- Shortening of diastole causes joining of the two sounds ( $S_3$  and  $S_4$ ) and produce a single loud sound.

## **Pericardial Friction Rub**

### **Q. Write short note on pericardial rub.**

- It is the sound produced due to sliding (apposition) of the two inflamed layers (visceral and parietal pericardium) of the pericardium.
- **Phases:** It is triphasic (1) mid-systolic, (2) mid-diastolic and (3) pre-systolic.
- **Character:** It is scratchy, grating, leathery or creaking in character. Its intensity vary over time, and with the position of the patient.
- **Best heard:** With diaphragm of stethoscope on the left sternal boarder (3rd and 4th space) leaning over at the end of expiration. It may be audible

over any part of the precordium but is often localized.

- Confused with Hamman's sign in post-open heart surgery (crunch sound from mediastinal air).
- A pleuropericardial rub is a similar sound that occurs in time with the cardiac cycle but is also influenced by respiration and is pleural in origin. Occasionally a 'crunching' noise can be heard caused by air in the pericardium (pneumopericardium).

## Cardiac Sounds on Auscultation

**Q. Write short note on other cardiac sounds on auscultation.**

**Ejection sound/click:** Usually sharp, high frequency sound audible immediately after  $S_1$ . Its causes are listed in Box 7.7.

**Box 7.7:** Causes of ejection sound/click.

- **Aortic valve:** Aortic stenosis, bicuspid aortic valve
- **Pulmonary valve:** Pulmonic stenosis, vary with respirations
- **Prosthetic valves:** Mechanical, not bioprosthetic

## Mid-Late Systolic Sounds

- Click, high frequency sound found in mitral valve prolapse.
- Occurs earlier with Valsalva maneuver or squatting to standing.

## Early Diastolic Sounds

**Q. Write short note on opening snap.**

### Opening snap of mitral stenosis (MS)

- It is caused by the opening of atrioventricular valve.
- **Characteristics:** High pitched sound audible at the apex in left lateral decubitus position. 0.04–0.12 sec after  $A_2$  ( $S_3$  occurs 0.12 sec after  $A_2$ ). Occurs after  $S_2$ , before  $S_3$ .
- Severe mitral stenosis is associated with short  $A_2$ -OS interval and softer OS or absent OS.

### Mechanism of opening snap (OS)

- Stenotic anterior mitral valve leaflet suddenly bulging downward into the

left ventricular cavity like a dome, with a snapping sound when the mitral valve is rapidly opened during diastole. So, OS is audible only if anterior mitral leaflet of mitral valve is mobile.

- OS occurs when movement of AMV suddenly stops, at point when LVP drops below that of LAP.

Differences between opening snap second and third heart sound are listed in Table 7.19.

**Table 7.19:** Differences between opening snap second and third heart sound.

	<i>Opening snap (OS)</i>	<i>S<sub>2</sub> (second heart sound)</i>	<i>S<sub>3</sub> (third heart sound)</i>
Area	Just inside apex/entire chest wall	2nd and 3rd left intercostal space	Only apex
Relation to posture	A <sub>2</sub> -OS interval widens on standing	A <sub>2</sub> -P <sub>2</sub> interval narrows on standing	Disappear of sitting
Intensity on standing	Remain same/intensified	Decreases	-
Relation to respiration	A <sub>2</sub> -OS interval constant throughout respiration	Split increase on respiration	None
Intensity on respiration	Same	-	RVS <sub>3</sub> load during inspiration
A <sub>2</sub> -OS/A <sub>2</sub> -P <sub>2</sub> /A <sub>2</sub> -S <sub>3</sub> interval	-	A <sub>2</sub> -P <sub>2</sub> interval shorter than A <sub>2</sub> -OS interval	A <sub>2</sub> -S <sub>3</sub> interval is longer than A <sub>2</sub> -OS interval
Pitch	High (Best heard with diaphragm)	High	Low (Best heard with bell)

## MURMURS

- Sudden deceleration of blood produces heart sounds. Heart murmurs are produced by turbulent flow (Raynold's number >2000) across an abnormal valve, septal defect or outflow obstruction, or by increased volume or velocity of flow through a normal valve.
- Murmurs may occur in a healthy heart. These 'innocent' murmurs occur when stroke volume is increased, e.g. during pregnancy, and in athletes

with resting bradycardia or children with fever (Box 7.8).

### Box 7.8: Mechanism of murmurs.

- **Blood viscosity:** Increased or decreased blood velocity
- **Valve:** Narrowed or incompetent, organic or relative
- Abnormal connection
- Vibration of loose structure
- Diameter of vessel increased or decreased.

### Features to be Observed in Murmur

- **Timing:** By simultaneous palpation of the carotid arterial pulse and note whether systolic, diastolic, continuous.
- **Shape:** Crescendo (grows louder), decrescendo, crescendo-decrescendo, plateau
- **Intensity**
  - Systolic murmurs are graded on a 6 point scale (Levine and Freeman) (Box 7.9)
  - Diastolic murmurs are usually not graded but can be described as (1) **very soft** (2) **soft**, and (3) **loud with or without thrill**.
- **Duration**
- Location of maximum intensity depends on the site where the murmur originates.
- **Character** blowing, harsh, rumbling, and musical
- **Pitch** high, medium, low depending on the velocity of the jet
- **Radiation/conduction**
  - Reflects the intensity of the murmur and the direction of blood flow
  - Mitral regurgitation murmur (PSM) radiates to axilla
  - Aortic stenosis murmur (ESM) conducts to the carotid.
- **Variation** with respiration/position/other maneuvers
- **Best heard** with bell or diaphragm of the stethoscope.

### Box 7.9: Grading of systolic murmurs (Freemans and Levine).

- Grade 1 = very faint
- Grade 2 = quiet but heard immediately
- Grade 3 = moderately loud
- Grade 4 = loud with thrill

- Grade 5 = heard with stethoscope partly off the chest, thrill present
- Grade 6 = no stethoscope needed, thrill present

Note:

- Thrills are associated with murmurs of grades 4–6
- Diastolic murmurs are only graded till 4.

## Systolic Murmurs

**Q. Write short essay/note on differential diagnosis of ejection systolic murmurs (ESM). List the causes of systolic murmurs.**

### *Ejection Systolic (Mid-systolic) Murmurs*

Ejection systolic (mid-systole) murmurs occur when there is ventricular outflow tract obstruction. It begins shortly after the first heart sound ( $S_1$ ) and ends before the second heart sound with a crescendo–decrescendo or diamond-shaped pattern, reflecting the changing velocity of blood flow.

### *Various Systolic Murmurs and its Causes (Table 7.20)*

**Q. Write short note on causes of pansystolic murmur.**

**Table 7.20:** Various systolic murmurs and its causes.

Early systolic murmurs <ul style="list-style-type: none"> <li>• VSD (small muscular VSD/large VSD with pulmonary hypertension)</li> <li>• Acute severe MR</li> <li>• Acute severe TR</li> </ul>	Late systolic murmurs <ul style="list-style-type: none"> <li>• Mitral valve prolapse</li> <li>• Tricuspid valve prolapse</li> <li>• Papillary muscle dysfunction</li> </ul>
Mid-systolic/ejection systolic murmurs <ul style="list-style-type: none"> <li>• Aortic stenosis</li> <li>• Pulmonary stenosis</li> <li>• Hypertrophic obstructive cardiomyopathy (HOCM)</li> </ul>	Pansystolic murmurs <ul style="list-style-type: none"> <li>• Mitral regurgitation</li> <li>• Tricuspid regurgitation</li> <li>• Ventricular septal defect</li> <li>• Rare: Early PDA/PDA with Eisenmenger</li> </ul>

### *Various Diastolic Murmurs and its Causes (Table 7.21)*

**Q. Write short note on causes of mid-diastolic murmurs.**

**Table 7.21:** Various diastolic murmurs and its causes.

Early diastolic murmur	Mid diastolic murmur	Late diastolic murmurs/presystolic murmur
<ul style="list-style-type: none"> <li>• Aortic regurgitation</li> <li>• Pulmonary regurgitation</li> </ul>	<ul style="list-style-type: none"> <li>• Mitral stenosis</li> <li>• Tricuspid stenosis</li> <li>• Carey Coombs murmur of acute rheumatic fever</li> <li>• Austin Flint murmur of chronic aortic regurgitation</li> <li>• Flow MDM</li> <li>• Across mitral valve: MR, AR, VSD, PDA</li> <li>• Across tricuspid valve: ASD, TR, TAPVC (total anomalous pulmonary venous connection)</li> <li>• Atrial myxoma</li> <li>• Ball-valve thrombus</li> <li>• Cor triatriatum</li> <li>• Rytand's murmur of complete heart block</li> </ul>	<ul style="list-style-type: none"> <li>• Mitral stenosis</li> <li>• Tricuspid stenosis</li> <li>• Myxoma</li> </ul>

## Continuous Murmurs

**Q. Write short note on the common causes of continuous murmurs of heart.**

The continuous murmur is a murmur that begins in systole and continues without interruption, encompassing the second sound, throughout diastole or part of diastole.

### *Causes of Continuous Murmurs (Table 7.22)*

**Table 7.22: Causes of continuous murmurs.**

<ul style="list-style-type: none"> <li>• <b>Systemic to pulmonary communication</b> <ul style="list-style-type: none"> <li>– Patent ductus arteriosus</li> <li>– Aortopulmonary window</li> <li>– Anomalous origin of left coronary artery from pulmonary artery (ALCAPA)</li> <li>– Tricuspid atresia</li> <li>– Truncus arteriosus</li> <li>– Shunts for TOF surgery: Waterson, Potts, or Blalock- Taussig shunt</li> </ul> </li> <li>• <b>Systemic to right heart connection</b> <ul style="list-style-type: none"> <li>– Coronary AV fistula</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>Arteriovenous fistula</b> <ul style="list-style-type: none"> <li>– Systemic</li> <li>– Pulmonary</li> </ul> </li> <li>• <b>Normal flow through constricted arteries</b> <ul style="list-style-type: none"> <li>– Coarctation of aorta</li> <li>– Peripheral pulmonary stenosis</li> <li>– Renal artery stenosis</li> </ul> </li> <li>• <b>Increased flow through normal vessels</b> <ul style="list-style-type: none"> <li>– Venous: Cervical venous hum, Cruveilhier-Baumgarten murmur</li> </ul> </li> </ul>
---	--

- Rupture sinus of Valsalva
- **Left atrium to right atrium connection**
- Lutembacher syndrome

- Arterial: Mammary soufflé, uterine soufflé, thyrotoxicosis, tumors (e.g. hepatocellular carcinoma, renal cell carcinoma)

## Systolic-Diastolic Murmur/To-and-Fro Murmur

- The presence of a systolic-diastolic murmur (systolic murmur and diastolic murmur) so called a to-and-fro murmur, is not a continuous murmur.
- It is separating the two murmurs through a small ‘silence’.
- It involves two components: A systolic one, in which the blood flows in one direction, and a diastolic one in which the blood flows in the opposite direction.
- In contrast to true continuous murmur, the blood flows in the same direction in both systole and diastole.
- To-and-fro murmurs are two murmurs that occur through a single channel.
- Causes of systolic-diastolic murmur are presented in Table 7.23.

**Table 7.23:** Causes of systolic-diastolic and to-and-fro murmur.

### Systolic-diastolic murmur

- VSD with AR

### To-and-fro murmur

- AS with AR
- Pulmonary hypertension with pulmonary regurgitation

## Innocent Murmurs

**Q. Write short note on innocent murmurs.**

**Characteristics:** Short, systolic (rarely continuous) soft murmur. Normal heart sounds and no hemodynamic abnormalities.

Examples of innocent murmurs are listed in Box 7.10.

Venous hum (jugular venous hum; cervical venous hum, Pontian’s murmur).

Named murmurs and its causes are listed in Table 7.24.

**Box 7.10:** Examples of innocent murmurs.

### Systolic

- Vibratory systolic murmur (Still’s murmur)

- Pulmonic systolic murmur (pulmonary trunk)
- Mammary soufflé
- Peripheral pulmonic systolic murmur (pulmonary branches)
- Supraclavicular or brachiocephalic systolic murmur
- Aortic systolic murmur
- Still's murmur: Medium frequency, vibratory, originating from leaflets of pulmonary valve

**Continuous**

- Venous hum
- Continuous mammary soufflé

**Q. Write short note on mammary soufflé.**

Mammary soufflé is an innocent systolic or continuous cardiac murmur (probably of arterial origin) heard during late pregnancy or in the early postpartum period. It is to be differentiated from pathologic lesions and is unaffected by the Valsalva maneuver.

**Table 7.24: Named murmurs.**

<i>Name of the murmur</i>	<i>Cause/lesion</i>
Carey Coombs murmur: Mid-diastolic murmur	Rheumatic fever
Austin Flint murmur: Mid-late diastolic murmur	Aortic regurgitation
Graham-Steel murmur: High pitched, diastolic murmur	Pulmonary regurgitation
Rytand's murmur: Mid-diastolic atypical murmur	Complete heart block
Dock's murmur: Diastolic murmur	Left anterior descending (LAD) artery stenosis
Mill wheel murmur due to air in RV cavity	Following cardiac catheterization
Still's murmur: Inferior aspect of lower left sternal border, systolic ejection sound, vibratory/musical quality	Subaortic stenosis, small VSD
Gibson's murmur: Continuous machinery murmur	Patent ductus arteriosus (PDA)
Key-Hodgkin murmur: Diastolic murmur	Aortic regurgitation, e.g. syphilitic
Cabot-Locke murmur: Diastolic murmur heard best at the left sternal border	Anemic patients and the murmur resolves with treatment of anemia
Roger's murmur: Loud pansystolic murmur heard maximally at the left sternal border	Small VSD
Pontain's murmur: Cervical venous hum	Severe anemia
Cole-Cecil murmur	AR murmur in left axilla due to higher position of apex
Cruveilhier-Baumgarten murmur	Venous hum diagnostic of portal vein

## Changing Murmurs

Murmurs which change in character or intensity from moment to moment (Box 7.11).

### Box 7.11: Changing murmurs.

- Carey-Coombs' murmur
- Infective endocarditis
- Atrial thrombus
- Atrial myxomas

## Dynamic Auscultation

### **Q. Write short essay/note on dynamic auscultation in cardiac diseases.**

This is a technique of altering circulatory dynamics by means of a variety of physiological and pharmacological maneuvers and determining their effects on heart sounds and murmurs.

### **Q. Write short essay/note on maneuvers useful in differentiating murmurs due to various cardiac diseases.**

- Interventions most commonly employed are:
  - Respiration
  - Postural changes
  - Valsalva maneuver
  - Isometric exercise
  - Post-premature ventricular contractions (PVC)
  - Vasoactive agents, e.g. amyl nitrite, methoxamine, phenylephrine.

Various valvular lesions and dynamic auscultation findings are presented in Table 7.25.

**Table 7.25: Various valvular lesions and dynamic auscultation findings.**

Valvular lesion	Features that augmenting/increasing the murmur intensity	Features that decrease/reduce the murmur intensity
Mitral stenosis (MS)	MDM accentuated by:	Reduced mid-diastolic murmur

	Exercise, squatting, amyl nitrate, isometric hand grip, left lateral position	(MDM), softening of opening snap (OS) and A <sub>2</sub> -OS gap widening by: Inspiration, sudden standing
Mitral regurgitation (MR)	Augmentation of the murmur by: Squatting, isometric exercise and left lateral position	Decrease murmur by: Sudden standing, Valsalva and amyl nitrate
Aortic stenosis (AS)	Murmur increases on: Post PVC beat, squatting and lying flat from standing	Reduces AS murmur by: Valsalva, standing and handgrip
Aortic regurgitation (AR)	Early diastolic murmur (EDM) increases on: Expiration, sitting up and leaning forward, squatting, isometric exercise and vasopressors	Decreases with: Amyl nitrate and Valsalva
Mitral valve prolapse (MVP)	Murmur and click later, LV volume increase by: Squatting, post-ectopic, isometric exercise (intensity increases)	Murmur and click earlier (intensity decreases) and left ventricle (LV) volume decrease by: Standing and Valsalva
Hypertrophic obstructive cardiomyopathy (HOCM)	Increase murmur by: Expiration, Valsalva strain, standing, post-ectopic and amyl nitrate	Decrease murmur by: Inspiration, sustained handgrip, squatting and methoxamine

Usefulness of dynamic auscultation in differential diagnosis of valvular lesions (Table 7.26).

**Table 7.26:** Usefulness of dynamic auscultation in differential diagnosis of valvular lesions.

<b>Differential diagnosis</b>	
Aortic stenosis (AS) versus hypertrophic obstructive cardiomyopathy (HOCM)	Squatting: Increases in AS, decreases in HOCM
	Valsalva/standing: Decreases in AS, increases in HOCM
Aortic stenosis (AS) versus mitral regurgitation (MR)	Handgrip and phenylephrine: Decreases in AS, increases in MR
	Post-PVC and amyl nitrate: Increases in AS, decreases in MR
Mitral stenosis (MS) versus Austin Flint murmur	Amyl nitrate: Increases in MS, decreases in Austin Flint murmur
Pulmonary stenosis (PS) versus aortic stenosis (AS)	Respiration: Increases with inspiration in PS, increases with expiration in AS

Mitral stenosis (MS) versus tricuspid stenosis (TS)	Respiration: Increases with expiration (MS) and increases with inspiration (TS)
Mitral regurgitation (MR) versus tricuspid regurgitation (TR)	Respiration: Increases with expiration (MR) and increases with inspiration (TR)
Pulmonary stenosis (PS) versus small ventricular septal defect (VSD)	Amyl nitrate: Increases in PS, decreases in VSD
	Phenylephrine: Decreases in PS and increases in VSD
	Respiration: Increases with inspiration in PS, no variation with respiration in VSD
Pulmonary regurgitation (PR) versus aortic regurgitation (AR)	Squatting and sustained handgrip: No change in PR, increased in AR

Usefulness of amyl nitrate in differential diagnosis of murmurs (Table 7.27).

**Table 7.27: Usefulness of amyl nitrate in differential diagnosis of murmurs.**

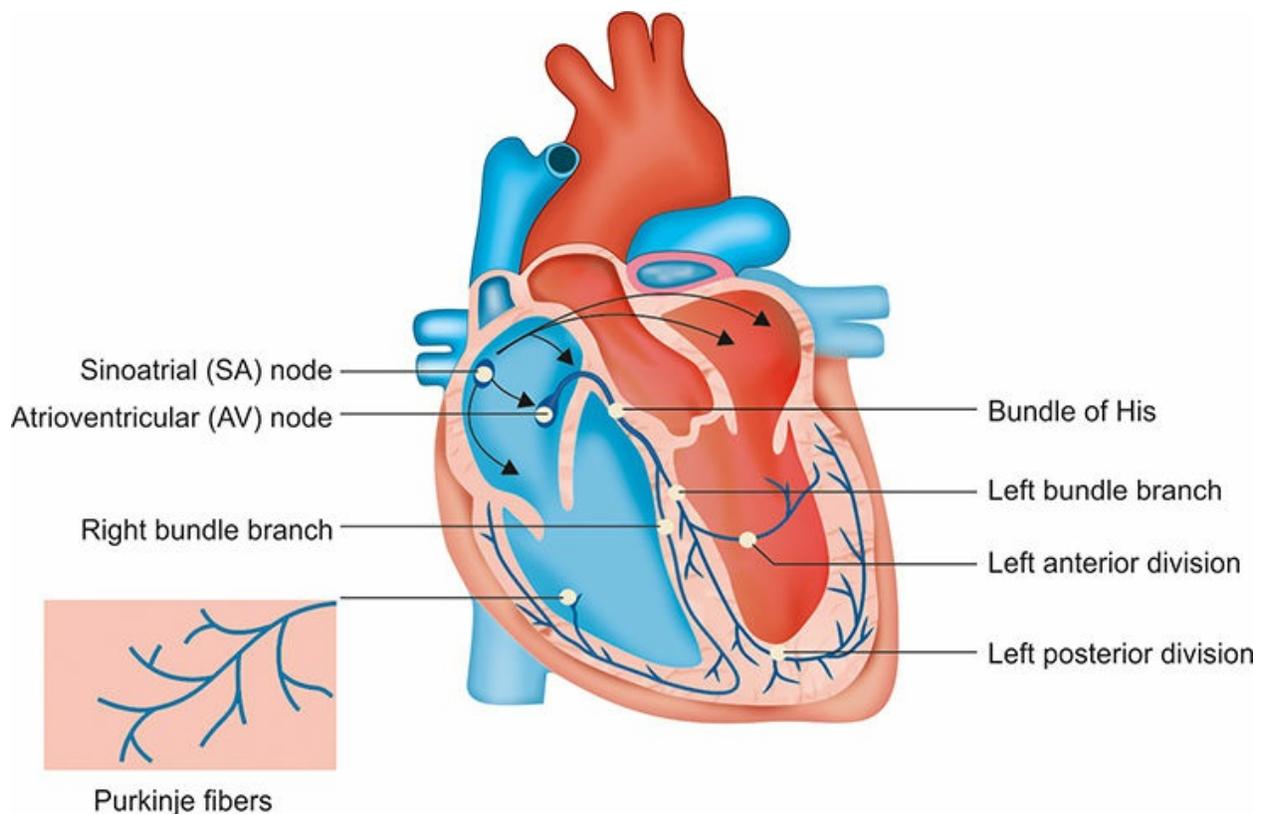

<i>Valvular lesions</i>	<i>Amyl nitrate response</i>
<b>Systolic murmur</b>	
Aortic stenosis (AS) versus mitral regurgitation (MR)	Increased in AS and decreased in MR
Tricuspid regurgitation (TR) versus mitral regurgitation (MR)	Increased in TR and decreased in MR
Pulmonary stenosis (PS) versus tetralogy of Fallot (TOF)	Increased in PS and decreased in TOF
Pulmonary stenosis (PS) versus ventricular septal defect (VSD)	Increased in PS and decreased in VSD
<b>Diastolic murmur</b>	
Mitral stenosis (MS) versus Austin Flint murmur	Increased in MS and decreased in Austin Flint murmur
End-diastolic murmur of pulmonary regurgitation (PR) with aortic regurgitation (AR)	Increased in PR and decreased in AR

## CONDUCTION SYSTEM OF THE HEART (FIG. 7.9)

**Q. Write short essay/note on the conduction system of the heart.**

An electrical discharge from the sinoatrial (sinus) node initiates the normal heart beat. It is then sequentially depolarized in the atria followed by ventricles as it passes through specialized conducting tissue.

- **Sinus node (SA node):** It is located in the lateral and epicardial aspect where the superior vena cava joins the right atrium. It is a natural pacemaker of the heart and controls the rate and rhythm of the heart (rate of 60–100 beats/minute). It has the fastest inherent discharge.
- **Atrioventricular (AV) node:** The impulse from the SA node spreads through the atrial musculature and down to the atrioventricular (AV) node that is situated above the tricuspid valve. Passage via the AV node is relatively slow, and is responsible for the normal physiological delay in ventricular depolarization. AV node functions as a back-up pacemaker with an intrinsic rate of 40–60 beats/minute.

**Fig. 7.9:** Conduction system of heart.

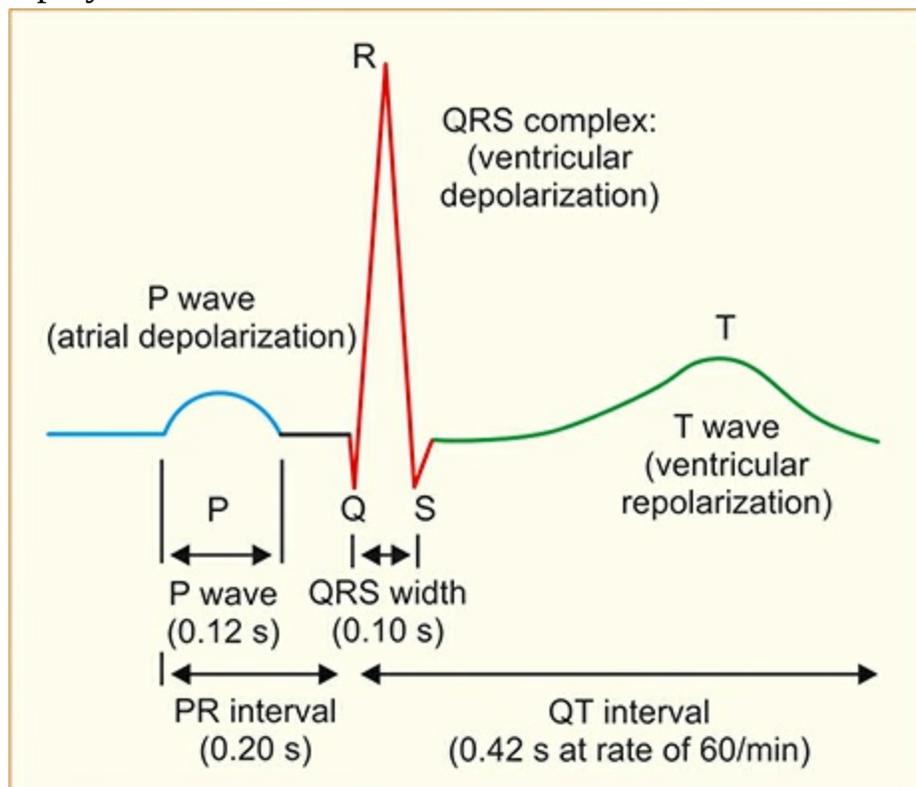

- **His bundle and Purkinje fibers:** The impulse then travels downwards to the bundle of His and through its branches (right bundle branch and left bundle branch) to the Purkinje network of fibers that convey the impulse to the ventricular endocardium and then epicardium. Potential pacemaking properties also exist in the cells of the AV node, bundle of His and Purkinje fibers. Ventricular cells also act a back-up pacemaker with an intrinsic rate of 20–45 betas/minute.

# ELECTROCARDIOGRAM

**Q.** Write short essay on analysis of an electrocardiogram (ECG).

## Sinus Rhythm: Waveforms and Intervals (Fig. 7.10)

ECG is the recording of sequential sum of depolarization and repolarization of all myocardial cells. The electrical depolarization of myocardial tissue produces a small dipole current. It can be detected by electrode pairs on the body surface. These signals are amplified and either printed on special graph paper or displayed on a monitor.

**Fig. 7.10:** Electrocardiograph showing various components.

- **Depolarization** is the sudden change within myocardium, during which it undergoes a dramatic electrical change. Entire myocardium is depolarized in a coordinated manner.
  - **P wave:** The ECG waveforms are labeled alphabetically beginning with the P wave (represents atrial depolarization). The SA node triggers **atrial depolarization**, producing a beginning P wave.
  - **QRS complex:** Depolarization slowly spreads through the AV node, which produces a depolarization wave which is too small to be

detected from the body surface. The bundle of His, bundle branches and Purkinje system are then activated, initiating ventricular myocardial depolarization. During this, QRS complex is produced that represents the duration of ventricular depolarization. Because of the larger size of the ventricular muscle mass than that of the atria, the QRS complex is larger than the P wave. Normal value is 100–110 ms or less. The QRS complex is subdivided into specific deflections or waves.

- ◆ **Q wave:** If the initial QRS depletion in a particular lead is negative, it is termed a Q wave, indicates septal depolarization.
- ◆ **R wave:** The first positive deflection is termed an R wave.
- ◆ **S wave:** A negative deflection after an R wave is an S wave.
- ◆ **Subsequent positive or negative waves** are labeled R' (R prime) and S' (S prime) respectively.
- ◆ Lowercase letters (qrs) are used for waves of relatively small amplitude. An entirely negative QRS complex is termed a QS wave.
- **PR interval:** It is the interval between the onset of the P wave and the onset of the QRS complex. Normal value is 120–200 ms. It largely reflects the duration of AV nodal conduction between atrial and ventricular depolarization.
- **Repolarization** is the restoration of the electrical polarity of myocardial muscle.
  - Repolarization is slower process and spreads from the epicardium to the endocardium.
  - Atrial repolarization does not produce a detectable signal (too low in amplitude) whereas ventricular repolarization produces the T wave. However, atrial repolarization may become apparent in conditions such as acute pericarditis and atrial infarction.
  - **QT interval:** It represents the total duration of both ventricular depolarization and repolarization. It varies inversely with the heart rate.
  - **ST-T-U complex:** It consists of ST segment, T wave, and U wave and is due to ventricular repolarization. The J point represents the junction between the end of the QRS complex and the beginning of the ST segment.

- **U wave:** Small, rounded, upright wave following T wave. Most easily seen with a slow heart rate. Indicates repolarization of Purkinje fibers.

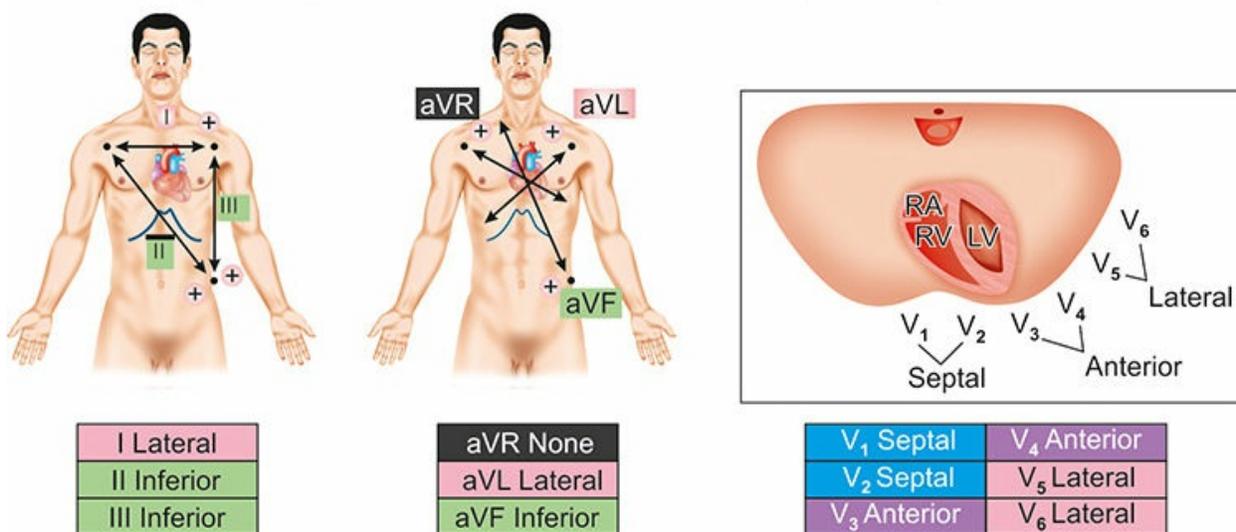

## ECG Leads

The standard 12-lead ECG record the difference in potential between ten physical electrodes placed on the surface of the body. The term twelve ‘leads’ of the ECG is for twelve number of recordings made from pairs or sets of these electrodes.

### Type of Leads (Fig. 7.11)

1. Six limb (extremity) leads

2. Six chest (precordial) leads

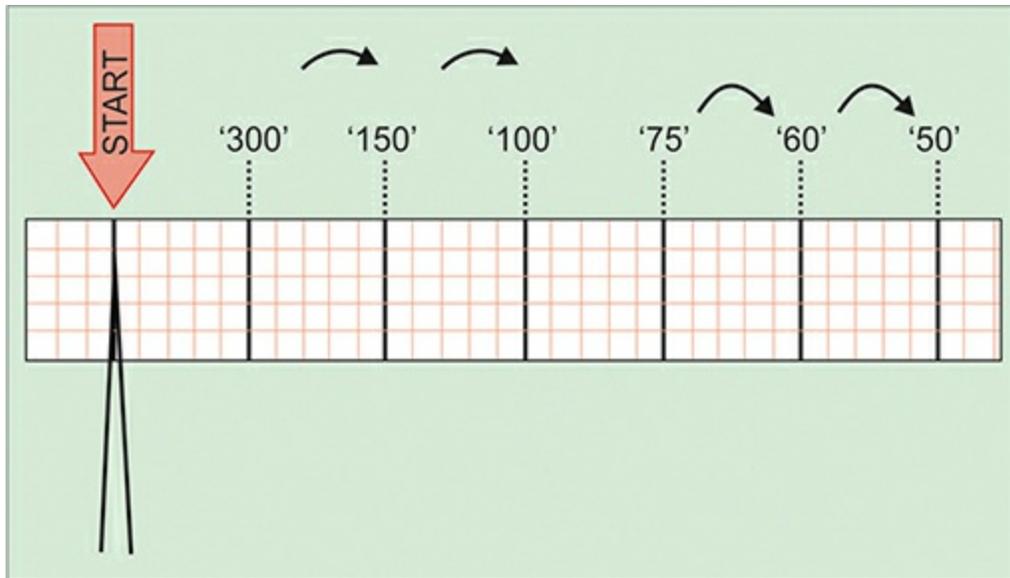

**Fig. 7.11:** Diagrammatic representation of the connections or directions, net axis of each lead in a 12-lead electrocardiogram.

ECG leads are divided into two groups: (1) six limb (extremity) leads and (2) six chest (precordial) leads. The limb leads record potentials transmitted onto the frontal plane, and the chest leads record potentials transmitted onto the horizontal plane.

### Reading 12-lead ECGs

The best way to read 12-lead ECGs is to develop a step-by-step approach (Box 7.12).

**Fig. 7.12:** Determination of heart rate by ECG.

### Table 7.28: Variations of heart rate and its causes.

**Normal:** 60-99 beats per minute (bpm)

**Bradycardia <60 bpm:** Hypothermia, increased vagal tone (due to vagal stimulation or e.g. drugs), athletes, hypothyroidism, beta blockade, marked intracranial hypertension, obstructive jaundice, uremia, structural SA node disease, or ischemia

**Tachycardia >100 bpm:** Any cause of adrenergic stimulation (including pain); thyrotoxicosis; hypovolemia; vagolytic drugs (e.g. atropine) anemia, pregnancy; vasodilator drugs, including many hypotensive agents; fever, myocarditis

#### Step 1: Determining the heart rate (Fig. 7.12)

- The ECG is normally recorded at a speed of 25 mm/second. Each small square, in the graph is 1 mm and represents 0.04 seconds and big boxes with heavier lines represents 0.20 s (200 ms).
- **Rule of 300/1500:** For regular rhythms, count the number of 'big boxes' between two QRS complexes, and divide this into 300. The heart rate (beats per minute) can also be computed readily from the interbeat (R-number of small (0.04 s) units into 1500.
- **6-second rule:** For irregular rhythms, ECGs record 6 seconds of rhythm per page, count the number of beats present on the ECG, multiply by 10
- Variations of heart rate and its causes are listed in Table 7.28.

#### Box 7.12: Steps in reading ECG.

- Calculate **rate**
- Determine **rhythm**
- Determine **QRS axis**
- Check individual **waves**
- Calculate **intervals**
- Assess for **hypertrophy**
- Look for evidence of **infarction**/dys electrolyte drug effects

**Q. Write short note on sinus tachycardia.**

**Step 2: Determine regularity** (Figs. 7.13 to 7.25)

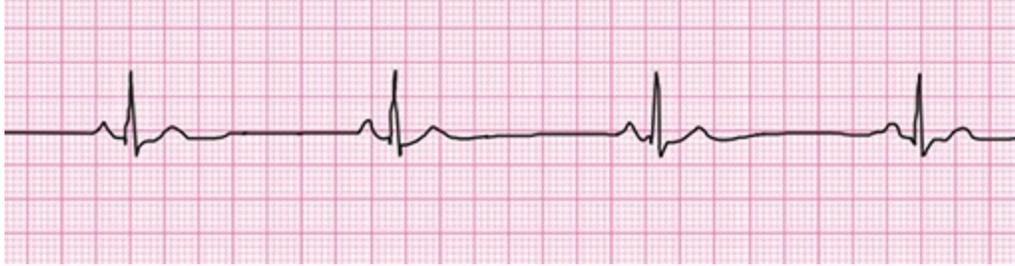

- Look at the R-R distances (using a caliper or markings on a paper).
- Regular (are they equidistant apart)? Occasionally irregular? Regularly irregular?
- Irregularly irregular-atrial fibrillation.

**Step 3: Determining the axis** (Fig. 7.26)

- Normal QRS axis from  $-30^\circ$  to  $+110^\circ$ ,  $-30^\circ$  to  $-90^\circ$  is referred to as a left axis deviation (LAD),  $+110^\circ$  to  $+180^\circ$  is referred to as a right axis deviation (RAD) and  $-180^\circ$  to  $-90^\circ$  is referred as north-west axis/extreme axis/axis in no man's land/indeterminate axis.
- QRS complex in leads I and aVF determine if they are predominantly positive or negative. The combination should place the axis into one of the 4 quadrants above.
- Various causes of axis deviation are listed in Table 7.29.

**Fig. 7.13:** Sinus rhythm: Cardiac impulse originates from the sinus node. Every QRS must be sinus node. Every QRS must be preceded by a P wave.

**Fig. 7.14:** Sinus bradycardia: Rhythm originates in the sinus node. Rate of less than 60 beats per minute.

**Fig. 7.15:** Sinus tachycardia: Rate >100 bpm, otherwise, normal.

**Fig. 7.16:** Sinus pause. In disease (e.g. sick sinus syndrome) the SA node can fail in its pacing function. If failure is brief and recovery is prompt, the result is only a missed beat (sinus pause). If recovery is delayed and no other focus assumes pacing function, cardiac arrest follows.

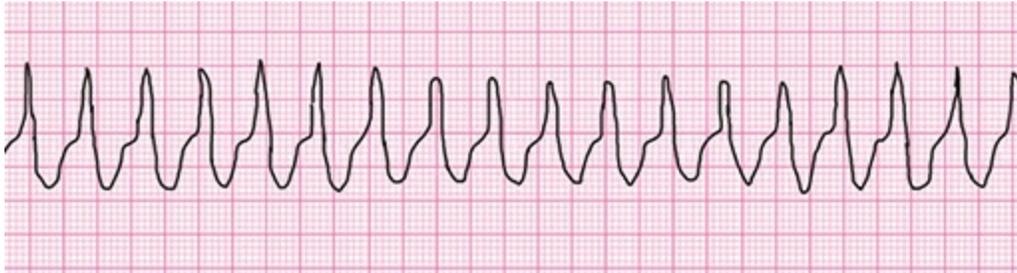

**Fig. 7.17:** Atrial fibrillation. Rate = ~150 bpm, irregularly irregular, baseline irregularity, no visible p waves, QRS occur irregularly with its length usually <0.12 s, fibrillary waves.

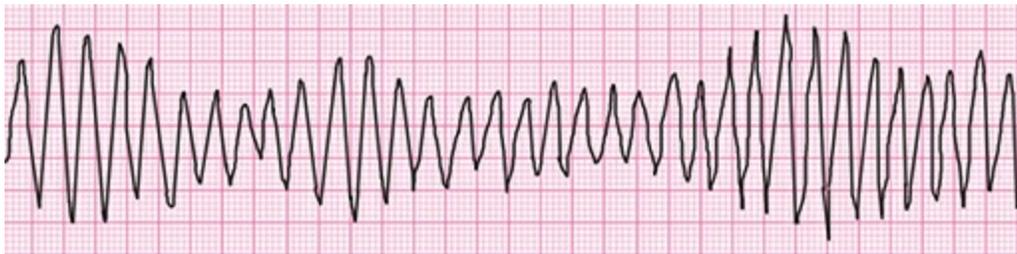

**Fig. 7.18:** Atrial flutter. Atrial rate = ~300 bpm, P waves absent but have flutter waves, ECG baseline adapts 'saw-toothed' appearance'.

**Fig. 7.19:** Ventricular fibrillation. Rate cannot be discerned, rhythm unorganized, QRS broad  $>0.12$  s.

**Fig. 7.20:** Ventricular tachycardia. Rate = 100–250 bpm, broad QRS, regular.

**Fig. 7.21:** Torsades de pointes (literally means twisting of points) is a distinctive form of polymorphic ventricular tachycardia characterized by a gradual change in the amplitude and twisting of the QRS complexes around the isoelectric lines.

**Fig. 7.22:** Supraventricular tachycardia. Tachycardiac rhythm originating above the ventricular tissue. Atrial and ventricular rate = 150–250 bpm regular rhythm, p is usually not discernable.

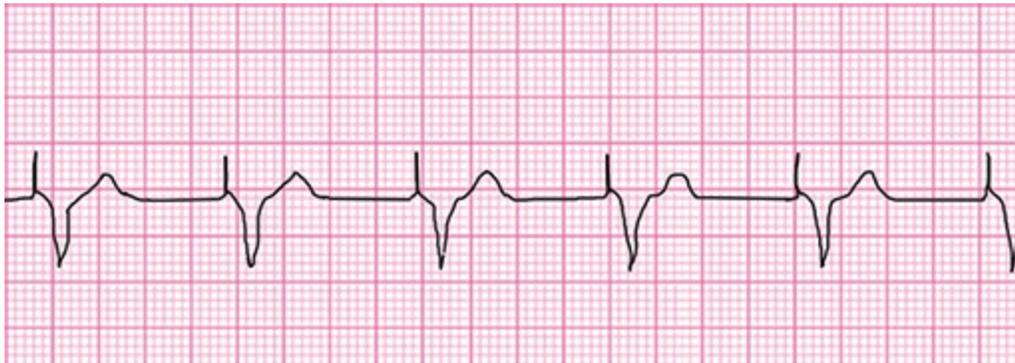

**Fig. 7.23:** Atrial premature beat (APB). Arises from an irritable focus in one of the atria. APB produces

different looking P wave, because depolarization vector is abnormal. QRS complex has normal duration and same morphology.

**Fig. 7.24:** Premature ventricular complexes (PVCs). Occasionally irregular rhythm, broad QRS arising from ventricles no p-wave associated with PVCs. Can be monomorphic/polymorphic.

**Fig. 7.25:** Artificial pacemaker. Sharp, thin spike before each complex, ventricular paced rhythm shows wide ventricular pacemaker spikes.

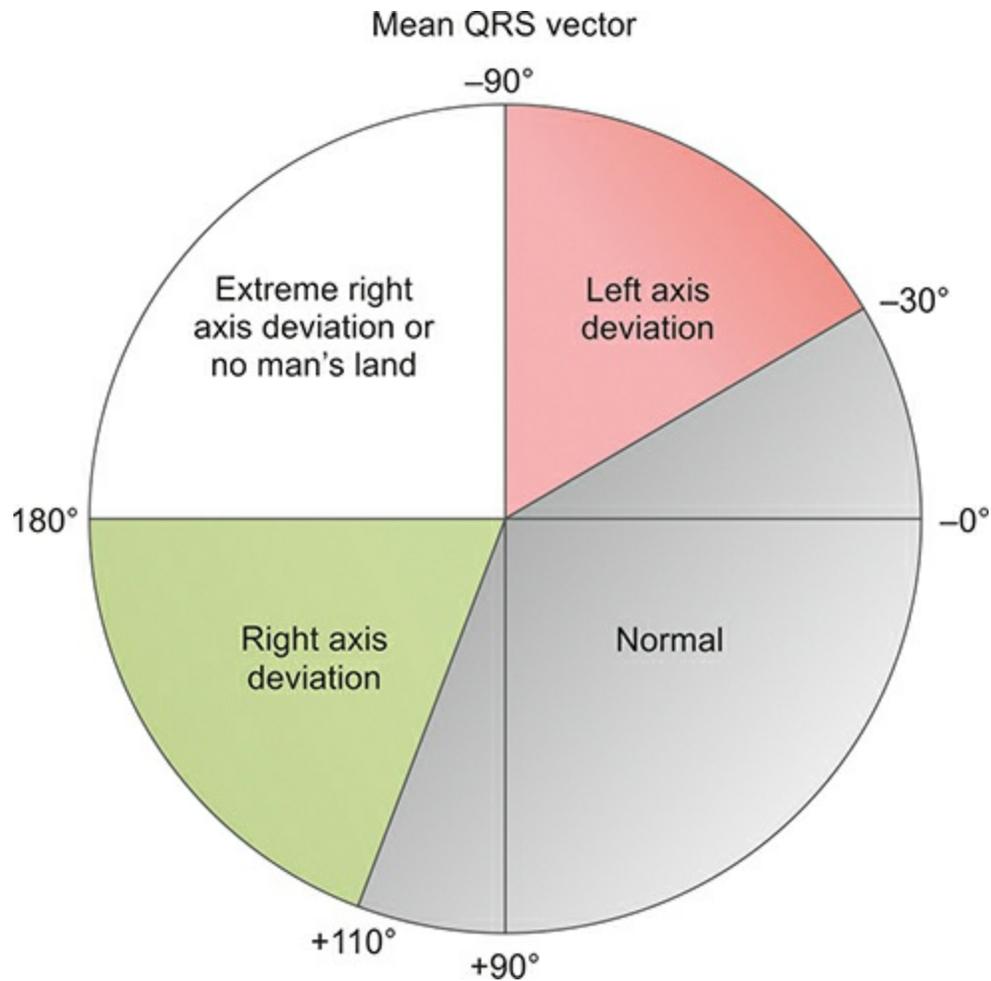

Fig. 7.26: Axis of ECG.

**Table 7.29:** Causes of axis deviation.

<i>Cardiac axis</i>	<i>Causes</i>
Left axis deviation	Left anterior hemiblock, left ventricular hypertrophy, Wolff-Parkinson-White syndrome, inferior MI, ostium primum ASD, ventricular tachycardia Normal variation in pregnancy, obesity; ascites, abdominal distention
Right axis deviation	Normal finding in children and tall thin adults, chronic lung disease (COPD), left posterior hemiblock, Wolff-Parkinson-White syndrome, anterolateral MI
North West	Dextrocardia, severe emphysema, hyperkalemia, lead transposition, artificial cardiac pacing, ventricular tachycardia

#### Step 4: Check individual waves

- **Assess P waves (Box 7.13)**
- **Normal:** Always positive in lead I and II, always negative in lead aVR. Commonly biphasic in lead V<sub>1</sub> and best seen in leads II. <2.5 small squares in duration and <2.5 small squares in amplitude.

#### Box 7.13: Abnormal P waves and its causes.

**Tall (> 2.5 mm), pointed P waves (P pulmonale):** Suggests right atrial enlargement. Seen in COPD, ASD, TS, Ebstein anomaly (Himalayan P waves)

**Notched/bifid ('M' shaped) P wave (P 'mitrale') in limb leads:** Suggests left atrial enlargement. Seen in MS, MR, and systemic hypertension. Coarse atrial fibrillation suggests LAE

**Absent P waves:** Atrial fibrillation/flutter

**Inverted P waves in lead II:** Dextrocardia

#### Step 5: Calculate intervals

**PR interval:** Normal is 0.12–0.20 seconds.

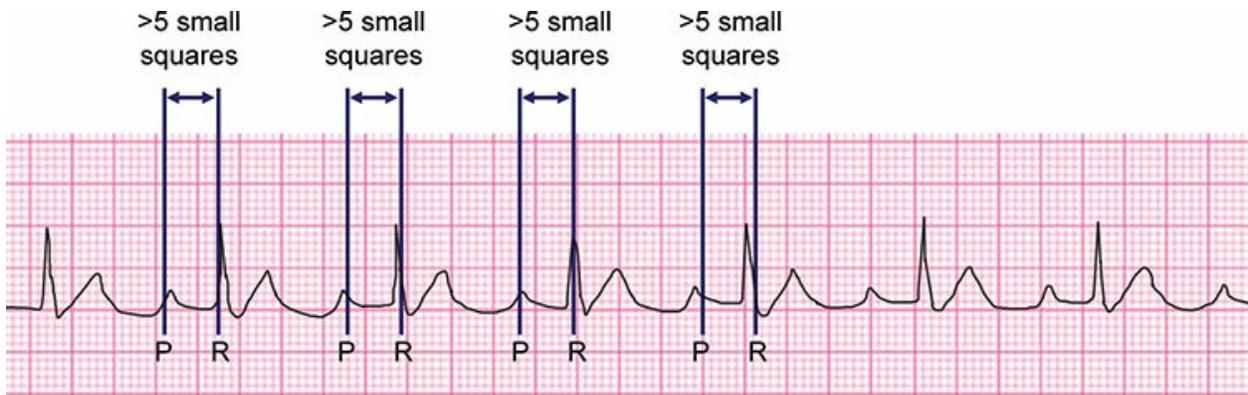

- **Long PR interval** may indicate heart block (Figs. 7.27 to 7.30)
- **Short PR interval:** Tachycardia and pre-excitation syndromes (e.g. Lown-Ganong-Levine syndrome, Wolff-Parkinson-White syndrome).

#### QRS-complex

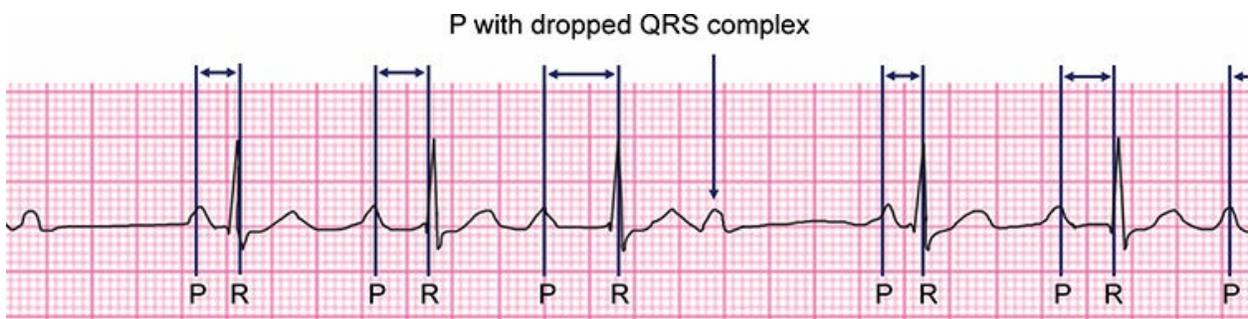

- **Normal characteristics:** Duration is 0.04–0.11 seconds.
- **Broad/wide QRS (>0.12s):** Ventricular hypertrophy, intraventricular conduction disturbance, bundle branch blocks, aberrant ventricular conduction, ventricular preexcitation, ventricular ectopic or escape pacemaker, ventricular pacing by cardiac pacemaker
- Height of QRS–Sokolow index (SV<sub>2</sub> + RV<sub>5</sub>) <35 mm (<45 mm for young)
- Increased height: In RV/LV hypertrophy
- **Decreased height:** Low voltage QRS (<5 mV in limb leads/<10 mV in chest leads): Obese patient, restrictive cardiomyopathy, pericardial effusion, hypothyroidism, hypothermia, and myocarditis.

#### Q Waves

- The normal Q wave in lead I is due to septal depolarization. It is small in amplitude (less than 25% of the succeeding R wave, or less than 3 mm). Its duration is <0.04 sec or one small box. It is seen in L1 and sometimes in V<sub>5</sub>, V<sub>6</sub>.
- **Pathological Q wave** of infarction in the respective leads is due to dead muscle. May also be seen in cardiomyopathies i.e. hypertrophic (HOCM), infiltrative myocardial disease.
- **Absent Q waves** in V<sub>5-6</sub> is most commonly due to LBBB.

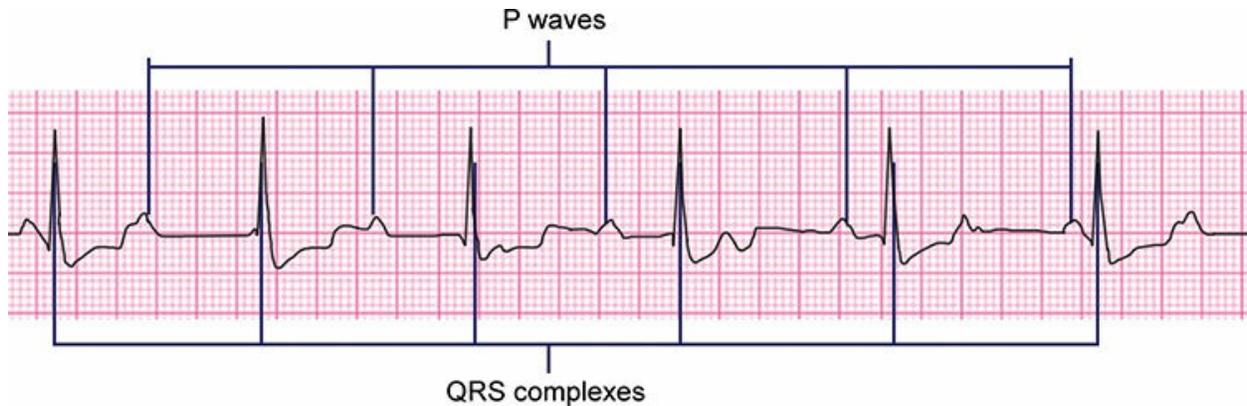

**Fig. 7.27:** First degree heart block. P wave precedes QRS complex but P-R intervals prolong (>5 small squares) and remain constant from beat to beat.

**Fig. 7.28:** Second degree heart block—Mobitz type I or Wenckebach. Runs in cycle, first P-R interval is often normal. With successive beat, P-R interval lengthens until there will be a P wave with no following QRS complex. The block is at AV node, often transient, may be asymptomatic.

**Fig. 7.29:** Second degree heart block—Mobitz type 2. P-R interval is constant, duration is normal/prolonged. Periodically, no conduction between atria and ventricles—producing a p wave with no associated QRS complex (blocked p wave). The block is most often below AV node, at bundle of His or BB, may progress to third degree heart block.

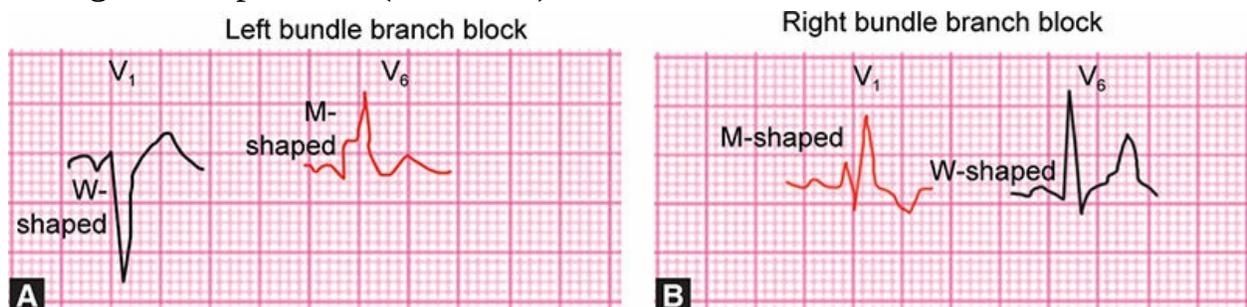

**Fig. 7.30:** Third degree heart block (complete heart block). No relationship between P waves and QRS complexes. An accessory pacemaker in the lower chambers will typically activate the ventricles-escape rhythm. Atrial rate = 60–100 bpm. Ventricular rate based on site of escape pacemaker. Atrial and ventricular rhythms both are regular.

### Bundle branch blocks (Fig. 7.31)

- **Left bundle branch block (LBBB):** Indirect activation causes left ventricle to contract later than the right ventricle.
- **Right bundle branch block (RBBB):** Indirect activation causes right ventricle to contract later than the left ventricle.

### ST Segment

- ST segment is isoelectric and at the same level as subsequent PR-interval. The length between the end of the S wave (end of ventricular depolarization) and the beginning of repolarization. From J point on the end of QRS complex, to inclination of T wave.
- Causes of ST segment elevation (Box 7.14 and Fig. 7.32) and causes of ST segment depression (Box 7.15).

**Figs. 7.31A and B:** (A) Left bundle branch block: QS or rS complex in  $V_1$  - W-shaped  $R_sR'$  wave in  $V_6$ - M-shaped. Mnemonic: WILLIAM; (B) Terminal R wave ( $rSR'$ ) in  $V_1$  - M-shaped. Slurred S wave in  $V_6$  - W-shaped. Mnemonic: MARROW.

### Box 7.14: Causes of ST segment elevation.

- Ischemia
- Early repolarization
- Acute pericarditis: ST elevation in all leads except aVR
- Pulmonary embolism
- Hypothermia
- Hypertrophic cardiomyopathy
- High potassium
- Cerebrovascular accident (CVA)
- Acute sympathetic stress
- Brugada syndrome
- Cardiac aneurysm
- Left ventricular hypertrophy
- Idioventricular rhythm including paced rhythm

### *T Wave*

- Normally, a repolarization directs from epicardium to endocardium = T wave is concordant with QRS complex
- Causes of T wave inversions (Box 7.16)
- **Tall T waves** (height more than 2/3 of neighboring QRS): Hyperkalemia (steep T waves), hyperacute MI.

### *QT-interval*

- Represents the time taken for ventricular depolarization and repolarization. The duration of the QT interval is proportionate to the heart rate. The faster the heart beats, the faster the ventricles repolarize so the shorter the QT interval. Therefore, what is a 'normal' QT varies with the heart rate. QT interval should be 0.35–0.45 seconds.
- For each heart rate you need to calculate an adjusted QT interval, called the 'corrected QT' (QTc):
- $QTc = QT / \text{square root of RR interval}$ —**Bazett's formula**
- **Prolonged QTc** (>440 ms) (Box 7.17): A prolonged QT can be very dangerous. It can predispose an individual to a type of ventricular tachycardia—Torsades de pointes.
- **Short QTc** (<350 ms): Hypercalcemia, digoxin effect.

**Fig. 7.32:** ECG showing ST segment elevation.

### U Waves

- U wave need not be always seen on an electrocardiogram. It is small, round, symmetrical and follows the T wave and seen positive in lead II. U waves are due to repolarization of the papillary muscles or Purkinje fibers. It is the same direction as T wave in that lead.
- **Prominent U waves:** Seen in hypokalemia, hypercalcemia, thyrotoxicosis, or exposure to digitalis, epinephrine, and Class 1A and 3 antiarrhythmics.
- An inverted U wave may represent myocardial ischemia or left ventricular volume overload.

### Box 7.15: Causes of ST segment depression.

- Myocardial ischemia/NSTEMI
- Reciprocal change in STEMI
- Posterior MI
- Digoxin effect (Reverse tick mark/'sagging' morphology, resembling Salvador Dali's moustache)
- Hypokalemia
- Bundle branch block
- Ventricular hypertrophy
- Ventricular pacing

### Step 6: Assess for hypertrophy

#### Left ventricular hypertrophy (LVH)

**Q. Write short note on causes of left ventricular hypertrophy and left ventricular dilatation.**

- Criteria of LVH
  - High QRS voltages in limb leads: Sokolow-Lyon index: S in V1 or V2

- + R in V5 or V6 (whichever is larger)  $\geq 35$  mm OR R in aVL  $\geq 11$  mm
- Deep symmetric T inversion in V4, V5 and V6
- QRS duration  $> 0.09$  sec, associated left axis deviation
- Romhilt-Estes scoring system is used for diagnosing LVH.

**Box 7.16:** Causes of T wave inversions.

- CAD/ischemia
- Cardiomyopathies (hypertrophic)
- Myocarditis, pericarditis
- Pulmonary embolism
- Valvular disorders
- Raised intracranial tension, CNS bleed
- Ventricular hypertrophy
- Bundle branch block
- Pacing

- **Romhilt-Estes point score system ( $\geq 5$  points definite LVH)**
  - i. Any limb lead R or S  $\geq 20$  mm/SV<sub>1</sub> + SV<sub>2</sub>  $\geq 30$  mm or RV<sub>5</sub> + RV<sub>6</sub>  $\geq 30$  mm—3 points
  - ii. ST-T changes with digitalis—1 point, without digitalis—3 points
  - iii. LAE—3 points
  - iv. Left axis deviation ( $\leq 30$ )—2 points
  - v. QRS duration  $\geq 90$  ms—1 point
  - vi. Delayed intrinsicoid deflection in V<sub>5</sub>/V<sub>6</sub>  $\geq 50$  ms—1 point

**Box 7.17:** Causes of prolonged QTc.

- Hypokalemia, hypomagnesemia, hypocalcemia
  - Hypothermia
  - Myocardial ischemia
  - Raised intracranial pressure
  - Congenital long QT syndrome, e.g. Jervell and Lange-Nielsen syndrome, Romano-Ward syndrome
  - **Drugs**, e.g. chlorpromazine, haloperidol, quetiapine, quinidine, procainamide
- **Common causes of left ventricular hypertrophy and left ventricular dilatation** are listed in Table 7.30.

**Table 7.30:** Common causes of left ventricular hypertrophy and dilatation.

<i>Common causes of left ventricular hypertrophy</i>	<i>Common causes of left ventricular dilatation</i>
<ul style="list-style-type: none"> <li>• Pressure overload: Systemic hypertension, aortic stenosis, IHD, coarctation of aorta</li> </ul>	<ul style="list-style-type: none"> <li>• Aortic regurgitation (AR)</li> </ul>

(COA)

- Volume overload: Mitral or aortic regurgitation, dilated cardiomyopathy
  - Both right and left ventricular volume overload: Ventricular septal defect (VSD)
  - No pressure or volume overload: Hypertrophic cardiomyopathy (HCM) systemic
- Mitral regurgitation (MR)
  - Ventricular septal defect (VSD)
  - Persistent ductus arteriosus (PDA)
  - Ischemic heart disease (IHD)
  - Hyperkinetic circulatory states, e.g. anemia, thyrotoxicosis and beriberi
  - Dilated cardiomyopathy

### *Right ventricular hypertrophy (RVH)*

Criteria of right ventricular hypertrophy and its causes are listed in Table 7.31.

**Table 7.31: Criteria of right ventricular hypertrophy and its causes.**

<b>Criteria of right ventricular hypertrophy</b>	<b>Causes of right ventricular hypertrophy (RVH)</b>
<ul style="list-style-type: none"><li>• Tall R in V<sub>1</sub> with R &gt;&gt; S, or R/S ratio &gt;1</li><li>• Deep S waves in V<sub>4</sub>, V<sub>5</sub> and V<sub>6</sub></li><li>• Associated right axis deviation, RAE</li><li>• Deep T inversion in V<sub>1</sub>, V<sub>2</sub> and V<sub>3</sub></li></ul>	<ul style="list-style-type: none"><li>• Long standing mitral stenosis</li><li>• Pulmonary hypertension of any cause</li><li>• VSD or ASD with initial left to right shunt</li><li>• Congenital heart with RV overload</li><li>• Tricuspid regurgitation, pulmonary stenosis</li></ul>

### **Step 7: Look for evidence of infarction/dyselectrolytemia**

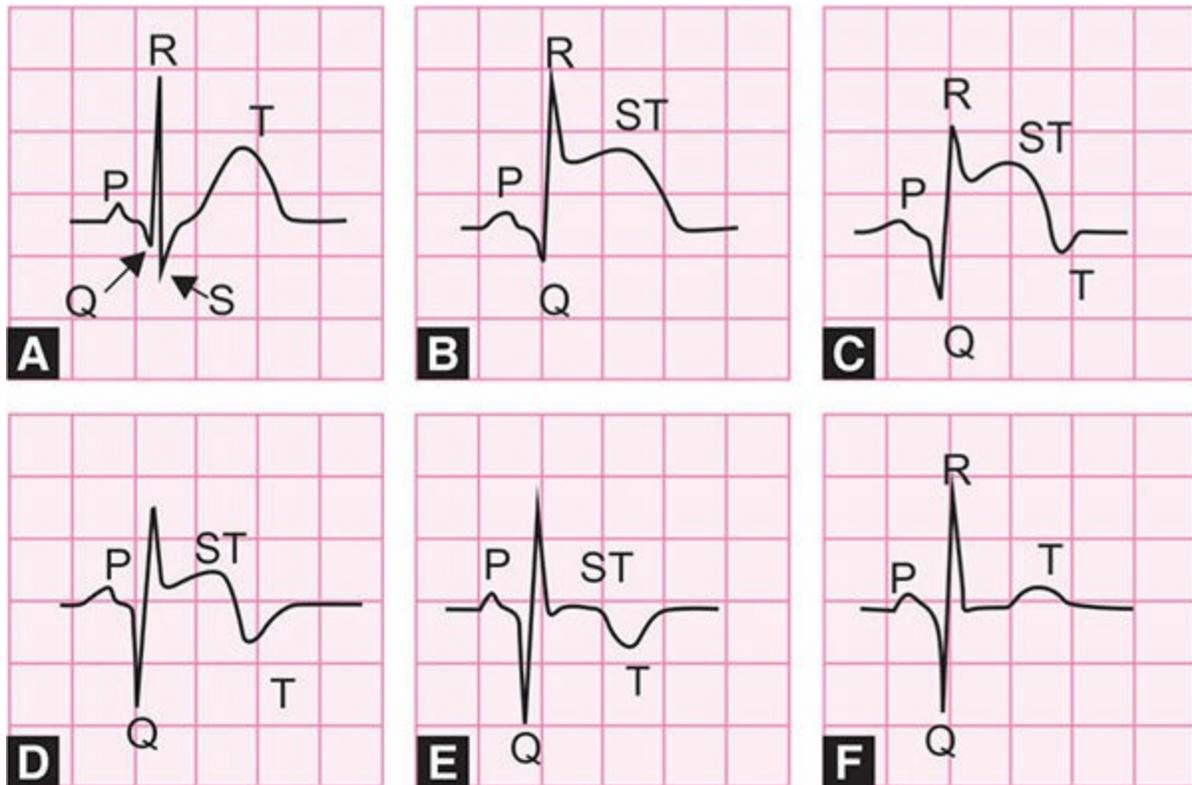

- **ECG in myocardial infarction (MI):** There are two types of MI. STEMI and NSTEMI
  - **STEMI Criteria**
    - ◆ ST elevation in >2 chest leads >2 mm elevation
    - ◆ ST elevation in >2 limb leads >1 mm elevation
    - ◆ Q wave > 0.04s (1 small square).

ECG findings depending on the location of myocardial infarct are presented in Table 7.32. Sequential ECG Changes in STEMI are presented in Figures 7.33A to F.

**Table 7.32: ECG findings depending on the location of myocardial infarct.**

<b>Location of MI</b>	<b>Lead with ST changes</b>	<b>Affected coronary artery</b>
Anterior	V <sub>1</sub> , V <sub>2</sub> , V <sub>3</sub> , V <sub>4</sub>	Left anterior descending artery (LAD)
Septum	V <sub>1</sub> , V <sub>2</sub>	

Left lateral	I, aVL, V <sub>5</sub> , V <sub>6</sub>	Left circumflex
Inferior	II, III, aVF	Right coronary artery (RCA)
Right atrium	aVR, V <sub>1</sub>	
Posterior	Posterior chest leads	
Right ventricle	Right sided leads	

**Figs. 7.33A to F:** Sequential ECG changes in STEMI: (A) Normal ECG; (B) 0 hour: pronounced/hyper acute tall T wave initially, ST elevation (convex type); (C) 1–24 hours: depressed R wave, and pronounced T wave. Pathological Q waves may appear within hours or may take greater than 24 hr.-indicating full-thickness MI. Q wave is pathological if it is wider than 40 ms or deeper than a third of the height of the entire QRS complex; (D) Day 1–2: exaggeration of T wave continues for 24 hours; (E) Days later: T wave inverts as the ST elevation begins to resolve. Persistent ST elevation is rare except in the presence of a ventricular aneurysm; (F) Weeks later: ECG returns to normal T wave, but retains pronounced Q wave.

### • Non ST-elevation MI (NSTEMI)

- NSTEMI is also known as subendocardial or non Q-wave MI. In a patient with acute coronary syndrome (ACS) in which the ECG does not show ST elevation, NSTEMI (subendocardial MI) is suspected if ECG shows T wave inversion (symmetrical, arrowhead) with or without ST depression.
- An ST depression is more suggestive of myocardial ischemia than

infarction.

Usefulness of electrocardiogram are inlisted in Box 7.18.

**Box 7.18:** Usefulness of electrocardiogram.

- Cardiac arrhythmias
- Conduction defects
- Hypertrophy of cardiac chamber (atrium or ventricle)
- Electrolyte abnormalities (hypokalemia, hyperkalemia, hypocalcemia, hypercalcemia)
- Effects of drugs (digitals)
- Hypothermia
- Pericarditis

## ISCHEMIC HEART DISEASE

**Q. Discuss the etiology, risk factors, clinical features, investigation and treatment of ischemic heart disease (IHD).**

**Definition:** Ischemic heart disease is a group of heart diseases in which there is an imbalance between myocardial blood supply and its oxygen demand. IHD is the **leading cause of death** in both males and females.

### Etiology

- Coronary arterial occlusion is the main cause of myocardial ischemia.
  - Mostly due to coronary atherosclerosis and its complications. Coronary atherosclerosis narrows one or more of the epicardial coronary arteries → decreases the coronary blood flow in about 90% of cases. Hence, IHD is often known as coronary artery disease (CAD) or coronary heart disease.
- Other rare causes: Emboli, vasculitis, coronary vasospasm, hematologic disorders like sickle cell disease, diminished availability of blood or oxygen (lowered systemic blood pressure as in shock).

### *Risk Factors for Atherosclerosis*

**Q. Write short essay/note on:**

- **Risk factors for coronary arterial disease (CAD).**
- **Risk factors for atherosclerosis.**

They were identified through several studies most important being the Framingham heart study and atherosclerosis risk in communities study.

### *Classification of risk factors*

The risk factors may be broadly classified as modifiable, non-modifiable and additional (Table 7.33).

**Table 7.33: Risk factors for atherosclerosis.**

#### **A. Modifiable major risk factors**

- Hyperlipidemia, hypertension, cigarette smoking, diabetes mellitus

#### **B. Nonmodifiable risk factors**

- Increasing age (men  $\geq 45$  years and females  $\geq 55$  years), male gender, family history, genetic abnormalities (e.g. familial hypercholesterolemia)

#### **C. Additional risk factors**

- Inflammation, raised CRP level, hyperhomocystinemia, metabolic syndrome, lipoprotein (a), raised procoagulant levels, inadequate physical activity, stressful lifestyle, obesity, alcohol

## **Pathogenesis of Atherosclerosis**

### **Q. Discuss pathogenesis of atherosclerosis.**

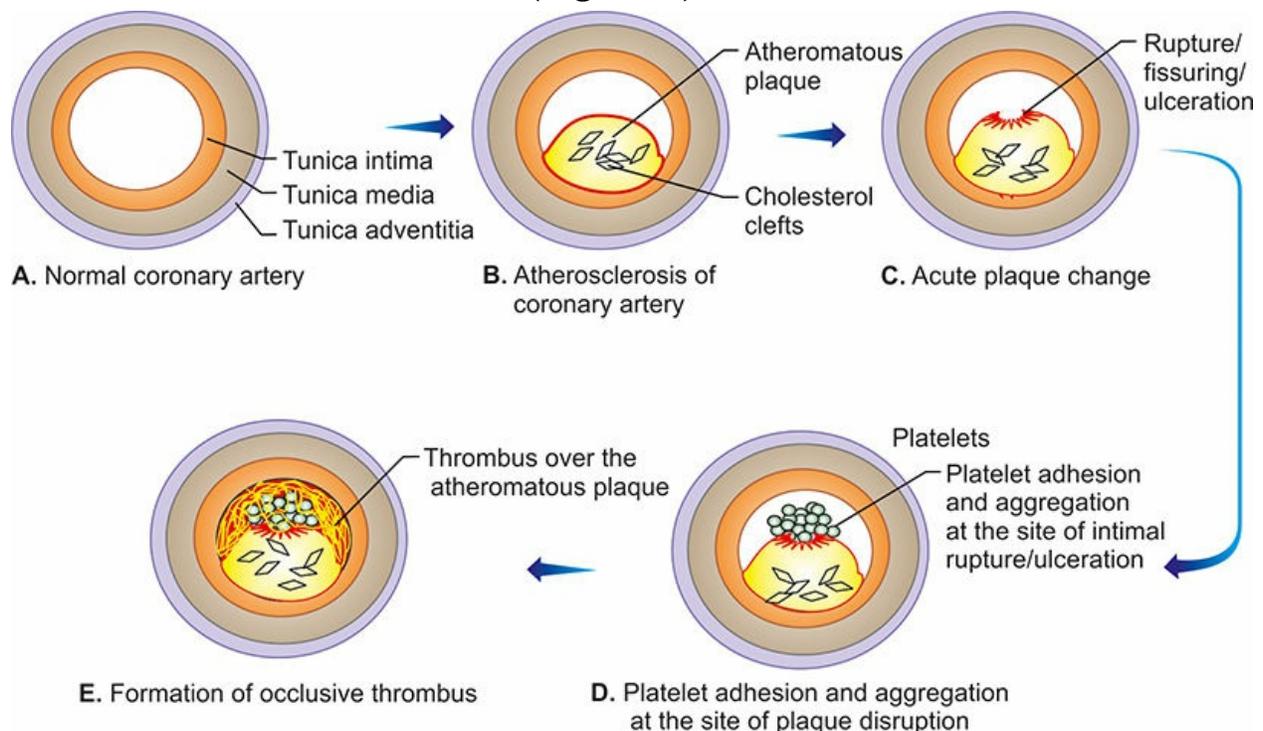

Atherosclerosis is a progressive inflammatory disorder of the arteries characterized by focal deposits of lipids in the intima. It may be clinically silent until they become large enough to reduce tissue perfusion, or until ulceration and disruption of the atheromatous lesion lead to thrombotic occlusion or distal embolization of the vessel.

### **Early Atherosclerosis**

- **Fatty streaks** may be the earliest or precursor lesions of atherosclerosis. Endothelial injury and dysfunction leads to adhesion of leukocyte (mainly monocyte) to endothelium, increased vascular permeability, platelet adhesion and movement of low-density lipoproteins (LDL) across the endothelium into the intima. This initiates the atheroma formation. Lipid accumulated in the intima is engulfed by the macrophages and form foam cells. This is followed by migration and proliferation of smooth muscle cells into the intima. Lipids accumulate both intracellularly (within macrophages and smooth muscle cells) and extracellularly. This results in formation of atheromatous plaque.

- **Atheromatous plaque (Figs. 7.34A to F):** It consists of three regions: (1) Superficial fibrous cap (formed by fibrous tissue synthesized by smooth muscle cells around the lipid core), (2) lipid-rich necrotic core (formed by lipid-laden foam cells that have undergone apoptosis) and (3) shoulder. Some atheromatous plaques bulge into the lumen of the coronary artery and narrow its lumen. This may limit the blood flow, particularly during increased myocardial demand leading to ischemic symptoms. Depending on the structure of plaque, they can be divided into stable and vulnerable (unstable) plaques:
  - **Stable plaques:** They have dense collagenous and thick fibrous caps with minimal inflammation and negligible underlying atheromatous necrotic core. These are less likely to undergo rupture.
  - **High-risk or vulnerable plaque:** They have core with many foam cells and abundant extracellular lipid (large lipid core). The fibrous cap is thin with few smooth muscle cells or groups of inflammatory cells (high density of macrophages and T lymphocytes) and increased inflammation. These are likely to undergo rupture.

Sequential changes in coronary artery atherosclerosis causing occlusion of lumen in ischemic heart disease (Fig. 7.34).

**Figs. 7.34A to E:** Sequential changes in coronary artery atherosclerosis causing occlusion of lumen in ischemic heart disease.

**Advanced atherosclerosis/complicated plaques:** Atherosclerotic plaques can undergo clinically important changes (Box 7.19)

- **Rupture, ulceration, or erosion:** Plaque protrudes into the lumen and can disturb the blood flow → resulting in turbulent flow of blood → which can damage the endothelium → cause rupture, ulceration or erosion of the intimal surface of plaques.
- **Hemorrhage into a plaque:** It may occur due to rupture of the fibrous cap of the plaque or of the thin-walled vessels formed due to neovascularization.
- **Thrombosis and embolism:** Ulceration/erosion/rupture of endothelial surface → exposes the blood to highly thrombogenic subendothelial collagen → favors **thrombus formation** → can partially or completely occlude the lumen (depending on the size of the lumen) → lead to ischemia. The thrombus may become organized or fragment to form thromboemboli.
- **Atheroembolism:** Plaque rupture → discharge atherosclerotic debris into the bloodstream → results in atheroemboli.
- **Aneurysm formation:** Atherosclerosis even though an intimal disease may cause pressure or ischemic atrophy of the underlying media. It may also damage the elastic tissue and cause weakening the wall → result in aneurysmal dilation → which may rupture.
- **Calcification:** It may occur in the central necrotic area of the plaque (dystrophic calcification).

**Box 7.19:** Complications of atheromatous plaque.

- Rupture, ulceration, or erosion
- Hemorrhage into a plaque
- Thrombosis and embolism
- Atheroembolism
- Aneurysm formation
- Calcification

## CORONARY ARTERY DISEASE

**Q.** Discuss etiology, clinical manifestations, investigations, diagnosis and management of angina pectoris.

## Angina Pectoris

**Definition:** Angina pectoris is a clinical syndrome that presents as **paroxysmal and recurrent attacks of substernal or precordial chest discomfort** due to **transient myocardial ischemia**, which falls short of inducing necrosis of myocardial cell.

- **Cause:** Transient myocardial ischemia is due to: (1) obstruction of coronary flow by atherosclerosis, (2) coronary arterial spasm or (3) thrombosis of coronary artery. Others include embolus, coronary ostial stenosis, and coronary arteritis (e.g. in SLE).
- **Precipitate factors for angina:** These include factors that either increase the oxygen requirement of myocardium or reduce blood supply to the myocardium (Table 7.34).

### *Stable Angina Pectoris*

**Q. Discuss the clinical features, investigations and treatment of chronic stable angina.**

- Coronary autoregulation is modified by coronary atherosclerosis, left ventricular hypertrophy, and alterations in autonomic nerve function and endothelial function.
- Coronary atherosclerosis reduces the lumen of the coronary arteries. It cannot increase in perfusion when the demand for flow is increased (e.g. during exertion or excitement). This leads to a situation where when the demand for blood flow is increased (e.g. during exertion or excitement), there cannot be a corresponding increase in perfusion due to the atheroma.
- In stable angina is due to transient myocardial ischemia. Stable angina shows a fixed reduction of at least 70% in the diameter of coronary arteries which causes reduction in coronary blood flow. Inability to increase oxygen extraction or reduced coronary blood flow, together with increased myocardial demand, leads to angina.

**Table 7.34:** Factors precipitating angina.

<i>Factors that increase oxygen demand or cardiac work</i>	<i>Factors that decrease oxygen supply or coronary blood flow</i>
<ul style="list-style-type: none"><li>• Exercise, tachycardia</li><li>• Hypertension, anemia, pregnancy</li></ul>	<ul style="list-style-type: none"><li>• Decreased oxygenation due to anemia or reduced oxygen saturation</li></ul>

- Left ventricular hypertrophy
  - Emotional stress (anger, fright, excitement)  
Hyperthyroidism, arrhythmias
  - Aortic stenosis or regurgitation
- Duration of diastole (coronary blood flow occurs mainly in diastole)
  - Coronary perfusion pressure (aortic diastolic pressure minus coronary sinus or right atrial diastolic pressure)

## Clinical Features

### History

Diagnosis of angina is mainly depends on the clinical history.

### Classical or stable or exertional angina pectoris

It is characterized by:

- **Chest pain:** Constricting discomfort/squeezing/tightening/heaviness/aching in the front of the chest. Pain may radiate to left arm, neck (throat), jaw (chin) or less commonly to right arm, back, and epigastrium. Typical chest pain lasting 2–5 minutes. **Levine’s sign** (clenched fist held over the chest) may be positive.
- **Brought on by physical exertion**, such as after meals and in cold, windy weather or by anger or excitement/emotion.
- **Relieved** (usually within minutes) with **rest or sublingual glyceryl trinitrate**. Occasionally, it may disappear with continued exertion (‘walking through the pain’). Pain seldom lasts more than 20 minutes.

*Typical angina has all the three features mentioned above. Atypical angina has two out of the three, and non-anginal chest pain (Table 7.35) one or less of these features. Many patients with angina may have silent episodes of angina, i.e. without any symptoms.*

**Table 7.35:** Differentiating features of chest pain of ischemic and non-ischemic origin.

	<i>Favors ischemic origin</i>	<i>Against ischemic origin</i>
Character	Constricting, squeezing, burning, heaviness	Dull ache, knife-like, sharp, jabs, pleuritic
Location	Substernal, anterior thorax, arms, shoulders, neck, teeth, interscapular	Left submammary area, left hemithorax
Provoking factors	Exertion, excitement, cold, meals, stress	Pain after completion of exercise, pain with movement

## Types of Angina

- **Stable angina** (described above)
- **Unstable angina** (refer pages 431-2)

- **Refractory angina:** Patients with severe coronary disease in whom revascularization is not possible and angina is not controlled by medical therapy.
- **Variant (Prinzmetal's/vasospastic) angina** (refer pages 432-3): Pain occurs without exertion and usually at rest. It is due to spasm of coronary artery and more frequent in women. Characteristically, it is associated with transient ST segment elevation on the ECG during the pain. Provocation tests (e.g. hyperventilation, cold pressure testing or ergometrine challenge) may be needed for establishing the diagnosis. Prognosis is usually better than those with fixed, significant obstructive lesions. Usually the response to  $\beta$ -blockers may be poor. Calcium channel blockers are used for the treatment.

**Q. Write short note on angina decubitus.**

- **Angina decubitus:** Pain develops while lying flat (raises end-diastolic left ventricular volume, myocardial wall tension and hence oxygen demand).

**Q. Write short note on nocturnal angina.**

- **Nocturnal angina:** Unusual form of angina that develops in aortic regurgitation especially syphilitic. It is characterized by paroxysmal, nocturnal angina pains accompanied by nightmares, dyspnea, palpitations, skin flushing, profuse sweating and wide pulse pressure. It does not relieved by sublingual nitroglycerine.

**Q. Write short note on microvascular angina.**

- **Cardiac syndrome X (microvascular angina):** These patients have angina-like pain, a positive exercise test and angiographically normal coronary arteries. They form a heterogeneous group. It occurs in patients with metabolic syndrome and is more common in women. This type has a good prognosis. Response to nitrates is less reliable and they are difficult to treat. The myocardium shows an abnormal metabolic response to stress, indicating that the myocardial ischemia probably results from abnormal dilator responses of the coronary microvasculature to stress. About 1% die and 0.6% suffer a stroke within 1 year after their first hospital admission.

## Others

- **Status anginosus:** Frequent, recurrent, sustained angina refractory to usual treatment.
- **Walk-through angina:** Angina with effort that disappears gradually during activity that is sustained (although usually at reduced intensity) and after which improved exercise tolerance results.
- **Second-wind angina:** A brief rest after an initial attack results in a markedly improved threshold free from angina. A synonym is "warm-up" angina.
- **Caudal angina:** Angina symptoms occurring in the scalp or head via referred pain.
- **Angina equivalents:** Symptoms other than pain or discomfort that are ischemic related and serve as angina surrogates, e.g. dyspnea, diaphoresis, fatigue, or light-headedness.

- **Silent angina:** Objective manifestations of ischemia without symptoms.

**Table 7.36:** Canadian cardiovascular society (CCS) functional classification of angina.

<i>Class</i>	<i>Features</i>
I	Ordinary physical activity does not cause angina, such as walking and climbing stairs. Angina with strenuous or rapid or prolonged exertion at work or recreation
II	Slight limitation of ordinary activity. Walking or climbing stairs rapidly, walking uphill, walking or stair climbing after meals, or in cold, or in wind, or under emotional stress, or only during the few hours after awakening. Walking more than two blocks on the level and climbing more than one flight of ordinary stairs at a normal pace and in normal conditions
III	Marked limitation of ordinary physical activity: Walking less than two blocks, climbing less than one flight of stairs
IV	Any physical activity brings on angina; angina at rest

### ***Classification of Angina***

- Severity of angina is classified by New York Heart Association Classification in class I to class IV (described earlier).
- Canadian Cardiovascular Society functional classification of angina (Table 7.36).

### ***Physical Examination***

- Usually no abnormal findings in angina. Occasionally a third/fourth heart sound may be detected during an angina episode, dyskinetic cardiac apex, mitral regurgitation and even pulmonary edema may be appreciated.
- Physical examination should include a careful search for evidence hyperlipidemia (e.g. xanthelasma, tendon xanthoma) valve disease (particularly aortic stenosis characterized by slow rising carotid impulse and ejection systolic murmur radiating to the neck), important risk factors (e.g. hypertension, diabetes mellitus), left ventricular dysfunction (cardiomegaly, gallop rhythm), manifestations of arterial disease (carotid bruits, peripheral vascular disease) and unrelated conditions that may exacerbate angina (anemia, thyrotoxicosis), and obesity. Check the blood pressure to identify coexistent hypertension.
- Physical signs of myocardial ischemia: The presence of one or more of these during an attack of pain may be suggestive of myocardial ischemia.

## Investigations

### Electrocardiography (ECG)

**Q.** Write a short essay/note on the investigations in a case of suspected angina pectoris.

**Resting ECG** and ECG in between attacks is normal in most patients (even in patients with severe coronary artery). ECG may show evidence of previous MI and there may be T-wave flattening or inversion in some leads, due to myocardial ischemia or damage. The most convincing ECG evidence of myocardial ischemia is the demonstration of reversible ST segment depression or elevation, with or without T-wave inversion, during the attack of pain (whether spontaneous or induced by exercise testing such as treadmill testing or bicycle ergometry).

**Exercise ECG:** An exercise tolerance test (ETT) is usually done by using a standard treadmill or bicycle ergometer protocol (recording of ECG before, during and after exercise). During this process, patient's ECG, BP and general condition are monitored.

- **Indications**

- Two sets of cardiac enzymes at 4-hour intervals should be normal.
- No significant abnormality in 12-lead ECG at the time of arrival and pre-exercise.
- Absence of ischemic chest pain at the time of exercise testing.

- **Contraindications for exercise testing (Box 7.20)**

- Indications for terminating exercise testing of ECG (Box 7.21)
- **Interpretation:** Planar or down-sloping ST segment depression of 1 mm or more indicates ischemia. Up-sloping ST depression is less specific and often found in normal individuals (modified Bruce protocol is followed).
- **Advantages:** Exercise testing is useful means of assessing the severity of coronary disease and identifying high-risk individuals (i.e. post-infarct angina, poor effort tolerance, ischemia at low workload, left main or three-vessel disease, poor LV function).
- **Disadvantages:** It may produce false-positive results in the presence of digoxin therapy, left ventricular hypertrophy, bundle branch block or Wolff-Parkinson-White (WPW) syndrome. The accuracy is lower in women than in men. The test is considered inconclusive (rather than negative) if the patient cannot achieve an adequate level of exercise because of locomotor or other non-cardiac problems.

### Box 7.20: Contraindications for exercise testing.

#### Absolute

- Acute myocardial infarction (within 2 days)
- High-risk unstable angina
- Uncontrolled cardiac arrhythmias causing symptoms or hemodynamic compromise
- Symptomatic severe aortic stenosis

- Uncontrolled symptomatic heart failure
- Acute pulmonary embolus or pulmonary infarction
- Acute pericarditis or myocarditis
- Acute aortic dissection

#### **Relative**

- Left main coronary stenosis
- Moderate stenotic valvular heart disease
- Electrolyte abnormalities
- Severe arterial hypertension
- Bradyarrhythmias or tachyarrhythmias
- Hypertrophic cardiomyopathy and other forms of outflow tract obstruction
- Mental or physical impairment leading to inability to exercise adequately
- High-degree atrioventricular block

### *Other forms of stress testing*

#### **Box 7.21:** Indications for terminating exercise testing.

- Drop in systolic BP of >10 mm Hg from baseline BP despite an increase in workload, when accompanied by other evidence of ischemia
- Moderate to severe angina
- Increasing nervous system symptoms (e.g. ataxia, dizziness, or near-syncope)
- Signs of poor perfusion (cyanosis or pallor)
- Sustained ventricular tachycardia
- ST elevation (>1.0 mm) in leads without diagnostic Q-waves (other than V<sub>1</sub> or aVR)

- **Myocardial perfusion scanning:** It is performed using radioactive isotopes. It may be helpful in the (1) evaluation of patients with an equivocal or uninterpretable exercise test and (2) patients who cannot perform exercise. The scintiscans of the myocardium are obtained at rest and during stress (either exercise testing or pharmacological stress, such as a controlled infusion of dipyridamole, adenosine or dobutamine), after the administration of an intravenous radioactive isotope, such as thallium (<sup>201</sup> thallium) or technetium (<sup>99</sup> technetium sestamibi). The radioactive isotopes are taken up by viable perfused myocardium. If there is a perfusion defect during stress but not at rest, it indicates evidence of reversible myocardial ischemia, whereas a persistent perfusion defect seen during both phases is usually indicative of previous MI.
- **Stress echocardiography:** It is an alternative to myocardial perfusion scanning and has similar predictive accuracy. On transthoracic echocardiography the ischemic segments show reversible defects in

contractility during exercise or pharmacological stress, whereas infarcted regions do not contract at rest or during stress.

**Table 7.37: Indications for coronary angiography.**

• Strongly positive stress test	• Noninvasive tests have failed to establish the cause of atypical chest pain
• Indeterminate stress tests but clinical features of IHD	• Previous re-vascularization procedure
• Strong suspicion of left main coronary artery or three vessel disease	• Presence of heart failure
• Patients with known or possible angina pectoris who have survived cardiac arrest	• Non-atherosclerotic cause of ischemia (e.g. coronary arterial anomaly)
• Patients considered for revascularization, i.e. a percutaneous coronary intervention (PCI) or coronary artery bypass grafting (CABG)	• Frequent re-admission for chest pain. Occupation demands a definitive diagnosis
• Unable to perform non- invasive tests	• Chronic stable angina pectoris with severely symptomatic despite medical therapy

**Coronary arteriography:** It gives detailed anatomical information about the extent and nature of coronary artery disease. It usually done with a view to coronary artery bypass graft (CABG) surgery or percutaneous coronary intervention (PCI). It is done under local anesthesia and requires specialized radiological equipment, cardiac monitoring and an experienced team. Indications for coronary angiography are listed in Table 7.37.

#### *Newer modalities*

These include multiple-slice spiral computed tomographic coronary angiography (CTCA), intravascular ultrasound, magnetic resonance coronary angiography (MRCA) and positron emission tomography (myocardial viability is assessed using glucose metabolism).

#### **Laboratory Tests**

- Fasting lipid profile
- Fasting glucose and/or glycated hemoglobin (HbA1c) level if available; additional oral glucose tolerance test (OGTT) if both are inconclusive.
- Complete blood count (CBC) and hematocrit.
- Creatinine level with estimation of glomerular filtration rate (GFR).

- Biochemical markers of myocardial injury (Troponin T or I) if clinical evaluation suggests an acute coronary syndrome (ACS).
- Thyroid function tests.
- Liver function tests early after beginning statin therapy.

Advice to patients with angina is presented in Table 7.38.

**Table 7.38: Advice to patients with angina.**

<p><b>Stop smoking</b></p> <p><b>Reduce/maintain ideal body weight</b></p> <p><b>Exercise</b></p> <ul style="list-style-type: none"> <li>• Take regular exercise (may promote collateral vessels) but avoid unaccustomed strenuous exercises</li> <li>• Avoid walking or exercise after a heavy meal or in very cold weather</li> <li>• Take sublingual nitrate before any exertion that may induce angina</li> </ul>	<p><b>ABCDE</b></p> <p><b>A</b> = Aspirin and Antianginal therapy</p> <p><b>B</b> = Beta-blocker and Blood pressure</p> <p><b>C</b> = Cigarette smoking and Cholesterol</p> <p><b>D</b> = Diet and Diabetes</p> <p><b>E</b> = Education and Exercise</p>
---	--

**Q. Write a short essay/note on:**

- **Treatment of angina pectoris.**
- **Management of chronic stable angina.**
- **Drugs used in the treatment of chronic stable angina/anti-anginal drugs.**
- **Drug treatment of angina pectoris.**

**Box 7.22: Goals of treatment of angina pectoris.**

- Assessment of severity and extent of arterial disease
- Measures to control symptoms
- Identification and control of risk factors (e.g. smoking, hypertension, diabetes and hyperlipidemia)
- Identification of high-risk patients for treatment and measures to improve life expectancy

**Management of Angina Pectoris**

Management can be discussed under three headings: (A) general measures, (B) drug treatment and (C) surgical treatment.

Goals of treatment of angina pectoris are listed in Box 7.22.

**General Measures**

- Careful explanation about the nature of their condition (disease process).
- Evaluate the risk factors and steps to correct them where possible. Advice to be given to the patient is listed in Table 7.38.

- Correction of precipitating underlying conditions, e.g. anemia, hyperthyroidism, valvular disease and arrhythmias should be treated.
- **Management of coexistent conditions:** Identification and treatment of aggravating conditions like aortic stenosis, hypertrophic cardiomyopathy, control of hypertension and diabetes (ACE inhibitors are useful in these patients).
- **Lipid management:** Identify hypercholesterolemia (hyperlipidemia) and treat with diet and drugs (with the goal of reducing LDL <100 mg dL; goal of <70 mg/dL in very high-risk patients).
- Lifestyle modification.

**Q. Write short essay/note on lifestyle modifications in cardiovascular disease.**

- **Healthy diet:** Increase polyunsaturated fatty acid consumption, mainly from oily fish: **2 to 3 servings of oily fish per week** may help prevent cardiovascular disease (CVD).
- Saturated fatty acids must comprise less than 10% of the total energy intake. Protein with low saturated fats should replace those high in these harmful fats.
- Limit salt intake to less than 5 grams per day.
- Consume 30 to 45 grams of fiber/day (e.g. wholegrain products, fruits and vegetables). Avoid simple carbohydrates with high glycemic load.
- Consume 200 grams of vegetables and 200 grams of fruits per day.
- Limit consumption of alcoholic beverages.

### **Anti-anginal Drug Treatment**

Anti-angina drugs can be divided into five groups. They are used to relieve or prevent the symptoms of angina. These include (1) nitrates, (2)  $\beta$ -blockers, (3) calcium antagonists, (4) potassium channel activators and (5)  $I_f$  channel antagonist.

#### **1. Nitrates**

Short acting (Glyceryl trinitrate (GTN), nitroglycerine) or long acting (Isosorbide dinitrate, Isosorbide mononitrate)

**Mechanism of action:** Nitrates directly act on smooth muscle in the walls of blood vessels and produces dilatation of arteries and veins. This lowers blood pressure, reduces venous return to heart and produces dilatation of coronary blood vessels. Nitrates cause reduction in myocardial oxygen demand (lower preload and afterload) as well as an increase in myocardial oxygen supply (coronary vasodilatation) predominantly by perfusing the subendocardial region.

**Indications:** Prophylaxis and treatment of angina. Prophylactically to use the drug before taking exercise that is liable to produce pain. Prophylactic use of glyceryl trinitrate (GTN) should be encouraged because physical activity promotes the formation of collateral vessels. For predominant nocturnal angina, long-acting nitrates can be given at the end of the day.

**Contraindications:** Nitrates should not be given along with phosphodiesterase type-5 (PDE-5), inhibitors (e.g. sildenafil, tadalafil, vardenafil) within the same 24 hours period because it may produce severe hypotension. Other contraindications include obstructive hypertrophic cardiomyopathy, severe aortic stenosis, constrictive pericarditis, mitral stenosis and closed-angle glaucoma.

- **Glyceryl trinitrate (GTN):**

- **Preparations:** (1) metered-dose aerosol (400  $\mu$ g per spray) or (2) as a tablet (300 or 500  $\mu$ g).
- **Action:** Sublingual GTN has a short duration of action will relieve an attack of angina in 2–3 minutes.

- **Isosorbide dinitrate** (10–20 mg 2 to 3 times daily) has prolonged action and is given by mouth. Headache is a common side effect but tends to diminish if the patient perseveres with the treatment. Tolerance can develop with continuous nitrate therapy which can be avoided by a 6–8-

hour nitrate-free period. Hence, doses are given in the morning and afternoon.

- **Isosorbide mononitrate** (20–60 mg once or twice daily) also can be given by mouth.

## 2. $\beta$ -blockers

**Mechanism:** These drugs lower oxygen demand of myocardium by reducing heart rate, blood pressure and myocardial contractility. They inhibit apoptosis by inhibiting beta adrenoceptors, and have antioxidant and antiproliferative properties. They also counteract the direct adverse effects of catecholamines and have antiarrhythmic action. They are useful to control tachycardia, hypertension and continued angina.

- **Cardioselective  $\beta$ -blockers:** Include slow-release **metoprolol** 50–200 mg daily, **bisoprolol** 5–15 mg daily, and **atenolol**(50–200 mg/day). They have fewer peripheral side effects.
- **Non-selective  $\beta$ -blockers:** **Propranolol** is started in a small initial dose (20 mg thrice daily) and gradually increased to 80–120 mg three times daily. They may aggravate coronary vasospasm by blocking the coronary artery  $\beta$ 2-adrenoceptors.
- **Carvedilol** (3.125–25 mg twice a day) has additional advantage of having antiarrhythmic effects.

## 3. Calcium channel antagonists (calcium channel blockers)

- **Dihydropyridine calcium antagonists** [e.g. nifedipine, amlodipine (dihydropyridines), felodipine, and nicedipine]. They produce coronary and peripheral arterial dilatation, and negative inotropy. They often cause a reflex tachycardia.
  - **Nifedipine:** It is a powerful coronary and systemic arteriolar dilator. This can caused marked reflex tachycardia. Short-acting nifedipine are not used because it can increase mortality due to myocardial infarction. Long-acting preparations are given usually along with a  $\beta$ -blocker. Dose is 5–20 mg 3 times daily.
  - **Amlodipine:** Dose is 2.5–10 mg daily. Side effects ankle edema and reflex tachycardia.
- **Non-dihydropyridine calcium antagonists**, e.g. verapamil (phenyl alkylamines), diltiazem (benzothiapines). They produce coronary and peripheral arterial dilatation, and negative inotropy and also reduce conductivity. Because of its negative inotropic effect, they should be avoided in patients with impaired ventricular function (uncompensated heart failure).
  - **Verapamil:** Dose is 40–80 mg thrice daily. Useful anti-arrhythmic properties. Common adverse effect is constipation.
  - **Diltiazem:** 60–120 mg 3 times daily. Similar anti-arrhythmic properties to verapamil.
  - $\beta$ -blockers reduce mortality after myocardial infarction. Hence, it is reasonable to start a  $\beta$ -blocker and then add a calcium channel blocker if needed. However,  $\beta$ -blockers should not be combined with verapamil, because of their synergistic effect on heart rate and myocardial contractility.

## 4. Second-line anti-anginal drugs

- Potassium channel activators/openers: **Nicorandil** increases potassium ion conductance by opening ATP-sensitive potassium channels resulting in smooth muscle relaxation causing arterial and venous dilatation. It does not develop tolerance as seen with nitrates. They also provide protection of myocardium during ischemia and prevention of intracellular calcium toxicity. It is given in the dose of 10–30 mg twice daily orally.
- $I_f$  channel antagonist: **Ivabradine** selectively inhibits inward sodium-potassium current (important pacemaking current in the cells sinus (SA) node). This slows the rate of diastolic depolarization and induces bradycardia ('bradycardic' drug). In contrast to  $\beta$ -blockers and rate-limiting calcium antagonists, it does not have other cardiovascular effects. Thus, it does not affect contractility, AV nodal conduction or hemodynamics. It can be combined with other agents and is safe to use in patients with heart failure. It may produce brightness in visual fields because it also blocks the retinal current and is transient side effect. Contraindicated in sick sinus syndrome, AV block.

- **Ranolazine:** It inhibits late sodium channels in cardiac cells. It does not affect heart rate and blood pressure. It is the drug of choice in bradycardic and hypertensive patients. It is metabolized by cytochrome P450 3A4. Dose is 500–1000 mg twice a day. Side-effects include constipation, dizziness, prolongation of QT interval.

None of these groups is more effective than another group. It is conventional to start therapy with low-dose aspirin, a statin, sublingual GTN and a  $\beta$ -blocker. If needed later add a calcium channel antagonist or a long-acting nitrate. The goal is the control of angina with minimum side-effects and the simplest possible drug regimen. Indications and contraindications of various antianginal drugs are given in Table 7.39.

**Table 7.39:** Indications and contraindications of various antianginal drugs.

<b>Drug</b>	<b>Indication</b>	<b>Contraindication</b>
<i><math>\alpha</math>-Blockers</i>	<ul style="list-style-type: none"> <li>• Post-myocardial infarction</li> <li>• CHF (compensated)</li> <li>• Ventricular tachycardia</li> <li>• Supraventricular tachycardia (SVT)</li> <li>• Systemic hypertension</li> <li>• Hyperthyroidism</li> </ul>	<ul style="list-style-type: none"> <li>• Decompensated HF</li> <li>• Severe bradycardia or AV block</li> <li>• Severe depression</li> <li>• Symptomatic PAD</li> <li>• Raynaud's phenomenon</li> <li>• Severe COPD</li> </ul>

(AV: atrioventricular; CCBs: calcium channel blockers; COPD: chronic obstructive pulmonary disease; DHP: dihydropyridine calcium antagonists; LV: left ventricular; PAD: peripheral artery disease; PDE-5

inhibitor: phosphodiesterase type 5 inhibitor)

**Q. Write a short essay/note on antiplatelet drugs and its indications.**

### 5. Antiplatelet therapy

Anti-anginal drugs ameliorate only symptoms but may not reduce mortality. To reduce the risk of adverse events such as MI, antiplatelet drugs are given.

#### Aspirin

- Aspirin inhibits the synthesis of prostaglandins namely thromboxane A<sub>2</sub> which is a potent vasoconstrictor and platelet activator.
- Dose: Low-dose therapy in the dose of 75–150 mg/day.

#### P2Y<sub>12</sub> antagonists

##### • Clopidogrel

- It is a thienopyridine which inhibits ADP dependent activation of the GPIIb/IIIa complex and prevents platelet aggregation.
- It is an equally effective antiplatelet agent that can be used in patients who cannot tolerate aspirin.
- It may have a synergistic effect when combined with aspirin in patients following acute coronary syndrome or implantation of a drug-eluting stent. The benefit of its combination with aspirin was not found chronic stable angina.
- Dose: 75 mg daily.
- **Prasugrel and ticagrelor** are new P2Y<sub>12</sub> antagonists have higher platelet inhibition compared to clopidogrel.

**6. Statins:** Irrespective of the LDL or cholesterol levels.

### ***Invasive (Surgical) Treatment: Revascularization***

#### *Percutaneous coronary intervention (PCI)*

- Percutaneous coronary interventions include angioplasty [percutaneous transluminal coronary angioplasty (PTCA)] or stent placement in the coronary artery. It is the process to maximize and maintain dilatation of a stenosed coronary artery. A coronary stent is a piece of coated metallic 'scaffolding' (fine guidewire) that can be deployed on a balloon. In this process, a small inflatable balloon and metallic coronary stent introduced percutaneously into the arterial circulation via an arterial catheter through the femoral, radial or brachial artery under radiographic control. It is passed across the coronary stenosis and balloon is inflated to dilate the stenosis. Dilatation can be repeated if symptoms recur.
- **Types of stents:** Two types namely **(1) bare-metal stents** and **(2) drug-eluting stents**. The drug-eluting stents are coated stents lined with substances (e.g. sirolimus and paclitaxel) that prevent neo-intimal hyperplasia and reduce the risk of coronary artery re-occlusion. Recent data suggest both types of stents to be equally effective over long-term follow-up.
- **Indications for percutaneous coronary interventions (PCI)**
  - Ideal for single-vessel or two vessel coronary disease without significant lesions in the proximal left anterior descending artery (LAD), with normal LV function, with high risk on noninvasive testing and a large area of viable myocardium.
  - Undergone prior PCI with either recurrence of stenosis or high risk on noninvasive testing.
  - Failure of medical therapy and with acceptable risk for PCI. Treatment of choice for unstable angina (UA) when rest pain recurs in spite of full medical treatment.
  - Lesion suitable for PCI

– No diabetes.

- **Complications of the procedure:** Bleeding, hematoma, dissection and pseudo-aneurysm from the arterial puncture site. Serious complications are acute myocardial infarction (2%), stroke (0.4%) and death (1%). Long-term complication is re-stenosis (33% of cases) which is due to a combination of elastic recoil and smooth muscle proliferation (neo-intimal hyperplasia). It tends to occur within 3 months.

#### *Coronary artery bypass grafting (CABG)*

- In coronary artery bypass grafting, autologous veins (reversed segments of the patient's own saphenous vein) or arteries (internal mammary artery/radial artery/gastroepiploic arteries) are anastomosed to the ascending aorta at one end and to the native coronary arteries distal to the area of occlusion/stenosis at the other end.
- Usually done under cardiopulmonary bypass but, in few cases, it can be done in the beating heart ('off-pump' surgery). Aspirin (75–150 mg daily) and clopidogrel (75 mg daily) both improve graft patency, and one or other should be given indefinitely.
- **Indications:**
  - Significant left main coronary disease.
  - Triple vessel disease/two blood vessel disease with reduced left ventricular function (left ventricular ejection fraction is <50%).
  - Two vessel disease with significant proximal left anterior descending artery disease and either LVEF <50% or demonstrable ischemic on noninvasive testing.
  - Failure of medical therapy and with acceptable risk for CABG.
  - Diabetes
  - Prior CABG, PCI (percutaneous coronary interventions) with recurrent restenosis
  - Abnormal stress test.
- **Risks:** Higher risks in elderly, those with poor left ventricular function and those with significant comorbidity, such as renal failure.
- **Minimally invasive operative procedures for bypass grafting (MIDCAB):** Laparoscopic approaches may be useful in patients with previous CABG and those with coexistent medical conditions which would increase the operative risks of 'full' CABG).

Novel therapy in angina is summarized in Box 7.23.

Flowchart 7.1 shows scheme for the investigation and management of stable angina.

### **Prognosis**

- Critical stenosis (>70%) of coronary arteries and 5 years mortality rate: One artery—2%, two arteries—8%, three arteries—11%. 50% stenosis of left main coronary artery has a mortality rate of about 15% per year.
- Other poor prognostic factors are advanced age (>75 years), diabetes, morbid obesity, accompanying peripheral vascular and or cerebrovascular disease, previous myocardial infarction, high levels of plasma CRP, evidence of LV dysfunction.

## Box 7.23: Novel therapy in angina.

### Newer drugs

- Ivabradine: Selectively blocks  $I_f$  in a current-dependent fashion in pacemaker cells of the sinoatrial node
- Ranolazine: Partial fatty acid oxidation (pFOX) inhibitor, late sodium current blocker
- Trimetazidine: Inhibitor of partial fatty acid oxidation (pFOX)
- Perhexilene: Inhibits mitochondrial carnitine palmitoyltransferase-1(CPT-1)
- Etomoxir/Oxfenicine: CPT 1 inhibitor
- Nicorandil: Activation of ATP-sensitive  $K^+$  channels
- Rho kinase inhibition: Fasudil
- Molsidomine and linsidomine act by releasing nitric oxide
- Others: Testosterone, endothelin receptor blockers (bosentan), allopurinol

TMLR: Transmyocardial laser revascularization

EECP: Enhanced external counter pulsation

Chelation therapy: Intravenous EDTA infusions

Spinal cord stimulation, coronary sinus reducing device, apheresis

### Other novel agents

- **Monoclonal antibodies:** Inclacumab is a P-selectin monoclonal antibody, in patients with NSTEMI-ACS undergoing PCI. It reduces myocardial damage
- **Stem cell therapy:** The use of stem cells derived from bone marrow or myocardium to improve cardiac function has been promising

## ACUTE CORONARY SYNDROME

### Q. Write short essay on acute coronary syndromes.

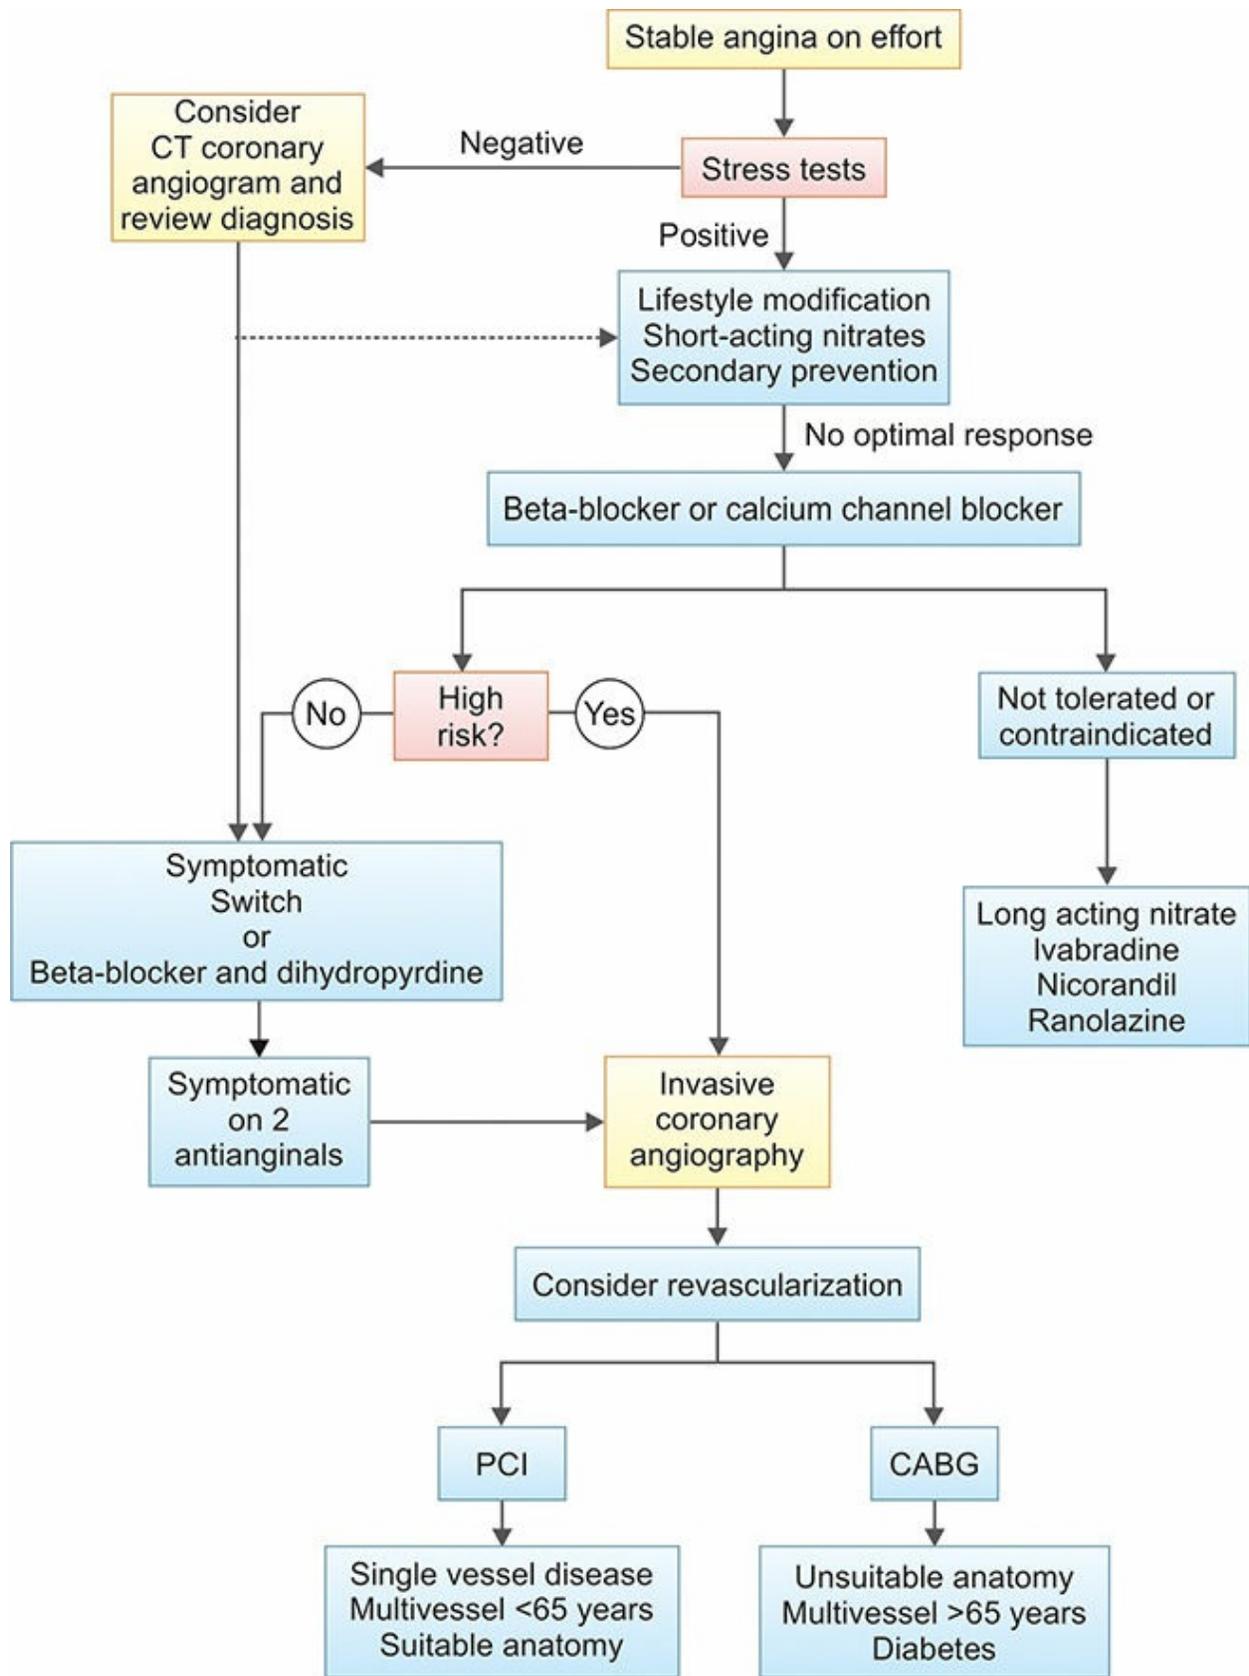

**Ischemic heart disease (IHD)** forms a spectrum of diseases (Flowchart 7.2) and consists of stable angina and acute coronary syndromes (includes STEMI, NSTEMI and unstable angina).

**Acute coronary syndrome (ACS)** is a term used for spectrum of clinical presentations due to acute myocardial ischemia. It includes:

- **ST elevation myocardial infarction (STEMI) (Flowchart 7.3):** Majority of STEMI has Q-wave MI (QwMI).
- **Non ST elevation myocardial infarction (NSTEMI):** A small percentage of STEMI and majority of NSTEMI have non- Q-wave MI (NQwMI, previously known as subendocardial infarction). However, the terms Q-wave or non Q-wave infarctions are not used at present.
- **Unstable angina (UA):** Includes patients with acute coronary syndrome

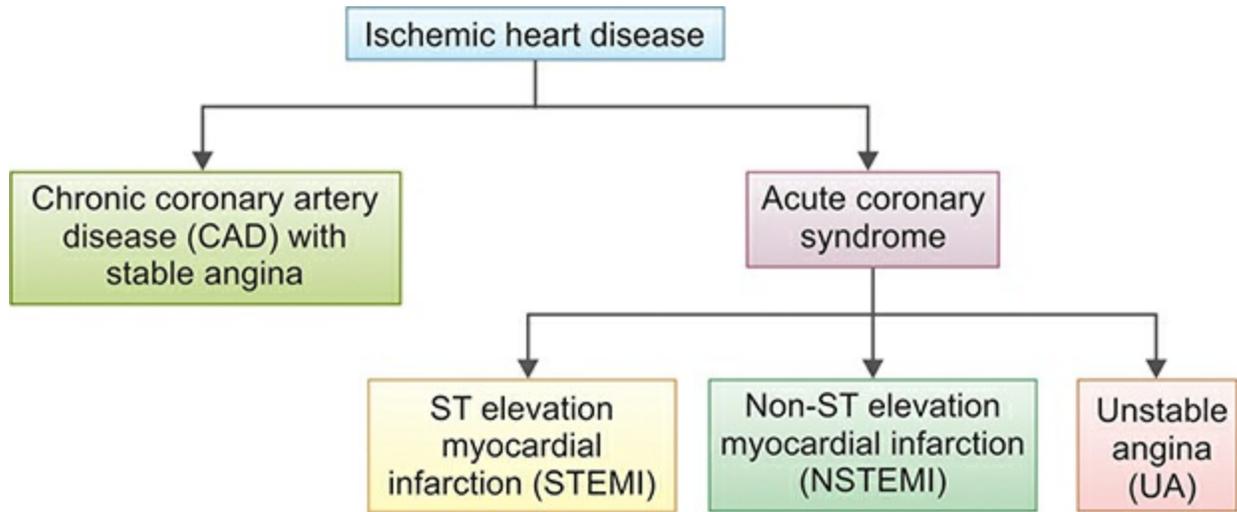

but with normal ECG, without elevation of cardiac injury markers and no ST elevation in the ECG. Management of unstable angina and NSTEMI is similar.

**Flowchart 7.1:** Scheme for the investigation and management of stable angina.

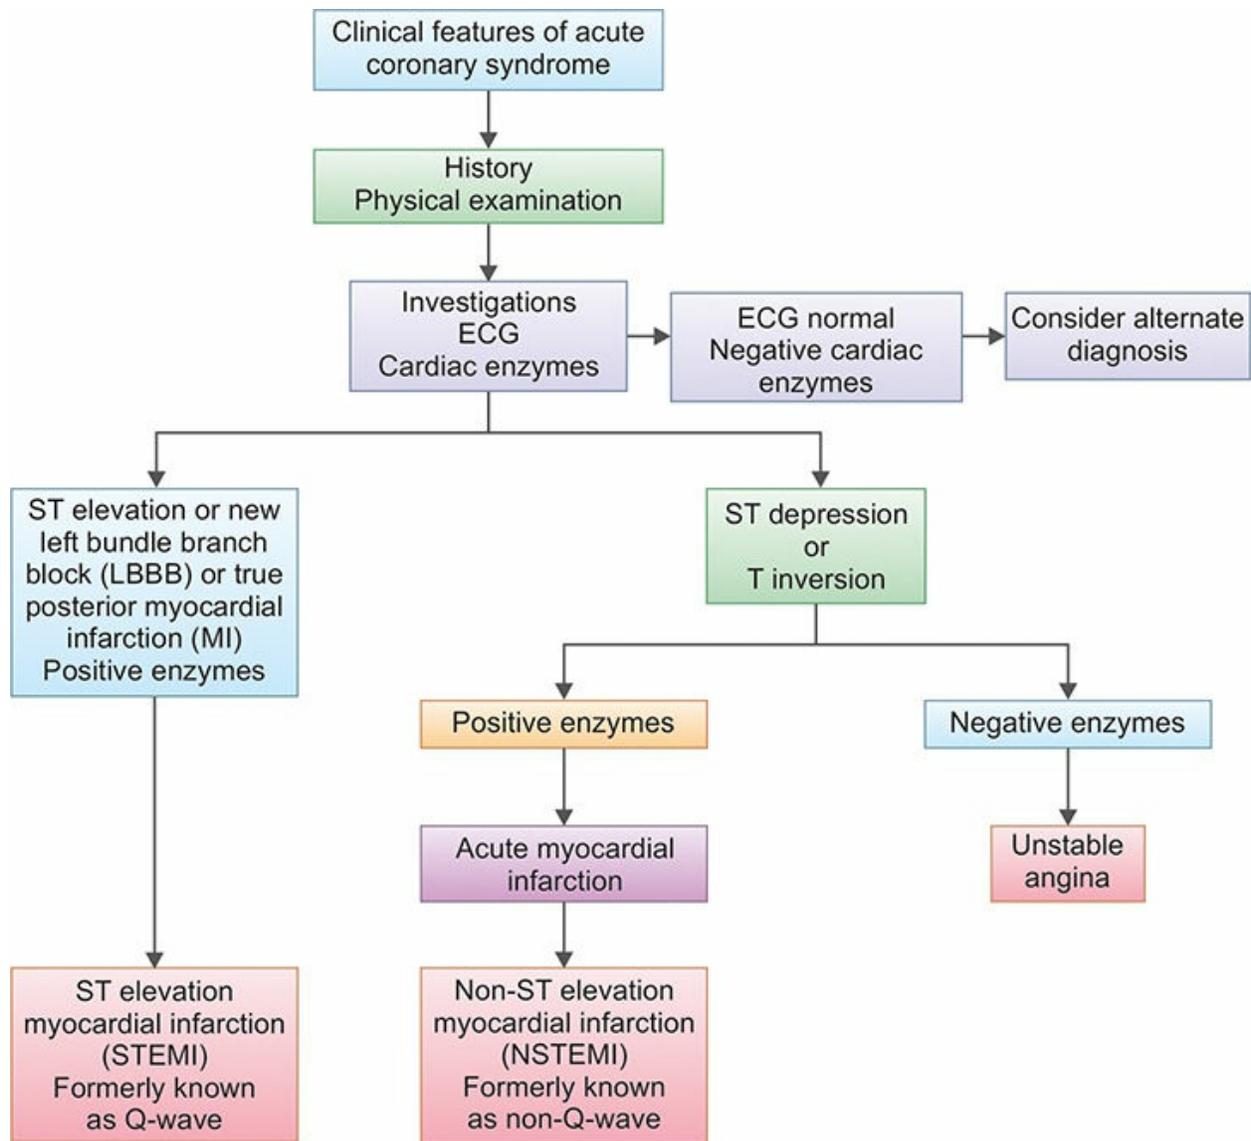

(CABG: coronary artery bypass grafting; PCI: percutaneous coronary intervention)

**Flowchart 7.2:** Spectrum of ischemic heart disease

**Flowchart 7.3:** New classification scheme of acute coronary syndrome.

### Pathophysiology (Table 7.40)

**Table 7.40:** Pathophysiology of stable angina and acute coronary syndrome.

<i>Stable angina</i>	<i>Unstable angina</i>	<i>NSTEMI</i>	<i>STEMI</i>
<ul style="list-style-type: none"> <li>Progressive narrowing of coronary lumen</li> <li>Stable fibrous cap</li> </ul>	<ul style="list-style-type: none"> <li>Progressive narrowing</li> <li>Acute worsening of coronary lumen due to thrombus formation</li> </ul>	<ul style="list-style-type: none"> <li>Acute worsening of coronary lumen due to thrombus formation</li> <li>Sub-occlusive/transient coronary thrombus with myocardial necrosis</li> </ul>	<ul style="list-style-type: none"> <li>Minimal prior narrowing of coronary lumen</li> <li>Acute rupture of thin fibrous cap</li> <li>Occlusive thrombus formation</li> <li>Acute injury pattern</li> </ul>

## ST Elevation Myocardial Infarction (STEMI)

**Q. Discuss the etiology (risk factors), clinical features, investigations, complications, and management of acute coronary syndrome/ACS (ST elevation myocardial infarction—STEMI)/acute myocardial infarction.**

### *Causes of Myocardial Infarction*

**Q. Write short essay/note on risk factors of acute myocardial infarction.**

- STEMI is due to the **formation of an occlusive thrombus at the site of rupture of an atheromatous plaque** in a coronary artery. Usually there is minimal prior narrowing of coronary lumen.
- **Other causes:** Coronary spasm, rarely coronary emboli as well as by ostial narrowing due to aortitis, hypercoagulable state and use of cocaine. Congenital anomalies such as the origin of the left anterior descending coronary artery from the pulmonary artery may cause myocardial ischemia in infancy, but this cause is very rare in adults.
- Limitation of the ability to increase flow to meet increased myocardial demand occurs with 50% coronary stenosis while 80% coronary stenosis causes myocardial ischemia at rest or with minimal stress.

### *Types of Myocardial Infarction*

- **Type 1:** Spontaneous myocardial infarction with ischemia due to a primary coronary event, e.g. plaque erosion/rupture, fissuring or dissection
- **Type 2:** Myocardial oxygen demand supply mismatch, i.e. secondary to ischemia due to increased oxygen demand or decreased supply (e.g. coronary spasm, coronary embolism, anemia, arrhythmias, hypertension, or hypotension).
- **Type 3:** Diagnosis of MI resulting in sudden cardiac death.
- **Type 4:** MI after percutaneous coronary intervention (PCI)—post PCI related.
- **Type 5:** MI after coronary artery bypass graft (CABG)—post CABG.

Transmural infarct is an infarct that involves the full thickness of myocardium. Subendocardial infarct is an infarct which involves subendocardial region. However, these terms are no longer used. Silent infarct is infarct without symptoms but with only ECG changes.

## Non-ST Elevation Myocardial Infarction (NSTEMI)

### *Causes*

- It is most commonly caused by an imbalance between oxygen supply and oxygen demand. This imbalance results from a partially occluding thrombus forming on a disrupted atherothrombotic coronary plaque or on eroded coronary artery endothelium.
- Severe ischemia or myocardial necrosis may develop due to the reduction of coronary blood flow caused by the partially occluding thrombus and by downstream embolization of platelet aggregates and/or atherosclerotic debris.
- **Other causes:** More than one of the following processes may be involved.
  - Dynamic obstruction (e.g. coronary spasm, as in Prinzmetal’s variant angina)
  - Severe mechanical obstruction due to progressive coronary atherosclerosis
  - Increased myocardial oxygen demand produced by conditions such as fever, tachycardia, and thyrotoxicosis in the presence of fixed epicardial coronary obstruction.

## ***Diagnosis of NSTEMI***

- **Clinical presentation:** Diagnosis of NSTEMI is largely based on the clinical presentation. Typically, chest discomfort is severe and has at least one of three features:
  1. Occurs at rest (or with minimal exertion) lasting for >10 minutes.
  2. Relatively recent onset (i.e. within the prior 2 weeks) and/or
  3. Occurs with a crescendo pattern (i.e. distinctly more severe, prolonged, or frequent than previous episodes).
- **Evidence of myocardial necrosis:** Diagnosis of NSTEMI is established, if a patient with the above clinical features shows the evidence of myocardial necrosis, as reflected in abnormally elevated levels of biomarkers of cardiac necrosis.

## **Clinical Features of Acute Coronary Syndrome**

### ***Symptoms***

- **Prolonged cardiac pain:** Myocardial ischemia causing chest discomfort is termed angina pectoris. Thus, classic manifestation of ischemia is angina, which is usually described as a heavy chest pressure or squeezing, a burning feeling, or difficulty breathing.
- The discomfort often radiates to the left shoulder, neck, or arm. It typically builds in intensity over a period of a few minutes.

- The pain may begin with exercise or psychological stress, but ACS most commonly occurs without obvious precipitating factors.
- Pain may be absent in patients with prior cardiac, prior stroke, age >75 years, and diabetes mellitus. Painless MI is more common in females compared to males.
- Any patient with severe chest pain that lasts for more than 20 minutes may be suffering from a myocardial infarction. This pain is usually does not respond to sublingual GTN.
- **Other features:** Include anxiety and fear of impending death, nausea and vomiting, breathlessness, collapse/syncope.

### **Physical Signs (Table 7.41)**

Sometimes infarction occurs without any physical signs.

**Table 7.41:** Various signs of acute coronary syndrome and its causes.

<i>Cause of signs</i>	<i>Sign</i>
Tissue damage	Mild fever
Sympathetic activation	Pallor, sweating, tachycardia
Impaired myocardial function	Hypotension, oliguria, cold peripheries, narrow pulse pressure, raised JVP, third heart sound, soft first heart sound, diffuse apical impulse, basal crepitations in the lung
Vagal activation	Vomiting, bradycardia
Complication	Systolic murmur due to mitral regurgitation or uncommonly due to VSD, pericardial friction rub due to pericarditis

### **Complications of Acute Coronary Syndrome**

Major mechanical and structural complications occur only with significant, often transmural, MI (Table 7.42).

#### **Arrhythmias**

- Many patients with acute coronary syndrome may develop arrhythmia and they are transient in most of cases and are of no hemodynamic or prognostic importance. Relief of pain relief, rest and the correction of hypokalemia may prevent arrhythmias.
- **Ventricular fibrillation:** Develops in 5–10% of patients and appears to be the major cause of death in those who die before receiving medical

attention.

- **Atrial fibrillation** is common but usually transient and does not need emergency treatment. However, if it produces a rapid ventricular rate with hypotension or circulatory collapse, prompt cardioversion by immediate synchronized DC shock is required. In other cases digoxin or a  $\beta$ -blocker is given.
- **Bradycardia:** Usually does not need treatment, but if there is hypotension or hemodynamic deterioration, atropine (0.6–1.2 mg IV) may be given. Various arrhythmias in acute coronary syndrome (Box 7.24).

**Table 7.42:** Complications of acute myocardial infarction.

Type	Complication
Ischemic	Infarct extension, reinfarction, angina
Mechanical	Cardiogenic shock, cardiac failure, mitral regurgitation, ventricular aneurysm, cardiac rupture (papillary muscle, ventricular septum, cardiac wall)
Arrhythmic	Atrial or ventricular arrhythmia, dysfunction of sinus or atrioventricular node
Thromboembolic	Left ventricular mural thrombus, CNS embolus (e.g. stroke) and peripheral embolus
Inflammatory	Pericarditis

### **Cardiogenic Shock**

- Causes:
  - Arrhythmia
  - Hypovolemia due to excessive diuretic therapy or recurrent vomiting
  - Extensive myocardial damage (has bad prognosis).
- **Risk factors:** Older age, hypertension, diabetes mellitus, multivessel coronary artery disease, anterior MI, prior MI or angina, prior heart failure, STEMI and left bundle branch block.

### **Box 7.24:** Various arrhythmias in acute coronary syndrome.

- Atrial fibrillation
- Atrial tachycardia
- Bradycardia (especially after inferior MI) and tachycardia
- Atrioventricular heart blocks
- Ventricular fibrillation

- Ventricular tachycardia
  - Accelerated idioventricular rhythm
  - Ventricular ectopic beats
- 

## ***Left Ventricular Failure***

Commonly leads to pulmonary edema.

## ***Mechanical Complications***

- **Myocardial rupture:** Part of the necrotic muscle in a fresh infarct can result in tear or cardiac rupture. Most frequent during 3 to 7 days after transmural infarcts.
- **Rupture of the ventricular free wall:** It is most common and result in hemopericardium and cardiac tamponade. It is usually fatal.
- **Rupture of the ventricular septum:** It is less common and can lead to an acute VSD and left-to-right shunt. It usually presents with sudden hemodynamic deterioration and produces a new loud pansystolic murmur radiating to the right sternal border.
- **Rupture of papillary muscle:** Can lead to acute severe mitral regurgitation, which presents with a pansystolic murmur and third heart sound.

## ***Embolism***

Thrombus may form on the endocardial surface of freshly infarcted myocardium due to local abnormality in myocardial contractility (causing stasis) and endocardial damage (creating a thrombogenic surface). This can lead to systemic thromboembolism and occasionally causes a stroke. Venous thrombosis and pulmonary embolism may also develop patients on prolonged bed rest, but are now less common with the use of prophylactic anticoagulants and early mobilization.

## ***Ventricular Aneurysm***

After acute transmural infarction, the affected ventricular wall may bulge outward during systole resulting ventricular aneurysm. It develops as a late complication of large transmural infarcts.

## ***Pericarditis***

- **Early pericarditis:** A transmural myocardial infarct → can involve the pericardium → cause fibrinous or fibrinohemorrhagic pericarditis. Usually develops on second or third day.
- **Delayed form of pericarditis (postmyocardial infarction syndrome/Dressler syndrome):** Develops 2 to 10 weeks after infarction —probably immunologically mediated reaction to necrotic muscle. It is characterized by fever, pericarditis and pleurisy. Treatment is with aspirin or other nonsteroidal anti-inflammatory drugs (NSAIDs) or corticosteroids.

## Investigations

**Q. Write short essay/note on ECG changes in acute myocardial infarction.**

### *Electrocardiogram (ECG)*

The 12-lead ECG is central to confirming the diagnosis and should be done and interpreted within 10 minutes of arrival. The initial ECG may be normal or non-diagnostic in about 30% of cases. Repeated ECGs are needed, especially where the diagnosis is uncertain or the patient has recurrent or persistent symptoms.

**Changes in ECG:** Characteristic changes are observed in leads that ‘face’ the ischemic or infarcted area (e.g. anteroseptal, anterolateral, strict anterior, inferior and posterior wall infarction).

- **STEMI: ST-segment deviation** is the earliest ECG change. With proximal occlusion of a major coronary artery, ST-segment elevation (or new bundle branch block) is observed initially. Later there is diminution in the size of the R wave and, in transmural (full-thickness) infarction; there is development of a Q wave. Subsequently, the T wave becomes inverted and persists after the ST segment has returned to normal.
- **NSTEMI and unstable angina:** It is due to partial occlusion of a major vessel or complete occlusion of a minor vessel, causing unstable angina or partial-thickness (subendocardial) MI. They usually produce ST-segment depression and T-wave changes. When infarction is present, there may be some loss of R waves in the absence of Q waves.

Anatomic site of infarct, ECG lead and location of myocardial infarct is

discussed on pages 421-2.

## ***Plasma Cardiac Biomarkers (Biochemical Markers of Cardiac Injury)***

**Q.** Write a short essay/note on serum markers in acute myocardial infarction.

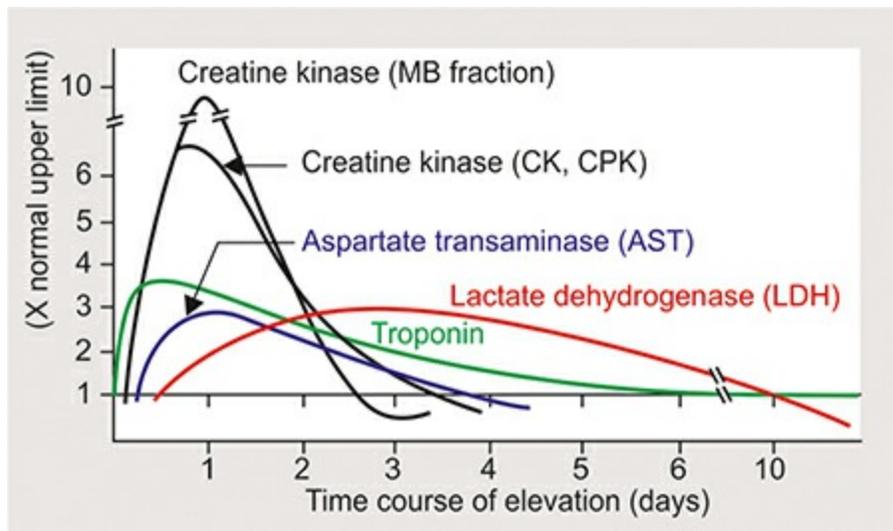

**Unstable angina:** There is no detectable rise in cardiac biomarkers or enzymes in unstable angina and the initial diagnosis is made from the clinical history and ECG only.

**Myocardial infarction:** Causes arise in the plasma concentration of enzymes and proteins that are normally concentrated within cardiac cells. These include creatine kinase (CK), aspartate aminotransferase (AST), lactate dehydrogenase (LDH), myoglobin and troponins (troponin I and troponin T). These markers leak from the necrotic myocardial cells into the blood circulation.

- **Cardiac creatine kinase (CK):** It is a **nonspecific enzyme marker** and it is present in brain, myocardium, and skeletal muscle. It has two isoforms designated 'M' and 'B'. **MB** heterodimers chiefly in cardiac muscle (lesser amounts in skeletal muscle).
  - MB form of creatine kinase (CK-MB) is sensitive but not specific, because it is also raised with skeletal muscle injury.
  - CK-MB levels rise within 4 to 6 hours of the onset of MI, peaks at 12 hours, and returns to normal within 72 hours.
  - Total CK is also raised elevated in diseases of skeletal muscle (e.g. polymyositis, muscular dystrophies), hypothyroidism and stroke.
- **Lactate dehydrogenase (LDH):** It not specific marker. It **starts rising** after **24–48 hours**. It remains **for many days** and **returns to normal in 7–14 days**. An elevated LDH<sub>1</sub> (an isoenzyme of LDH) is a more sensitive indicator of myocardial infarction than total LDH.
- **Myoglobin:** It is an oxygen-carrying respiratory protein found only in skeletal and cardiac muscle. It is an **earliest marker of MI**, the level rises within 1–3 hours, **peaks in about 8–12 hours** and **return to normal in about 24–36 hours**.
- **Cardiac troponins:** These are proteins involved in heart muscle

contraction. **Increased plasma levels establish the diagnosis of myocardial infarction.** Cardiac-specific proteins are of two types namely cardiac **Troponins I (cTnI) and T (cTnT)**. They are **most sensitive and specific markers** of myocardial infarction. Levels begin to **rise at 4–6 hours** and **peaks at 48 hours**. The elevated troponin levels may **remain for 7–10 days** after acute MI and therefore, this assay is particular useful in the evaluation of patients who present sufficiently long after their episode of chest pain. Further, about one-third of patients with unstable angina also have elevated cTn, which classifies these groups of patients to non-ST elevation MI.

- **Aspartate aminotransferase:** Starts to rise by about 12 hours and reaches a peak on the 1st or 2nd day.
- **Other enzymes:** (1) Ischemia modified albumin, (2) N terminal Pro BNP, (3) suPAR (soluble urokinase-type plasminogen activator receptor) and (4) Glycogen phosphorylase isoenzyme BB.

**Fig. 7.35:** Various enzyme levels following acute myocardial infarction.

**Table 7.43:** Characteristics of plasma biomarkers for acute myocardial infarction (AMI).

Marker protein	Elevation in plasma after AMI (h)	Peak plasma concentration (h)	Normalization of plasma level (days)
Myoglobin	2–3	6–12	1–2
Cardiac troponin I	3–8	12–24	7–10
Cardiac troponin T	3–8	12–24	7–10

Various enzyme levels in acute coronary syndrome are shown in Figure 7.35 and Table 7.43.

### ***Other Blood Tests***

- Leukocytosis with a peak on first day.
- Erythrocyte sedimentation rate (ESR): Raised and may remain so for days.
- C-reactive protein: Elevated.
- **Heart-type fatty acid-binding protein (H-FABP)** as a plasma marker for the diagnosis of patients presenting with chest pain suggestive of myocardial infarction, especially in the early hours (within 2 hours) after onset of symptoms. However, their use as a diagnostic tool for MI is limited.

### ***Chest X-ray***

- May show evidence of pulmonary edema that is not evident on clinical examination.
- Heart size is usually normal but there may be cardiomegaly due to previous myocardial damage or pericardial effusion.

### ***Echocardiography***

Useful for assessing ventricular function and for detecting complications (e.g. mural thrombus, cardiac rupture, ventricular septal defect, mitral regurgitation and pericardial effusion).

### ***Radionuclide Scanning***

To detect the site of necrosis and the extent of damage to ventricular function.

#### **Q. Write short essay/note on:**

- **Management of a case of acute myocardial infarction in the first 24 hours.**
- **Management of a case of acute myocardial infarction.**

#### **Management**

**Immediate management:** The first 24–48 hours, the patients should be admitted immediately to hospital. During first 24–48 hours the risk for fatal arrhythmia is highest and as a result, there is a significant risk of death or recurrent myocardial ischemia. Patients are best treated in an intensive

coronary care unit.

### **Management of Acute Myocardial Infarction**

#### *Initial treatment*

Admit in intensive coronary care unit, attach a cardiac monitor and secure an intravenous line.

- **General treatment ('M O N A C')**

- Morphine 2–4 mg q 5–10 minute to control chest pain.
- Oxygen 4 L/minute: Hypoxemia in uncomplicated MI is usually due to ventilation-perfusion abnormalities and may be exacerbated by CHF. Therefore, oxygen is given to patients suspected of having an acute coronary syndromes and oxygen saturation <90%.
- NTG (nitroglycerine) sublingual or spray, followed by infusion for persistent chest pain
- Aspirin 160–325 mg chew and swallow or/and
- Clopidogrel 300 mg oral

- **Confirm diagnosis:** By investigations namely:

- Electrocardiogram (ECG)
- Plasma cardiac biomarkers: Troponin T or I and CK-MB

- **Specific therapy**

- Thrombolysis or percutaneous coronary interventions
- $\beta$ - blockers unless contraindicated
- Treat complications (arrhythmias, congestive failure and shock).

#### *Control of pain by analgesics*

- Proper control of pain is necessary not only to relieve distress but also to lower adrenergic drive which reduces vascular resistance, BP, infarct size and susceptibility to ventricular arrhythmias.
- **Intravenous opiates:** Initially, morphine in the dose of 2–4 mg or diamorphine 2.5–5 mg is administered along with antiemetics (metoclopramide 10 mg) should be administered, and repeated until the patient is comfortable.
- $\beta$ -blockers, nitroglycerine and thrombolysis may also help in reducing the pain.

Anti-anginal therapy (refer page 417-20)

#### **Antithrombotic therapy**

**Q. Write short essay/note on indications for low dose aspirin therapy.**

#### *Antiplatelet therapy*

(discussed in detail on page 419):

- **Aspirin:** In acute coronary syndrome, oral aspirin (75–325 mg daily) improves survival, and reduce mortality. The first dose (300 mg) should be given orally within the first 12 hours and should be continued indefinitely if there are no side-effects.
- **Combination therapies:** Combination of aspirin and an ADP-receptor blocker (clopidogrel, prasugrel or ticagrelor) is recommended in patients with STEMI who are undergoing primary PCI (for up to 12 months) or (clopidogrel) fibrinolysis and in those who have not undergone reperfusion therapy. In acute coronary syndrome, with or without ST-segment elevation, ticagrelor (180 mg, followed by 90 mg twice daily) is found to be more effective than clopidogrel in reducing vascular death, MI or stroke, and other causes of death.
- **Glycoprotein IIb/IIIa receptor antagonists:** These are powerful inhibitors of platelet aggregation and prevent thrombus formation (e.g. **tirofiban, eptifibatide, and abciximab**). Abciximab is a monoclonal antibody which binds tightly and has a long half-life. They are beneficial in patients who undergo PCI, those with recurrent ischemia and those with high risk (e.g. diabetes mellitus, raised troponin concentration).

Various antiplatelet agents and their dosage are mentioned in Table 7.44.

#### *Anticoagulants (antithrombin therapy)*

**Prophylactic anticoagulants** are given to prevent deep vein thrombosis and pulmonary embolism in patients who do not receive fibrinolytic agents. They reduce the risk of thromboembolic complications, and prevent re-infarction in the absence of reperfusion therapy or after successful thrombolysis.

#### *Preparations*

- **Unfractionated heparin:** Given as an initial bolus dose of 60 IU/kg (with a maximum dose of 4000 units) followed by an initial infusion of 12 IU/kg/hour (maximum 1000 units/hour). The dose is adjusted to attain the activated partial thromboplastin time at 1.5–2 times control. Heparin is given before the completion of infusion of rt-PA or tenecteplase or patients receiving STK.
- **Low-molecular weight heparin:** It is used as an adjunct to thrombolytics. It produces higher reperfusion rate and lower re-occlusion rate compared to unfractionated heparin. Dose of 5000 units given twice a day subcutaneously.
- **Direct thrombin inhibitors:** Appear better than the unfractionated heparin in patients undergoing PCI. These include hirudin and bivalirudin. Pentasaccharides (subcutaneous fondaparinux 2.5 mg daily) safe and effective. However, fondaparinux is not be used as sole agent and contraindicated if PCI is planned.

**Table 7.44: Various antiplatelet agents and their dosage.**

<b>Oral antiplatelets</b>	
Aspirin	Initial dose of <b>325 mg</b> nonenteric formulation followed by <b>75–100 mg/day</b> of an enteric or a nonenteric formulation
Clopidogrel	Loading dose of <b>300–600 mg</b> followed by <b>75 mg/day</b>
Prasugrel	Pre-PCI: Loading dose <b>60 mg</b> followed by <b>10 mg/day</b>
Ticagrelor	Loading dose of <b>180 mg</b> followed by <b>90 mg twice daily</b>
<b>Intravenous antiplatelet therapy</b>	
Abciximab	0.25 mg/kg bolus followed by infusion of 0.125 µg/kg per min (maximum 10 µg/min) for 12–24 hours
Eptifibatide	180 µg/kg bolus followed 10 min later by second bolus of 180 µg with infusion of 2.0 µg/kg per min for 72–96 hours following first bolus
Tirofiban	5 µg/kg per min followed by infusion of 0.15 µg/kg per min for 48–96 hours
Others	<b>Phosphodiesterase inhibitors</b> —Cilostazol

Antithrombin preparations should be continued for at least 48 hours and preferably for 8 days or till discharge or coronary revascularization.

#### **Statins**

**High-dose statins** are recommended in all patients during the first 24 hours of admission for STEMI, irrespective of the patient's cholesterol concentration, if there is no contraindications (e.g. allergy, active liver disease). They are recommended during the early phase of therapy up to at least four weeks. Patient on statin therapy presenting with STEMI should continue statin.

### Advantages

- Lowers cholesterol, direct effects on endothelial function, oxidative stress, inflammation, thrombosis as well as plaque stabilization. High dose atorvastatin (40–80 mg) or rosuvastatin (20–40 mg) therapy before emergency percutaneous coronary intervention has following advantages:
  - Reduce periprocedural inflammatory response
  - Reduce myocardial dysfunction
  - Prevent contrast-induced nephropathy.

Management of acute coronary syndrome are indicated in Flowchart 7.4.

### Thrombolytic (or fibrinolytic) therapy in acute coronary syndrome

**Q. Write short essay/note on indications, contraindications and therapeutic schedule of thrombolytic therapy in acute myocardial infarction.**

#### Indications for thrombolysis in acute myocardial infarction (Box 7.25)

Fibrinolytic therapy should be initiated within 30 minutes (door-to-needle time or first medical contact-to-needle time).

**Thrombolytic agents (Table 7.45):** These include plasminogen activators, i.e. *streptokinase (STK)*, *urokinase (UK)*, *human tissue plasminogen activator (tPA-alteplase)*, *recombinant plasminogen activator (rPA-retetplase)*, *tenecteplase*, *anisoylated plasminogen streptokinase activator complex (APSAC, anistreplase)* and *single-chain urokinase plasminogen activator (scu-PA)*.

**Mechanism of action:** Thrombolytic or fibrinolytic agents lyse thrombi/clot to recanalize the occluded vessels (mainly coronary arteries) by the activation of plasminogen to form plasmin. They are curative rather than prophylactic.

- **Fibrin-specific fibrinolytics:** They generate fibrin-specific fibrinolytics at the site of thrombus/clot. Examples include rPA (reteplase), tenecteplase (TNK) and scu-PA. They have lower mortality rate compared with STK and also lack the significant acute side effects of hypotension and allergy caused by STK.
- **Generation plasmin in the systemic circulation:** These agents generate plasmin in systemic circulation producing a systemic lytic state. This leads to a reduction in blood viscosity, and produces strong anticoagulant and antiplatelet effects. Examples include streptokinase (STK); urokinase (UK). STK use is associated with lower incidence of intracranial hemorrhage, especially in older individuals.

**Box 7.25:** Indications for thrombolysis in acute myocardial infarction.

#### Thrombolysis: Definitely beneficial

- ST segment elevation of more than 0.1 mV in two or more contiguous leads, with time to therapy 12 hours or less
- Left bundle-branch block (LBBB) obscuring ST segment analysis and history of acute myocardial infarction for less than 12 hours

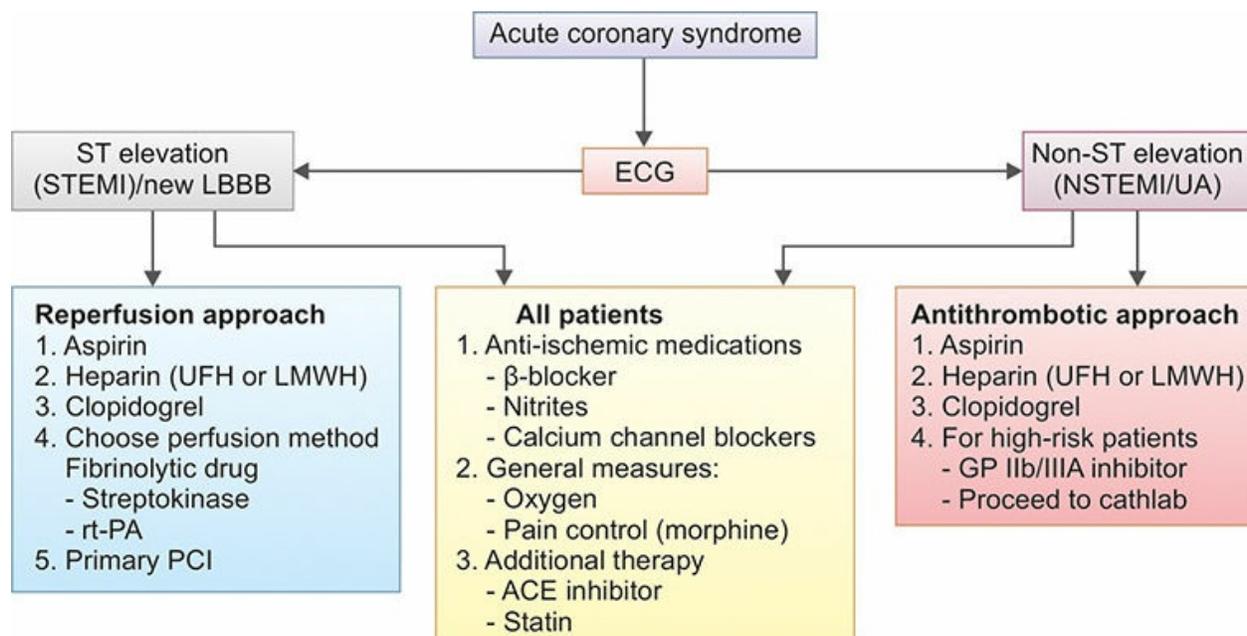

#### Thrombolysis: Some benefit

- ST segment elevation with time to therapy 12–24 hours

#### Thrombolysis: Not indicated

- ST segment depression only (unless leads V<sub>1</sub>-V<sub>4</sub> show ST depression related to posterior wall myocardial infarction).
- Time to therapy >24 hours.

Thrombolytic therapy is not recommended for patients with NSTEMI and unstable angina.

**Flowchart 7.4:** Management of acute coronary syndrome

**Table 7.45:** Various thrombolytic agents and their dosage.

<b>Thrombolytic agent</b>	<b>Dose</b>
Alteplase (tissue plasminogen activator-tPA)	15 mg bolus followed by 50 mg intravenously over the first 30 minute, followed by 35 mg over the next 60 minutes
Streptokinase (STK)	1.5 million units (MU) intravenous infusion over 1 hour
Tenecteplase (TNK)	Given as a single weight-based intravenous bolus of 0.53 mg/kg over 10 seconds
Retepase (rPA)	Double-bolus regimen consisting of a 10-MU bolus given over 2–3 minutes, followed by second 10-MU bolus 30 minutes later

**Box 7.26:** Signs of reperfusion.

- Immediate relief of chest pain
- Reduction of the initial ST-segment elevation by 50% within 60–90 minutes of fibrinolytic therapy
- Onset of reperfusion arrhythmias (e.g. accelerated idioventricular rhythm and frequent ventricular ectopics)
- Early peaking of CK-MB enzyme.

**Box 7.27:** Contraindications to thrombolytic therapy.

**Absolute**

- History of cerebrovascular hemorrhage anytime in life
- History of nonhemorrhagic stroke or other cerebrovascular event within the past one year
- Uncontrolled marked hypertension (systolic BP >180 mm Hg, diastolic BP >110 mm Hg). However, STK can be given
- Suspected aortic dissection
- Active internal bleeding (excluding menses)
- Known intracranial aneurysm/AV malformation/neoplasm (primary or metastatic)
- Intracranial/spinal surgery within last 3 months)

#### **Relative**

- Current use of anticoagulants (INR  $\geq$ 2)
- Recent (<2 weeks) invasive or surgical procedure, prolonged (>10 min) CPR
- Known bleeding diathesis
- Recent trauma (including traumatic resuscitation)
- Pregnancy
- Hemorrhage ophthalmic condition
- Active peptic ulcer disease
- History of severe hypertension that is currently controlled

### **Box 7.28:** Thrombolysis in myocardial infarction (TIMI) grading system.

- **TIMI 0:** Absence of antegrade flow beyond a coronary occlusion
- **TIMI 1:** Faint antegrade coronary flow beyond the occlusion, although filling of the distal coronary bed is incomplete
- **TIMI 2:** Flow is delayed or sluggish antegrade flow with complete filling of the distal territory
- **TIMI 3:** Flow is normal which fills the distal coronary bed completely.

*Signs of Reperfusion (Box 7.26)*

#### **Contraindications to Thrombolytic Therapy (Box 7.27)**

*Complications of thrombolytic therapy:*

- **Hemorrhage:** It is the major complication. The most common site is in the region of puncture sites, genitourinary system and intracranial hemorrhage (in about 0.5% of patients).
- **Allergic reactions:** May develop with use of STK and APSAC.
- **Hypotension:** May develop if STK is infused rapidly.

**Thrombolysis in myocardial infarction (TIMI) grading system (Box 7.28):** It is a simple qualitative scale to grade the flow in the culprit coronary artery when assessed by angiography.

- Rescue PCI should be considered in patients with failure of reperfusion (persistent chest pain and ST-segment elevation >90 minutes) with thrombolytic agents.

*Percutaneous coronary interventions (PCI)*

PCI is the treatment of choice, provided it is performed promptly by a qualified interventional cardiologist in an appropriate facility.

**Indications:** Patients with STEMI with following features

- Symptoms of ischemia of less than 12 hours duration.
- Symptoms of ischemia of less than 12 hours duration who have contraindications to fibrinolytic therapy, irrespective of the time delay from first medical contact.

- Cardiogenic shock or acute severe heart failure (HF), irrespective of time delay from MI onset.
- May be recommended if there is clinical and/or ECG evidence of ongoing ischemia between 12 and 24 hours after symptom onset.

**Maximum acceptable delay** for primary PCI from presentation to balloon inflation is 60 minutes if a patient presents within 1 hour of symptom of onset or 90 minutes if a patient present later.

**Types of PCI:** Include primary PCI, rescue PCI and facilitated PCI (described below).

Glycoprotein IIb/IIIa inhibitors (e.g. abciximab, tirofiban) may be used in patients undergoing percutaneous interventions.

### Reperfusion options for STEMI

- **Fibrinolysis:** It is usually preferred in the following situations:
  - Early presentation ( $\leq 3$  hours from symptom of onset)
  - In patients where primary PCI cannot done because of the following:
    - ◆ Catheterization laboratory occupied/unavailable
    - ◆ Vascular access difficulties
    - ◆ Lack of access to a skilled PCI laboratory
  - Delay to primary PCI
    - ◆ Door-to-balloon time minus door-to-needle time is  $> 1$  hour.
    - ◆ Door-to-balloon time is  $> 90$  minutes.
- **Primary PCI:** In which PCI is used solely in acute MI. It is indicated in cardiogenic shock, and in patients in whom thrombolytic therapy is contraindicated. **It is generally preferred with following conditions:**
  - Skilled PCI laboratory is available with good surgical backup.
    - ◆ Door-to-balloon time is  $\leq 90$  minutes.
    - ◆ Door-to-balloon time minus door-to-needle time is  $\leq 1$  hour.
  - High-risk STEMI
    - ◆ Cardiogenic shock
    - ◆ Killip class CHF  $\geq 3$
  - Contraindications to fibrinolysis including increased risk of bleeding and intracranial hemorrhage.
  - Late presentation ( $> 3$  hours after symptom of onset).
- **Rescue PCI:** It is combination of PCI with thrombolytic therapy and PCI is performed within 12 after failed thrombolysis/fibrinolysis for patients with continuing or recurrent myocardial ischemia.
  - **Indications:** STEMI in aged  $< 75$  years who received fibrinolytic therapy and have cardiogenic shock, severe congestive heart failure (Killip class III) or hemodynamically compromising ventricular arrhythmias.
  - May be performed in patients with symptoms of persistent ischemia.
- **Facilitated PCI:** In this type PCI is done following initial pharmacological regimen aimed at improving patency of coronary arteries before PCI.
  - The pharmacological regimens include GP IIb/IIIa inhibitors, full-dose or reduced-dose of fibrinolytic therapy, and combination of a GP IIb/IIIa inhibitor and a reduced-dose fibrinolytic/thrombolytic agent. However, this type of re-perfusion may be inferior to thrombolysis alone or primary PCI and is usually not recommended in most patients with STEMI.

### Coronary artery bypass grafting

- Recommended in:
  - Failed PCI with persistent pain or hemodynamic instability in patients with coronary anatomy suitable for surgery.
  - Persistent or recurrent ischemia refractory to medical therapy in patients who have coronary anatomy suitable for surgery, and are not candidates for PCI or fibrinolytic therapy.
  - Patients with STEMI at the time of operative repair of mechanical defects.

### Management of right ventricular infarction

- Right ventricular infarction is characterized by reduced right ventricular stroke volume which results impaired left ventricular filling → leading to hypotension, raised JVP and clear lungs on auscultation.
- **Volume expansion** with saline is the initial treatment for hemodynamically significant right ventricular infarction.
- Avoid use of diuretics, ACE inhibitors and nitrates.
- Inotropics and vasodilators may be needed when a significant left ventricular dysfunction is also present.
- Routinely considered for re-perfusion therapy (fibrinolysis or PCI).

**Box 7.29:** Killip classification of ventricular dysfunction.

- Class I: No signs of pulmonary/venous congestion
- Class II: Moderate heart failure, rales at lung bases, S3 gallop, venous or hepatic congestion
- Class III: Severe heart failure, pulmonary edema
- Class IV: Shock with systolic BP < 90 mm Hg, mental confusion, oliguria, peripheral cyanosis

### Management of complications

#### • Ventricular dysfunction

After STEMI ventricular remodeling occurs, ventricular dysfunction can be prevented by ACE inhibitors and nitrates.

Killip classification of ventricular dysfunction (Box 7.29)

This classification has prognostic value with highest mortality in class IV patients.

#### • Cardiogenic shock

- This results when there is infarction of  $\geq 40\%$  of left ventricle. The patient has systolic BP <90 mm Hg and pulmonary capillary wedge pressure >18 mm Hg.
- Cardiogenic shock is best managed by invasive means (Primary PCI). Use of intra-aortic balloon pump and IV vasopressors may be beneficial.

#### • Right ventricular infarction

- Clinically significant right ventricular infarction is rare and occurs in patients with inferior infarction.
- ST elevation in V<sub>4</sub>R is common in first 24 hours.
- **Signs of severe right ventricular failure:** These include jugular venous distension, Kussmaul's sign, hepatomegaly, with hypotension.
- Investigation: 2-D echocardiography is useful for diagnosis and assessment of severity.
- Treatment: Volume expansion to maintain adequate right ventricular preload.

#### • Pericarditis

- Common complication in first week of transmural myocardial infarct.
- Radiation of pain to trapezius muscle is helpful in distinguishing it from ischemia.
- Pericardial rub may be present.
- **Treatment:** Aspirin 650 mg qid and **withhold anticoagulants.**

**Management of other complications:** These include (1) thromboembolism, (2) left ventricular aneurysm, (3) sinus bradycardia, (4) AV block, (5) ventricular tachycardia and fibrillation and acute mitral regurgitation, VSR and tricuspid regurgitation.

Their management is discussed in individual sections.

### **Aftercare and rehabilitation**

- **Physical activities:** To be restricted for 4–6 weeks because replacement of infarct by fibrous tissue takes 4–6 weeks. Advised gradual mobilization and return to work over 6 weeks. Exercise and sexual activity within the limits.
- **Complications:** Patients who had complications, the regimen depends on the type of complication.
- **Lifestyle and risk factor modification:** Control of risk factors such as obesity by regular exercises, cessation of smoking, lifestyle modifications and control of plasma lipids by diets and drugs.
- Secondary prevention drug therapy
  - **Aspirin and clopidogrel:** Low dose aspirin (75–150 mg daily) unless there is any contraindication. Clopidogrel (75 mg daily) for up to 12 months, particularly after stent implantation. It may be given as an alternative when aspirin is contraindicated, or in combination with aspirin particularly in patients with unstable angina or recurrent cardiac events.
  - **$\beta$ -blocker:** Oral  $\beta$ -blockers are continued indefinitely (unless any contraindications). Carvedilol, bisoprolol or metoprolol (extended release) are given to patients with heart failure. Role of  $\beta$ -blockers in the secondary prevention in unstable angina is not known.
  - ACE inhibitor given early after an acute coronary syndrome. Long-term treatment with an ACE inhibitor (e.g. enalapril 10 mg twice daily or ramipril 2.5–5 mg twice daily) is found to counteract ventricular remodeling, prevent the onset of heart failure, and reduce recurrent MI.
  - **Statin therapy** started in the hospital for all patients with coronary artery disease.
  - **Warfarin** after myocardial infarction is given to patients having a high-risk of systemic thromboembolism due to atrial fibrillation, mural thrombus, congestive heart failure or previous embolization.
  - **Nitrates:** Short-acting nitrates, for chest pain. Long-acting nitrates are given for relief of symptom when  $\beta$ -blocker alone is unsuccessful or is contraindicated.
  - **Aldosterone antagonist** (e.g. eplerenone) is given early after myocardial infarction to patients who have LVEF  $\leq$ 40%, despite optimum dose of ACE inhibitors and  $\beta$ -blockers, and have either CHF or diabetes.
- **Device therapy:** Implantable cardiac defibrillators can prevent sudden cardiac death in patients who have severe left ventricular impairment (ejection fraction  $\leq$ 30%) after MI.

## **Non-ST Segment-Elevation Acute Coronary Syndrome (NSTEACS)**

**Q. Briefly discuss unstable angina and non-ST elevation myocardial**

## infarction.

- It includes unstable angina (UA) and non-ST elevation myocardial infarction (NSTEMI).
- Both are caused by coronary artery spasm, progression of the underlying coronary artery disease (CAD) or hemorrhage into a non-occluding atheromatous plaque with subsequent thrombosis producing coronary obstruction over a period of few hours. The difference between UA and NSTEMI is that in the NSTEMI shows an occluding thrombus, which leads to myocardial necrosis and a rise in serum troponins or CKMB.

### ***Non-ST elevation MI (STEMI)***

- It is usually shows ST depression and T inversion in the ECG along with elevation in serum troponins or CKMB.
- Myocardial function (as shown by ejection fraction) in NSTEMI is less deranged when compared to STEMI. However, in NSTEMI early as well as late reinfarction rates are higher than in STEMI.

### ***Unstable angina (UA)***

#### **Q. Write a short essay/note on unstable angina.**

- **Three principal presentations include:**
  - **Rest angina:** Angina occurring at rest and prolonged, usually >20 minutes.
  - **New-onset angina:** New-onset angina of at least CCS Class III severity.
  - **Increasing angina:** Previously diagnosed angina that has become distinctly more frequent, longer in duration, or lower in threshold (i.e. increased by >1 CCS) class to at least CCS Class III severity.

**Table 7.46: Risk categories in NSTEMI/UA.**

<b>Category</b>	<b>Management</b>
<b>High risk (12–30%)</b>	
<ul style="list-style-type: none"><li>• Prolonged chest pain (&gt;20 minutes or ongoing), plus:</li><li>• ECG: (1) Transient ST changes, (2) sustained ST depression and (3) deep T wave inversion (&gt;5 leads)</li><li>• Biochemical markers: Troponin/CKMB abnormal</li><li>• Recurrent ischemia</li></ul>	<ul style="list-style-type: none"><li>• Aspirin + heparin/low molecular weight heparin (LMWH)</li><li>• GP IIb/IIIa antagonist</li><li>• Early percutaneous coronary intervention (PCI)</li></ul>

<ul style="list-style-type: none"> <li>• Acute MI in last 4 weeks</li> <li>• Hemodynamic compromise</li> </ul>	
<b>Intermediate risk (4–8%)</b>	
<ul style="list-style-type: none"> <li>• No high-risk features but ≥ 1 of: <ul style="list-style-type: none"> <li>– Ongoing chest pain</li> <li>– Crescendo angina</li> <li>– Borderline positive troponin I (0.4–2.0)</li> <li>– Previous intervention: PCI or CABG</li> <li>– Increased baseline risk (diabetes mellitus, elderly)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Aspirin ± clopidogrel</li> <li>• Ultrafraction heparin (UFH) or low molecular weight heparin (LMWH)</li> <li>• PCI</li> </ul>
<b>Low-risk (&lt;2%)</b>	
<ul style="list-style-type: none"> <li>• No high or intermediated features</li> <li>• Chest pain, single episode, exertional</li> <li>• ECG: Normal or nonspecific or unchanged</li> <li>• May include previous history of CAD or risk factors</li> </ul>	<ul style="list-style-type: none"> <li>• Aspirin</li> <li>• No heparin</li> <li>• Observe</li> </ul>

- Normal ECG (no ST elevation), without elevation of cardiac injury markers (normal level of cardiac enzymes).
- Patients with UA have a high risk of developing MI or sudden death when compared to patients with stable angina. Thus, they need aggressive treatment in the hospital.

Classification of risk categories in NSTEMI/UA and its management is mentioned in Table 7.46.

## Prinzmetal's Variant Angina

**Q. Write a short essay/note on clinical features and treatment of Prinzmetal's angina (variant angina).**

In 1959 Prinzmetal et al. described a syndrome of severe ischemic pain that usually occurs at rest and is associated with **transient ST-segment elevation**.

### *Etiology*

- **Focal spasm of an epicardial coronary artery** is the cause of Prinzmetal's variant angina (PVA) and leads to severe transient myocardial ischemia and occasionally infarction.
- The cause of the spasm is not well defined, but it may be related to hypercontractility of vascular smooth muscle due to adrenergic vasoconstrictors, leukotrienes, or serotonin.

## ***Clinical Features***

- Pain occurs without exertion and usually at rest. It is more frequent in women.
- Associated with migraine, Raynaud's phenomenon and aspirin-induced asthma. Younger patients with history of cigarette smoking.

## ***Investigation***

- Characteristically, it is associated with transient ST segment elevation on the ECG during the pain.
- Coronary angiography is gold standard for diagnosis. Focal spasm commonly accompanied by **stenosis within 1 cm of spasm** is the hallmark (most commonly in right coronary artery).
- Provocation tests (e.g. hyperventilation, cold pressor testing or ergometrine or intracoronary acetylcholine challenge) may be needed for demonstration of focal spasm and establishing the diagnosis.

### **Management**

- Nitrates and calcium channel blockers are the main therapeutic agents. Aspirin may actually increase the severity of ischemic episodes, possibly as a result of the sensitivity of coronary tone to modest changes in the synthesis of prostacyclin.
- The response to  $\beta$ -blockers is variable but usually poor. Prazosin can be useful.
- Coronary revascularization may be helpful in patients with discrete, flow-limiting, proximal fixed obstructive lesions.

## **Prognosis**

- Many patients pass through an acute, active phase, with frequent episodes of angina and cardiac events during the first 6 months after presentation.
- Prognosis is better in patients with no or mild fixed coronary obstruction than patients with severe, fixed, significant obstructive lesions. Survival at 5 years is excellent (~90–95%).
- Nonfatal MI occurs in up to 20% of patients by 5 years. Patients with PVA who develop serious arrhythmias during spontaneous episodes of pain are at a higher risk for sudden cardiac death. In most patients who survive an infarction or the initial 3- to 6-month period of frequent episodes, there is a tendency for symptoms and cardiac events to diminish over time.

# **HYPERTENSION**

**Q. Classify hypertension. Discuss the clinical features, baseline investigations, diagnosis, complications and management of essential hypertension.**

**Q. Discuss the causes and investigations of secondary hypertension.**

Hypertension is a hemodynamic disorder and about 15% of the general population can be regarded as hypertensives.

Definition: A well-accepted definition of hypertension was suggested by Evans and Rose:

- ‘Hypertension should be defined in the terms of blood pressure level above which investigation and treatment do good more than harm’.
- The following diagnostic criteria has been suggested by the 2017 ACC/AHA guidelines; meeting one or more of these criteria using ambulatory blood pressure monitoring (ABPM) to qualify as hypertension.
  - A 24-hour mean of 125/75 mm Hg or above
  - Daytime (awake) mean of 130/80 mm Hg or above.
  - Nighttime (asleep) mean of 110/65 mm Hg or above.

Hypertension is defined arbitrarily at levels above generally accepted normal (Joint National Committee—JNC 7/8 recommendations) is presented in Table 7.47.

**Table 7.47: Systolic and diastolic values used in the classification of hypertension (JNC7/8).**

<i>Classification</i>	<i>Systolic BP (mm Hg)</i>		<i>Diastolic BP (mm Hg)</i>
Normal	<120	AND	<80
Pre-hypertension	120–139	OR	80–89
Stage 1 hypertension	140–159	OR	90–99
Stage 2 hypertension	≥160	OR	≥100
Isolated systolic hypertension	>140	AND	<90

## Classification and Causes (Table 7.48 and Fig. 7.36)

**Q. Write short note on the causes of hypertension.**

- **Primary or essential hypertension:** Constitutes about 85% of the cases in which it is not possible to define a specific underlying cause. About

70% of these patients give a positive family history.

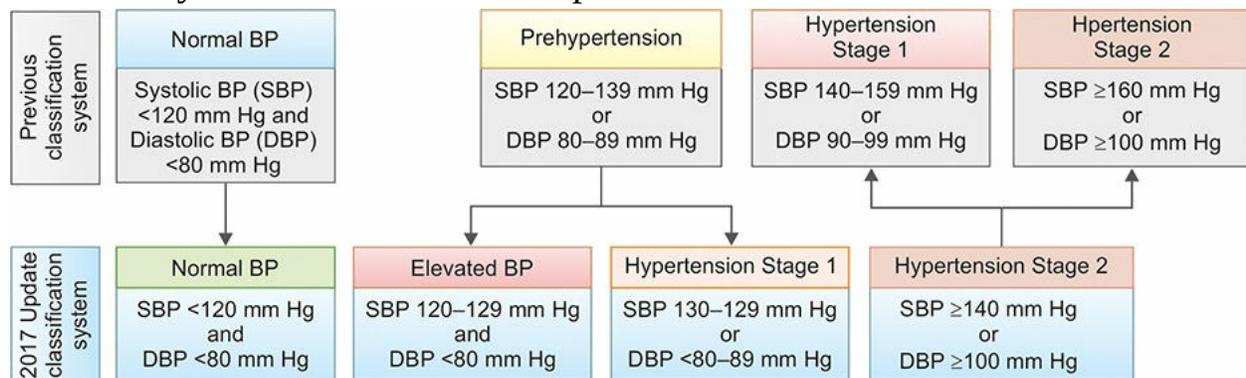

- **Secondary hypertension:** Constitutes remaining 15% of the cases and are due to a specific disease or abnormality.

**Q. Write short essay or note on secondary hypertension and its causes.**

**Q. Write short note on causes of isolated systolic hypertension.**

## Essential Hypertension

In about 85–95% of cases, a specific underlying cause of hypertension cannot be identified and such hypertension is termed as essential hypertension. The exact pathogenesis is not known. It has multifactorial etiology and many factors may contribute to its development.

**Fig. 7.36:** 2017 updated classification of high blood pressure in adults.

### Table 7.48: Major causes of hypertension (systolic and diastolic).

**Primary/essential hypertension** (~ 85% of case)

**Secondary hypertension** (~ 15% of case)

#### Renal

**Renal parenchymal disease** (most common cause of secondary hypertension): Acute glomerulonephritis, polycystic kidney disease, chronic nephritis, diabetic nephropathy, hydronephrosis (obstructive uropathy)

Renal artery stenosis (renovascular hypertension)

Renin producing tumors

#### Endocrine

Adrenal disorders: Cushing's syndrome, primary aldosteronism, primary adrenal hyperplasia, pheochromocytoma

Others: Hypothyroidism (myxedema), hyperthyroidism (thyrotoxicosis), hypercalcemia, acromegaly, carcinoid, exogenous hormones

#### Cardiovascular

Coarctation of aorta, polyarteritis nodosa

### **Neurologic**

Psychogenic, porphyria, lead poisoning, primary dysautonomia (Riley-day syndrome), increased intracranial pressure, GB syndrome

### **Obstructive sleep apnea**

### **Preeclampsia/eclampsia**

### **Medications and toxins**

High-dose estrogens, alcohol and drugs—oral contraceptives, anabolic steroids, corticosteroids, decongestants, nonsteroidal anti-inflammatory agents (NSAIDs), COX-2 inhibitors, carbenoxolone, sympathomimetics, cyclosporine, sibutramine, bromocriptine, erythropoietin

### **Stress**

Postoperative, pain, burns, hypoglycemia, alcohol withdrawal, hypoglycemia

**Causes of isolated systolic hypertension:** Atherosclerosis, aortic regurgitation, patent ductus arteriosus, thyrotoxicosis, coarctation of aorta

## **Etiology**

### **Q. Write short essay or note on risk factors for hypertension.**

**Genetic factors:** Blood pressure tends to run in families and this may be partly due to environmental influences.

**Environmental factors:** Several environmental factors may be involved and these include salt intake, obesity, occupation, alcohol intake, family size and crowding.

- **Obesity:** Higher blood pressures are seen in obese individuals compared to thin individuals. Sleep disordered breathing/ obstructive sleep apnea often observed with obesity may be an additional risk factor.
- **Alcohol intake:** There is close relationship between the consumption of alcohol and blood pressure level.
- **Sodium intake:** Higher sodium intakes may be associated with an increase in blood pressure. A high potassium diet can have protective role against the effects of a high sodium intake. *About 60% of hypertensive are salt sensitive. Primary aldosteronism, bilateral renal artery stenosis, renal parenchymal disease and low-renin essential hypertension are all salt sensitive.*
- **Stress:** Acute pain or stress is associated with raised blood pressure. However, the relationship between chronic stress and blood pressure is not known.

### **Humoral mechanisms**

The autonomic nervous system, the renin-angiotensin, natriuretic peptide and

kallikrein kinin system, plays a role in the physiological regulation of short-term changes in blood pressure. They may also be probably involved in the pathogenesis of essential hypertension.

- *A low renin, salt-sensitive, essential hypertension* in which patients have renal sodium and water retention has been found. Low renin hypertension is more common in elderly and diabetics. These patients are salt-sensitive and diuretic responsive.
- *Normal renin hypertension* (non-modulators) is more common in males and post-menopausal females. They are salt sensitive.
- *High renin hypertension* is characterized by high plasma renin activity and responsiveness to angiotensin II antagonists.
- Low calcium intake has been associated with an increase in blood pressure in epidemiologic studies.

**Insulin resistance** is responsible for essential hypertension in majority of the patients.

- **Metabolic syndrome:** It is characterized by hyperinsulinemia, glucose intolerance, reduced levels of HDL cholesterol, hypertriglyceridemia and central obesity (all related to insulin resistance). Metabolic syndrome is associated with hypertension and is a major risk factor for cardiovascular disease.

### *Fetal factors*

Impaired intrauterine growth resulting in low birth weight is associated with subsequent development of high blood pressure.

## **Approach to Newly Diagnosed Hypertension**

### **Q. Discuss the approach to a case of hypertension in the young.**

Hypertension is usually asymptomatic and the diagnosis is usually made at routine examination or when a complication arises. A routine BP checkup is necessary every 5 years in adults.

Goals of the initial evaluation with high BP are to:

- Obtain accurate BP measurements
- Identify contributing factors, and risk factors and any underlying cause (secondary hypertension)
- Quantify cardiovascular risk

- Detect any complications (target organ damage)
- Identify comorbidity that may influence the choice of antihypertensive therapy.

These are attained by a careful history, clinical examination and few simple investigations.

## Ambulatory Blood Pressure Monitoring (ABPM)

### Q. Write short note on ambulatory blood pressure monitoring.

ABPM is the preferred method for confirming the diagnosis of hypertension. High-quality data suggest that ABPM predicts target-organ damage and cardiovascular events better than office blood pressure readings. ABPM records the blood pressure at preset intervals (usually every 15 to 20 minutes during the day and every 30 to 60 minutes during sleep).

Uses of ABPM (Box 7.30).

#### Box 7.30: Uses of ambulatory blood pressure monitoring.

- Confirm white coat and masked hypertension
- Suspected episodic hypertension (e.g. pheochromocytoma)
- Determining therapeutic response (i.e. blood pressure control) in patients who are known to have a substantial white coat effect)
- Hypotensive symptoms while taking antihypertensive medications
- Resistant hypertension
- Autonomic dysfunction

#### *Home and ambulatory BP recordings*

A transient rise in BP may occur by exercise, anxiety, discomfort and unfamiliar surroundings.

- **White coat hypertension:** It is a transient increase in blood pressure in normal individuals when blood pressure is recorded either in a hospital or in a physician's clinic.
- **Isolated ambulatory or masked hypertension**
  - It is reversal of white coat hypertension in which individuals have normal blood pressure (<140/90 mm Hg) in a hospital or in a physician's clinic but have increased ambulatory or home blood pressure values.
  - These individuals have increased prevalence of organ damage, with an

increased prevalence of metabolic risk factors.

- Paradoxical hypertension
  - It is characterized by a paradoxical increase in blood pressure in patients on antihypertensive agents.
  - This is observed in patients with:
    - ◆ Diabetes and hypertension who are on  $\beta$ -blockers, if they develop hypoglycemia. It is due to sympathetic stimulation following hypoglycemia.
    - ◆ Bilateral renal artery stenosis who are given ACE inhibitors.
    - ◆ Pheochromocytoma who is administered pure  $\beta$ -blockers.

## History

- Record family history, lifestyle (exercise, salt intake, smoking), other risk factors, history of drug intake or alcohol.
- Symptoms of causes of secondary hypertension (Table 7.49) or complications such as coronary artery disease (e.g. angina, breathlessness).

## Clinical Features

Clinical features of hypertension may be due to hypertension itself and the underlying cause of hypertension. Clinical features due to hypertension per se

- Majority of patients are asymptomatic and hypertension is usually detected during routine examination.
- Acute hypertension may produce transient headache and polyuria.
- Long-standing hypertension may cause left ventricular hypertrophy and heaving apical impulse, accentuation of the aortic component of the second heart sound (A2), a fourth heart sound (S4), very short early diastolic murmur and fundal changes (refer complications).

**Table 7.49:** Findings and specific investigations in various secondary hypertension.

<i>Findings</i>	<i>Disease suspected</i>	<i>Specific investigation</i>
Paroxysmal hypertension, palpitations, headache, diaphoresis	Pheochromocytoma	Urine VMA, metanephrine, plasma metanephrine
Fatigue, weight gain, menstrual irregularities, diastolic hypertension	Hypothyroidism	Serum thyroid stimulating hormone (TSH)

Weight loss, tachycardia, tremors, heat intolerance, systolic hypertension	Hyperthyroidism	Serum TSH
Depression, muscle weakness, kidney stones, osteoporosis	Hyperparathyroidism	Serum calcium, parathormone (PTH)
Headaches, fatigue, visual disturbances, enlarged tongue, enlarged extremities	Acromegaly	Growth hormone (GH)
Weight gain, muscle weakness, striae, obesity, amenorrhoea, moon facies	Cushing's syndrome	Serum cortisol
Obesity, snoring, daytime somnolence	Obstructive sleep apnea (OSA)	Polysomnography
Enlarged palpable kidneys, family history positive	Autosomal dominant polycystic kidney disease (ADPKD)	Ultrasound abdomen
Proteinuria, elevated serum creatinine, edema, anemia	Chronic kidney disease (CKD)	Ultrasound
Abdominal/renal bruit	Renovascular cause	MR angiogram
Fatigue, hypokalemia, hypernatremia	Aldosteronism	Plasma renin to aldosterone ratio, MRI abdomen

### *Objectives of clinical examination*

- Identify any underlying cause of hypertension
- Recognize risk factors that lead to complications
- Abnormal signs to detect complications if already developed.

**Nonspecific findings:** Optic fundi may be abnormal; there may be evidence of generalized atheroma or specific complications, such as aortic aneurysm or peripheral vascular disease. Findings and specific investigations in various secondary hypertension are mentioned in Table 7.49.

**Q. Write short note on causes and investigations of secondary hypertension.**

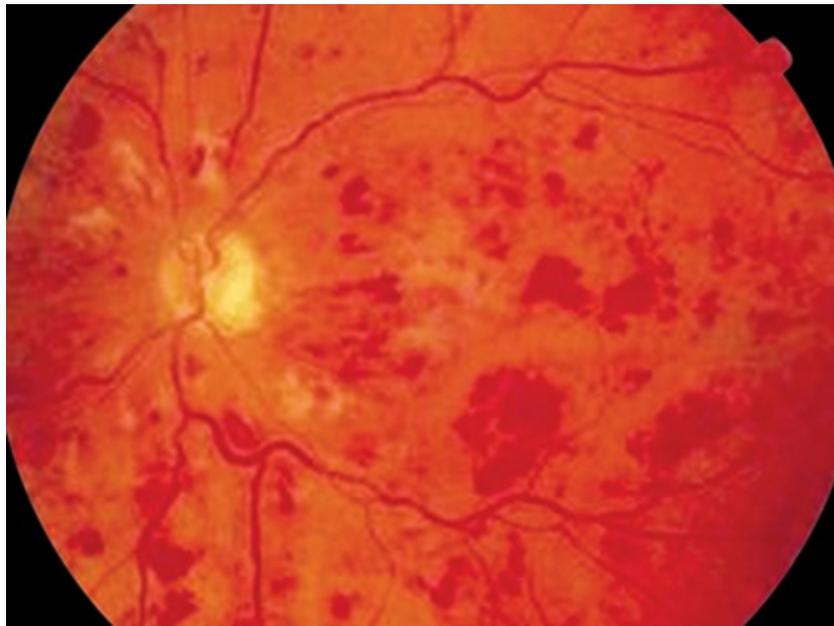

### **Target Organ Damage (Complications of Hypertension)**

**Q. Write short essay or note on complications of hypertension/target organ damage in systemic arterial hypertension.**

Target organ damage in hypertension can be clinically detected.

### ***Central Nervous System Complications***

- **Transient ischemic attacks (TIAs):** Carotid atheroma and TIAs are more common in patients with hypertension.
- **Cerebrovascular accidents (strokes)** is a common complication of hypertension and may be due to cerebral hemorrhage or infarction (due to cerebral atherothrombosis)
- **Subarachnoid hemorrhage** is also a complication of hypertension
- **Hypertensive encephalopathy** is a rare complication characterized by very high blood pressure, neurological manifestations (includes transient disturbances in speech and vision, paresthesias, seizures, disorientation, loss of consciousness) and papilledema.

**Fig. 7.37:** Fundus image of hypertensive retinopathy.

### ***Ophthalmic (Retinal) Complications***

**Q. Write short essay or note on grades of hypertensive retinopathy.**

- Hypertensive retinopathy (Table 7.50 and Fig. 7.37).

### ***Cardiovascular Complications***

- **Coronary artery disease** (angina, myocardial infarction): Increased cardiac mortality and morbidity associated with hypertension are chiefly due to a higher incidence of coronary artery disease. High BP may produce left ventricular hypertrophy with a forceful apex beat and fourth heart sound. ECG or echocardiography is useful in risk assessment.

- **Left ventricular failure and pulmonary edema:** May develop with severe hypertension.
- **Atrial fibrillation** is common and may be due to diastolic dysfunction caused by left ventricular hypertrophy or the effects of coronary artery disease.

**Table 7.50: Grading of hypertensive retinopathy—Keith-Wagener-Barker classification.**

**Grade 1:** Mild narrowing of the arterioles—‘copper wire’

**Grade 2:** Moderate narrowing—copper wire and AV nicking, changes associated with long standing essential hypertension

**Grade 3:** Severe narrowing—silver wire changes, hemorrhage, cotton wool spots, hard exudates

**Grade 4:** Grade 3 + papilledema. Grade 3 and 4 highly correlated with progression to end-organ damage and decreased survival

## ***Blood Vessels***

Larger arteries show thickening of the internal elastic lamina, hypertrophy of smooth muscle and deposition of fibrous tissue. Smaller arteries show hyaline arteriosclerosis in the wall, narrowing of the lumen and aneurysm. **Atherosclerosis** may develop in coronary and cerebral blood vessel. Hypertension is a major risk factor involved in the pathogenesis of **aneurysm of aorta** and dissecting hematoma of aorta (**aortic dissection**).

## ***Renal Complications***

Long-standing hypertension may cause damage the renal vasculature and produce (1) proteinuria, (2) hematuria and (3) progressive renal failure.

## **Investigations**

### ***Basic investigations in all patients***

- **Urinalysis:** For protein, blood and glucose.
- **Blood urea and creatinine:** To assess renal function.
- **Serum electrolytes:** For hypokalemia (is usually due to diuretic therapy) and alkalosis in hyperaldosteronism
- **Fasting and post-prandial blood glucose:** For hyperglycemia
- **Lipid profile:** Serum total cholesterol and HDL cholesterol
- **Electrocardiogram:** 12-lead ECG for left ventricular hypertrophy, coronary artery disease.

### ***Secondary investigations in selected patients***

- **Chest radiograph:** For detecting the cardiac size, evidence of cardiac failure and aortic dilatation, coarctation of the aorta
- **Ambulatory BP recording:** To detect borderline, masked hypertension or ‘white coat’ hypertension.
- **Echocardiogram:** To detect or quantify left ventricular hypertrophy and function.
- **Renal ultrasound:** To detect renal disease
- **MRI, renal isotope scan and renal angiography:** To detect or confirm renal artery stenosis
- **Urinary catecholamines:** To detect pheochromocytoma
- **Urinary cortisol and dexamethasone suppression test:** To detect Cushing’s syndrome
- **Thyroid function tests:** To detect hypothyroidism or hyperthyroidism
- **Serum calcium and parathyroid hormone level:** To detect hyperparathyroidism
- **Plasma renin activity and aldosterone:** To detect possible primary aldosteronism
- **Growth hormone:** To detect acromegaly.

#### Treatment

- **Objective of antihypertensive therapy:** To reduce the incidence of adverse cardiovascular events (e.g. coronary artery disease), stroke and heart failure.
- **Target blood pressure:** For most patients, a target is <140 mm Hg systolic blood pressure and ≈85 mm Hg diastolic blood pressure. For patients with diabetes, renal impairment or established cardiovascular disease the target is <130/80 mm Hg.

Management of hypertension can be studied under three headings.

- General measures
- Antihypertensive drug therapy
- Treatment of underlying cause (in secondary hypertension).

### Table 7.51: Various antihypertensive drugs (dose).

#### Diuretics

##### 1. Thiazide diuretics

- Chlorothalidone/hydrochlorothiazide (12.5–25 mg once daily)
- Chlorothiazide (125–500 mg once daily)
- Indapamide (1.25–2.5 mg once daily)

- Metolazone (2.5–5.0 mg once daily)

## **2. Loop diuretics**

- Furosemide (10–40 mg twice daily)
- Bumetanide (0.5–1.0 mg twice daily)
- Torsemide (2.5–10 mg once daily)

## **3. Potassium-sparing diuretics**

- Amiloride (5–10 mg once daily)
- Triamterene (25–100 mg once daily)

## **4. Aldosterone-receptor blockers**

- Spironolactone (25–100 mg once daily)
- Eplerenone (50–100 mg once daily)

## **$\beta$ -blockers**

- Propranolol (20–80 mg twice or thrice daily)
- Metoprolol (25–100 mg twice daily)
- Atenolol (25–100 mg once daily)
- Bisoprolol (2.5–10 mg once daily)
- Nebivolol (5–10 mg once daily)

## **Combined $\alpha$ - and $\beta$ -blockers**

- Carvedilol (6.25–25 mg twice daily)
- Labetalol (100–900 mg twice daily)

## **Angiotensin-converting enzyme (ACE) inhibitors**

- Enalapril (2.5–20 mg once daily or twice daily)
- Captopril (12.5–50 mg thrice daily)
- Lisinopril (2.5–40 mg once daily)
- Ramipril (2.5–20 mg once daily)
- Perindopril (2–8 mg once daily)
- Quinapril (10–80 mg once daily)

## **Angiotensin II receptor antagonists**

- Losartan (25–50 mg twice daily)
- Candesartan (8–32 mg once daily)

- Irbesartan (75–300 mg once daily)
- Valsartan (80–320 mg once daily)
- Telmisartan (20–80 mg once daily)
- Olmesartan, Azilsartan (20–40 mg once daily)

### **Direct renin inhibitors**

- Aliskiren (75–300 mg once daily)

### **Calcium channel blockers**

- Nifedipine (SR)(30–60 mg once daily)
- Verapamil and diltiazem (40–160 mg twice daily)
- Diltiazem (SR)(90–360 mg once daily)
- Amlodipine and felodipine (2.5–20 mg once daily)
- Nicardipine (SR)(60–120 mg twice daily)

### **α-blockers**

- Prazosin (1–4 mg once daily or twice daily)
- Terazosin (1–20 mg once daily)
- Doxazosin (1–16 mg once daily)

### **Direct vasodilators**

- Hydralazine (12.5–50 mg twice daily)
- Minoxidil (1.25–40 mg twice daily)

### **Central α<sub>2</sub>-blockers and other centrally acting drugs**

- Clonidine (0.05–0.3 mg twice daily)
- Alpha-methyldopa (250–1000 mg four times/day)
- Reserpine (0.05–0.25 mg once daily)
- Moxonidine (0.2–0.3 mg once daily or twice daily)

## **A. General Measures**

### **Q. Write short essay/note on non-pharmacological treatment of hypertension.**

- **Lifestyle modifications:** Recommended for all patients with hypertension and pre-hypertension. A reduction in systolic blood pressure of 5 mm Hg has been associated with about 10% reduction in mortality caused by stroke and heart disease:
  - Control of obesity: Maintain normal body weight (BMI 20–25 kg/m)
  - Diet: Dietary Approaches to Stop Hypertension or **DASH** eating plan.
    - ◆ Restrict salt in the diet (<100 mEq sodium or <6 g NaCl or <2.4 g Na/day).

- ◆ Reduce intake of fat and saturated fat.
- ◆ Increase consumption of diet rich in fruit vegetables ( $\geq 5$  portions of fresh fruit and vegetables/day), potassium.
- ◆ Limit/reduce alcohol consumption to  $\leq 3$  units/day men and  $\leq 2$  units/day women.
- Cardiovascular risk reduction: Stop/avoid cigarette smoking and increase intake of oily fish.
- Regular aerobic/physical exercises: Perform  $\geq 30$  min brisk walk most days of the week. Relaxation classes, meditation and biofeedback.

**Q. Write short essay or note on various types of antihypertensive drugs.**

### **B. Antihypertensive Drug Therapy (Table 7.51)**

**Q. Write short note on  $\alpha$  adrenergic blockers.**

#### *Diuretics*

- Indications include heart failure, elderly and systolic hypertension
  - **Thiazide diuretics**
    - ◆ **Adverse drug reactions:** These include impotence, postural hypotension, allergic rashes, bone marrow depression, hypokalemia, hyperuricemia, hypercalcemia and impaired glucose tolerance/diabetes.
    - ◆ Used as first-line agent in elderly patients with systolic hypertension. If blood pressure is not controlled with a thiazide diuretic, add ACE inhibitors, angiotensin receptor blockers or calcium channel blockers.
    - ◆ **Loop diuretics:** Furosemide or others are used if there is renal impairment or when greater sodium excretion is needed or they are used in conjunction with an ACE inhibitor.

#### *$\beta$ -adrenoreceptor antagonists ( $\beta$ -blockers)*

**Q. Write short essay or note on  $\beta$ -blockers, uses and its side effects.**

Uses and contraindications for  $\beta$ -blockers are mentioned in Table 7.52. Beta blockers are no longer used as first-line antihypertensive therapy. They may be useful in following situations in:

- Younger individuals, particularly who have an intolerance or contraindication to ACE inhibitors and angiotensin II receptor antagonists.
- Women of childbearing potential
- Patients with increased sympathetic drive
- Patients having hypertension and other diseases such as coronary heart disease (post-myocardial infarction or angina), heart failure.

#### *Nonselective ( $\beta_1$ and $\beta_2$ )*

- **Mechanism of action:** Sympatholytic effect, antihypertensive effect, and relief of anxiety, palpitation and angina. Large portion of the drug is destroyed during its passage through liver, e.g.
  - **Dosage:** Started with 40 mg twice a day and gradually increased to 160 mg 6 hourly. Slow-release forms are administered as a single daily dose, e.g. propranolol
  - **Side effects:** Gastric disturbances, bronchospasm, bradycardia, cardiac failure, tiredness, bad dreams, hallucinations, cold hands and muscle weakness.

#### *Cardioselective ( $\beta_1$ )*

- **Mechanisms of action:** They act more on the cardiac  $\beta_1$ -adrenoceptors than  $\beta_2$ -adrenoceptors that mediate vasodilatation and bronchodilatation. **Examples: Metoprolol and atenolol**
- **Dose:** Metoprolol 50 mg twice daily to 100 mg thrice daily, atenolol 50–100 mg once daily and bisoprolol 5–10 mg daily. Sustained release preparation of metoprolol is given in the dose of 12.5–

100 mg once daily.

- **Indications**

- Hypertensive with mild airway obstruction (COPD, asthma), peripheral vascular disease and type 1 diabetes. However, caution is necessary.
- Ischemic heart disease and supraventricular tachycardia.

- **Side effect:** Similar to propranolol and also cause hyperkalemia.

**Combined  $\alpha$ - and  $\beta$ -blockers (labetalol and carvedilol)**

- Sometimes these combined  $\beta$ - and  $\alpha$ -adrenoceptor antagonists are more effective than pure  $\beta$ -blockers.
- **Mechanism of action and side effects:** Similar to propranolol.
- **Dose:** Labetalol 100–200 mg twice daily and carvedilol 6.25–25 mg twice daily. Labetalol can be used as an infusion in the treatment of malignant phase hypertension.

**Table 7.52: Uses and contraindications for  $\beta$ -blockers.**

***Uses of  $\beta$ -blockers***

- |  |  |

|--|---|

***Angiotensin converting enzyme (ACE) inhibitors***

**Q. Write short essay or note on mechanism of action, indications and side effects of angiotensin converting enzyme (ACE) inhibitors.**

**Q. Write short note on ramipril.**

- These include captopril, enalapril (20 mg daily), lisinopril (10–40 mg daily), ramipril (5–10 mg daily), perindopril (refer page 489).

- **Mechanisms of action:** They inhibit the conversion of angiotensin I to angiotensin II and produce powerful arteriolar and venous dilatation, and inhibit release of aldosterone.
- **Dosage:** Start with a small dose (captopril 6.25 mg and enalapril 2.5 mg) and then gradually increase.
- **Indication:** Used in hypertension, chronic cardiac failure or left ventricular dysfunction, post-myocardial infarction or cardiovascular disease, diabetic nephropathy, stroke secondary prevention.
- **Contraindication:** Renal failure (creatinine >3 mg/dL) and bilateral renal artery stenosis because they can reduce the filtration pressure in the glomeruli and precipitate renal failure. Electrolytes and creatinine levels should be checked before and 1–2 weeks after starting therapy. Other contraindications include peripheral vascular disease hyperkalemia and pregnancy.
- **Adverse reaction:** First-dose postural hypotension, cough, angioedema, skin rashes, blood dyscrasias, hyperkalemia, renal dysfunction neuropathy and diarrhea.

#### **Peripheral vasodilators**

- **Mechanism of action:** Act on arteriolar smooth muscles or smooth muscles of venules and produce peripheral arteriolar and venous dilatation.
- Drugs include hydralazine, prazosin (alpha blocker), diazoxide, sodium nitroprusside.

#### **Angiotensin receptor blockers**

##### **Q. Write short essay or note on angiotensin receptor blockers and indications.**

- **Mechanism of action:** They block the angiotensin II type I receptor and have similar effects to ACE inhibitors. Renin-angiotensin-aldosterone system (RAAS) plays an important role in the regulation of blood pressure.
  - Renin catalyzes cleavage of angiotensinogen and produces angiotensin I.
  - Angiotensin I is converted to angiotensin II by the action of ACE. Angiotensin II is the most active hormone of the renin-angiotensin system. There are two angiotensin II receptors namely AT1 (most effective) and AT2 (its function is not established).
  - When angiotensin II binds to its AT1 receptor, it mediates produces many effects such as vasoconstriction, cell proliferation, hypertrophy and aldosterone secretion, provides feedback inhibition of further renin release by the kidney.
  - The angiotensin receptor blockers block the action of angiotensin II by blocking AT1 receptors.
- **Dose:** Losartan 50–100 mg daily, candesartan 2.0–32 mg daily, valsartan 40–320 mg daily, telmisartan 40 mg daily, olmesartan 10–40 mg daily, irbesartan, azilsartan (40–80 mg daily).
- **Side effects:** These drugs are better tolerated than ACE inhibitors. Side effects include hypotension, drowsiness and dizziness. Does not cause cough.
- **Indications:** ACE inhibitor intolerant hypertension, <55 years old, hypertension with LVH, heart failure or left ventricular dysfunction, myocardial infarction (to reduce myocardial remodeling), diabetic nephropathy (to slow its progression) and chronic renal disease.

#### **Calcium channel blockers (calcium antagonists)**

##### **Q. Write short essay or note on uses/indications of calcium channel blockers and its side effects.**

**Table 7.53: Indications of calcium channel blockers.**

- |                                |                          |
|--------------------------------|--------------------------|
| • Angina pectoris/Prinzmetal's | • Peripheral vasospastic |
|--------------------------------|--------------------------|

<p>angina</p> <ul style="list-style-type: none"> <li>• Hypertension and hypertensive crisis</li> <li>• Cardiac arrhythmias</li> <li>• Elderly patients with systolic hypertension</li> <li>• Congestive cardiac failure</li> <li>• Valvular diseases (mitral and aortic regurgitation)</li> <li>• Hypertrophic cardiomyopathy</li> </ul>	<p>conditions, e.g. Raynaud's disease, migraine</p> <ul style="list-style-type: none"> <li>• Pulmonary hypertension</li> <li>• Cor pulmonale (chronic bronchitis with pulmonary hypertension)</li> <li>• Subarachnoid hemorrhage (to prevent vasospasm)</li> <li>• Achalasia cardia</li> <li>• Biliary dyskinesia</li> </ul>
--	--

- They are effective and usually well-tolerated antihypertensive drugs. Various indications of calcium channel blockers are listed in Table 7.53.
- **Contraindications:** Unstable angina, heart failure, hypotension, post-infarct patients, severe aortic stenosis, 2nd and 3rd degree AV block.
- **Side-effects:** Flushing, palpitations and fluid retention. The main side effect of verapamil is constipation.

*Nifedipine and verapamil*  
(refer page 418)

**Dosage:** Nifedipine 10–20 mg three to four times daily and verapamil 180–360 mg/day in divided doses. Short-acting nifedipine should be avoided.

*Centrally acting drugs*

**Reserpine:** It is a mild antihypertensive with central and peripheral action. It is given in the dose of 0.1–0.5 mg daily. Its side effects include nasal congestion, depression and Parkinsonism.

**α methyldopa:** It is a precursor of dopamine and noradrenaline

- **Mechanism of action:** Converted to α-methyl noradrenaline which acts on alpha-2 receptors in brain and causes inhibition of adrenergic discharge in adrenal medulla → fall in peripheral vascular resistance and fall in blood pressure.
- **Side effects:** Cognitive impairment, postural hypotension, positive Coomb's test, etc. Not used therapeutically now except in hypertension during pregnancy.
- **Dose:** 250–500 mg twice or thrice daily.

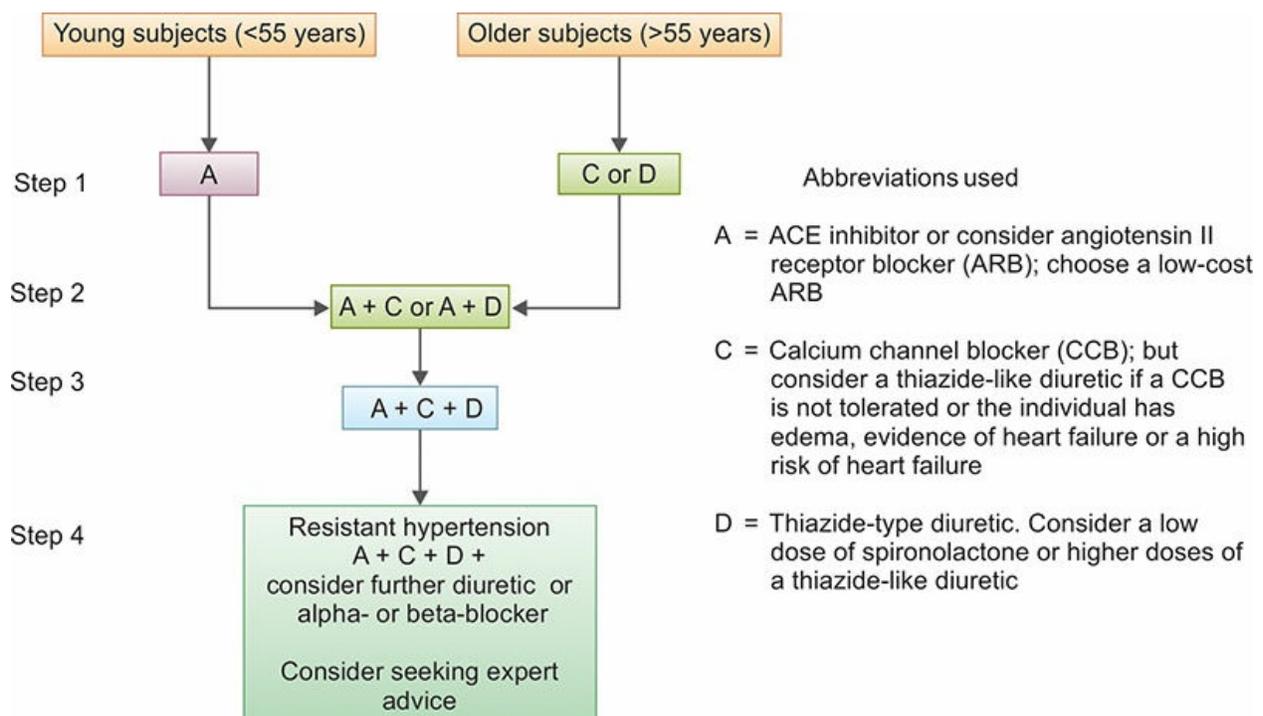

**Clonidine:** Not frequently used because of tolerance and withdrawal hypertension. Side effect is dryness of mouth. Dose: 0.1–1.0 mg daily.

Newer antihypertensive agents are listed in Table 7.54.

**Table 7.54: Newer antihypertensive agents.**

Direct renin inhibitor	Aliskiren
Protein kinase C inhibitors	Staurosporin

Calcium channel blocker	Cilnidipine, azelnidipine, clevidipine
Non-selective $\beta$ -blocker and weak $\alpha$ -blocker	Bucindolol
Chymase inhibitors	SPF-32629A
Prostacycline analog	Treprostinil
Serotonin receptor antagonist	Ketanserin
Endothelin receptor antagonist	Ambrisentan, sitasenten, bosentan, darusentan
Advanced glycation end product (AGE) crosslink breaker	Alagebrium
Phosphodiesterase type 5 (PDE5) inhibitor	Sildenafil

**Fig. 7.38:** Choosing antihypertensive drug and its combinations for patients newly diagnosed with hypertension.

## Guidelines for starting antihypertensive agents (Fig. 7.38)

### Recommendations in hypertension management suggested by JNC8 (Table 7.55)

**Q. Discuss the recommendations in hypertension management suggested by JNC8.**

#### Table 7.55: JNC8 recommendations in hypertension management.

1. **Elderly: In the general population aged  $\geq 60$  years:** Start drug treatment to reduce BP of

	≥150/90 mm Hg <b>AND</b> Treat patients for blood pressure goal of <150/90 mm Hg
2.	<b>Diastolic blood pressure:</b> In general individuals aged <60 years: Initiate drug treatment to reduce diastolic BP of ≥90 mm Hg <b>AND</b> Treat patients for diastolic BP goal of <90 mm Hg
3.	<b>Systolic blood pressure:</b> In general individuals aged <60 years: Initiate drug treatment to reduce systolic BP of ≥140 mm Hg <b>AND</b> Treat patients for systolic BP goal of <140 mm Hg
4.	<b>Chronic kidney disease: In the population aged ≥18 years with chronic kidney disease:</b> Initiate drug treatment to reduce BP of ≥140/90 mm Hg <b>AND</b> Treat patients for BP goal of <140/90 mm Hg
5.	<b>Diabetes mellitus: In the population aged ≥18 years with diabetes:</b> Initiate drug treatment to reduce BP of ≥140/90 mm Hg <b>AND</b> Treat patients for BP goal of <140/90 mm Hg
6.	<b>Non-black-first line: In the non-black individuals, including patients with diabetes</b> recommend antihypertensive treatment with the following: Thiazide-type diuretic, calcium channel blocker (CCB), angiotensin-converting enzyme inhibitor (ACEI), or angiotensin receptor blocker (ARB)
7.	<b>Black-first line: In the black individuals, including patients with diabetes:</b> Recommend antihypertensive treatment with: Thiazide-type diuretic <b>OR</b> calcium channel blocker (CCB)
8.	<b>Chronic kidney disease-first line or add on in adults aged ≥18 years with chronic kidney disease and hypertension:</b> Initial or add-on antihypertensive treatment to improve kidney outcomes with: An ACEI <b>OR</b> An ARB
9.	<ul style="list-style-type: none"> <li>• <b>Do not combine</b> ACEI and ARB</li> <li>• If BP goal is not reached <b>within 1 month of treatment</b> increase the dose of the drug or add 2nd drug and if not reached with 2 drugs, add and titrate a third drug from the above mentioned class.</li> <li>• If goal BP cannot be reached using only the drugs from class of thiazide-type diuretic, CCB, ACEI, or ARB due to some contraindication or the need to use more than 3 drugs to reach goal BP, antihypertensive drugs from <b>other classes</b> can be added.</li> </ul>

## Hypertensive Encephalopathy

### **Q. Discuss briefly about hypertensive crisis/hypertensive emergencies.**

- It is more **generalized** term and is not defined by a specific blood pressure reading.
- It develops in previously hypertensive/normotensive patients.
- It is a clinical syndrome that is associated with acute severe or abrupt elevation of blood pressure. Characterized by severe increase in systolic and/or diastolic blood pressure associated with signs or symptoms of acute end-organ damage.

- No blood pressure threshold for diagnosis. Usually, systolic blood pressure >180–220 mm Hg, diastolic blood pressure >120–130 mm Hg and mean arterial pressure (MAP) >180 mm Hg
- Increased cerebral blood flow → hyperfiltration → localized or diffuse cerebral edema → cerebral ischemia resulting from arteriolar spasm.
- Severe headache, vomiting, visual disturbances, confusion, focal or generalized seizures.
- Fundoscopy examination (key role): **Papilledema**
- It includes: (1) hypertensive emergency, and (2) hypertensive urgency.

### ***Hypertensive Emergencies***

Reason includes renovascular disease, pheochromocytoma, non-adherence to antihypertensive medication, hyperaldosteronism, erythropoietin administration, acute glomerular nephropathy and eclampsia.

### ***Hypertensive Urgency***

- Severe elevation in BP >180/120 mm Hg without symptoms or signs of acute target organ involvement.
- Adequate treatment of these conditions, a BP lowering within 24 hours by administration of oral drugs.
- ICU admission is usually not required.

**Treatment:** Requires an immediate BP reduction in few minutes to hours in an ICU care and brought by IV drugs.

### **‘Malignant’ or ‘Accelerated’ Phase Hypertension**

#### **Q. Write short essay or a note on accelerated hypertension.**

- It is a rare condition that may complicate hypertension of any etiology. It occurs when blood pressure rises rapidly with severe hypertension (diastolic blood pressure >120 mm Hg). Histologically it is characterized by fibrinoid necrosis in the walls of small arteries and arterioles and intravascular thrombosis.
- **Diagnosis:** Presence of high BP and rapidly progressive end-organ damage, such as retinopathy (grade 3 or 4 with flame-shaped hemorrhages, cotton wool spots, hard exudates and papilledema), renal dysfunction (e.g. proteinuria, hematuria) and/or cerebral edema and

hemorrhage with resultant hypertensive encephalopathy. Left ventricular failure may develop.

- If this is untreated, it may lead to death within months from progressive renal failure, heart failure, aortic dissection or stroke.

**Q. Write short essay or note on treatment of hypertensive crisis (hypertensive emergencies).**

**Q. Discuss the management of accelerated/malignant hypertension.**

#### **Management of Hypertensive Emergencies**

- Normalization of BP is usually not recommended.
- Sudden fall in BP may cause acute hypoperfusion of vital organs and results in myocardial ischemia or infarction, hemiplegia, or acute renal failure.
- Older patients with long lasting hypertension and preclinical organ involvement (LVH, atherosclerosis and arteriolar remodelling) are at risk of these complications as the lower limit of autoregulation shifted to right.

#### ***How fast and how much BP to be lowered to be given importance***

- **Goal:** Reduce mean arterial pressure (MAP) by no more than 20–25%, diastolic blood pressure (DBP) to 100–110 mm Hg within few minutes to 2 hours.
- More aggressive and rapid BP reduction needed in acute pulmonary edema and aortic dissection.
- More slow reduction needed for acute cerebrovascular damages with monitoring of neurological status.
- Constant infusion of intravenous agents required (no intermittent IV boluses/oral/sublingual drugs—drastic BP fall).

Various hypertensive emergencies and their treatment are presented in Table 7.56.

Drugs used in hypertensive emergencies and their dosage, action and adverse effects are presented in Table 7.57.

## **Resistant Hypertension**

**Q. Write short note on resistant hypertension.**

**Definition:** Resistant hypertension is defined as blood pressure above goal (>140/90 mm Hg; >130–139/80–85 mm Hg in patients with diabetes mellitus; >130/80 mm Hg in chronic kidney disease), *despite treatment with  $\geq 3$  antihypertensive drugs of different classes, including a diuretic, at optimal doses.*

- Resistant hypertension is observed in about 10–20% of patients with hypertension.

- Almost 50% of these patients experience an adverse cardiovascular event compared with patients with blood pressure controlled by three or fewer antihypertensive agents. Non-compliance to medication is an important cause.
- Diagnosis requires exclusion of both pseudo-resistance and reversible or organic causes.

**Table 7.56: Various hypertensive emergencies and their treatment.**

<b>Diagnosis</b>	<b>Suggested drugs</b>	<b>Targets</b>	<b>Remarks</b>
Acute aortic dissection	Esmolol/labetelol + nitroprusside would be a better combination	Reduce SBP as rapidly as possible down to 100–110 mm Hg, simultaneously control tachycardia due to the sympathetic activation	Avoid volume depletion Use $\beta$ -blockers before vasodilators Hydralazine is contraindicated
Acute pulmonary edema	Nitroglycerine infusion, IV enalaprilat, Nitroprusside infusion, IV furosemide	Reduce blood pressure by 20–30%	Hypotension may develop with enalaprilat
Acute coronary syndrome	Nitroglycerine infusion b-blockers (metoprolol or labetalol)	Reduce blood pressure by not more than 20–30%	Beware of hypotension in right ventricular infarction Avoid hypotension
Acute renal failure	Labetalol IV, nicardipine infusion, dialysis	Reduce blood pressure not more than 20–30%	Avoid nitroprusside and ACE inhibitors
Subarachnoid hemorrhage	Labetalol bolus and infusion Esmolol bolus and infusion Nicardipine infusion	Systolic pressure <160 mm Hg or mean arterial pressure <130 mm Hg (to reduce recurrence)	Control of pain will help in BP control
Intracranial bleed	Labetalol and infusion Nitroglycerine infusion Nimodipine, a dihydropyridine calcium blocker is effective	To prevent rebleeding and reduce edema formation. May benefit from gradual 20–25% reduction in BP	Avoid lowering blood pressure by more than 10–15% in 24 hours
Hypertensive encephalopathy	IV sodium nitroprusside is the drug of choice, rapid onset of action). IV labetalol, nicardipine,	Mean BP should be reduced by 20% within first hour	

**Table 7.57: Drugs used in hypertensive emergencies.**

<i>Drug</i>	<i>Initial dose (mg)</i>	<i>Onset (minutes)</i>	<i>Duration (hours)</i>	<i>Adverse effects</i>
Labetalol	200–400	30–120	2–12	Orthostatic hypotension, bronchoconstriction
Clonidine	0.150–0.300	30–60	8–16	Hypotension, dry mouth
Prazosin	1–2	60–120	8–12	Syncope (first dose), tachycardia
Nicardipine	20–40	30–60	8–12	Headache, tachycardia
Amlodipine	5–10	60–120	12–18	Headache, flushing
Captopril	25–50	15–45	6–8	Renal failure in bilateral renal artery stenosis

**Treatments for resistant hypertension**

- **Non-pharmacologic intervention:** Reinforce lifestyle changes.
- **Drug intervention:** Look for drug compliance, optimize doses. Add drugs from other classes.
- **Device therapy:** Two techniques
  1. Percutaneous transluminal radiofrequency sympathetic denervation of the renal arteries.
  2. Carotid baroreflex activation.
- **Medical therapy:** Aldosterone antagonist, angiotensin-converting enzyme (ACE) inhibitors and angiotensin II receptor blockers (ARBs) plus chlorthalidone.
- Percutaneous angioplasty with or without stent placement.
- Surgical revascularization or, nephrectomy in unilateral cases.

## RHEUMATIC HEART DISEASE

**Q. Define rheumatic fever. Discuss the etiology, risk factors, pathogenesis, clinical features, investigations, diagnosis, complications and management of rheumatic fever.**

**Definition:** Rheumatic fever (RF) is an **acute, post-streptococcal, immune-mediated, multisystem inflammatory disease**. It occurs as a sequel to group A streptococcal pharyngitis.

- Multisystem disease affecting connective tissue particularly of the heart, joints, brain, cutaneous and subcutaneous tissues.

### Two Major Phases

- **Acute rheumatic fever (ARF):** It frequently manifest as acute rheumatic

carditis.

- **Chronic rheumatic heart disease (RHD)** is the permanent heart valve damage resulting from one or more attacks of ARF. About 40–60% of patients with ARF will develop RHD. The commonest valve affected is the mitral followed by aortic, in that order. However, all four valves can be affected. The deforming fibrotic valvular lesions are the principal/key features of chronic RHD.

## Epidemiology and Incidence

- **Age group:** Most common in children between 5 and 15 years. It is rare <3 years of age.
- **Sex:** Both sexes are equally affected. However, certain clinical manifestations, such as mitral stenosis and Sydenham chorea have a female preponderance after puberty
- **Socioeconomic conditions:** Rheumatic fever is a worldwide disease and it is prevalent in regions with poor economic conditions, overcrowding and substandard housing. Incidence and mortality rate of RF and RHD have markedly decreased over the past century, due to improved socioeconomic conditions and rapid diagnosis and treatment of streptococcal pharyngitis. In India, the annual incidence is 0.18 to 0.3 per 1000 school children.
- **Poor economy and overcrowding:** It is a predisposing factor in developing countries. It is a major cause of death and disability in children and adolescents in socioeconomically deprived regions.

## Etiology

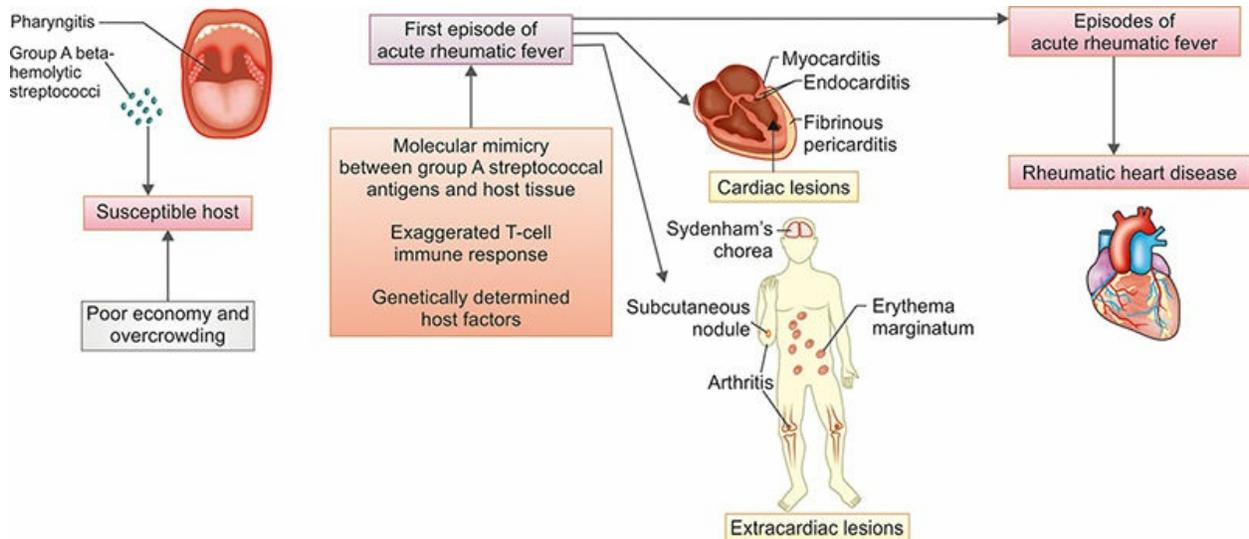

- Acute rheumatic fever is a post-streptococcal disease.
- It develops after a latent period of 2 to 6 weeks after an episode of pharyngitis (sore throat) or tonsillitis by group A  $\beta$ -hemolytic streptococci. It occurs most often in children.
- Rheumatogenic potential of various serotypes of group A streptococci vary. M-protein is one of the well-defined determinants of bacterial virulence. M-type 5 is commonly responsible for rheumatic fever and other rheumatogenic sero-types include 1, 3, 5, 14, 18, 19 and 24. M-type 12 is highly prevalent, but usually does not cause rheumatic fever.
- Recently virus (coxsackie B-4) has been suggested as causative agent with streptococcus acting as conditioning agent.

## Pathogenesis (Fig. 7.39)

**Immunologically mediated disease:** Exact pathogenesis of rheumatic fever is not known. Streptococcal infection introduces the streptococcal antigens into the body may activate both antibody and T cell-mediated reactions against streptococci.

### *Molecular Mimicry*

- Antibodies may be produced by B-lymphocytes against various antigenic components of the *Streptococcus*.
- These antibodies cross react with human tissues because of the antigenic similarity between streptococcal components and human connective tissues (molecular mimicry). One of them produced against the M-proteins of streptococci seems to cross-react with certain similar self-antigens in the myocardial cells and glycoproteins of the valves in the heart. This may be the mechanism for pancarditis in acute rheumatic fever.
- Immunologically mediated inflammation and damage (autoimmune) to human tissues which have antigenic similarity with streptococcal components—like heart, joint, brain connective tissues.

**Fig. 7.39:** Pathogenesis of rheumatic fever and rheumatic heart disease.

### *Streptococcal Super Antigens*

- Super antigens are glycoproteins synthesized by bacteria and viruses. They can bridge class II major histocompatibility complex molecules to specific T-cell receptors, simulating antigen binding and activation of **CD4+** T-

**cells.** These T-cells along with antibodies **cross react with self-proteins in the heart.** These reactions produce cytokines leading to activation of macrophages, which are seen in lesions of rheumatic fever.

### ***Host Factors***

- Rheumatic fever occurs in a susceptible host and only 0.3–3% of individuals with acute streptococcal pharyngitis develops rheumatic fever.
- In India, HLA-DR3 is associated more frequently in patients with rheumatic fever and rheumatic fever has low frequency of HLA-DR2.

### **Clinical Manifestations**

Acute rheumatic fever is a multisystem disorder. It usually presents with fever, anorexia, lethargy and joint pain.

**Previous history of sore throat:** Only two-thirds of patients remember having any upper respiratory symptoms (episode of streptococcal pharyngitis) in the past 2–3 weeks.

### ***Migrating Polyarthriti***

- Most common major manifestation. It occurs early when streptococcal antibody titers are high in about 75–90% of patients.
- It is acute, painful, migratory, and asymmetric and is of short duration (**fleeting and flitting**). Usually >5 joints are affected and mainly involves large joints (knees, ankles, wrists, elbows, shoulders). The joints are involved in quick succession. Small joints and cervical spine less commonly involved.
- Involved joints show signs of inflammation (red, swollen and tender) with or without effusion. Pain and swelling develops quickly and subsides within 5–7 days. Arthritis does not progress to chronic disease and over a period of time involved joints heal without any residual deformity (licks the joints).
- Excellent response of high dose aspirin (salicylates) and NSAIDs.
- **Jaccoud's arthritis** is a rare deformity of the metacarpophalangeal joints following repeated attacks of rheumatic fever.
- In children below 5 years, arthritis is usually mild but carditis is more prominent

### ***Poststreptococcal Reactive Arthritis (PSRA)***

- Arthritis developing after an episode of Group A streptococcal pharyngitis without other major criteria of acute rheumatic fever is known as PSRA.
- PSRA develops 10 days after pharyngitis, can involve large joints, small joints or axial skeleton, cumulative and persistent and does not respond to acetylsalicylic acid.

- In contrast, arthritis of rheumatic fever develops 2 to 3 weeks after an episode of Group A streptococcal pharyngitis, migratory and transient, and usually involves only the large joints and responds well to acetylsalicylic acid.
- A small percentage of PSRA patients may subsequently develop valvular heart disease. Hence, patients should be followed up carefully for several months to look for evidence of carditis.

## **Carditis**

### **Q. Write short essay/note on diagnosis of rheumatic fever.**

- Early and most serious manifestation that occur in 60–70% of patients
- It manifest as pancarditis involving all three layers of the heart (**endocardium, myocardium, and pericardium**). On microscopic examination myocardium shows **Aschoff body** that is pathognomonic of rheumatic myocarditis. **Rheumatic endocarditis** may involve valvular (valvular endocarditis) or mural endocardium (mural endocarditis). Rheumatic pericarditis produces pericardial effusion and thick fibrino-serous exudates.
- Carditis leaves a sequelae and permanent damage to the organ (bites the heart).
- Valvular damage is the hallmark of RF. Chronic phase is characterized by fibrosis, calcification and stenosis of heart valves (fish-mouth valves).
- It is more common in younger children, and may be asymptomatic. It is detected only on echocardiograph.

## *Manifestations of carditis*

**Pancarditis** involves the endocardium, myocardium and pericardium. Incidence of carditis decreases with increasing age. It ranges from 90% at 3 years to around 30% in adolescence.

- **Myocarditis**

- Tachycardia: Disproportionate to fever and persists during sleep.
- Features of congestive heart failure: Breathlessness (due to heart failure or pericardial effusion). Cardiac failure may be either caused by dysfunction of myocardium or valvular regurgitation.
- Physical examination may reveal third heart sound (S<sub>3</sub>), fourth heart sound (S<sub>4</sub>) or a summation gallop.
- Arrhythmias, prolongation of PR interval being the commonest.

- **Endocarditis:** Murmurs are most commonly observed during acute rheumatic fever. It may be a new or changed murmurs and includes:

- Apical pansystolic murmur is a high-pitched, blowing-quality murmur of mitral regurgitation that radiates to the left axilla.

**Q. Write short note on Carey Coombs murmur.**

- Apical soft mid-diastolic murmur (also known as a **Carey-Coombs murmur**) is heard during active carditis due to valvulitis with nodules forming on the mitral valve leaflets. It accompanies severe mitral insufficiency.
- An early diastolic murmur of aortic regurgitation and is high-pitched, blowing, decrescendo, and heard best along the right upper and mid-left sternal border after deep expiration while the patient is leaning forward.

- **Pericarditis**

- Chest/pericardial pain (due to pericarditis or pancarditis)
- Pericardial friction rub and precordial tenderness
- Pericardial effusion (uncommon and always small). Rheumatic pericarditis never causes constriction.

**Other clinical features of acute rheumatic carditis:** These include palpitations, cardiac enlargement (cardiomegaly) and syncope due to conduction defects.

## ***Skin Lesions***

**Q.** Write short essay/note on skin lesions in acute rheumatic fever.

### *Subcutaneous nodules*

- Occur in 9–20% of cases and often associated with carditis.
- Appears as a small (0.5–2.0 cm), painless, mobile hard nodules beneath skin appears 4 weeks after onset of RF. Thus, it helps to confirm rather than make the diagnosis.
- Most common along extensor surfaces of joint-knees, elbows, wrists and also on bony prominences, tendons, dorsum of feet, occipital or cervical spine.
- Delayed manifestation, disappears: Leaves no residual damage.

### *Erythema marginatum*

- Occur in <7% and often associated with chronic carditis and are evanescent.
- Unique, transient, serpiginous-looking lesions of 1–2 inches in size.
- Pink/red macules clear centrally, serpiginous spreading edge. More on trunks and limbs, non-itchy and almost never on the face. The resulting red rings or ‘margins’ may coalesce or overlap.
- Worsens with application of heat.

***Chorea (Sydenham’s chorea, Chorea Minor, Saint Vitus Dance)***(refer pages 449-50)

### ***Others***

- Epistaxis, arthralgia, tender lymph nodes, scarlet fever rash, abdominal pain, tonsillar exudates in older children, etc.
- Systemic manifestations are rare and include pleurisy, pleural effusion and pneumonia.

### ***Duration of Attack of Rheumatic Fever***

- **Acute rheumatic fever:** Average duration of an untreated acute attack is about 3 months.
- **Chronic rheumatic fever:** It is defined as persistence of disease for more than 6 months. It occurs in less than 5% of patients and may lead to persisting congestive heart failure.

## Laboratory Investigations

### *Investigations for Evidence of Preceding Streptococcal Infection (Specific)*

- **Isolation of group A streptococci/Throat swab culture:** Group A  $\beta$ -hemolytic streptococci is usually in only 10–25% of cases. It can be done also in family members and contacts. However, serologic tests are usually done to show the evidence of streptococcal infection.
- **Streptococcal antibody tests (serologic tests)**
  - Serological tests usually confirm a recent group A  $\beta$ -hemolytic streptococcal infection.
  - Raised streptococcal antibody levels are found in the early stages of acute rheumatic fever. However, in two situations their levels may be low:
    - ◆ When the interval between the streptococcal pharyngitis and detection of rheumatic fever is more than 2 months (e.g. chorea).
    - ◆ In patients with rheumatic carditis only.

#### – Common serologic tests

- ◆ **Antistreptolysin O antibodies (ASO titers):** Rising titers, or levels of >200 U (adults) or >300 U (children). This test is positive in 80% of cases. ASO titers are normal in 20% of adult cases of rheumatic fever and most cases of chorea.
- ◆ Anti-DNase B
- ◆ Antihyaluronidase (AH)
- ◆ Antistreptozyme test (ASTZ) is a very sensitive indicator of recent streptococcal infection and is also helpful in ruling out rheumatic fever. Titers more than 200 units/mL are considered positive.

The above four tests when combined together are helpful in confirming the diagnosis in 95% of cases.

### *Investigations for Evidence of a Systemic Illness (Nonspecific)*

- **Acute phase reactants:** These tests confirm the presence of an inflammatory process, but are nonspecific.
  - Erythrocyte sedimentation rate (ESR) is raised.
  - Raised C-reactive protein (CRP) in the blood.
- **Other tests confirming an inflammatory reaction**
  - **Peripheral blood:** Polymorphonuclear leukocytosis and anemia (due to suppression of erythropoiesis)

- **Serum:** Increase in serum complements, and increase in serum mucoproteins,  $\alpha_2$  and  $\gamma$  globulin levels.

### ***Investigations for Evidence of Carditis***

- **Chest radiography:** Chest X-ray may show evidences of cardiac failure, cardiomegaly, pulmonary congestion.
- **Electrocardiogram:** ECG changes commonly include:
  - Most consistent change is a prolongation of the PR interval and T-wave inversion.
  - Other findings are rarely second-degree AV block features of pericarditis and reduction in QRS voltages.
- **Echocardiography:** It can detect myocardial dysfunction, cardiac dilatation, valvular abnormalities and pericardial effusion.

### **Diagnosis of Acute Rheumatic Fever**

**Q. Write short essay/note on diagnosis of rheumatic fever/revised Dukett Jones criteria for the diagnosis of rheumatic fever.**

- Diagnosis of acute rheumatic fever (ARF) is made by the presence of combination of typical clinical features together with evidence of the precipitating group A streptococci (GAS) infection. This uncertainty led Dr T Duckett Jones in 1944 to develop a set of criteria known as Jones Criteria to aid diagnosis.
- **Modified Jones criteria:** Presently diagnosis is based on modified Jones criteria (Table 7.58).

### ***Exceptions to Jones Criteria***

- Chorea alone, if other causes have been excluded.
- Insidious or late-onset carditis (Indolent carditis) with no other explanation.
- Patients with documented RHD or prior rheumatic fever, one major criterion, or of fever, arthralgia or high CRP suggests recurrence.

**Table 7.58** World Health Organization criteria (2002–2003) for the diagnosis of rheumatic fever and rheumatic heart disease (based on the 1992 revised Jones criteria).

<b>Diagnostic categories</b>	<b>Criteria</b>
Primary episode of rheumatic fever	<b>Two major or one major and two minor manifestations plus evidence of preceding group A streptococcal infection</b>
Recurrent attack of rheumatic fever in a patient without established rheumatic heart disease	
Recurrent attack of rheumatic fever in a patient with established rheumatic heart disease	Two minor manifestations plus evidence of preceding group A streptococcal infection
Rheumatic chorea	Other major manifestations or evidence of group A streptococcal infection not required
Insidious onset rheumatic carditis	
Chronic valve lesions of rheumatic heart disease (patients presenting for the first time with pure mitral stenosis or mixed mitral valve disease and/or aortic valve disease)	Do not require any other criteria to be diagnosed as having rheumatic heart disease
<b>Major manifestations</b>	<b>Minor manifestations</b>
<ul style="list-style-type: none"> <li>• Carditis</li> <li>• Polyarthrititis</li> <li>• Chorea</li> <li>• Erythema marginatum</li> <li>• Subcutaneous nodules</li> </ul>	<ul style="list-style-type: none"> <li>• Clinical: Fever, polyarthralgias</li> <li>• Laboratory: Elevated erythrocyte sedimentation rate or leukocyte count</li> <li>• Electrocardiogram: Prolonged P-R interval</li> </ul>
Supporting evidence of a preceding streptococcal infection within the last 45 days	
<ul style="list-style-type: none"> <li>• Elevated or rising antistreptolysin O or other streptococcal antibody or</li> <li>• A positive throat culture or</li> <li>• Rapid antigen test for group A <i>Streptococcus</i> or</li> <li>• Recent scarlet fever</li> </ul>	

## **Q. Write short essay/note on treatment of rheumatic fever with carditis.**

### **Management of Acute Rheumatic Fever**

- Step I: Primary prevention (eradication of streptococci).
- Step II: Anti-inflammatory treatment (aspirin, steroids).
- Step III: Supportive management and management of complications.
- Step IV: Secondary prevention (prevention of recurrent attacks).

### **Q. Write short essay/note on prophylaxis of rheumatic fever.**

#### **Step I: Primary Prevention (Eradication of Streptococci)**

- Primary prevention is accurate diagnosis and treatment of group A  $\beta$ -hemolytic streptococcal pharyngeal infection.
- Antistreptococcal therapy/primary prevention are mentioned in Table 7.59.

#### **Step II: Anti-inflammatory treatment**

##### **• Arthritis only**

- **Aspirin** usually rapidly relieves the symptoms of arthritis within 24 hours and also helps to confirm the diagnosis. Aspirin is given in the dose of **75–100 mg/kg body weight/day** divided into 4 doses for 6 weeks (attain a body level 20–30 mg/dL). It should be continued till the ESR has fallen. It produces mild toxicity such as nausea, tinnitus and deafness and serious toxicity

as vomiting, tachypnea and acidosis.

- **Carditis or severe arthritis**

- **Corticosteroids** produce more rapid symptomatic relief compared to aspirin. They are indicated in patients with carditis or severe arthritis. However, their long-term use is not found to be beneficial.
- Prednisolone given in the dose of **1.0–2.0 mg/kg per day** in divided doses for 4–6 weeks (until the ESR is normal) and then to be tapered off.

**Step III: Supportive Management and Management of Complications**

- **Bed rest** is important, because it reduces joint pain and cardiac workload.
  - **Patients without carditis:** Advice bed rest until temperature and ESR are normal.
  - **Patients with carditis:** Bed rest to be continued for 2–6 weeks after the ESR and temperature has returned to normal. Avoid strenuous exercise in patients who had carditis.
- **Treatment of congestive cardiac failure:** Digitalis, diuretics.
- **Treatment of chorea:** Diazepam or haloperidol.
- Rest to joints and supportive splinting.

**Step IV: Secondary Prevention of Rheumatic Fever (Prevention of Recurrent Attacks)**

- Patients with acute rheumatic fever are susceptible to further attacks of rheumatic fever if another streptococcal infection occurs.
- Secondary prevention is directed at preventing acute group A  $\beta$ -hemolytic streptococcal (GABHS) pharyngitis in patients at substantial risk of recurrent acute rheumatic fever by long-term prophylaxis. Duration of prophylaxis is controversial and its broad outlines are provided in Table 7.60.
- Regimens for secondary prevention of rheumatic fever are mentioned in Table 7.61.

**Table 7.59** Antistreptococcal therapy for primary prevention.

<b>Drug</b>	<b>Dose</b>	<b>Mode and duration</b>
Benzathine penicillin G <b>OR</b>	600000 U for patients <27 kg 1200000 U for patients >27 kg	Intramuscular Once
Penicillin V (phenoxymethylpenicillin) <b>OR</b>	Children: 250 mg 2–3 times daily or adolescents and adults: 500 mg 2–3 times daily	Oral for 10 days
Procaine penicillin	Daily 6,00,000 units	Intramuscular for 10 days
Erythromycin	20–40 mg/kg/day 2–4 times daily (maximum 1 g/day)	Oral for 10 days

**Table 7.60** Categories of rheumatic fever and duration of prophylaxis.

<b>Category</b>	<b>Duration</b>
Rheumatic fever without carditis	At least for 5 years or until age 21 year, whichever is longer
Rheumatic fever with carditis but without residual heart disease (no valvular disease)	At least for 10 years or well into adulthood, whichever is longer

Rheumatic fever with carditis and residual heart disease (persistent valvular disease) and post-valve surgery cases

At least 10 years since last episode and at least until age 40 years; sometime lifelong

**Table 7.61** Regimens for secondary prevention of rheumatic fever.

<b>Drug</b>	<b>Dose</b>	<b>Route</b>
Penicillin G benzathine <b>OR</b>	600,000 U for children, $\leq 27$ kg and 1.2 million U for children $> 27$ kg, every 3 week	Intramuscular
Penicillin V <b>OR</b>	250 mg, twice a day	Oral
Sulfadiazine or sulfisoxazole	0.5 g, once a day for patients $\leq 60$ lb; 1.0 g, once a day for patients $> 60$ lb	Oral
For individuals who are allergic to penicillin and sulfonamide drugs		
Macrolide or azalide (erythromycin, azithromycin)	Variable	Oral

## Rheumatic Chorea

**Q.** Write short essay/note on clinical features, diagnosis and treatment of Sydenham's chorea.

It is also known as **Sydenham's chorea**, **Saint Vitus dance**, St. Johannis' chorea, **chorea minor** or rheumatic chorea.

**Definition:** Rheumatic chorea is a syndrome characterized by chorea, muscle weakness and emotional instability.

### **Etiology**

Triggering factor is pharyngeal infection by group A  $\beta$ -hemolytic streptococci.

### **Clinical Features**

- **Age and gender:** Occur in 5–10% of cases, mainly in girls of 1–15 years of age.
- **Onset of chorea:** Rheumatic chorea is a late neurological manifestation of acute rheumatic fever. Usually occurs 3–8 months after the triggering infection by A  $\beta$ -hemolytic streptococci when all the other signs may have disappeared. If there is no previous rheumatic manifestation, the term pure chorea is used.

- **First sign:** Emotional lability, difficulty walking, talking, writing which is observed in 30% of patients with acute rheumatic fever (ARF).
- Characterized by spasmodic, brief, purposeless (unintentional), involuntary, jerky movements. Choreiform movements particularly affect the head/face (darting movement of tongue) upper limb hands or feet. Speech may be affected and may be explosive and halting and fidgety. It can be unilateral (hemichorea) or bilateral.
- **Mild forms** may be difficult to diagnose and following signs are helpful in these cases:
  - **Milkmaid’s grip:** When the patient is asked to squeeze the examiner’s fingers, a squeezing and relaxing motion (like milking a cow) occurs. This is described as milkmaid’s grip and is due to inability to maintain muscular contraction.
  - **Bag-of-worms appearance** is due to asynchronous contractions of the lingual muscles.
  - **Jack-in-the-box sign:** When the patient is asked to keep the tongue protruded out, it retracts involuntarily.
  - **Pronator sign:** Holding the arms outstretched may elicit ‘spooning’ (hyperextension of the fingers with dorsiflexion of the wrist).
- **Severe forms:** Patients is unable to get up or sit, and has violent continuous jerks that may cause physical injury.
- Additional features include hypotonia, pendular knee jerks, and mild generalized muscular weakness.

## ***Prognosis***

- Usually benign and spontaneously resolves in 2–3 months. Disappears leaving no residual damage.
- About 25% of affected patients develop chronic rheumatic valve disease.

## **Management**

- Rule out other causes of chorea such as systemic lupus erythematosus, Huntington’s disease, and Wilson’s disease.
- Rest: Complete mental and physical rest. Keep the patient in a quiet room.
- Padded side-boards for beds to prevent physical injury.
- Drugs: Haloperidol or sodium valproate with diazepam. Steroids may be needed in severe cases.
- Rheumatic fever prophylaxis (refer pages 448-9).

# VALVULAR HEART DISEASE

## Mitral Valve

It is called so because it resembles the Bishops 'mitre'.

### *Mitral Valve Apparatus*

It consists of different components (Box 7.31). Normal mitral valve is bicuspid (two leaflets), funnel-shaped valve between left atrium and left ventricle with its apex in the left ventricle. The two valve leaflets are attached by (about 120) chordae tendineae to two papillary muscles. Mitral valve orifice is about 4–6 cm<sup>2</sup> (average 5 cm<sup>2</sup>).

**Box 7.31:** Different components of mitral valve apparatus.

- Mitral annulus
- Mitral leaflets: (1) anterior mitral leaflet (AML) and (2) posterior mitral leaflet (PML)
- Subvalvular apparatus: Chordae tendineae and papillary muscles
- Left Ventricular wall where the papillary muscle attaches
- Left atrium

## Mitral Stenosis

**Q. Discuss the etiology, pathophysiology, clinical features, investigations, complications and management of mitral stenosis.**

**Q. Write short essay/note on juvenile mitral stenosis and pediatric mitral stenosis.**

**Mitral stenosis** (MS) is a valvular heart disease is characterized by the narrowing of the orifice of the **mitral** valve due to structural abnormality of the **mitral** valve apparatus.

### *Etiology (Table 7.62) and Pathology*

- Rheumatic fever is the most common cause of mitral stenosis. It develops secondary to previous rheumatic fever due to infection with group A  $\beta$ -hemolytic *Streptococcus*
- Mitral stenosis is more common in females.
- The latent period from the first attack of rheumatic fever and the development of onset of symptoms due to mitral stenosis is usually as short as 1–2 years in India, compared to long in Western countries. This

may due to repeated attacks of severe carditis in India.

- Clinical manifestation in **juvenile mitral stenosis**/malignant mitral stenosis develops below the age of 19 years and is common in India. Pediatric mitral stenosis manifest below the age of 12 years. Pin-point mitral valve is seen. Atrial fibrillation is rare. Valve calcification is uncommon.

**Table 7.62** Causes of mitral stenosis.

<ul style="list-style-type: none"> <li>• Rheumatic fever (leading cause)</li> <li>• Congenital mitral stenosis (parachute mitral valve/Shone complex)</li> <li>• Metastatic carcinoid tumor to the lung, or primary bronchial carcinoid.</li> <li>• Severe calcification of mitral valve apparatus, e.g. in elderly</li> <li>• Systemic lupus erythematosus</li> <li>• Rheumatoid arthritis (extremely rare)</li> <li>• Endomyocardial fibrosis</li> <li>• Gout</li> <li>• Methysergide treatment</li> </ul>	<ul style="list-style-type: none"> <li>• Lutembacher's syndrome (combination of acquired mitral stenosis and an atrial septal defect)</li> <li>• Mucopolysaccharidosis—Hurlers syndrome, Hunters</li> <li>• Whipple's disease</li> <li>• Infective endocarditis with large vegetations</li> </ul> <p><b>Mimics of MS</b></p> <ul style="list-style-type: none"> <li>• Myxoma</li> <li>• Ball valve thrombus</li> <li>• Cor triatriatum</li> </ul>
--	---

## Rheumatic Mitral Stenosis

In rheumatic MS, chronic inflammation produces:

- Diffuse thickening of the mitral valve leaflets due to fibrosis and/or calcification
- Fusion of commissures and cusp
- Fusion and shortening of the chordae tendineae.

### Box 7.32: Salient features of mitral stenosis (MS).

- First chamber to fail in MS: Left atrium
- Ventricle to fail in MS: Right ventricle
- Atria that fibrillates in MS: Affects both right and left atria
- Left ventricle in MS: Left ventricular end-diastolic volume (LVEDV) is reduced in 15% while it is normal in the rest
- Commonest complication of MS: Atrial fibrillation (AF)

The above morphological changes progress and cause rigidity of mitral valvular cusps which in turn leads to narrowing at the apex of the funnel-shaped ('fish-mouth') mitral valve → severe narrowing (stenotic) of valve

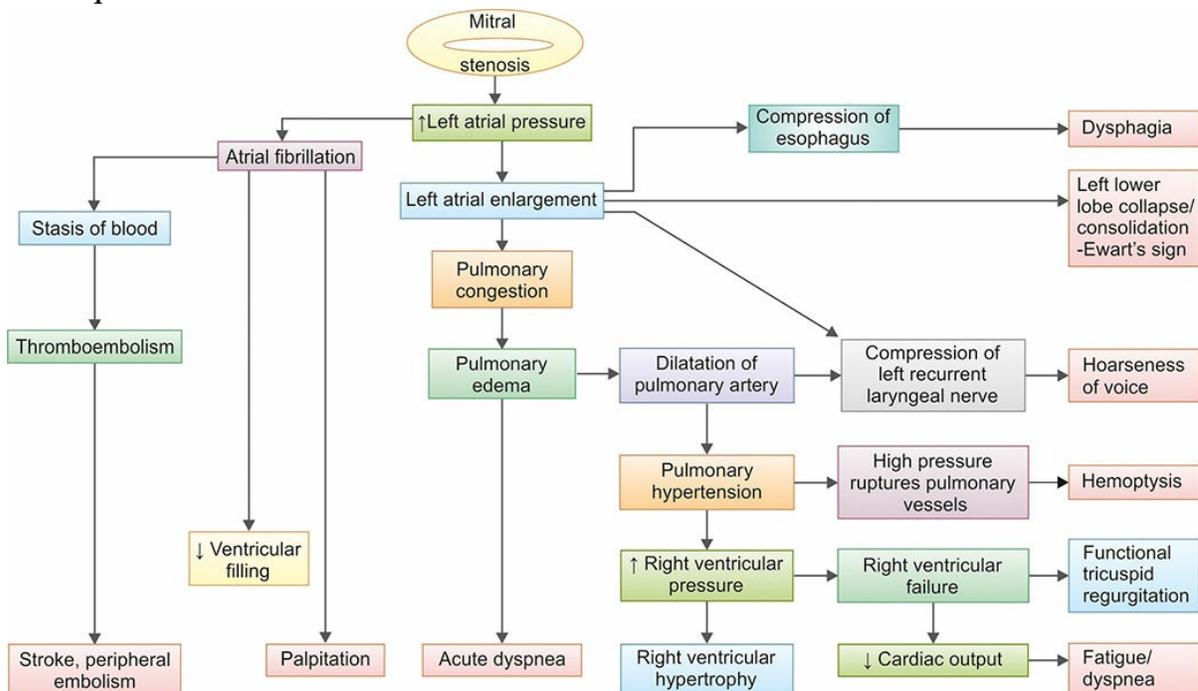

orifice and progressive immobility of the valve cusps.

Salient features of mitral stenosis are presented in Box 7.32.

### **Pathophysiology and Hemodynamics (Fig. 7.40)**

**Long latent period:** Mitral stenosis clinically manifests after a latent period about 20 years from the first episode of acute rheumatic fever. Its symptoms usually start when the mitral valve surface area reduces to 2.5 cm<sup>2</sup>.

- Normally, the mitral valve opens during (left ventricular) diastole and allows the flow of blood from left atrium to the left ventricle. During ventricular diastole, the pressures in the left atrium and the left ventricle are equal.

**Fig. 7.40:** Pathophysiology of mitral stenosis.

- Mitral stenosis obstructs the blood flow from left atrium to left ventricle and raises the pressure in the left atrium (up to 25 mm Hg in severe stenosis). Initially, this **rise in left atrial pressure** may occur only during exercise, but later it is raised even during rest.
- Raised left atrial pressure is reflected back in the pulmonary veins that produce **pulmonary venous hypertension** and subsequently pulmonary arteries which produce **pulmonary arterial hypertension**. The symptoms consist of episodes of paroxysmal nocturnal dyspnea (PND) evident as

pulmonary edema and hemoptysis, i.e. **Winter bronchitis**.

- Repeated episodes of PND produce arteriolarization of pulmonary capillaries and veins → pulmonary arterial hypertension. During this period, there may be resolution of symptoms and signs of pulmonary venous hypertension. **Patient develops progressive exertional dyspnea**. Patient feels better in terms of symptoms, although the disease has progressed.
- Pulmonary arterial hypertension (pulmonary hypertension) progressively increases in severity over the next 10–15 years till finally the right ventricle fails (early fourth decade). Types of pulmonary hypertension in MS are presented in Box 7.33.
- **Consequences of chronic pulmonary hypertension:**
  - **Hypertrophy of right ventricle:** Which may later undergo dilatation → right ventricular failure.
  - **Functional tricuspid regurgitation** due to dilatation tricuspid valve ring secondary to dilatation of right ventricle.
  - **Pulmonary valve incompetence** (regurgitation) may develop due to dilatation of pulmonary valve ring.
- **Consequences of raised left atrial pressure:** Causes left atrial dilatation and this enlarged left atrium is prone to:
  - Atrial fibrillation
  - Stasis of blood with thrombus formation
  - Detachment of the thrombus resulting in systemic embolism.
- Reduced ejection fraction of left ventricle is found one-third of patients due to:
  - Decreased preload due to impaired filling
  - Increased afterload secondary to reflex vasoconstriction (secondary to decreased cardiac output)
- **Severe mitral stenosis:** There is decompensation by tachycardia or high flow. Tachycardia reduces diastolic LV filling time thereby increasing pressure in LA. Hyperkinetic circulatory states increase flow rate across mitral valve leading to increased transmitral gradient leading to increased LA pressure.

**Box 7.33:** Types of pulmonary hypertension in MS.

- 
- **Passive pulmonary hypertension:** Due to passive backward transmission of elevated left atrial

pressure by venous and capillary.

- **Reactive pulmonary hypertension:** Due to reflex spasm of pulmonary arterioles in response to elevated pulmonary venous and left atrial pressure.
- **Obliterative pulmonary hypertension:** Due to chronic hypertension producing fibrosis of pulmonary bed.

## Clinical Features

**Q. Write short essay/note on clinical features of mitral stenosis.**

### Symptoms

- **Dyspnea on exertion** is due to pulmonary hypertension and is slowly progressive.
  - Precipitated by severe exertion, excitement, fever, anemia, sexual intercourse, pregnancy, thyrotoxicosis and atrial fibrillation.
- **Fatigue on exertion:** Due to pulmonary hypertension and low cardiac output. It is slowly progressive.
  - **Hemoptysis**
    - Rupture of bronchial veins or of pulmonary vein or bronchial vein collaterals—pulmonary apoplexy
    - Rupture of pulmonary capillaries during pulmonary edema
    - Pulmonary congestion, embolism and infarction
    - Winter bronchitis
    - Pulmonary hemosiderosis due to chronic recurrent pulmonary edema
    - Anticoagulant use
- **Chest pain:** Develops in about 15% patients due to (1) right ventricle enlargement, right ventricular hypertrophy, and pulmonary hypertension, (2) coexistent coronary artery disease (CAD), (3) coronary embolism and (4) angina due to decreased cardiac output.
- Palpitations develop when there are atrial fibrillations (AF), chamber enlargement (right ventricle and pulmonary artery).
- **Systemic thromboembolism:** Paroxysmal AF results in embolism most commonly to the cerebral vessels resulting in stroke, but mesenteric, renal and peripheral emboli (e.g. ischemic limb) can also develop.
- **Syncope:** PAH, arrhythmias, ball valve thrombus
- **Hoarseness of voice—La Ortner’s syndrome:** Due to compression of the left recurrent laryngeal nerve due to the dilated pulmonary artery or giant left atrium.

- Right heart failure
- **Orthopnea and paroxysmal nocturnal dyspnea:** Due to left atrial failure.
- **Winter bronchitis:** Patients with MS are susceptible to recurrent attacks of bronchitis, especially during the winter.

### *Physical signs*

#### *General examination*

- **Mitral facies** is characterized cyanotic lips and face, malar flush (dusky pink discoloration over the upper cheeks due to arteriovenous anastomoses and vascular stasis) and mild jaundice. It may develop when MS is very severe with low cardiac output and peripheral vasoconstriction.
- Peripheral edema and ascites when right heart failure develops.
- Pulse
  - Pulse in low volume and peripheral pulse may be absent if embolism develops.
  - Pulse rhythm is irregularly irregular and varying volume in atrial fibrillation.
- **Blood pressure:** May be mildly reduced. Mean of 3 readings to be taken if atrial fibrillation is present
- Jugular veins
  - **Jugular venous pressure** is raised when congestive heart failure develops.
  - **Jugular venous pulse:** (1) Prominent a waves (due to vigorous right atrial systole) observed when there is pulmonary hypertension without atrial fibrillation, (2) absence of waves in atrial fibrillation and (3) prominent v waves (c-v waves) and rapid y descent when there is development of functional tricuspid regurgitation.

### ***Inspection and Palpation of Precordium***

- **Apex beat** is not shifted and is tapping character of S<sub>1</sub> at apex (closing snap). Apex beat is shifted when there is coexistent of MS with mitral regurgitation (MR)/aortic stenosis (AS)/systemic hypertension/ischemic heart disease (IHD)/myocarditis
- **Diastolic thrill** at apex

- **Palpable pulmonary component of second heart sound (P<sub>2</sub>)** if there is pulmonary arterial hypertension.
- **Left parasternal heave:** Present when there is right ventricular hypertrophy or left atrial enlargement.
- **Epigastric pulsations** of right ventricular type.
- Precordial bulge in juvenile/malignant MS.

**Other findings:** Right heart failure is associated with peripheral edema, tender hepatomegaly, and ascites.

### *Auscultation*

**Q. Write short essay/note on auscultatory findings in mitral stenosis.**

- **Loud first heart sound**
  - In mitral stenosis, the forces that open and close the mitral valve increase as left atrial pressure increases. Hence, the first heart sound (S<sub>1</sub>) is loud and can be palpable (tapping apex beat) in mitral stenosis.
  - When associated with atrial fibrillation, the intensity of first heart sound varies.
  - A low intensity of the first heart sound in MS may be due to (1) calcification of the mitral valve, (2) congenital MS and (3) dominant associated mitral/aortic regurgitation.
- **Loud second heart sound**
  - It is a sign of pulmonary hypertension. The second heart sound is closely split and the pulmonary component of the second heart sound (P<sub>2</sub>) is loud.

- **Mitral opening snap**

- OS is a sharp, snappy sound heard during early diastole, following the sound of aortic valve closure (A<sub>2</sub>) by 0.05–0.12 s.
- Opening snap (OS) is produced due to the sudden (abrupt) opening of the dome of the stenosed mitral valve with the force of the increased left atrial pressure during diastole. It is the most important auscultatory sign of valvular involvement in MS. Absent OS indicates the calcification of body of the leaflets.
- The time interval between A<sub>2</sub> and OS is inversely proportional to the severity of the MS.
- **Best heard:** During expiration, just medial to the cardiac apex with the diaphragm of the stethoscope.
- **Other conditions with OS:** Mitral regurgitation (10%), tricuspid stenosis, atrial septal defect.

- **Well's index:** Q-S1 interval minus A<sub>2</sub>-OS interval and is expressed in units of 0.01 seconds. More than 2 units indicate MVA less than 1.2 cm<sup>2</sup>.
- **Murmur of mitral stenosis**
  - **Mid-diastolic/presystolic murmur:** Turbulent blood flow through stenosed mitral valve produces the characteristic **low pitched, rumbling, mid-diastolic murmur** and sometimes accompanied by a thrill. Murmur is best heard with the bell of the stethoscope held lightly at the apex with the patient lying on the left side.
    - ◆ Duration of the murmur varies and usually depends on the severity of stenosis. In severe MS, the mid-diastolic murmur is long and merges with the presystolic murmur to produce a holodiastolic murmur.
    - ◆ **To increase intensity of MDM:** Left lateral position using bell of stethoscope, while holding expiration auscultate after walking (isotonic exercise), and squatting (increased peripheral resistance in these procedures contribute to the increased murmur).
    - ◆ In the early phase of mitral stenosis, a **presystolic murmur** may be the only auscultatory abnormality. Mechanism of presystolic murmur: (1) atrial contraction, (2) persistent atrioventricular gradient, and (3) left ventricular contraction in presystole reducing mitral funnel.
    - ◆ **Presystolic accentuation of the murmur:** Atrial contraction contributes to increased gradient in pre systole. Hence, mid-diastolic murmur is accentuated by exercise. In patient with sinus rhythm, the murmur becomes louder during atrial systole and during long R-R interval in atrial fibrillation termed as **presystolic accentuation**.
    - ◆ **Absence of presystolic murmur in MS:** Atrial fibrillation, mild MS, prolonged PR interval, bradycardia, elevated left ventricular dysfunction (LVEDP).
    - ◆ **Causes of absent mid-diastolic murmur:** Thick chest wall and emphysema, **dampened MS** (severe pulmonary hypertension throttling the left sided input), low cardiac output and marked RV enlargement with RV occupying the apex.
  - **Systolic murmur:** When **pulmonary hypertension** develops it will lead to right ventricular hypertrophy and dilatation with secondary tricuspid regurgitation. This produces a systolic murmur and giant 'v waves' in the venous pulse.
    - ◆ If MS coexists with mitral regurgitation, it produces a loud pansystolic murmur that radiates towards the axilla and is heard at the lower left sternal border. Functional tricuspid regurgitation produces a pan-systolic murmur. It is accentuated during inspiration (de Carvalho's sign).
  - **Murmur of pulmonary regurgitation (Graham Steell murmur):** It is a high-pitched early diastolic decrescendo murmur heard along the left sternal border and indicative of severe pulmonary hypertension.

Diagrammatic representation of timing of heart sounds and murmur in mitral stenosis are shown in Figure 7.41.

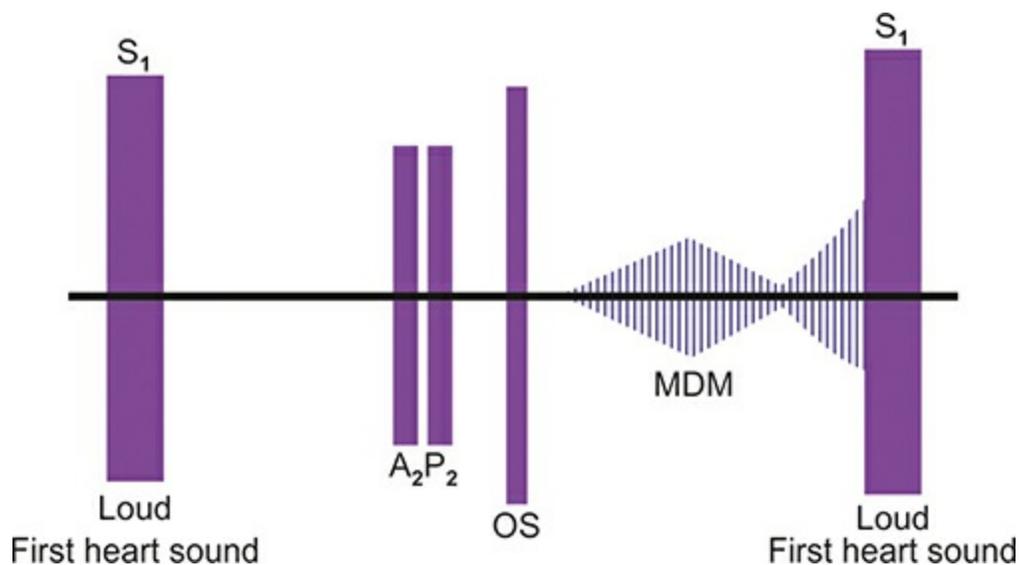

Auscultatory findings in mitral stenosis are listed in Box 7.34.

Grades of mitral stenosis and its features are presented in Table 7.63.

**Box 7.34:** Auscultatory findings in mitral stenosis.

- Loud S<sub>1</sub>

- Loud P<sub>2</sub> and narrow split of S<sub>2</sub> if pulmonary arterial hypertension
- Opening snap
- Mid-diastolic murmur at apex with presystolic accentuation
- Tricuspid regurgitation: Pansystolic murmur
- Pulmonary hypertension: Ejection systolic/early diastolic (Graham Steell) murmur.

**Fig. 7.41:** Diagrammatic representation of timing of heart sounds and murmur in mitral stenosis features are loud first heart sound, an opening snap (OS), mid-diastolic murmur (MDM) with presystolic accentuation.

**Q. Write short essay/note on grading the severity of mitral stenosis based on mitral valve orifice size.**

**Clinical judgment of the severity of mitral stenosis:** Following features suggest severe MS:

- Presence of pulmonary hypertension.
- More closeness of the opening snap to the second heart sound (short A<sub>2</sub>-OS interval).
- Lengthy mid-diastolic murmur.

**Investigations**

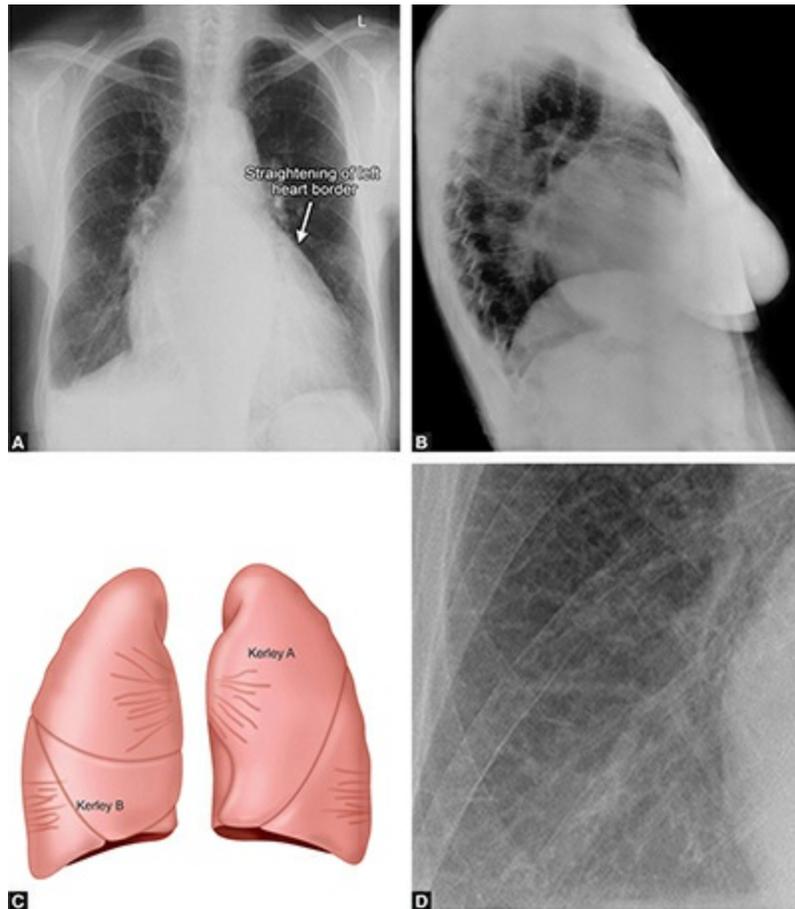

Radiological features of mitral stenosis (Chest X-ray)(Figs. 7.42A to D)

**Q. Write short essay/note on radiological/X-ray chest findings in mitral stenosis.**

**Table 7.63** Grades of mitral stenosis and its features.

<b>Grade of mitral stenosis (valve area in cm<sup>2</sup>)</b>	<b>S<sub>2</sub>-OS interval in second</b>	<b>Signs</b>
Very mild (2.5 to 2.1)		
Mild (2 to 1.6)	0.08–0.12	Short MDM/or presystolic murmur or murmur may appear with exercise
Moderate (1 to 1.5)	0.06–0.08	MDM + presystolic murmur with a gap between them. Varying degree of MDM in atrial fibrillation
Severe (less than 1)	0.04–0.06	MDM + presystolic murmur with no gap, presystolic murmur with atrial fibrillation

*Note:* Normal mitral valve orifice is 4–6 cm<sup>2</sup>  
(S<sub>2</sub> : second heart sound; OP: opening snap; MDM: mid-diastolic murmur)

**Figs. 7.42A to D:** (A) X-rays of mitral stenosis showing double atrial shadow and straightening of left heart border; (B) Lateral X-ray of mitral stenosis showing walking man sign; (C) Diagrammatic of Kerley lines; (D) X-ray of Kerley lines.

*Due to enlargement of left atrium*

- Enlarged left atrial appendage causes filling up of normal concavity between pulmonary artery shadow and the left ventricle.
- **Double atrial shadow:** Border of enlarged left atrium together with right atrial border gives an appearance like atrium within an atrium.
- **Straightening of left heart border:** Mitralization of heart

Due to left atrial appendage enlargement, large pulmonary artery, hypoplastic aorta, under filled left ventricle.

- Consequences of left atrial enlargement:
  - Pushing of left main bronchus upwards causing wide carinal angle (splaying of carina).
  - Pushing esophagus backwards visible in lateral view of chest X-ray.
  - Left shift of aorta (Bedford sign).
  - Walking man sign (shift of left bronchus forwards)(Fig. 7.42B).

#### *Pulmonary venous/capillary hypertension*

- **Grade 1:** Cephalization (prominence of veins of upper lobe of lung) of pulmonary vasculature (pulmonary venous pressure  $\leq$  20 mm Hg) (inverted moustache sign/antler's horn sign).
- **Grade 2:** Kerley's lines (A, B, C) (pulmonary venous pressure 20–25 mm Hg), peribronchial, perivascular cuffing (Figs. 7.42C and D)
  - **Kerley's A line:** Linear opacities extending from the periphery to hila; they are caused by distension of anastomotic channels between periphery and central lymphatic's
  - **Kerley's B line:** Short horizontal lines situated perpendicularly to the pleural surface at the lung base; they represent edema of inter lobar septa.
  - **Kerley's C line:** Reticular opacities at lung base, representing Kerley's B line en face.
- **Grade 3:** Batwing opacities (pulmonary venous pressure  $>$ 25 mm Hg).

#### *Pulmonary arterial hypertension*

Prominent pulmonary outflow tract: enlarged pulmonary arteries (diameter of right descending pulmonary artery  $>$ 14 mm in women and  $>$ 16 mm in men) + pruning of peripheral pulmonary vessels.

#### *Right ventricle*

- **Right ventricular hypertrophy:** In presence of cardiomegaly, acute angle is observed between apex of enlarged heart and diaphragm.
- **Sternal contact sign:** Earliest and most sensitive sign in the lateral X-ray is obliteration of Holtzneck's space, i.e. retrosternal space.

#### *Others*

- Right atrial enlargement
- Calcification of mitral valve/pericardium/MacCallum patch
- Pulmonary hemosiderosis.

### *Electrocardiogram*

It can confirm enlargement of left atrium ('P' mitrale), right ventricular hypertrophy, tall R waves in  $V_1$ – $V_3$ , P mitrale, and atrial fibrillation.

### *Echocardiogram*

- It can reveal thickening of mitral valve area, valvular leaflet, thickening and shortening chordae tendinae, fusion of commissures,

calcification of leaflets and chordae, and diastolic doming (due to commissural fusion).

- **Wilkins score (4 to 16):** 4 points each for leaflet thickness, leaflet mobility, leaflet calcification and chordal involvement.

### *Transesophageal echocardiography (TEE)*

To assess mitral regurgitation (MR) severity and to rule out left atrial appendage (LAA) thrombus.

### *Doppler*

Provides definite evaluation of MS. It shows pressure gradient across mitral valve, pulmonary artery pressure and left ventricular function.

### *Cardiac catheterization*

It is not usually needed. It is used to assess coexisting condition such as coronary artery disease, pulmonary artery pressure, mitral stenosis and regurgitation.

## **Complications of Mitral Stenosis (Table 7.64)**

### **Q. Write short essay/note on complications of mitral stenosis.**

#### • **Atrial fibrillation (AF)**

- Commonest complication of MS prevalence and incidence varies according to age and roughly parallels the age of the patient (e.g. second decade—10% and sixth decade and beyond—80%).
- **AF worsens symptoms of MS by:** (1) Decreasing diastolic filling time—leads to increased LA pressure, (2) loss of atrial contribution to LV filling—leads to increased LA pressure and (3) LA thrombus leading to systemic embolization.
- **Prognosis:** 5-year survival of AF without MS is 85% and with MS is 64%.
- AF causes decrease in cardiac output by 20% in MS.

**Table 7.64** Complications of mitral stenosis.

• Atrial fibrillation	• Ortner's syndrome	• Pulmonary edema
• Thrombus formation	• Hemoptysis	• Pulmonary infarction
• Systemic embolization	• Dysphagia	• Cardiac cirrhosis
• Pulmonary hypertension	• Lower lobe pneumonia	• Pulmonary hemosiderosis

- Infective endocarditis

- Right heart failure

- **Systemic embolism**

- **Source of emboli:** Left atrial thrombus, vegetations of infective endocarditis (rare).
- **Factors predisposing to systemic embolism in MS:** Atrial fibrillation, spontaneous echo contrast in left atrium, size of left atrium, age and low cardiac output.
- **Clinical features:** Depends on the localization of emboli. Cerebral (strokes, abscess), coronary (leads to chest pain), renal (leads to hypertension)
  - ◆ Leriche's syndrome: Claudication of thigh (due to embolism at branching of common iliac artery) + impotence.
  - ◆ Ball valve or free floating thrombus may produce syncope in specific body position, variability in physical findings and requires urgent surgery.

- **Infective endocarditis:** May develop infrequently with isolated mitral stenosis.
- **Ortner's syndrome** is a very rare complication of severe pulmonary hypertension secondary to mitral stenosis. It is characterized by paralysis of left recurrent laryngeal nerve due to compression between the enlarged tense pulmonary artery and the aorta at ligamentum arteriosum. It produces hoarseness of voice.
- **Damped MS:** Development of pulmonary hypertension diminishes the cardiac output (throttle effect) and results in temporary symptom-free period (period of illusion). The MDM may not be audible, only OS will be present.

### Management

Mild mitral stenosis may not require any treatment other than treatment of attacks of bronchitis.

- **Medical management: MS with** minor symptoms are treated medically.
  - Rheumatic fever prophylaxis to be given. However, infective endocarditis prophylaxis is not necessary.
  - **Indications for anticoagulation:** (1) Atrial fibrillation (persistent or paroxysmal), (2) embolic events, (3) left atrial thrombus, (4) left atrial diameter >55 mm, and (5) spontaneous echo contrast.
  - Restrict/decrease sodium intake.
  - **Diuretics:** Early symptom such as mild dyspnea (due to pulmonary congestion) is usually

treated with low doses of diuretics.

- Beta blockers or non-dihydropyridines (DHP) calcium channel blockers (e.g. verapamil or diltiazem) to reduce heart rate (even in sinus rhythm, more useful in atrial fibrillation).
- Digoxin if atrial fibrillation with right heart failure. Atrial fibrillation also needs anticoagulation to prevent atrial thrombus and systemic embolization.

- **Surgical management**

Four operative measures available.

- **Trans-septal balloon mitral valvotomy (BMV)**

- ◆ Also known as percutaneous balloon valvuloplasty (PBV) is the treatment of choice.
- ◆ **Procedure:** Under local anesthesia a catheter is passed through the femoral vein into the right atrium. The interatrial septum is punctured and the catheter is passed into the left atrium and across the mitral valve. A balloon is passed over the catheter across the valve, and briefly inflated to split the valve commissures.
- ◆ **Indications:** Pliable mitral valves with little involvement of the subvalvular apparatus and minimal mitral regurgitation.
- ◆ **Contraindications:** Moderate or severe mitral regurgitation, severe calcification, severe subvalvular fibrosis, thrombus in left atrium or ventricle, recent embolism, bleeding disorders and interatrial septal thickness more than 3 mm (relative contraindication).
- ◆ **Complications:** Mitral regurgitation may be severe enough to need surgery (2%), mortality (1–2%), cardiac perforation (1%), and cerebral embolism (1%).

- **Closed mitral valvotomy (CMV)**

- ◆ **Indication:** Mobile, non-calcified mitral valves without regurgitation.
- ◆ **Contraindication:** Left atrial thrombus, mitral valvular calcification, severe subvalvular disease or moderate or severe mitral regurgitation.
- ◆ **Advantages:** Cardiopulmonary bypass is not required and good result is obtained for 10 years or more.
- ◆ **Disadvantage:** The valve cusps may refuse necessitating another operation.

- **Open mitral valvotomy (OMV)**

- ◆ It is usually performed and is preferred over closed valvotomy or mitral valve replacement.
- ◆ **Procedure:** Under direct view, the valvular cusps are carefully separated from each other and commissures are incised.
- ◆ **Advantage:** Less chances of traumatic mitral regurgitation, concurrent annuloplasty can be done for mitral regurgitation. Removal of LA thrombus (if present), calcium in leaflets, amputation of LA appendage and separation of fused chordae can also done along with this surgical procedure.
- ◆ **Disadvantage:** Needs cardiopulmonary bypass.

**Q. Write short essay/note on indications for mitral valve replacement.**

- **Mitral valve replacement (MVR)**

- ◆ Indications
  - ◇ Mitral stenosis associated with mitral regurgitation.
  - ◇ Severely damaged or severely calcified stenotic valve which cannot be reopened without producing significant mitral regurgitation.
  - ◇ Moderate or severe mitral stenosis and presence of thrombus in the left atrium even after anticoagulation therapy.
- ◆ **Type of prosthesis:** Mechanical prosthesis if age is less than 65 years and bioprosthesis if

age is more than 65 years.

- ◆ Artificial valves usually work successfully for >20 years and anticoagulants are usually given postoperatively to prevent thrombus formation and its embolization.

## Mitral Regurgitation

**Q. Discuss the etiology, pathophysiology, clinical features, investigations, complications and management of chronic mitral regurgitation.**

- **Management of acute severe mitral regurgitation in pulmonary edema.**

Mitral regurgitation (MR) or mitral insufficiency (MI) or mitral incompetence is a disorder of the heart in which the mitral valve does not close properly.

### ***Etiology (Box 7.35)***

**Box 7.35:** Causes of mitral regurgitation.

#### **Causes of acute mitral regurgitation**

- **Infective endocarditis, rupture of a papillary muscle** (e.g. acute myocardial infarction, mitral valve prolapse), chest trauma, cardiac surgery, acute rheumatic carditis, dysfunction of prosthetic valve.

#### **Causes of chronic mitral regurgitation**

- **Damage to valve leaflets: Rheumatic heart disease**, myxomatous degeneration, mitral valve prolapse (MVP), **infective endocarditis**, SLE
- **Damage to annulus: Abscess (IE), annular calcification**, dilated cardiomyopathy
- **Damage to chordae tendineae: Myxomatous degeneration (MVP, Marfan syndrome, Ehlers-Danlos syndrome)**, infective endocarditis, acute rheumatic fever
- **Damage to papillary muscles: Coronary artery disease** [ischemia, myocardial infarction, rupture (MI), dilated cardiomyopathy]
- **Damage to left ventricle: Ischemia**, dilated cardiomyopathy

*Note:* Major causes are highlighted in bold letter

**Q. Write short essay/note on causes of acute mitral regurgitation/mitral regurgitation.**

**Lesion in any one of 5 component of mitral valve apparatus** namely (1) valve leaflets, (2) the annulus, (3) the chordae tendineae or (4) papillary muscles, or (5) the left ventricle can produce mitral regurgitation (MR).

Mitral regurgitation may be **acute or chronic**.

- **Causes of MR in IE:** Leaflet perforation, vegetations preventing leaflet function, rupture of chordae tendineae, annular abscess.
- **Causes of MR in RHD:** Rigid and retracted leaflet, shortening of chordae tendineae.
- **Causes of MR in CAD:** Regional wall motion abnormalities, ischemia of papillary muscle, LV failure.

## ***Pathophysiology***

- **Acute mitral regurgitation:** During this, the normal compliance of the left atrium does not permit much dilatation and the pressure of left atrium rises. This markedly increases the left atrial pressure and pulmonary venous pressure and cause pulmonary edema. Since part of the stroke volume is regurgitated, the stroke volume increases (to a lesser degree than it does in chronic MR) to maintain the forward cardiac output. This may result in enlargement of left ventricle.
- **Chronic mitral regurgitation:** Causes gradual dilatation of left atrium but little increase in left atrial pressure because the regurgitant flow is accommodated by the large left atrium. In longstanding cases, the left ventricle slowly dilates and the left ventricular diastolic and left atrial pressures gradually increase due to chronic volume overload of the left ventricle. MR begets MR.

## ***Clinical Features***

### *Symptoms*

- Symptoms depend on the rapidity of development of the mitral regurgitation.
- **Acute mitral regurgitation:** Usually presents dyspnea due to acute pulmonary edema.
- **Chronic mitral regurgitation:** It may asymptomatic for many years. It may become symptomatic only after the onset of irreversible LV dysfunction.
  - **Palpitation** is the most common symptom due to increased stroke volume or atrial fibrillation.
  - **Dyspnea and orthopnea:** Due to pulmonary venous hypertension and left ventricular failure occur late in the course of mitral regurgitation.
  - **Fatigue and lethargy:** Due to reduced cardiac output.
  - **Symptoms of right heart failure:** Develop in the late stages and lead

to congestive cardiac failure.

- Cardiac cachexia
- **Thromboembolism:** Less common than in mitral stenosis. However, subacute infective endocarditis is more common.
- *Other symptoms and complications are similar to mitral stenosis.*

### *Signs*

**Pulse:** Volume is high and in severe mitral regurgitation it may be mildly collapsing.

- Irregular rhythm and varying volume if there is atrial fibrillation.

### *Jugular veins*

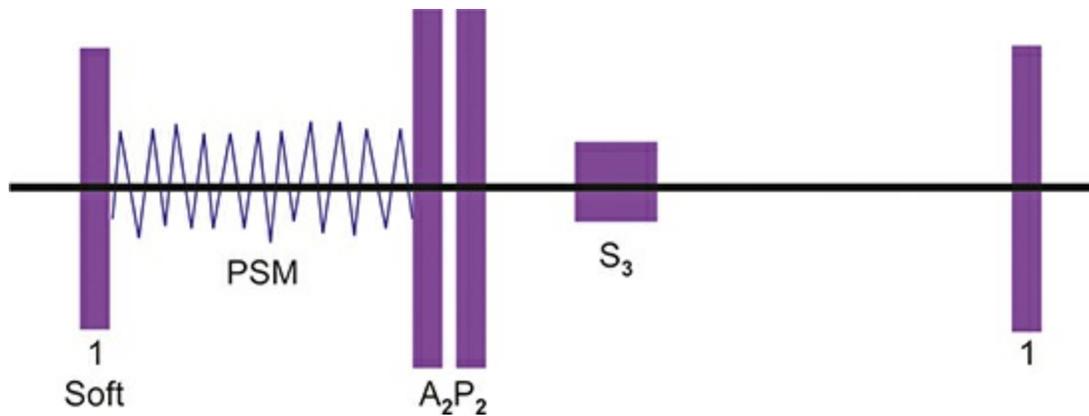

- **Uncomplicated mitral regurgitation:** Jugular venous pressure (JVP) is normal.
- **With atrial fibrillation:** Disappearance of a waves.
- **With pulmonary hypertension:** Prominent a waves.
- **With right ventricular failure and functional tricuspid regurgitation:** Jugular venous pressure is raised and very prominent v waves.

**Blood pressure:** In severe mitral regurgitation: wide pulse pressure. Three recordings are necessary if patient has atrial fibrillation (AF). Pulsus alternans in acute MR.

### *Inspection and palpation*

- Hyperdynamic precordium
- **Apex beat:** Shifted to the left (due to left ventricular dilatation), forceful (feels active and rocking) and diffuse (hyperdynamic) in character due to left ventricular volume overload.
- **Cardiomegaly:** In chronic MR. Acute MR does not produce cardiomegaly.
- Systolic thrill (if MR is severe) at the apex.
- Left parasternal heave and palpable P<sub>2</sub>.
- Epigastric pulsations of right ventricular type.

### *Auscultation (Fig. 7.43)*

**Fig. 7.43:** Diagrammatic representation of timing of heart sounds and murmur in mitral regurgitation. Features are normal or soft first heart sound, pansystolic murmur (PSM), extending to the second heart sound ( $A_2$ ,  $P_2$ ). A third heart sound ( $S_3$ ) may develop with severe mitral regurgitation.

- **Soft first heart sound ( $S_1$ ):** Because of the incomplete apposition of the mitral valve cusps and partial closure of these valve cusps when ventricular systole begins. It is loud if there is coexistent MS, MVP-MR or papillary muscle dysfunction MR.
- **Widely split second heart sound ( $S_2$ )** is due to aortic valve closure ( $A_1$ ) occurring early but the split is mobile.
- **Pulmonary component ( $P_2$ ) of  $S_2$**  is loud and palpable in pulmonary hypertension and also due to anterior displacement of pulmonary artery caused by dilated LA.
- **Left ventricular third heart sound ( $S_3$ ):** Indicates severe mitral regurgitation.
- $S_4$  is a sign of acute MR as left atrium is not dilated in acute MR.
- Pulmonary ejection sound in pulmonary hypertension.

#### *Murmur of mitral regurgitation*

- **Apical pansystolic murmur:** The typical features of murmur in mitral regurgitation are:
  - High pitched, blowing and usually holosystolic/pansystolic loudest at the apex.
  - Plateau shaped best heard with diaphragm of stethoscope
  - Commonly radiates widely over the precordium and into the axilla and left interscapular area (if anterior leaflets involved as in rheumatic) or radiating to base (if posterior leaflets involved).

- It is produced due to the mitral regurgitant jet occurring throughout the whole of systole.
- It may be accompanied by a thrill.
- Character of murmur depends on the underlying pathology in mitral regurgitation (Table 7.65).
- **Severe MR with soft or no murmur (silent MR):** It is observed with left ventricular dilation, acute mitral regurgitation (MR), paraprosthetic MR, COPD, obesity, dampened MR.
- **Dynamic auscultation:**
  - Non-MVP MR murmur is distinguished from MVP murmur by increase with squatting and decrease with standing (opposite with MVP).
  - MR murmur is distinguished from AS/HCM murmur by increase with isometric handgrip (opposite for AS/HCM).
- Short mid-diastolic flow murmur: Sometimes a short, rumbling mid-diastolic murmur may be detected at the apex in severe cases due to an increased flow across the mitral valve. It may follow the third heart sound.
- Other murmurs
  - Ejection systolic murmur or early diastolic murmur at pulmonary area when there is pulmonary hypertension.
  - Pansystolic murmur at lower left sternal border when there is functional tricuspid regurgitation.
  - Opening snap can be heard in 10% patients with MR.

**Table 7.65** Features of murmur depending on the underlying pathology in mitral regurgitation.

<i>Pathology</i>	<i>Features of murmur</i>
Giant left atrium (>6 cm)	Radiates to the entire interscapular region
Ruptured chordate tendineae	Cooling' or 'sea gull' quality
Flail mitral leaflet	Musical' quality and late systolic
Papillary muscle dysfunction	Late systolic
MVP-MR	Mid-systolic
Acute MR	Musical and tapering
Severe MR	Holo systolic murmur with mid-systolic accentuation, i.e. Christmas tree appearance

*Signs indicating severity of mitral regurgitation (Box 7.36)*

**Box 7.36:** Signs indicating severity of mitral regurgitation.

**Mild MR:** Only murmur

**Moderate MR:** Murmur + thrill and cardiomegaly

**Severe MR:** Murmur + thrill, cardiomegaly, LV S3, flow mid-diastolic murmur, pulmonary hypertension

**Q. Write short note on clinical assessment of the severity of mitral regurgitation.**

**Other signs in MR:** These include signs related to:

- Atrial fibrillation/flutter
- Pulmonary venous congestion, e.g. crepitations, pulmonary edema, effusions
- Pulmonary hypertension and right heart failure
- Left and right heart failure.

*Signs in acute mitral regurgitation*

- Normal apical impulse since there is no ventricular dilatation.
- Third and/or fourth heart sound.
- An early systolic or pansystolic murmur.

Differences between acute and chronic mitral regurgitation are listed in Table 7.66.

Differences between mitral regurgitation due to mitral valve prolapsed and that due to rheumatic heart disease are listed in Table 7.67.

**Table 7.66** Differences between acute and chronic mitral regurgitation.

<b>Characters</b>	<b>Acute MR</b>	<b>Chronic MR</b>
Pulse	Alternans	High volume
Atrial fibrillation	Absent	+
Jugular venous pressure (JVP)	Grossly elevated	Mild elevation
Cardiomegaly	Absent	Present
Pulmonary hypertension	Very severe	Variable
S <sub>1</sub>	Normal	Soft
S <sub>3</sub>	Present	+/-

S <sub>4</sub>	Present	Can never be present
Murmur	Late systolic	Pansystolic

**Table 7.67:** Differences between mitral regurgitation due to mitral valve prolapse and that due to rheumatic heart disease.

<i>Characters</i>	<i>Mitral valve prolapse MR</i>	<i>Rheumatic heart disease MR</i>
Leaflets affected	Any	Posterior
S <sub>1</sub>	Loud	Soft
Click	Midsystolic click	No
Murmur	Midsystolic	Holosystolic
Squatting and isometric handgrip	Decrease murmur	Increases murmur
Association	Atrial septal defect (ASD), polycystic kidney disease	Mitral stenosis

(MR: mitral regurgitation)

## ***Investigations***

- **Electrocardiogram (ECG):** It can reveal:
  - Enlargement/hypertrophy of left atrium (if not in atrial fibrillation)
  - Dilatation and hypertrophy of left ventricle
  - Hypertrophy of both left and right ventricle in pulmonary hypertension
  - Atrial fibrillation
- **Chest X-ray:** May show the following abnormalities: All signs as described for MS
  - Enlargement of left atrium (more than in MS), left ventricle
  - Pulmonary venous congestion
  - Pulmonary edema: Interstitial edema in acute MR, chronic decompensated MR or with coexistent MS.
  - Annular calcium appears as a C-shaped opacity in posterior third of heart in lateral or RAO (right anterior oblique) view.
- **Echocardiogram**
  - Shows a dilated left atrium and left ventricle.
  - Structural abnormalities of mitral valve, e.g. prolapsed, chordal or papillary muscle ruptures if present.

- **Doppler echocardiogram**
  - ◆ Detects and assesses the severity of regurgitation (quantification of regurgitation).
  - ◆ Mitral annular calcification between mitral valve apparatus and posterior wall.
- **Transesophageal echocardiography (TEE):** Useful to identify structural valve abnormalities and can be helpful before surgery especially in MVP. Intraoperative TEE helps in the assessment of the efficacy of valve repair. MVP is defined as more than 2 mm systolic displacement of mitral leaflet into left atrium (LA).
- **Cardiac catheterization:** This can show dilated left atrium and left ventricle mitral regurgitation, pulmonary hypertension and coexisting coronary artery disease (if present).

Complications of mitral regurgitation are listed in Box 7.37.

**Box 7.37:** Complications of mitral regurgitation.

- Progressive heart failure is the most common cause of death
- **Less frequent:** Sudden death, stroke and fatal endocarditis
- Atrial fibrillation, infective endocarditis, left ventricular failure
- Pulmonary hypertension (late), right ventricular failure (very late)
- Rarely systemic embolism

**Table 7.68:** European Society of Cardiology (ESC) guidelines for surgical intervention in mitral regurgitation.

<i>Symptomatic patients who present with</i>	<i>Asymptomatic patients with</i>
<ul style="list-style-type: none"> <li>• Severe mitral regurgitation</li> <li>• Left ventricular ejection fraction (EF) &gt;30%</li> <li>• End-diastolic dimension (ESD) of under 55 mm</li> </ul>	<ul style="list-style-type: none"> <li>• Left ventricular dysfunction</li> <li>• End-systolic dimension &gt;45 mm and/or ejection fraction of under 60%</li> <li>• New onset atrial fibrillation and/or pulmonary hypertension</li> </ul>

**Management**

- Asymptomatic mild mitral regurgitation can be managed conservatively.
- Moderate mitral regurgitation can be treated medically.

**Medical Management**

- **Acute MR:** Afterload reduction with nitroprusside.
- **Chronic MR:** In mitral regurgitation, high afterload may worsen the degree of regurgitation, and hypertension is treated with vasodilators, e.g. ACE inhibitors and nifedipine are used.

- Diuretics.
- Treatment of AF: Digoxin and anticoagulants.
- Anticoagulation.
- Infective endocarditis prophylaxis.
- Rheumatic fever prophylaxis.

**Surgery (Table 7.68 and Box 7.38) Mitral Valve Replacement**

**Box 7.38:** Conditions in which repair of mitral valve is possible.

- MVP (mitral valve prolapse)
- Chordal rupture
- Papillary muscle dysfunction
- Annular dilation
- Leaflet perforation due to IE
- Rheumatic MR in the young

**Combined Mitral Stenosis and Mitral Regurgitation**

Clinically assessment of the dominance of lesions (Table 7.69).

**Table 7.69:** Clinically assessment of the dominance of lesions in the presence of combined mitral stenosis and mitral regurgitation.

<i>Parameter</i>	<i>Predominant mitral regurgitation</i>	<i>Predominant mitral stenosis</i>
Pulse volume	High	Low
Blood pressure	Wide pulse pressure	Narrow pulse pressure
Cardiomegaly	++	--
S <sub>1</sub>	Soft	Loud
LVS3	++	-
Mid-diastolic murmur	Short	Long, loud with presystolic accentuation

**Mitral Valve Prolapse (MVP)**

**Q.** Write short essay/note on mitral valve prolapse (MVP) or Barlow’s syndrome.

- Mitral valve prolapse (MVP) is an abnormal movement of one or both of the mitral valve leaflets  $\geq 2$  mm beyond annular plan into the left atrium during systole with or without mitral regurgitation.
- **Barlow’s syndrome:** Involves the posterior leaflet and cusps. **Reads**

**syndrome/floppy valve syndrome** is considered as a variant of Barlow that affects both mitral cusps as well as other valves like aortic valve.

- **Cobb's syndrome** selectively affects the anterior mitral cusp.
- MVP syndrome is also called as **systolic click-murmur syndrome**.
- MVP is one of the more common causes of mild mitral regurgitation.

### ***Pathogenesis***

- It is caused by congenital anomalies or degenerative myxomatous changes (e.g. Marfan's syndrome and cystic medial necrosis) that are associated with excessive or redundant mitral leaflet tissue. Familial incidence with an autosomal dominant mode of inheritance.
- Prolapse of the cusp occurs in systole → tensing of the chordae → pulling of papillary muscles which sometimes may interfere with blood supply.
- **Conditions associated with MVP:** Atrial septal defect (20%), polycystic kidney disease, chronic rheumatic heart disease, ischemic heart disease, and cardiomyopathies.

### ***Clinical Features***

#### *Symptoms*

- **Age and gender:** More common in females between 15–30 years. But, severe mitral regurgitation caused by prolapsed mitral valve is more common in older males compared to young females.
- May be asymptomatic or present with anxiety neurosis.
- Symptoms include atypical chest pain (precordial stabbing), palpitation, syncope or presyncope and fatigue.
- **Rarely:** Symptoms of left ventricular failure (exertional dyspnea, orthopnea and paroxysmal nocturnal dyspnea) in patients with mitral regurgitation, sudden death and transient ischemic attacks.

#### *Signs*

- Asthenic built, straight back/pectus excavatum
- **Mid-systolic click:** In mildest forms, the valve is competent but bulges back into the atrium during systole, causing a mid-systolic click occur  $\geq 0.14$  seconds after  $S_1$  without any murmur.
- **Late systolic murmur:** When there is mitral regurgitation, the click is

followed by a late systolic murmur apical murmur (rarely ‘whooping’ or ‘honking’). Its length increases as the regurgitation becomes more severe. The systolic murmur of mitral valve prolapse increases during standing and Valsalva maneuver, but decreases during squatting and isometric exercise.

### **Investigations**

- **Electrocardiogram (ECG):** Nonspecific ST-T changes or inverted T waves in leads II, III and aVF.
- **Echocardiography:** Used for confirmation of the diagnosis. Color Doppler is used to assess the degree of mitral regurgitation.

### **Complications**

- These include arrhythmias, sudden rupture of the chordate, progressive mitral regurgitation, and infective endocarditis.
- Rare complications include transient cerebral ischemic attacks, embolism, acute severe mitral regurgitation and sudden death.

#### **Management**

- **Medical**
  - Reassurance for patients without symptoms
  - **β-blockers:** For atypical chest pain.
  - **Antiarrhythmic drugs:** For the treatment of arrhythmias.
  - **Transient ischemic attacks:** Aspirin, dipyridamole or anticoagulants.
  - No need for infective endocarditis prophylaxis.
- **Surgical:** Mitral valve repair or replacement in severe mitral regurgitation.

**Prognosis:** Long-term prognosis is good.

### **Aortic Stenosis**

**Q. Write a long essay on the classification, causes/etiology, clinical features, investigations and management of valvular aortic stenosis.**

- Aortic stenosis is a chronic progressive disease and characterized by obstruction to the left ventricular stroke volume.
- Normal aortic valve area 3–4 cm<sup>2</sup> without any gradient across it. Critical aortic stenosis develops when an aortic valve area becomes less than 0.8 cm<sup>2</sup> or a gradient of more than 50 mm Hg.

## ***Classification and Etiology of Aortic Stenosis (Table 7.70)***

### ***Pathophysiology***

- Normal aortic valve area is 2.5–3.5 sq cm.
- Hemodynamically significant AS occurs when the aortic valve is reduced by 60–75%.
- Critical AS when valve area  $<0.8 \text{ cm}^2$ /gradient  $>80\%$ .
- Initially, cardiac output is maintained. Pathological hallmark is fixed outflow obstruction to the left ventricle. It limits the increase in cardiac output required during exercise. The coronary blood flow may be inadequate and patients may develop angina even in the absence of concomitant coronary disease. Obstruction to the outflow leads to left ventricular hypertrophy (LVH). Wall stress due to outflow obstruction manifests in two forms.
  1. **Development of concentric LVH:** Wall stress is not allowed to rise by development of concentric LVH. This type is more likely in females.
  2. **Ventricular dilation and eccentric hypertrophy:** Rise in wall stress and systolic dysfunction are features of this type. This type is more likely in males.
- Later the left ventricle cannot overcome the outflow tract obstruction and pulmonary edema develops. In aortic stenosis, pulmonary arterial hypertension is due to increased LV diastolic pressure.

**Table 7.70** Classification and etiology of aortic stenosis.

#### **Valvular aortic stenosis**

- **Acquired:** **Rheumatic aortic stenosis** (young adults, middle-aged, elderly), **calcific aortic valvular disease** (CAVD—in middle aged to elderly), systemic lupus erythematosus (SLE), Fabry's disease, chronic kidney disease, Paget's disease of bone, rheumatoid arthritis, infective endocarditis, senile degenerative aortic stenosis (middle-aged to elderly), previous radiation exposure, homozygous familial hypercholesterolemia, ochronosis
- **Congenital:** Congenital aortic stenosis (infants, children, adolescents), bicuspid aortic valve (BAV), calcification and fibrosis of congenitally **bicuspid aortic valve** (young adults to middle-aged)

#### **Subvalvular aortic stenosis**

- Membranous diaphragm
- Hypertrophic cardiomyopathy
- Congenital subvalvular aortic stenosis (infants, children, adolescents)

### Supravalvular aortic stenosis

- Hourglass constriction of aorta
- Congenital supravalvular aortic stenosis (infants, children, adolescents)
- Williams' syndrome

**Williams syndrome:** Characterized by Elfin facies, supravalvular aortic stenosis, idiopathic hypercalcemia, mental retardation and behavioral profile. On examination, the right upper limb blood pressure may be higher than the left upper limb and the pulse volume on the right arm better than left. This is called *Coanda Effect*

**Shone's complex:** It is a rare combination of four left-sided congenital cardiac anomalies including parachute mitral valve, supravalvular ring, coarctation of the aorta, and subaortic obstruction

## Clinical Features

- Usually asymptomatic aortic stenosis is moderately severe (aortic orifice reduced to one third of its normal size). It is commonly diagnosed in asymptomatic patients during routine clinical examination.

### Symptoms

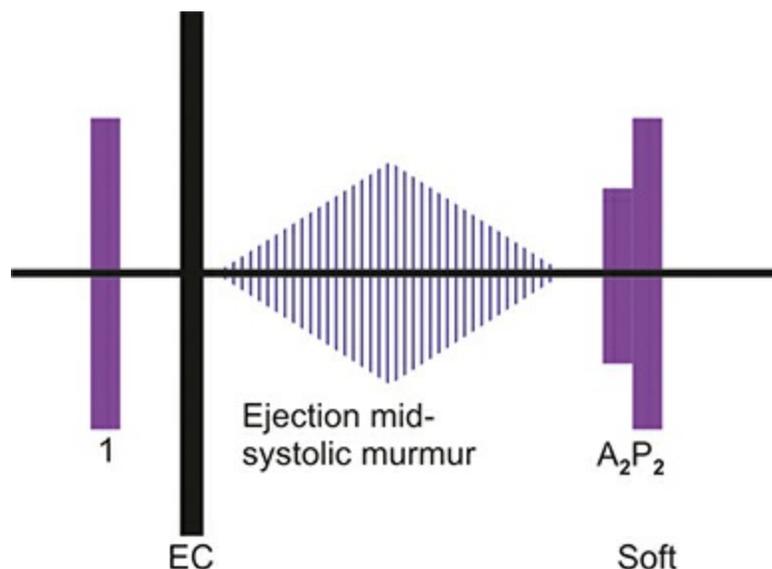

#### **Q. Write short note on symptomatic triad of aortic stenosis.**

- **Age of onset of symptoms:** Bicuspid aortic valve between 50 and 70 years, calcific aortic stenosis >70 years and rheumatic aortic stenosis between 40 and 50 years of age.
- **Symptomatic triad of aortic stenosis:** Three cardinal symptoms are (1) breathlessness (dyspnea), (2) angina, and (3) syncope.
- **Exercise intolerance:** Most common initial presentation. Dyspnea with exertion due to cardiac decompensation or fatigue with exertion due to inadequate rise of cardiac output with exertion.
- **Angina** is typical exertional and is due to mismatch in myocardial oxygen demand-supply ratio, or coexistent coronary artery disease (CAD).
- **Exertional syncope (or presyncope):** Due to failure of cardiac output to rise to meet demand, leading to a fall in BP.
- **Heart failure:** Orthopnea and paroxysmal nocturnal dyspnea (PND).
  - The average survival after the onset of symptoms were 5, 3 and 2 years respectively for angina, syncope and dyspnea.
- Infective endocarditis
- Embolism.
- Gastrointestinal bleed due to angiodysplasias (Heyde syndrome), acquired von Willebrand syndrome.

If untreated the approximate time interval from the onset of symptoms to death is 1.5–2 years for heart failure (Dyspnea, PND), 3 years for syncope, and 5 years for angina.

### Signs

- **Appearance:** Severe AS produces ‘Dresden China’ look-asthenic appearance with pale skin.
- **Pulse**
  - Parvus and tardus pulse: Slow rising, late peaking, and low amplitude.
  - Pulsus bisferens if AS is associated aortic regurgitation (AR).
  - Anacrotic pulse and apico-carotid delay in severe AS.
  - Coanda effect in supra-avalvular AS.
  - Normal pulse if there is coexistent AR, hypertension (HTN).
- **Blood pressure**
  - Low systolic and pulse pressures. Systolic decapitation (SBP<120 mm of Hg).
  - Normal BP if there is coexistent AR, hypertension (HTN).
- **Carotid shudder:** Thrill in carotids.
- **Jugular venous pressure (JVP):** Prominent a waves (**Bernheim effect**).
- **Apex beat:** Thrusting/heaving LV type apex beat due to LV pressure overload. It is not usually displaced because hypertrophy (as opposed to dilatation) does not produce significant cardiomegaly.
- Palpable LV S4.

**Fig. 7.44:** Diagrammatic representation of timing of heart sounds and murmur in aortic stenosis. Features are diamond-shaped ejection mid-systolic murmur. An ejection click (EC) may be present in young patients with a bicuspid aortic valve. Soft second heart sound ( $A_2$ ,  $P_2$ ).

### Auscultation (Fig. 7.44)

- $S_1$  is normal. If loud suspect coexistent MS.
- $S_2$ - $A_2$ : Soft (single  $S_2$ ) in rheumatic AS, loud in BAV, normal in sub/supravalvular AS. In severe AS paradoxical (reversed) split of second heart sound  $A_2$  (splitting on expiration).
- Systolic ejection click in bicuspid aortic valve (BAV)
  - **Ejection mid-systolic murmur:** Harsh/rough, radiates to the neck (to carotids arteries) and also the precordium with late peaking in severe AS. Best heard in the base of heart (aortic area). Murmur is likened to a saw cutting wood and especially in older patients may have a musical quality like the ‘mew’ of a seagull. It is diamond-shaped (crescendo decrescendo). The murmur is usually longer in severe AS. The intensity of the murmur should not be correlated with the severity of AS because it is less intense when the cardiac output is reduced. In severe AS it may not be audible. In calcific AS, high frequency components radiate to apex producing a long systolic murmur at apex—**Gallavardin phenomenon**/hour-glass conduction due to periodic wake phenomenon. With LV failure, murmur intensity decreases and murmur may disappear.
- Differences between aortic stenosis and mitral regurgitation presented in Table 7.71.

**Table 7.71:** Differences between aortic stenosis and mitral regurgitation.

<b>Features</b>	<b>Aortic stenosis</b>	<b>Mitral regurgitation</b>
Site of systolic murmur	Aortic area + Apex	Apex
Nature of murmur and its relation with $A_2$	Usually ejection-mid systolic. stops before $A_2$	Pan systolic. Continues till $A_2$
Post VPC intensity	Increases	No change/decreases
Carotid pulse	Slow rising, low volume	Quick rising high volume

### Severity of aortic stenosis (Box 7.39)

#### **Box 7.39:** Signs indicating severity of aortic stenosis.

**Mild:** Only murmur (early peaking)

**Moderate:** Low volume pulse, mid-systolic peaking murmur, pulsus parvus et tardus

**Severe:** Anacrotic pulse, paradoxical split  $S_2$ , late peaking murmur, palpable  $S_4$ , apico-carotid delay

## ***Investigations***

- Chest X-ray
  - Rounding of apex due to concentric left ventricular hypertrophy with normal heart size or a relatively small heart.
  - Prominent dilation of ascending aorta (more prominent if bicuspid aortic valve) due to turbulent blood flow above the stenosed aortic valve causing post-stenotic dilatation.
  - Calcification of aortic valve (if present).
- Electrocardiogram (ECG)
  - Left ventricular hypertrophy correlation between QRS voltage.
  - Atrial fibrillation in 10–15%.
  - AV conduction defects and IVCD in 5% of calcific AS due to extension of calcium to conduction system.
- Echocardiography
  - Helps in evaluation of severity and gradient across the aortic valve.
  - Dobutamine stress echo
    - ◆ **Severe AS:** Increase in gradient. No change in valve area.
    - ◆ **Mild AS:** Increase in valve area.
    - ◆ Also assesses contractile reserve, predicts improvement in LV function after surgery.
- **Doppler:** Useful for detecting the severity of stenosis and associated aortic regurgitation.
- **Cardiac magnetic resonance and cardiac CT:** They may be required for assessing the presence of aneurysm, dissection or coarctation thoracic aorta.
- **Cardiac catheterization** is rarely needed because since all these information can be obtained from noninvasive with echocardiography and CMR. **Coronary angiography is needed before aortic valve surgery and for detecting any associated coronary artery disease.**

### **Treatment**

- **Asymptomatic patients:** Irrespective of the severity of AS, asymptomatic patients have a good immediate prognosis. Hence, should be managed conservatively with regular review for assessment of symptoms and echocardiography.

### **Medical treatment**

- Avoid vigorous physical activity in patients with severe AS.
- **Diuretics** decrease dyspnea but may also reduce cardiac output.
- **ACE inhibitors:** To be used with caution and given only if there is LV failure.
- **Avoid beta blockers:** Because they produce LV failure.
- **Vasodilators for other purposes like angina:** Be careful in titration as there will be no compensatory increase in cardiac output.
- **Atrial fibrillation:** Cardioversion can be tried.
- Infective endocarditis prophylaxis for those who have undergone valvular replacement.
- Rheumatic fever prophylaxis.

### ***Surgical treatment***

#### *Indications*

- **Symptomatic patients:** Symptoms are a good index of severity in aortic stenosis, and all symptomatic patients should undergo aortic valve replacement.
- **Asymptomatic patients:** Surgical intervention for severe aortic stenosis is recommended in patients with:
  - Symptoms during an exercise test or with a fall of blood pressure.
  - Left ventricular ejection fraction of <50%.
  - Moderate to severe aortic stenosis undergoing CABG, surgery of the ascending aorta or other cardiac valve.

#### *Surgical procedures*

- **Balloon dilatation (valvuloplasty)** may be tried in adults (especially elderly) as an alternative to surgery. But results are poor and they should be reserved for patients unfit for surgery or as a 'bridge' to surgery (as systolic function will often improve).
- **Aortic valve replacement:** The above procedure causes only temporary relief from the obstruction and aortic valve replacement will usually be needed after a few years.
- **Percutaneous valve replacement:** Transcatheter implantation with a balloon expandable stent valve may be done for patients unsuitable for surgical aortic valve replacement.
- **ROSS procedure:** Replacement of diseased aortic valve by pulmonic valve and implantation of homograft instead of native pulmonic valve.
- **Transcatheter aortic valve replacement (TAVR), transcatheter aortic valve implantation (TAVI)** is a procedure for select patients with severe symptomatic aortic stenosis.

## **Aortic Sclerosis**

### **Q. Write short note on aortic sclerosis.**

- Aortic sclerosis is characterized by irregular thickening of the aortic valve leaflets seen on echocardiography but without significant aortic obstruction. It may produce a systolic ejection murmur without any symptoms. Pulse, BP will be normal.
- About 25% patients are above the age 65 years and 40% over 85 years.
- **Risk factors:** Dyslipidemia, diabetes, hypertension, and smoking. Higher prevalence in Paget disease and end stage renal disease (ESRD).

- There may be coexisting mitral annular calcification. Even if there is no AS, calcific aortic sclerosis increases cardiovascular death and MI by 50%.
- Rate of progression is variable so difficult to predict in an individual patient. The valve area declines 0.1–0.3 cm<sup>2</sup> per year; the systolic pressure gradient across the valve can increase by as much as 10–15 mm Hg per year.

#### Treatment

- No medical treatment available.
- Rosuvastatin has been shown to decrease progression of less severe AS to severe AS. Other drugs tried include ACE inhibitors.

## Bicuspid Aortic Valve (BAV) Disease

**Q.** Write a short note on bicuspid aortic valve disease.

- Bicuspid aortic valve is the commonest congenital heart disease found in 1–2% of live births.
- Male to female ratio is 3:1.
- Some cases are inherited as autosomal dominant and NOTCH1 gene mutation are found in some cases.
- **Associated conditions:** Other congenital cardiac diseases (e.g. dilatation of proximal ascending aorta secondary to abnormalities of the aortic media), coarctation of aorta, ventricular septal defect (VSD), atrial septal defect (ASD). Calcification is common in adults with bicuspid aortic valve.
- **Auscultatory findings:** Ejection click best heard at the apex and may be associated murmurs of aortic stenosis or aortic regurgitation.
- **Diagnosis:** By echocardiography.

### Complications

- **Aortic regurgitation:** About 20% develop severe AR.
- **Aortic stenosis:** Due to calcification and severe AS occurs after 50 years of age.
- **Infective endocarditis.**
- **Ascending aortic dilation:** Due to medial degeneration and is not related

to severity of aortic stenosis.

- **Aortic dissection:** Risk is increased by 5 to 9 times.

#### Treatment

- Medical management: Control of hypertension and use of  $\beta$ -blockers.
- Surgical treatment: Aortic valve replacement and may also require aortic root surgery.

**Prognosis:** Life-expectancy is usually not shortened.

#### Box 7.40: Causes of aortic regurgitation.

##### Acute aortic regurgitation

- Infective endocarditis
- Aortic dissection
- Acute rheumatic fever
- Ruptured sinus of Valsalva aneurysm
- Failure of prosthetic valve
- Trauma

##### Chronic aortic regurgitation

- **Congenital:** Bicuspid aortic valve or disproportionate cusps
- **Acquired:**
  - Rheumatic heart disease
  - Infective endocarditis
  - Trauma
  - Aortic dilatation, e.g. aneurysm, dissection
  - Arthritides, e.g. ankylosing spondylitis
  - Rheumatoid arthritis
  - Syphilitic aortitis
  - Hypertension
  - Connective tissue disorders, e.g. Marfan syndrome, Ehlers-Danlos syndrome
  - Osteogenesis imperfecta, methysergide

## Aortic Regurgitation

**Q. Discuss the etiology, clinical features, complications, investigations and treatment of aortic regurgitation.**

**Aortic regurgitation (AR)** is incompetency of the aortic valve which causes backflow (reflux) of blood from the aorta through the aortic valve into the left ventricle during diastole.

### *Etiology (Box 7.40)*

- Aortic regurgitation may be caused by diseases of the aortic valve (e.g. endocarditis) or diseases of the aortic root (e.g. Marfan's syndrome) causing dilatation of the aortic root.
- Aortic regurgitation can be acute or chronic.
- **Acute aortic regurgitation** of significant severity leads to sudden increased blood volume in the left ventricle during diastole. The left ventricle does not have sufficient time to dilate in response to the sudden increase in volume. This causes rapid increase in end-diastolic pressure of left ventricle → leading to an increase in pulmonary venous pressure. As pressure increases throughout the pulmonary circulation, the patient develops dyspnea and pulmonary edema. In severe cases, left ventricular failure with cardiogenic shock may develop. Decreased myocardial perfusion may lead to myocardial ischemia.
- **Chronic aortic regurgitation:** Produces increased blood volume in the left ventricle during diastole. To maintain the net cardiac output, the total volume of blood pumped from the left ventricle into the aorta increases, and consequently the left ventricle enlarges. AR begets AR. There is fall in the diastolic blood pressure and decreased coronary. Myocardial ischemia occurs due to:
  - Increased myocardial oxygen demand due to increased afterload, increased LV ejection time and increased LV mass.
  - Decreased myocardial oxygen supply due to decreased aortic diastolic pressure, decreased diastolic filling time due to increased LV ejection time and decreased effective stroke volume.

## ***Clinical Features***

### *Symptoms*

- **Age and gender:** About three-fourths of patients with pure or predominant valvular AR are males. Females with primary valvular AR have associated rheumatic mitral valve disease. Chronic AR usually begins during late 50s. Usually, the prevalence and severity of AR increase with age.
- Acute AR
  - Sudden, severe shortness of breath.
  - Chest pain if myocardial perfusion pressure is decreased or an aortic

dissection is present.

- Rapidly developing heart failure, pulmonary edema and cardiogenic shock.
- Chronic AR
  - Relatively asymptomatic for 10–15 years and significant symptoms occur late. Symptoms may not develop until left ventricular failure occurs.
  - Palpitations, especially on lying down may persist for many years. Sinus tachycardia, during exertion or with emotion may produce palpitations as well as head pounding.
  - Exertional dyspnea: Usually, the first symptom of diminished cardiac reserve. It depends on the extent of left ventricular dilatation and dysfunction. It is followed by orthopnea, paroxysmal nocturnal dyspnea, and excessive diaphoresis.
  - Angina pectoris: Anginal chest pain develops even in the absence of coronary artery disease (CAD) at rest as well as during exertion. Nocturnal angina may be accompanied by marked diaphoresis. These episodes of angina can be prolonged and usually do not respond satisfactorily to sublingual nitroglycerine. Mechanisms of angina in AR:
    - ◆ Associated CAD.
    - ◆ Low aortic diastolic pressure leading to decreased myocardial perfusion (because coronary flow occurs mainly in diastole).
    - ◆ Increased myocardial oxygen demand due to myocardial hypertrophy.
- Congestive heart failure
- Sudden cardiac death
- Arrhythmias are not common.

*Signs*

**Q. Write short essay/note on peripheral signs of aortic regurgitation.**

**Peripheral signs of aortic regurgitation**

**Pulses**

- **Peripheral pulses:** Prominent, large-volume (bounding) or ‘collapsing’.

- **Low diastolic and increased/wide pulse pressure:** Pulse pressure is the difference between the systolic and diastolic blood pressures. In aortic regurgitation there is increased/wide pulse pressure. Table 7.72 shows list of (rare) signs of wide pulse pressure that indicates a hyperdynamic circulation in aortic regurgitation.

### *Inspection and palpation*

- Prominent neck pulsations and thrill in the carotids
- **Apex beat:** Displaced inferiorly and toward the axilla. The point of maximal impulse may be diffuse or hyperdynamic.
- Pre-systolic impulse
- **Diastolic thrill:** May be palpable along the left sternal border in patients with thin-chest (Erbs maneuver).
- **Prominent systolic thrill:** May be palpable in the suprasternal notch and transmitted upward along the carotid arteries.

**Table 7.72** Signs of wide pulse pressure in aortic regurgitation.

<i>Sign</i>	<i>Feature</i>
<b>Light house sign/Morton and Mahon sign</b>	Alternate flushing and blanching of forehead
<b>Landolfi's sign</b>	Change in pupillary size in synchronous with cardiac cycle
<b>Becker's sign</b>	Retinal artery pulsations
<b>De Musset's sign</b>	Head nodding with each heart beat/pulse
<b>Muller's sign</b>	Systolic pulsations of uvula
<b>Quincke's sign</b>	Capillary pulsations in the lip or nail bed. Detected by pressing a glass slide on patients lip or nail bed
<b>Corrigan's sign</b>	Dancing carotids
<b>Locomotor brachii</b>	Prominent pulsation of brachial artery
<b>Watson's water hammer pulse/collapsing pulse</b>	Bounding and forcible, rapidly increasing and subsequently collapsing pulse
<b>Pulsus bisferiens</b>	Double peaking in single systole
<b>Pistol shot femorals or Traube's sign</b>	Sharp bang heard on auscultation over the femoral arteries in time with each a heart beat
<b>Duroziez's sign</b>	To and fro murmur heard when the femoral artery is auscultated with pressure applied distally
<b>Hill's sign</b>	Popliteal cuff systolic pressure exceeds brachial cuff pressure by >20 mm Hg (Mild AR: 20–40 mm Hg, moderate AR: 40–60 mm

	Hg, severe AR: > 60 mm Hg)
<b>Drummond sign</b>	Systolic expulsion of air from nose when mouth is closed
<b>Mayan's sign</b>	When arm is raised, diastolic BP drops by more than 15 mm Hg
<b>Quincke's sign</b>	Pressure on tip of fingernail, fingertip transillumination or glass slide on lip
<b>Rosenbach's sign</b>	Pulsations of liver
<b>Gerhardt's sign</b>	Pulsations of spleen
<b>Ashrafian sign</b>	Pulsatile pseudoproptosis
<b>Bozzolo sign</b>	Pulsatile nasal mucosa
<b>Palmar click</b>	Pulsating palm
<b>Dennison/Shelley sign</b>	Pulsatile cervix
<b>Lincoln sign</b>	Popliteal pulsation
<b>Sherman sign</b>	Dorsalis pedis prominent pulsation in age of 75 years or more

### *Auscultation*

- **First heart sound (S<sub>1</sub>):** May be soft.
- A<sub>2</sub> component of second heart sound (S<sub>2</sub>): Soft in rheumatic aortic regurgitation and loud and **'tambour'** like in syphilitic AR. Narrowly split, single or paradoxically split second heart sound.
- S<sub>3</sub> gallop, third heart sound (S<sub>3</sub>) if left ventricular dysfunction is present.
- Fourth heart sound (S<sub>4</sub>) prominent in left ventricular hypertrophy
- Murmurs
  - **Early diastolic murmur:** Early-holo diastolic murmur, immediately after A<sub>2</sub>, usually as a high-pitched blowing sound that is loudest at the left sternal border, and decrescendo. Best heard in at end of expiration, in sitting and leaning forward position. The duration of the murmur correlates better with the severity of AR than does the loudness of the murmur.
  - **Cole-Cecil murmur:** It is the term used for the diastolic murmur of AR when well or predominantly heard in the left axilla.
  - If the murmur is musical (cooing dove murmur), it signifies eversion or perforation of an aortic cusp.
  - **Harvey sign:** When regurgitation is caused by primary valvular disease, the diastolic murmur is heard best along the left sternal border

in the 3rd and 4th intercostal space. When murmur is caused mainly by dilation of the ascending aorta, the murmur is more readily audible along the right sternal border.

- A functional systolic flow murmur may also be present because of increased stroke volume, although concurrent AS may also be present.

**Q. Write short note on Austin flint murmur.**

- **Austin-Flint murmur:** It may be audible at the cardiac apex in severe AR. It is a low-pitched, mid-diastolic rumbling murmur caused due to:
  - AR jet impinges on anterior mitral leaflet (AML) forces it down and reduces the mitral orifice.
  - Turbulence produced when AR jet meets mitral inflow jet.
  - AML fluttering due to AR jet.
  - LV endocardial vibrations due to AR jet.
- The auscultatory features of AR are intensified by strenuous and sustained handgrip (increases systemic vascular resistance).
- As heart failure develops, peripheral vasoconstriction may occur and arterial diastolic pressure may rise, even though severe AR is present (Box 7.41). Thus, pulse pressure can be normal or narrow in severe AR.

**Box 7.41:** Causes of AR with normal/low pulse pressure.

- Acute AR
- AR with AS or severe MS
- AR with CHF
- AR

Indicators of severity of aortic regurgitation are listed in Box 7.42.

*Acute aortic regurgitation*

- **Clinical presentation:** Sudden in onset with acute left ventricular failure.
- Signs
  - **Pulse pressure:** Normal and near normal systolic and diastolic pressures.
  - **S<sub>1</sub>:** Soft or absent.
  - **P<sub>2</sub>:** Normal or increased
  - **S<sub>3</sub>:** Usually audible.
  - Murmur:

- ◆ Early diastolic murmur is short and functional systolic murmur across aortic valve is less loud.
- ◆ Austin flint murmur is usually absent.
- Investigations of acute aortic regurgitation:
  - **ECG and chest X-ray:** Do not show evidence of left ventricular enlargement. Chest X-ray may show redistribution of upper lobe vessels due to pulmonary venous hypertension.

**Box 7.42:** Indicators of severity of aortic regurgitation.

- **Duration of murmur:** If murmur > two thirds of diastole, murmur becomes holodiastolic and rough in quality
- Bisferiens pulse
- S<sub>3</sub>
- Positive Hill's sign >60 mm Hg
- **Cardiomegaly:** Apical impulse displaced down and out
- Austin-Flint murmur
- A<sub>2</sub> soft
- Marked peripheral signs

### ***Investigations of Chronic Aortic Regurgitation***

- **Chest X-ray:** It shows cardiomegaly due to the enlargement/dilatation of the left ventricle in an inferior and leftward direction. The ascending aorta (and the aortic arch or knob) is also severely dilated. Left atrial enlargement is not found unless there is significant left ventricular dysfunction. Calcification of the ascending aortic wall and the aortic valve may be observed in syphilitic aortic regurgitation. Later it may show features of left heart failure.
- **Electrocardiography (ECG):** It shows the adaptive changes in the left ventricle due to the volume overload. These include: (1) LV hypertrophy: Tall R waves and deeply inverted T waves in the left sided chest leads, (2) left axis deviation, (3) left atrial enlargement, (4) LV volume overload pattern (prominent Q waves in leads I, aVL, and V<sub>3</sub> to V<sub>6</sub> and relatively small r waves in V<sub>1</sub>) and 5) LV conduction defects (typically late in the disease process).
- **Echocardiography:**
  - Aortic valve structure and morphology (e.g. bileaflet versus trileaflet,

flail, thickening).

- Presence of vegetations or nodules (may require transesophageal echocardiography in selected cases)
- Quantitative measurements of regurgitant volume, fraction and orifice area assessed.
- Fluttering anterior mitral leaflet
- Regurgitant volume, fraction, and orifice area
- Associated lesions of the aorta, e.g. dilation, aneurysm, dissection, or ectasia
- LV structure and function
- Doppler echocardiography: To assess the severity. Transesophageal echocardiography is not usually needed.
- **Cardiac magnetic resonance and cardiac CT:** To assess the thoracic aorta for the aneurysm, dissection or coarctation but are rarely needed. Cardiac MR can quantify regurgitant volume.
- Cardiac catheterization
- **Coronary angiography:** Indicated for the assessment of coronary anatomy prior to aortic valve surgery in patients with risk factors for coronary artery disease
- Other tests
  - **VDRL and TPHA:** If syphilitic cause is suspected.
  - RA factor, ANA, ESR and CRP: To exclude connective tissue disorders.

#### **Box 7.43:** Indications for aortic valve surgery.

- Patient is symptomatic (dyspnea, NYHA class IIIB, angina) with chronic severe aortic regurgitation
- Patient is asymptomatic, with a resting left ventricular ejection fraction (EF) of  $\leq 55\%$
- Patient is asymptomatic, with left ventricular ejection fraction  $>55\%$  but with left ventricle dilation (LV end diastolic dimension  $>70$  mm or end-systolic dimension  $>55$  mm)
- Fractional shortening (FS)  $<0.27$
- Acute severe aortic regurgitation, e.g. endocarditis
- If undergoing CABG, surgery of the ascending aorta or other cardiac valve

**Q. Write short essay/note on management of acute severe aortic regurgitation in pulmonary edema.**

### Treatment

- Underlying cause of AR like dissection, endocarditis, syphilis has to be treated.
- **Prophylaxis:** Rheumatic fever prophylaxis is needed if due to rheumatic. Infective endocarditis prophylaxis is not required.
- **Acute severe AR:** Surgical intervention is usually needed, but the patient may be medically supported with **dobutamine** to augment cardiac output and shorten diastole and **sodium nitroprusside** to reduce afterload in hypertensive patients.
- **Chronic severe AR.**

### Medical treatment

- Vasodilator therapy may be used in selected conditions to reduce afterload in patients with systolic hypertension to reduce wall stress and optimize LV function. In normotensive patients, vasodilator therapy may not be useful because it does not reduce regurgitant volume (preload) significantly.
- The acute administration of sodium nitroprusside, hydralazine, nifedipine or felodipine reduced PVR and results in an immediate augmentation in forward cardiac output and a reduction in regurgitant volume. Nitroprusside and hydralazine induced acute hemodynamic changes lead to a consistent decrease in end-diastolic volume (EDV) and an increase in ejection fraction (EF).

### Surgical treatment

- AR usually requires replacement of the diseased valve with a prosthetic valve, although valve-sparing repair is available like **transcatheter aortic valve replacement/implantation (TAVR/TAVI)**.
- Indications for aortic valve surgery (Box 7.43)
- **Types of valves:** For patients undergoing AV replacement, careful consideration should be given to the relative risks and benefits of mechanical vs bioprosthetic valves.
  - **Mechanical valves:** More durable but require long-term anticoagulation with warfarin due to increased risk of thrombosis.
  - **Bioprosthetic (tissue) valves** carry a greater risk of long-term deterioration (e.g. rapid calcification and degeneration of the valves) and risk of reoperation but avoid the need for long-term warfarin. Thus they are preferred in the elderly and when anticoagulants must be avoided. They are contraindicated in children and young adults.
- **Aortic root dilation causing AR:** For example, Marfan's syndrome. Treated by encircling suture or subcommissural annuloplasty, or aortic graft with prosthetic valve (coronaries need to be reimplanted) or aortic graft alone.

## Difference between rheumatic and syphilitic aortic regurgitation (Table 7.73)

### Q. What are the differences between rheumatic and syphilitic aortic regurgitation?

**Table 7.73:** Differences between aortic regurgitation (AR) of rheumatic and syphilitic etiology.

Feature	Rheumatic AR	Syphilitic AR
Age group	10–40 years	Older than 40 years

Angina	Less common	More common
Early diastolic murmur (EDM) best audible at	Erb's area	Aortic area
Character of EDM	Soft, blowing	Cooling dove or seagull
Character of A <sub>2</sub>	Soft	Loud and tambour
Association with aortic stenosis or mitral valve disease	May be associated	Not associated
Decompensation	Relatively late	Relatively early
Calcification aorta	Not seen	May be present
Features of underlying cause or etiology	Other features of RHD may be present	Stigmata of syphilis present

## Difference between Acute and Chronic Aortic Regurgitation (Table 7.74)

**Q.** What are the differences between acute and chronic aortic regurgitation?

**Table 7.74:** Differences between acute and chronic aortic regurgitation.

<i>Clinical features</i>	<i>Acute aortic regurgitation</i>	<i>Chronic aortic regurgitation</i>
<b>Congestive cardiac failure</b>	Early and sudden	Late and insidious
<b>Arterial pulse</b>	Low volume Pulsus alternans	High volume, collapsing, water hammer, pulsus bisferans
<b>Blood pressure</b>	Normal/low	Wide pulse pressure
<b>Contour of peak of pulse</b>	Single	Bisferians
<b>Left ventricle impulse</b>	Near normal	Laterally displaced
<b>S<sub>1</sub></b>	Soft to absent	Normal
<b>A<sub>2</sub></b>	Soft	N/decreased
<b>S<sub>3</sub></b>	Common	Absent
<b>S<sub>4</sub></b>	Consistently absent	Usually absent
<b>Aortic systolic murmur</b>	Grade 3/less	Grade 3/more
<b>Aortic regurgitant murmur</b>	Short, medium pitched	Long, high pitched
<b>Austin Flint murmur</b>	Mid-diastolic	Presystolic, mid-diastolic
<b>Peripheral signs</b>	Absent	Present

**Difference between Austin Flint murmurs from the murmur of mitral**

stenosis (Table 7.75)

**Q. What are the differences between Austin Flint murmur and the murmur of mitral stenosis (MS)?**

**Table 7.75: Differences between Austin Flint murmur and the murmur of mitral stenosis.**

<i>Feature</i>	<i>Austin Flint murmur</i>	<i>Mitral stenosis murmur</i>
Diastolic thrill at apex	Absent	Present
Wide pulse pressure	Present	Absent
Peripheral signs of AR	++	–
<b>Heart sounds and murmur</b>		
• First heart sound (S <sub>1</sub> )	–	Loud
• P <sub>2</sub>	–	Loud
• Third heart sound (S <sub>3</sub> )	+	–
• Opening snap (OS)	–	+
• Presystolic accentuation	±	+
• Associated EDM at aortic area	++	–
• With amyl nitrite	Murmur decreases	No change
Evidence of pulmonary hypertension, RV enlargement and/or hypertrophy	Absent	Present
Evidence of LV enlargement and/or hypertrophy	Present	Absent
Atrial fibrillation	-	May occur

## Tricuspid Stenosis (TS)

**Q. Write short essay/note on tricuspid stenosis (TS).**

Tricuspid stenosis is a **narrowing of the tricuspid valve** opening. Uncommon valve lesion that is more common in females than males.

### ***Etiology (Box 7.44)***

**Box 7.44:** Causes of tricuspid stenosis.

- Rheumatic (frequently associated with mitral and/or aortic valve disease)
- **Carcinoid syndrome:** Tricuspid stenosis and regurgitation are found in carcinoid syndrome
- Congenital

- Infective endocarditis
- **Anorectics:** Fenfluramine
- Fabry's disease

## ***Pathophysiology***

- Tricuspid valve stenosis reduces the cardiac output, which is restored to normal when the pressure of right atrium increases → results in systemic venous congestion → hepatomegaly, ascites and dependent edema.

## ***Clinical Features***

### *Symptoms*

- Usually, symptoms are due to associated left sided rheumatic valve lesions (e.g. mitral stenosis).
- Tricuspid stenosis may produce symptoms of right heart failure: Abdominal pain/hepatic discomfort (due to hepatomegaly), peripheral edema, and ascites
- Little or no dyspnea and fatigue is common.

### *Signs*

- **Jugular venous pressure (JVP):** JVP is raised with prominent a waves (giant a waves) and slowly descent due to the loss of normal rapid right ventricular filling.
- **Mid-diastolic murmur:** Loud first heart sound and a rumbling mid-diastolic murmur (higher-pitched than the murmur of mitral stenosis) with presystolic accentuation, best heard at the lower left sternal border and increases/louder during inspiration (**De-Carvalho's sign**).
- **Tricuspid opening snap (OS):** Occasionally heard.
- **Right heart failure:** Hepatomegaly with presystolic pulsation felt over the liver, ascites and peripheral edema.

## ***Investigations***

- **Chest X-ray:** May show a prominent right atrial bulge.
- **ECG:** Enlarged right atrium
- **Echocardiogram:** May reveal thickened and immobile tricuspid valve.

### **Treatment**

- **Medical management:** Diuretic therapy and salt and fluid restriction.

- **Surgical treatment:** Tricuspid valve replacement.

## Tricuspid Regurgitation

**Q. Write short essay/note on tricuspid regurgitation. What is De-Carvalho's sign?**

In tricuspid regurgitation, tricuspid valve does not close properly, causing blood to flow backward (leak) into the right atrium.

### *Etiology*

Tricuspid regurgitation is common. Most commonly it is functional secondary to right ventricular dilatation.

### *Causes of Tricuspid Regurgitation*

- **Primary/organic:** Rheumatic heart disease, endocarditis (IV drug abuse) Ebstein's congenital anomaly carcinoid syndrome
- Secondary
  - **Functional tricuspid regurgitation:** Right ventricular dilatation due to chronic left heart failure
  - Right ventricular infarction, inferior wall infarction
  - Pulmonary hypertension (e.g. cor pulmonale)
  - Cardiomyopathy.

### *Clinical Features*

- Symptoms are usually nonspecific. Tiredness due to reduced forward flow.
- Valvular regurgitation increases the right atrial and systemic venous pressure. Patients may develop of right heart failure, i.e. edema, ascites and hepatomegaly with systolic pulsations due to venous congestion.
- **JVP:** Raised with most prominent 'giant' v wave in the jugular venous pulse (a cv wave replaces the normal x descent).
- Earlobe pulsations (**Lancisi's sign**)
- **Blowing pansystolic murmur:** At the lower-left sternal border that is increased during inspiration and reduced during expiration (De-Carvalho's sign).
- P<sub>2</sub> may be loud (due to pulmonary hypertension) and RV S<sub>3</sub> is heard.

- **Severe TR:** Right jugular venous thrill and an RV impulse at the left lower sternal border. Long-standing severe TR may lead to RV dysfunction–induced heart failure and atrial fibrillation (AF).
- **Echocardiogram:** It shows dilated right ventricle and thickened valve.

#### Treatment

- **Functional tricuspid regurgitation** due to right ventricular dilatation usually disappears with treatment of the underlying cause of right ventricular overload. Treatment consists of with diuretic and vasodilator treatment of congestive cardiac failure.
- **Organic tricuspid regurgitation:** TR is usually well tolerated when there is normal pulmonary artery pressure. Severe organic tricuspid regurgitation may require operative repair of the tricuspid valve by annuloplasty or plication or valve repair, or occasionally tricuspid valve replacement. In drug addicts with infective endocarditis of the tricuspid valve, surgical removal of the valve is recommended to eradicate the infection.

## Pulmonary Stenosis

**Q. Write short essay/note on pulmonary stenosis.**

**Pulmonary stenosis (PS)** is characterized by obstruction to blood flow from the right ventricle to the pulmonary artery.

### *Etiology*

- **Congenital:** Usually PS is a congenital lesion. It may be associated with rubella during pregnancy. May be an isolated lesion or associated with a ventricular septal defect (Fallot’s tetralogy).
- Acquired:
  - Rheumatic (very uncommon)
  - Carcinoid syndrome.

Pulmonary stenosis may be classified as valvular, subvalvular (infundibular) or supra-valvular.

### *Clinical Features*

#### *Symptoms*

- Mild pulmonary stenosis may be asymptomatic.
- Fatigue, syncope, dyspnea and the symptoms of right heart failure. Angina or syncope indicates severe pulmonary stenosis.

#### *Signs*

- **Systolic thrill:** The ejection systolic murmur (described below) is often associated with a thrill. It is best felt when patient sits up, leans forward and breathes out.
- Right ventricular heave (sustained impulse) and epigastric pulsation may be felt.
- Pulmonary closure sound (P<sub>2</sub>) is soft and delayed.
- **Wide splitting of second heart sound:** Due to delay in right ventricular ejection.
- **Ejection systolic murmur:** It is principal physical sign. It is best heard on inspiration at the left upper sternum in the second intercostal space. It radiates towards the left shoulder. With progressive severity, the murmur gets harsh/louder longer and peaks later in systole. This murmur is usually preceded by an ejection sound (click).
- **Ejection click:** Mild stenosis is characterized by a systolic ejection click which is often more prominent in expiration. This seemingly paradoxical behavior of the pulmonary ejection click is explained by an inspiratory increase in RV end-diastolic pressure, which opens the valve in late diastole and hence absence of systolic ejection click during inspiratory phase.
- **High-pitched diastolic murmur** after a prominent P<sub>2</sub> may be evident in patients with pulmonary regurgitation secondary to pulmonary hypertension (**Graham Steel murmur**).
- If stenosis is valvular, pulmonary ejection sound/click will be heard.
- **Moderately severe stenosis** is associated with a right ventricular fourth sound and a prominent jugular venous *a* wave.
- **Features of severe pulmonary stenosis:** (1) loud harsh murmur, (2) inaudible pulmonary closure sound (P<sub>2</sub>), (3) increased right ventricular heave, (4) prominent *a* waves in the jugular pulse, (5) right ventricular hypertrophy in ECG and (6) chest X-ray shows post-stenotic dilatation in the pulmonary artery.

### ***Investigations***

- **ECG:** Shows both right ventricular and right atrial hypertrophy.
- **Chest X-ray:** Shows a prominent pulmonary artery (extending into the left pulmonary artery branch) owing to post-stenotic dilatation.

- Doppler echocardiography is the definitive investigation.
- Cardiac catheterization.

#### Treatment

- Mild and even moderate pulmonary valve stenosis and regurgitation do not result in RV overload and may require no specific treatment other than prophylaxis for infective endocarditis.
- Moderately severe and severe pulmonary valve stenosis (resting gradient >50 mm Hg with a normal cardiac output) is currently treated by percutaneous balloon valvotomy or, if this is not available, by surgical valvotomy. Postoperatively pulmonary regurgitation may develop which is benign in nature.

**Prognosis:** Long-term prognosis is very good.

## INFECTIVE ENDOCARDITIS

**Q. Discuss the etiology, pathology, clinical features, laboratory features/investigations, management/treatment of infective endocarditis.**

**Q. Discuss the etiology, pathology, clinical features, complications, investigations, management/treatment of subacute bacterial endocarditis (SBE).**

Infective endocarditis (IE) is an **infection of the endocardium of heart valves or the mural endocardium.**

**Definition:** Infective endocarditis is defined as an endovascular infection of cardiovascular structures by microbes. These structures include heart valves, atrial and ventricular endocardium, large intrathoracic vessels and intracardiac foreign bodies (e.g. prosthetic valves, pacemaker leads and surgical conduits).

- The causative organism may be bacterium, fungus, chlamydia or rickettsia. Majority of cases are due to infection by streptococci and staphylococci.
- Consequences of infective endocarditis: Valvular dysfunction, localized or generalized sepsis and source for embolism.

### Classification

- **According to the clinical course:** Acute, subacute and chronic.
- **According to the causative organism:** Bacterial, viral, rickettsial, or

fungal.

- **According to the nature of valve or device:** Native or prosthetic.
- **According to the side affected:** Left-sided or right-sided infective endocarditis.
- **According to the side affected and nature of valve/device:** (1) Left-sided infective endocarditis, (2) left-sided prosthetic infective endocarditis, (3) right-sided infective endocarditis and (4) device-related (permanent pacemaker, implantable cardioverter defibrillator) infective endocarditis.

**Differences between acute endocarditis and subacute endocarditis (Table 7.76)**

**Table 7.76: Differences between acute and subacute endocarditis.**

<i>Characteristic</i>	<i>Acute infective endocarditis</i>	<i>Subacute infective endocarditis</i>
Onset	Acute	Insidious
Condition of valve	Infection of normal heart valve as well as damaged valves	Infection of structurally abnormal/deformed valves or at sites where the endothelium is damaged by a high pressure jet of blood
Virulence of organisms	Highly virulent (suppurative) and invasive organisms	Low virulent
Source of infection or portal of entry	Often evident	Common sources of infection are periodontal infections (dental treatment), gastrointestinal tract infections and urinary tract infections
Lesions	Vegetations are more florid. Affected valve is rapidly destroyed. Abscess (local and metastatic) formation is more common	Less destructive. Formation of vegetations, embolic episodes, mycotic aneurysms, valve regurgitation, splenic and renal infarcts, and immune glomerulonephritis
Clinical features	Of acute infection	Of complications
Course	Fulminant course, death within 6 weeks	Protracted course of weeks
Complications	Acute heart failure or	Infectious complications are

	overwhelming sepsis	uncommon
Causative organisms	<ul style="list-style-type: none"> <li>• <i>Staphylococcus aureus</i></li> <li>• <i>Pseudomonas</i></li> <li>• <i>Candida</i></li> <li>• <i>Streptococcus pneumoniae</i></li> <li>• <i>Neisseria gonorrhoeae</i></li> </ul>	<i>Streptococcus viridans</i> ( <i>S. sanguis</i> , <i>S. mitis</i> ), <i>Streptococcus milleri</i> , <i>Streptococcus bovis</i> , <i>Enterococcus faecalis</i> , <i>Staphylococcus aureus</i> HACEK Group*

(\***HACEK**: **H** = *Haemophilus parainfluenzae*, *Haemophilus aphrophilus*, *Haemophilus paraphrophilus*, *Haemophilus influenzae*; **A** = *Actinobacillus actinomycetem comitans*; **C** = *Cardiobacterium hominis*; **E** = *Eikenella corrodens*; **K** = *Kingella kingae*, *Kingella denitrificans*)

## Predisposing Factors

- Underlying heart disease:
  - About 72% of patients have a pre-existing structural cardiac abnormality.
  - Congenital isolated aortic valvular stenosis is most often associated with infective endocarditis (IE). Other congenital heart diseases include ventricular septal defect (VSD), tetralogy of Fallot (TOF), idiopathic subaortic stenosis and atrial septal defect (uncommon).
  - When IE involves valves it commonly involves mitral valve followed by aortic valve and uncommonly tricuspid valve (1%).
  - Major risk for IE are cardiac prosthetic valves and parenteral narcotic drug abuse.
- **Impaired host defense mechanism:** It may occur in diabetes mellitus, malignancies (e.g. leukemias and lymphomas), cytotoxic therapy and neutropenia.
- **Conditions with bacteremia:** Most important predisposing factors to the development of endocarditis are conditions that lead to bacteremia. Transient bacteremia from any cause may lead to infective endocarditis and include the following surgical procedures from different sources.
  - **Respiratory tract:** Tonsillectomy and/or adenoidectomy, surgical operations (incision or biopsy) involving respiratory mucosa and any invasive procedure of the respiratory tract used to treat an established infection (e.g. drainage of an abscess or empyema).
  - **Oral cavity:** All dental procedures in which there is handling of gingival tissue or the periapical region of teeth or perforation of the

oral mucosa (e.g. dental extractions, suture removal, placement of orthodontic band, root canal treatment).

- **Gastrointestinal tract:** Procedures done in an established GIT infection.
- **Genitourinary tract:** Procedures performed in an established infection (e.g. cystoscopy during known enterococcal urinary tract infection—UTI).
- **Skin and musculoskeletal system:** Procedures involving infected tissue.

## Common Organisms for Infective Endocarditis (Table 7.77)

**Q. Write short essay/note on common causative agents for infective endocarditis.**

More than 75% of infective endocarditis is caused by streptococci or staphylococci.

### ***Postoperative Endocarditis or Prosthetic Valve Endocarditis***

- It develops after cardiac surgery and may affect native or prosthetic valves and other prosthetic materials.
- Depending on the time of development of endocarditis following surgery, it can be divided into early, intermediate and late endocarditis.
  - Early (within 60 days of surgery) endocarditis is caused by intraoperative or hospital-acquired infections. The most common organism is a coagulase-negative *Staphylococcus* (*Staph. epidermidis*) which is a normal commensal in the skin and followed by fungi (*Candida*, *Aspergillus*).
  - Late (after 1 year) endocarditis is caused by infection with community-acquired organisms. The causative organism is the same with those causing acute and subacute endocarditis of native valve.
  - Endocarditis developing between 60 days and 1 year are due to a mixture of hospital-acquired episodes caused by less virulent organisms community-acquired episodes. The organisms include *Streptococcus viridans* and enterococci.
- Type of prosthetic valves:
  - Aortic prosthetic valve is more prone to endocarditis than mitral prosthetic valve.
  - During first 3 months after surgery mechanical heart valves develop endocarditis more frequently than bioprosthetic ones. However, later on the rates of infection for the two valve types are same and are comparable at 5 years.

**Table 7.77: Organisms causing infective endocarditis.**

<i>Native valves</i>	%	<i>Narcotic addicts</i>	%	<i>Prosthetic valves</i>	%

<i>Streptococcus viridians</i>	30–40	<i>Staphylococcus aureus</i>	50–60	<i>Staphylococcus epidermidis</i>	20–30
<i>Staphylococcus aureus</i>	10–30	Streptococci	8–15	<i>Staphylococcus aureus</i>	15–20
<i>Staphylococcus epidermidis</i>	1–3	<i>Staphylococcus epidermidis</i>	2–5	<i>Streptococcus viridans</i>	5–20
Enterococci	5–15	Enterococci	8–10	Enterococci	5–10
Other streptococci	15–20	Other streptococci	10–15	Other streptococci	1–5
Gram -ve bacilli	2–10	Gram -ve bacilli	4–8	Gram -ve bacilli	10–20
Fungi	2–4	Fungi	4–5	Fungi	5–15
Culture negative	5–10	Culture negative	5–8	Culture negative	<5

**Right-sided endocarditis:** Develops in intravenous drug users and are mainly caused by organisms found on the skin (e.g. *Staphylococcus aureus*, *Candida*). It usually presents with acute endocarditis and affects mainly tricuspid valve.

### ***Culture Negative Endocarditis (Box 7.45)***

- Defined as endocarditis without etiology following inoculation of at least three independent blood samples in a standard blood culture system with negative cultures after 7 days of incubation and subculturing.
- They constitute 5–10% of cases of endocarditis.

#### **Box 7.45:** Causes of culture negative endocarditis.

- It is usually due to prior antibiotic therapy
- Inadequate quantity of blood taken for culture
- Anaerobic infection
- Some may be due to a variety of fastidious organisms that does not grow in normal blood cultures. These include *Coxiella burnetti* (cause of Q fever), *Chlamydia* species, *Bartonella* species (cause trench fever and cat scratch disease) and *Legionella*
- Right-sided endocarditis
- Non-infective endocarditis.

### **Pathogenesis**

Mechanism by which virulent organisms infect apparently normal valves is poorly understood.

The probable sequence of events, which occur with the infection of a damaged valve by less-virulent organisms is as follows:

- **Endocardial damage/injury and denudation**

- **Formation of sterile thrombus**
- **Adherence of the microorganisms:** Transient bacteremia → microorganisms gain access to the circulation and adhere and get deposited to the sterile vegetations (infection of thrombi).
- **Proliferation of microorganisms within vegetations**
- **Formation of emboli:** The vegetation may get detached and form infective emboli → cause spread of infection to visceral organs such as kidney, spleen, and brain. They may result in infarction or abscess. Septic emboli cause arteritis with weakness of arterial wall leading to mycotic aneurysms.
- **Deposition of immune complexes: Antigen and antibody may form immune complexes and can produce** focal glomerulonephritis and microscopic hematuria, diffuse glomerulonephritis, vasculitis of cerebral vessels leading to cerebrovascular accidents and perisplenitis.

## Clinical Features

**Q. Write short essay/note on important signs of infective endocarditis.**

- The clinical features of infective endocarditis depend on the causative organism and the presence of predisposing cardiac conditions.
- Endocarditis may be acute or a more insidious ‘subacute’ form. However, there is overlap between the two because the clinical pattern depends not only on the causative organism, but also depends on the site of infection, prior antibiotic therapy and the presence of a valve or shunt prosthesis.

### ***Subacute Endocarditis (SBE)***

Clinical suspicion of subacute endocarditis is necessary when a patient with congenital or valvular heart disease develops certain features. These include:

#### **Evidence of infection**

- Vague symptoms such as unusual tiredness, fatigue, lassitude, loss of appetite, loss of weight.
- Persistent or intermittent low-grade or high-grade **fever** (84%) with night sweats, chills and rigors.
- **Clubbing** (Fig. 7.45A) in fingers is a late sign and is found only in 10–20% of patients.
- **Splenomegaly:** Spleen is frequently palpable and the liver may also be

enlarged.

- Brownish pigmentation of face and limbs.

### **Evidence of new valve lesion (regurgitant)/murmurs or change of murmur**

- **New murmur:** Particularly a diastolic murmur is the diagnostic feature. It is detected in about 15% of patients during initial period. However, most patients develop a murmur during the course of the disease.
- **Changing murmurs:** Apart from integrity of valves, factors such as change in cardiac output, temperature, and hematocrit may be responsible for change of murmurs. However, new regurgitant murmur developing in acute sepsis is almost diagnostic of endocarditis.

### **Evidence of embolism**

- **Cutaneous manifestations:** These include the following:
  - **Purpura and petichiae** (20–40%)(Fig. 7.45B) subconjunctival splinter (Fig. 7.45C) or subungual splinter hemorrhages due to microthromboemboli.
  - **Janeway lesions:** Erythematous, non-tender nodules on palms or soles.
  - **Ocular manifestations:** Roth spot (Fig. 7.45D) are flame-shaped hemorrhages which may occasionally appear like cotton wool spots.
- **Septic infarcts/abscess:** Spleen (painful splenomegaly), kidney (loin pain, hematuria and renal failure), brain (convulsions, hemiplegia, aphasia, loss of vision and cerebellar disturbances), peripheral arteries (claudication, absence of peripheral pulses and gangrene) or lungs (pulmonary infarction, pleurisy and pleural effusion due to right-sided endocarditis).
- **Mycotic aneurysms.**

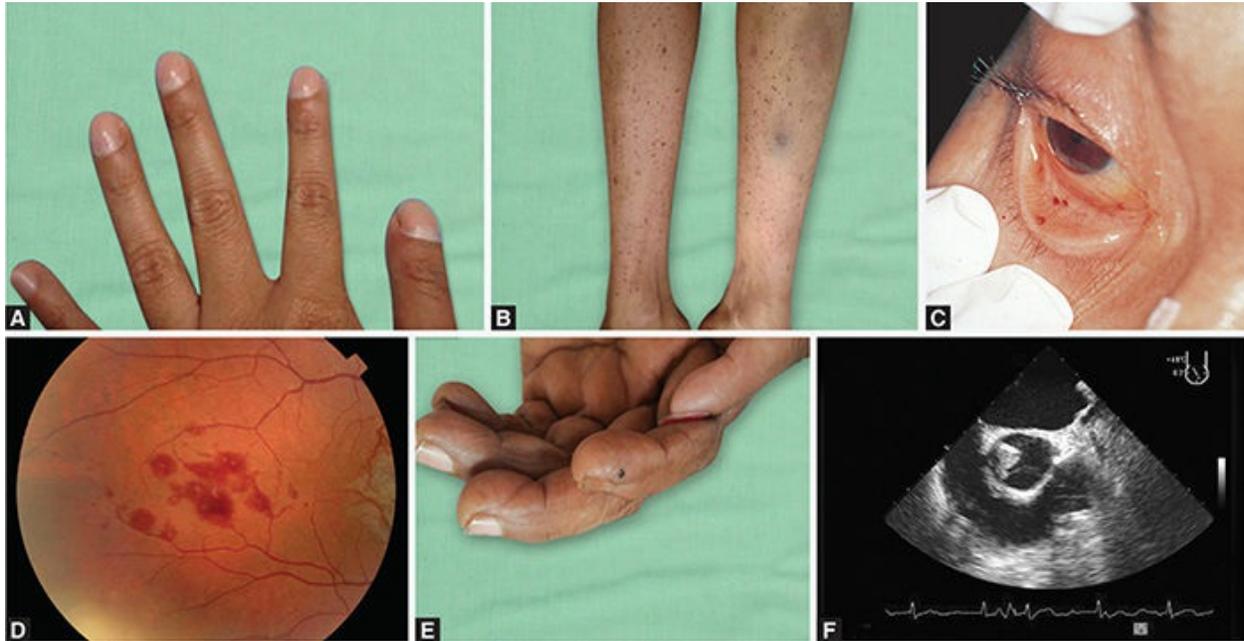

### **Evidence of immunological phenomena**

- **Osler nodes (Fig. 7.45E):** Tender, small, painful, swollen, purplish/erythematous subcutaneous papules/nodules in pulp of distal fingers due to hypersensitive angiitis. Cultures are negative and persist for hours to several days.
- **Roth spots (Fig. 7.45F)** are circular retinal hemorrhages with white or pale centers spots composed of fibrin.
- **Focal segmental glomerulonephritis:** Develop due to deposition of antigen-antibody complexes in glomeruli. Grossly, the outer surface of

kidney develops a flea-bitten appearance due to patchy hemorrhagic foci involving the glomeruli. Patients develop **microscopic hematuria**.

## Investigations

**Aim of investigations:** (1) To confirm the diagnosis of infective endocarditis, (2) to identify the causative organism for appropriate therapy, and (3) to assess the patient's response to therapy.

**Figs. 7.45A to F:** Signs of infective endocarditis: (A) Clubbing; (B) Petechiae; (C) Subconjunctival hemorrhage; (D) Roth spots; (E) Osler's nodes; (F) Echocardiography showing vegetation.

### **Q. Write short essay/note on tests for infective endocarditis.**

#### **Microbiological Investigations**

- **Blood cultures** are the crucial investigations in infective endocarditis (1) to identify the causative microorganism and (2) guide antibiotic therapy. At least 3 sets of blood samples for cultures should be taken from different venipuncture sites over 24 hours before commencing therapy. Aseptic technique should be followed and the risk of contaminants should be minimized. Blood samples for cultures should not be obtained from an in-dwelling line. Both aerobic and anaerobic cultures are needed.
- **Serological tests** are useful if there is suspicion of diagnosis and the cultures are negative. Culture negative cases may be due to organisms which will not grow in blood cultures such as *Coxiella*, *Bartonella*, *Legionella*, *Chlamydia*.

- **Electrocardiogram:** ECG will help to detect complications like conduction abnormalities (AV block) and occasionally myocardial infarction due to emboli. PR prolongation/heart block is associated with aortic root abscess.
- **Chest X-ray:** It may show evidence of cardiac failure, cardiomegaly, pulmonary edema in left-sided disease, pulmonary emboli/abscess in right-sided disease.
- **Echocardiography:** It plays a key role to identify the presence and size of vegetations (Fig. 7.45F), assess valve damage, abscess formation, detect intracardiac complications and assess cardiac function. However, if vegetations are not detected the diagnosis of endocarditis cannot be excluded.
  - **Transthoracic echocardiography (TTE):** It is a first-line noninvasive imaging test with sensitivity of 60–75% and high specificity for demonstrating vegetations, valvular dysfunction, ventricular function, abscesses. Vegetations as small as 2–4 mm can be detected.
  - **Transesophageal echocardiography (TOE):** It is a second-line invasive imaging test with greater sensitivity (>90%) and specificity than TTE. It can detect vegetations even smaller ones (1–1.5 mm), aortic root abscess, and prosthetic valve endocarditis.
- **Complete blood counts:** May show normocytic normochromic anemia (reduced hemoglobin) and increased WBC counts and increased or reduced platelets.
- **Urea and Creatinine:** May be increased due to glomerulonephritis.
- **Liver biochemistry:** Serum alkaline phosphatase may be increased.
- **Inflammatory markers:** Increased erythrocyte sedimentation rate (ESR) and C-reactive protein are observed. CRP also helps in monitoring response to therapy; it is reduced in response to therapy and increased with relapse.
- **Urine:** Proteinuria and hematuria occur frequently.

### Modified Duke Criteria for the Diagnosis of Infective Endocarditis (Table 7.78)

- Diagnosis by these guidelines requires either pathologic or clinical criteria.
- *If clinical criteria are used*

- *Definite endocarditis, two major, or one major + three minor, or five minor criteria are required for diagnosis.*
- *Possible endocarditis = One major and one minor, or three minor criteria.*

## Complications

### **Q. Write short essay/note on complications of infective endocarditis.**

- **Cardiac complications:** These are **due to direct valvular damage and consequences of local invasion.** The infection may spread locally from valve into the valve ring, adjacent mural endocardium or chordae tendineae.
  - **Ring abscess:** Vegetations may erode the **underlying myocardium** and produce an **abscess** which is known as ring abscess.
  - **Perforation and rupture:** May involve valve leaflets, aorta or interventricular septa (depending on the site of infection).
  - **Myocardial abscess** usually due to *S. aureus*
  - **Suppurative pericarditis.**
  - **Valvular dysfunction and heart failure:** Stenosis or insufficiency. Heart failure is most common and is due to valvular regurgitation.
  - Prosthetic dehiscence
  - Valvular distortion/destruction chordal rupture.
  - Conduction abnormalities
  - Purulent pericarditis
- **Renal :** At least in 4 forms: (1) prerenal due to low cardiac output, (2) microabscess formation secondary to septic emboli, (3) glomerular dysfunction as a result of circulating immune complexes and (4) renal failure as a result of antibiotics.
- **Embolic events** (discussed under evidence of embolism—subacute endocarditis)
  - Vegetations are usually friable and likely to be break, detach and cause embolism.
  - **Embolic complications** (due to septic emboli): Emboli contain large numbers of virulent organisms → abscesses develop at the sites of arrest of the emboli. Septic emboli from left side of the heart: They

enter systemic circulation and its consequences are:

- ◆ Septic infarcts (e.g. spleen, kidney or brain)
- ◆ Mycotic aneurysms
- ◆ Small emboli (microthromboemboli) may produce: (1) **splinter or subungual hemorrhages** and (2) **Janeway lesions**
- ◆ Septic emboli from right side of the heart: They enter pulmonary circulation → lead to pulmonary abscess.

- **Immunological phenomena**

- **Focal segmental glomerulonephritis:** Develop due to deposition of antigen-antibody complexes in glomeruli. Grossly, the outer surface of kidney develops a flea-bitten appearance due to patchy hemorrhagic foci involving the glomeruli.
- **Osler nodes:** They are small, tender subcutaneous nodules in the pulp of the digits and persist for hours to several days.
- **Roth spots** are retinal hemorrhages with white or pale centers composed of fibrin.

**Table 7.78** Modified Duke criteria for the diagnosis of infective endocarditis.

**Clinical Criteria**

**Major**

**Positive blood cultures for IE (one of the following):**

Typical microorganisms consistent with IE from two separate blood cultures:

- *Staphylococcus aureus*
- Viridans streptococci
- *Streptococcus gallolyticus* (formerly *S. bovis*), including nutritional variant strains (*Granulicatella* spp and *Abiotrophia defectiva*)
- HACEK group: *Haemophilus* spp, *Aggregatibacter* (formerly *Actinobacillus actinomycete comitans*), *Cardiobacterium hominis*, *Eikenella* spp., and *Kingella kingae*
- Community-acquired enterococci, in the absence of a primary focus; OR

Persistently positive blood culture:

- For organisms that are typical causes of IE: At least two positive blood cultures from blood samples drawn >12 hours apart
- For organisms that are more commonly skin contaminants: Three or a majority of ≥4 separate blood cultures (with first and last drawn at least one hour apart)

Single positive blood culture for *Coxiella burnetii* or phase I IgG antibody titer >1:800

**Evidence of endocardial involvement (one of the following):**

Echocardiogram positive for IE:

- Vegetation (oscillating intracardiac mass on a valve or on supporting structures, in the path of regurgitant jets, or on implanted material, in the absence of an alternative anatomic explanation) OR

- Abscess OR
- New partial dehiscence of prosthetic valve

New valvular regurgitation

*Increase in or change in preexisting murmur not sufficient*

**Minor**

- Fever  $\geq 38$  °C (100.4 °F)
- Predisposition: Predisposing heart lesion or intravenous drug use
- Vascular phenomena: Arterial petechiae, subungual/splinter hemorrhages, emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhages, Janeway lesions
- Immunological phenomena: Focal segmental glomerulonephritis, Osler nodes, Roth spots
- Microbiologic evidence, including a single culture positive but not meeting a major criterion, or for an unusual organism that can cause infective endocarditis

**Pathologic Criteria**

Demonstration of microorganisms by culture or histologic examination in:

- Vegetation
- Embolus from a vegetation
- Intracardiac abscess

Histological confirmation of active endocarditis in vegetation or intracardiac abscess

**Table 7.79** Antimicrobial treatment of common causative organisms in infective endocarditis.

<b>Organism</b>	<b>Antimicrobial treatment with dose and duration</b>
Infective endocarditis awaiting culture report, no suspicion of staphylococci	<p>Benzylpenicillin IV 1.2 g 4 hourly, 4–6 weeks  <b>Plus</b> Gentamicin IV 80 mg 12 hourly, 2–6 weeks</p> <p><b>OR</b> Amoxycillin/clavulanate 12 g/day in four divided doses plus gentamicin 1 mg/kg thrice a day for 4–6 weeks</p>
Suspected staphylococcal endocarditis (IVDU, recent intravascular devices or cardiac surgery, acute infection)	<p>Vancomycin IV 1 g 12 hourly (30 mg/kg/day—(not to exceed 2 g/day) for 6 weeks  <b>Plus</b> gentamicin IV 80–120 mg 8 hourly for 1–2 weeks. In prosthetic valve endocarditis, add rifampicin 20 mg/kg/day in two divided doses.</p>
Streptococci highly sensitive to penicillin	<p>Benzylpenicillin IV 1.2 g 4 hourly for 4 weeks <b>OR</b>            Ceftriaxone IV 2 g once a day for 4 weeks <b>OR</b>            Benzylpenicillin or ceftriaxone for 2 weeks plus gentamicin 3 mg/kg once a day for 2 weeks            Vancomycin 30 mg/kg/day in two divided doses (not to exceed 2 g/day) for 4 weeks in penicillin-sensitive patients</p>
Streptococci less sensitive to penicillin	<p>Benzylpenicillin IV 1.2 g 4 hourly or ceftriaxone IV 2 g for 4–6 weeks and gentamicin 3 mg/kg/day (as single infusion) for at least 2</p>

	weeks
Anaerobic streptococci	Benzylpenicillin IV 1.2 g 4 hourly, metronidazole
Staphylococcal endocarditis (methicillin-sensitive)	Cloxacillin 2 g 4 hourly <b>OR</b> Cefazolin 2 g 8 hourly, vancomycin 1 g 12 hourly, <b>OR</b> Flucloxacillin 2 g 4 hourly <b>OR</b> Benzylpenicillin 1.2 g 4 hourly for 4–6 weeks <b>PLUS</b> gentamicin 80–120 mg (1mg/kg) three times a day for 3–5 days
Enterococcal endocarditis	Ampicillin/amoxicillin 2 g 4 hourly for 4– 6 weeks <b>OR</b> vancomycin 1 g twice daily <b>plus</b> Gentamicin 1 mg/kg three times a day for 6 weeks
<i>Candida</i>	Amphoterecin B 1 mg/kg QID 2 weeks maximum up to 4 weeks. Do not exceed 50 mg/day Flucytocine 150 mg/kg oral for four days
<i>Coxiella burnetii</i>	Doxycycline 100 mg twice daily with either hydroxychloroquine 600 mg daily <b>OR</b> rifampin (900 mg/day) for 18–24 months
<i>Bartonella</i>	Doxycycline (100 mg PO or IV twice daily) <b>plus</b> gentamicin (1 mg/kg IV every eight hours) for 14 days

## Q. Write short essay/note on management of infective endocarditis/subacute infective endocarditis.

### Management

**Box 7.46:** Indications for surgical treatment in infective endocarditis.

- Endocarditis of prosthetic valve
- Large vegetations
  - Left-sided large vegetation (10 mm) with an episode of embolization
  - Very large (15 mm) and mobile vegetation (high-risk of embolism)
- Progressive cardiac failure due to valvular damage
- Active infection persisting, i.e. fever and evidence of bacteremia for more than 7–10 days in spite of adequate antibiotic treatment
- Abscess formation, perivalvular involvement, *Staph. aureus* and fungal endocarditis

### Medical treatment

- Blood should be collected for cultures before starting the empirical antibiotic therapy. However, this should not delay therapy in unstable patients.
- If source of infection is identified, it should be removed as soon as possible (e.g. tooth with an apical abscess should be extracted).
- **Empirical treatment regimen:** Penicillins are fundamental to the therapy of bacterial endocarditis. Empirical treatment regimen depends on the mode of presentation, the suspected organism, and whether the patient has a prosthetic valve or penicillin allergy (Table 7.79).

*Prognosis:* It is fatal in about 20% patients and higher in those with prosthetic valve endocarditis and those infected with antibiotic resistant organisms.

### Surgical treatment (Box 7.46)

Decisions to carry out surgical intervention in patients with infective endocarditis should take into

account the (1) patient specific features such as age, non-cardiac morbidities, presence of prosthetic material or cardiac failure and (2) infective endocarditis features such as causative organism, size of vegetation, presence of perivalvular infection, systemic embolization.

Cardiac surgery consists of debridement of infected material and valve replacement. Antimicrobial therapy should be started before surgery.

## Bacterial Endocarditis Prophylaxis

**Q. Write short essay/note on prevention of infective endocarditis/prevention of infective endocarditis before dental procedure.**

**Q. Write short essay/note on antibiotic prophylaxis against infective endocarditis during dental procedure/during urogenital surgery.**

**Q. Write short essay/note on prophylaxis of infective endocarditis.**

**Prophylaxis** is not needed for routine local anesthetic injections through noninfected tissue, placement of removable prosthodontic or orthodontic appliances, shedding of deciduous teeth, vaginal delivery, and hysterectomy or tattooing, bronchoscopy, laryngoscopy, endotracheal intubation, cystoscopy, colonoscopy or skin suturing.

### **Indications**

**Cardiac lesions:** For which antibiotic prophylaxis is advised is listed in Box 7.47.

**Box 7.47:** Infective endocarditis prophylaxis.

#### **High-risk group**

- Prosthetic heart valves
- Prior bacterial endocarditis
- Complex cyanotic congenital heart disease
- Surgically constructed systemic-pulmonary shunts
- Repaired shunts within 6 months
- Valvulopathy after cardiac transplantation

#### **Moderate-risk group**

- Congenital cardiac malformations (other than those listed in other 2 groups)
- Acquired valvular dysfunction (e.g. rheumatic heart disease)
- Hypertrophic cardiomyopathy
- Mitral valve prolapse with valvular regurgitation, thickened leaflets, or both

#### **Negligible-risk group**

- Isolated secundum atrial septum defect
- Surgical repair of atrial septal defect, ventricular septal defect, or patent ductus arteriosus
- Previous coronary artery bypass graft surgery
- Mitral valve prolapse without valvular regurgitation
- Physiologic, functional, or innocent heart murmurs
- Previous Kawasaki syndrome without valvular dysfunction
- Previous rheumatic fever without valvular dysfunction
- Cardiac pacemakers (intravascular and epicardial) and implanted defibrillators

**Q. Write short note on infective endocarditis/subacute infective endocarditis (SBE) prophylaxis.**

- **Procedures:** Endocarditis prophylaxis is advised in patient at high or moderate risk for endocarditis. These include following procedures:
  - **Dental procedures:** Extraction, periodontal procedures, implant placement, root canal instrumentation, intra- ligamentary injections (anesthetic).
  - **Respiratory procedure:** Bronchoscopy with rigid bronchoscope operations involving the mucosa.
  - **Gastrointestinal procedures:** Sclerotherapy of esophageal varices, stricture dilation, ERCP, biliary tract surgery, surgery involving mucosa.
  - **Genitourinary procedures:** Urethral dilation, prostate or urethral surgery or cystoscopy.

**Antibiotic regimen for prophylaxis of endocarditis in adults at moderate or high-risk**

***Oral Cavity, Respiratory Tract, or Esophageal Procedures***

- Standard regimen: **Amoxicillin 2.0 gm PO 1 hour before procedure.**
- Inability to take oral medication: Ampicillin 2.0 g IV or IM within 30 minutes of procedure.
- Penicillin allergy
  - Clarithromycin 500 mg PO 1 hour before procedure.
  - Cephalexin or cefadroxil 2.0 g PO 1 hour before procedure.
  - Clindamycin 600 mg PO 1 hour before procedure or IV 30 minutes before procedure.
- Inability to take oral medication: Cefazolin 1.0 g IV or IM 30 minutes before procedure.

**Note:** For patients at high-risk administer of half-dose 6 hours after the initial dose.

***Genitourinary and Gastrointestinal Tract Procedure***

- High-risk patients: Ampicillin 2.0 g IV or IM plus gentamicin 1.5 mg/kg IV or IM within 30 minutes of procedure. Repeat ampicillin, 1.0 gm IV or IM or amoxicillin 1.0 g PO 6 hours later.
- High-risk penicillin-allergic patients: Vancomycin 1.0 g IV or 1M over 1–2 h plus gentamicin 1.5 m/kg IV or IM within 30 minutes before procedure, no second dose recommended.

- Moderate-risk patients: Amoxicillin 2.0 g PO 1 hour before procedure or ampicillin 2.0 g IV or IM 30 minutes before procedure.
- Moderate-risk, penicillin-allergic patients: Vancomycin 1.0 g IV infused over 1–2 hours and completed within 30 minutes of procedures.

**Culture-negative infective endocarditis (IE)** is defined as endocarditis without etiology following inoculation of three blood samples in a standard blood culture system (e.g. negative cultures after 7 days).

Reasons for culture-negative in infective endocarditis:

1. Administration of antimicrobial agents prior to blood culture incubation.
2. Inadequate microbiological techniques.
3. Infection with highly fastidious bacteria or nonbacterial pathogens (e.g. fungi).

## Noninfective Endocarditis

**Q. Write short essay/note on noninfective endocarditis.**

Characterized by the formation of sterile platelet and fibrin thrombi on cardiac valves and adjacent endocardium.

- It develops in response to trauma, circulating immune complexes, vasculitis or a hypercoagulable state.
- Symptoms are caused due to systemic arterial embolism.
- Diagnosis is by echocardiography and negative blood cultures.

### ***Marantic Endocarditis (Nonbacterial Thrombotic Endocarditis—NBTE)***

#### *Etiology*

- NBTE is often encountered in a number of conditions. These include debilitated patients with cancer or sepsis, hence previously termed **marantic endocarditis** (root word **marasmus**, relating to malnutrition). It frequently develops concomitantly with deep venous thrombosis, pulmonary emboli, or underlying systemic hypercoagulable state and advanced malignancy. There is a striking association with mucinous adenocarcinomas, potentially relating to the procoagulant effects of tumor-derived mucin or tissue.
- Other less common causes include systemic lupus erythematosus, antiphospholipid syndrome, rheumatic heart disease, rheumatoid arthritis

and burns.

Vegetations are small, bland and usually attached to the line of closure of valve leaflets.

**Treatment:** Consists of systemic anticoagulant therapy and treatment of the underlying malignancy or associated condition.

### ***Libman-Sacks Endocarditis***

- Libman-Sacks endocarditis (otherwise known as verrucous endocarditis) is characteristic cardiac manifestation of the autoimmune disease such as systemic lupus erythematosus.
- Pathogenesis: It produced due to circulating immune complexes.
- Endocarditis: It is characterized by small or medium-sized vegetations on either side of the valve leaflets. They appear mulberry-like clusters of verrucae and consist of accumulations of immune complexes and mononuclear cells.

## HEART FAILURE

- Q. Define heart failure. Discuss the types, common cause, pathophysiology, clinical features and management of heart failure.
- Q. Describe the etiology, clinical features and management of chronic heart failure. Mention the factors which will acutely decompensate a patient with chronic stable heart failure.
- Q. Discuss the symptoms and signs of heart failure. Outline the rational management.
- Q. Describe the etiology, classification, clinical features, diagnosis and management of congestive cardiac failure (heart failure).
- Q. Outline the clinical features, investigations and treatment of congestive cardiac failure with hypertensive heart disease.
- Q. Define heart failure.

**Definition:** Heart failure or cardiac failure is the pathophysiological process in which the heart as a pump is unable to meet the metabolic requirements of the tissue for oxygen and substrates despite the venous return to heart is either normal or increased.

- It is a complex syndrome that can result from any structural or functional cardiac disorder. In heart failure, **heart is unable to pump blood at a rate of sufficient to meet the metabolic demands of the tissues** or can do so only at an elevated filling pressure.
- Older term **congestive heart failure** (CHF) should be avoided because not all patients with heart failure have volume overload. Hence the term heart failure is preferred.
- Heart failure is the **common end stage** of many forms of **chronic heart disease** and most **common reason for hospitalization in adults >65 years of age**.
- Heart failure **usually develops insidiously** from the cumulative effects of chronic work overload (e.g. in valve disease or hypertension) or ischemic heart disease (e.g. following myocardial infarction with heart damage).

However, acute hemodynamic stresses, such as fluid overload, sudden valvular dysfunction, or myocardial infarction, can cause sudden heart failure.

## Pathophysiology

### **Q. Write short essay/note on pathophysiology of heart failure.**

- Cardiac output is determined by preload (the volume and pressure of blood in the ventricles at the end of diastole), afterload (the volume and pressure of blood in the ventricles during systole) and myocardial contractility.
- Myocardial contractility (inotropic state): It depends on the adrenergic nervous activity and the levels of circulating catecholamines.

### ***Heart Failure***

- In the intact heart, myocardial failure causes reduction of the volume of blood ejected with each heart beat and an increase the volume of blood remaining after systole. This increased diastolic volume stretches the myocardial fibers and restores the myocardial contraction. However, the failing myocardium results in myocardial depression (of the ventricles).
- Heart failure is a progressive disorder that is initiated after an index event that either damages the heart muscle (with loss of functioning cardiac myocytes) or disturbs the myocardial ability to generate force (prevents the heart from contracting normally). The common feature of these events is a decrease in the pumping capacity of the heart. The compensatory mechanisms include tachycardia, increased myocardial contractility and activation of neurohumoral systems.

If the **heart failure progresses**, the compensatory mechanisms are overwhelmed and **become pathological**. Thus, there is pathological peripheral vasoconstriction and sodium retention. Heart failure is the **common end stage** of many forms of **chronic heart disease**.

- Heart failure **usually develops insidiously** from the cumulative effects of chronic work overload (e.g. in valve disease or hypertension) or ischemic heart disease (e.g. following myocardial infarction with heart damage). However, acute hemodynamic stresses, such as fluid overload, sudden valvular dysfunction, or myocardial infarction, can cause sudden heart failure.

**Q. Write short note on ventricular remodeling/cardiac remodeling.**

**Ventricular remodeling/cardiac remodeling:** Refers to the changes in size, shape, structure and physiology of the heart after injury to the myocardium.

- Left ventricular remodeling is the process by which mechanical, neurohormonal, and possibly genetic factors alter ventricular size, shape, and function.
- Remodeling occurs in several clinical conditions, including myocardial infarction, hypertension, cardiomyopathy and valvular heart disease.
- It is characterized by *hypertrophy, loss of myocytes, and increased interstitial fibrosis.*

Mechanism of heart failure is depicted in Flowchart 7.5.

## Types of Heart Failure

**Q. Write short note on types of heart failure.**

### *Depending on Output*

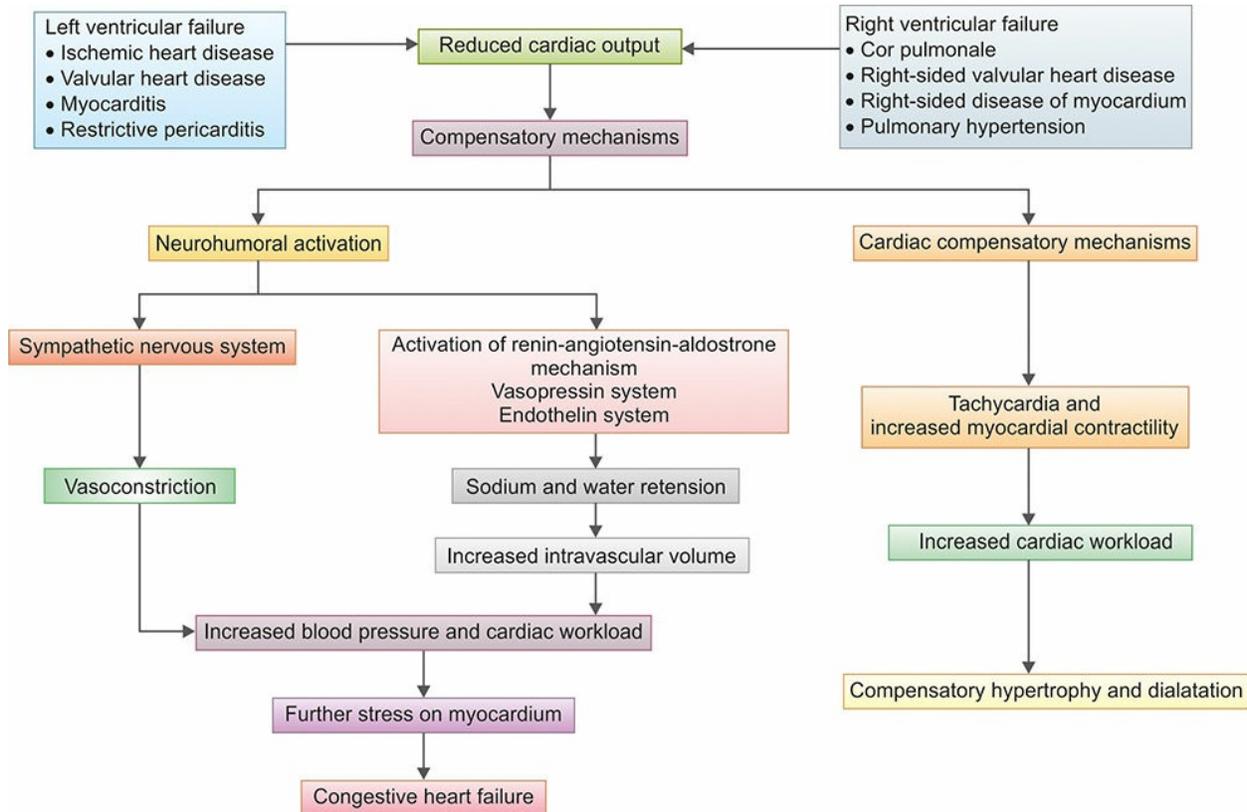

- **Low-output heart failure**
  - **Systolic heart failure:** Characterized by decreased cardiac output and decreased left ventricular ejection fraction.
  - **Diastolic heart failure:** Characterized by elevated left and right ventricular end-diastolic pressures and may have normal left ventricular ejection fraction.
- **High-output heart failure:** Characterized by failure of the heart to maintain sufficient circulation despite an increased cardiac output (*defined as cardiac output  $>8$  L/minute or a cardiac index  $>3.9$  L/minute/m<sup>2</sup>*). Examples include cardiac failure associated with hyperthyroidism, anemia, pregnancy, arteriovenous fistulae, beriberi and Paget's disease.

### *Diastolic and Systolic Dysfunction*

- **Systolic dysfunction:** Systolic heart failure is characterized by an abnormality of **ventricular contraction**. The ejection fraction is usually below 40%. Causes include coronary artery disease, hypertension and valvular heart disease.
- **Diastolic dysfunction:** Characterized by an impaired **ventricular relaxation** and increased ventricular stiffness resulting in reduced filling

(diastolic dysfunction). Causes include hypertension, coronary artery disease, hypertrophic obstructive cardiomyopathy (HOCM), restrictive cardiomyopathy.

**Flowchart 7.5:** Mechanism of heart failure

## ***Acute and Chronic Heart Failure***

- **Acute heart failure** is characterized by sudden development of heart failure. This suddenly reduces cardiac output and systemic hypotension without peripheral edema. Examples include acute myocardial infarction and rupture of a cardiac valve. Acute left heart failure may develop either de novo or as an acute decompensated episode, on a background of chronic heart failure (acute-on chronic heart failure).
- **Chronic heart failure** is characterized by gradual development of heart failure and systemic arterial pressure is well maintained, but edema develops. Examples include dilated cardiomyopathy and multivalvular disease.
- **Compensated heart failure** is the term used to describe the condition of those with impaired cardiac function, in whom adaptive/compensatory

changes have prevented the development of overt heart failure. Severe overt or acute heart failure may precipitated by minor insult such as an infection or development of atrial fibrillation.

### ***Left-sided, Right-sided and Biventricular Heart Failure***

The left side of the heart consists of the functional unit of the left atrium, left ventricle, mitral and aortic valves. The right side of the heart consists of the right atrium, right ventricle, and tricuspid and pulmonary valves.

- **Left-sided (left ventricular) heart failure** is characterized by:
  - Reduction in left ventricular output
  - **Increase in left atrial and pulmonary venous pressure:** An acute increase in left atrial pressure produces pulmonary congestion or pulmonary edema (e.g. myocardial infarction). A more gradual increase in left atrial pressure leads to reflex pulmonary vasoconstriction, which prevents the development pulmonary edema (e.g. in mitral stenosis, aortic stenosis). This increases pulmonary vascular resistance and leads to pulmonary hypertension, which in turn can impair the function of right ventricle.
- **Right-sided (right ventricular) heart failure** is characterized by:
  - Reduction in right ventricular output.
  - Increase in right atrial and systemic venous pressure.
  - Causes of isolated right heart failure, e.g. chronic lung disease (cor pulmonale), multiple pulmonary embolism and pulmonary valvular stenosis.
- **Biventricular heart failure** is characterized by failure of the ventricles of the left and the right heart.
  - Dilated cardiomyopathy or ischemic heart disease, affects both ventricles
  - Disease of the left heart leads to chronic elevation of the left atrial pressure, pulmonary hypertension and leading to right heart failure.

**Table 7.80** Causes of heart failure (HF).

**Reduced Ejection Fraction (<40% HFrEF)**

<ul style="list-style-type: none"> <li>• Nutritional disorders (beriberi)</li> </ul>	

### ***Forward and Backward Heart Failure***

- Forward heart failure is characterized by decreased cardiac output, inadequate perfusion of organs that causes poor tissue perfusion. Reduced renal perfusion activates renin-angiotensin-aldosterone system resulting in excessive absorption of sodium by renal tubules.
- Backward heart failure is characterized by a normal cardiac output, severe salt and water retention, and venous congestion in the pulmonary and systemic circulation.

Causes of heart failure are listed in Table 7.80.

#### **Q. Write short note on causes of heart failure.**

In practice, the most common causes of heart failure are ischemic heart disease, hypertensive heart diseases.

#### **Q. Write short essay/note on factors that precipitate heart failure.**

**Factors that may precipitate or aggravate heart failure in pre-existing heart disease (Box 7.48).**

**Risk factors for heart failure:** Hypertension, diabetes mellitus, use of cardiotoxic substances (e.g. alcohol, tobacco and cocaine), hyperlipidemia, coronary artery disease.

**Box 7.48:** Precipitating factors for heart failure.

- Intercurrent illness, e.g. **infection**

- Supervening heart diseases, e.g. myocardial ischemia or **infarction**, myocarditis, infective endocarditis
- Cardiac **arrhythmia**, e.g. atrial fibrillation
- Poor compliance with therapy
- Administration of a drug with negative inotropic ( $\beta$ -blocker), disopyramide, or fluid-retaining properties [nonsteroidal anti-inflammatory drugs (NSAIDs), corticosteroids]
- Pulmonary embolism
- Conditions associated with increased metabolic demand, e.g. **anemia** pregnancy, thyrotoxicosis
- IV fluid overload, e.g. postoperative IV infusion
- Systemic hypertension
- Excess salt intake
- Physical and emotional stress

## Clinical Manifestations of Heart Failure (Table 7.81)

**Q.** Write short essay/note on clinical features (symptoms and signs) of heart failure and acute left ventricular failure.

### *Symptoms*

#### *Dyspnea*

- **Exertional dyspnea**
- **Orthopnea**
- **Paroxysmal nocturnal dyspnea (PND)**
- **Cardiac asthma** is closely related to PND and nocturnal cough. It is characterized by wheezing (secondary to bronchospasm) which is most prominent at night. Acute pulmonary edema represents a severe form of cardiac asthma.
- **Acute pulmonary edema**
- **Cheyne-Stokes respiration.**

#### *Nocturia*

It is observed during early heart failure. It is because renal perfusion and diuresis is better at night when the patient is supine.

#### *Cerebral symptoms*

Includes confusion, difficulty in concentration, impaired memory, headache, insomnia and anxiety. These symptoms may be produced due to arterial hypoxemia and reduced cerebral perfusion.

### Nonspecific symptoms

- Fatigue due to low cardiac output and weakness due to decreased perfusion of skeletal muscles.
- Low-grade fever due to reduction of cutaneous blood flow.
- Anorexia, nausea, abdominal fullness/pain due to congestion of liver and portal venous system.

**Table 7.81** Symptoms and signs of heart failure.

Symptoms	Signs	
<b>Left ventricular failure</b>		
Dyspnea <ul style="list-style-type: none"> <li>• Exertional dyspnea</li> <li>• Orthopnea</li> <li>• Paroxysmal nocturnal dyspnea</li> <li>• Acute pulmonary edema</li> </ul> Cough Fatigue Decreased urine output	Cardiac sign <ul style="list-style-type: none"> <li>• Enlargement of LV</li> <li>• Gallop rhythm S<sub>3</sub></li> <li>• Systolic murmur in apex</li> </ul> Pulmonary sign <ul style="list-style-type: none"> <li>• Crepitations</li> </ul> Pleural effusion	<b>Think FACES:</b> Fatigue, Activities limited, Chest congestion, Edema or ankle swelling, and Shortness of breath.
<b>Right ventricular failure</b>		
Leg swelling Symptom of gastrointestinal— anorexia Symptom of renal origin— oliguria Pain in right hypochondrium Dyspnea	Raised JVP Hepatojugular reflux positive Hepatomegaly Edema Pleural fluid and ascites	

## Signs

### Dependent/cardiac edema

- **Dependent/cardiac edema:** Due to gravity, fluid accumulates over dependent parts of the body. In ambulant patients, it is found symmetrically in the both legs, particularly in the pretibial region and around the ankles. It is less in the morning and become more towards the evening. In bedridden patients, it is observed in the sacral region.
- **Anasarca:** In advanced heart failure, the fluid accumulating throughout the body and is severe termed as anasarca. Face and upper limbs are usually spared until the terminal stages.

*Cyanosis: It is usually observed in lips and nail beds. The extremities appear cold and pale due to reduced blood flow.*

*Pulse: Pulse volume is reduced and pulsus alternans is a sign of severe heart failure.*

#### *Blood pressure*

- Reduced pulse pressure is due to reduced stroke volume.
- Occasionally, there may be mild elevation of diastolic blood pressure due to generalized vasoconstriction.
- Hypotension is prominent in acute heart failure.

#### *Jugular venous pressure (JVP)*

- JVP is raised because of elevated systemic venous pressure.
- JVP may not be raised at rest during early stages of heart failure. It may be demonstrated:
  - During and immediately after exercise
  - With sustained pressure on the abdomen (positive hepatojugular or abdominojugular reflux).

#### *Third and fourth heart sound*

- Presence of a third heart sound is highly suggestive of heart failure.
- Triple/quadruple/summation gallop seen.

#### *Respiratory system*

- **Percussion:** Dull percussion notes over the bases of lungs (infra-scapular, infra-axillary areas).
- **Auscultation:** Inspiratory crepitations over the bases of lungs. If there is pulmonary edema, coarse crepitations are heard widely over both lung fields associated with expiratory rhonchi.

#### *Liver (congestive hepatomegaly)*

- **Hypoglycemia** can develop in long-standing cases due to depletion of glycogen stores in liver and increased production of lactic acid from glucose, induced by hypoxia.
- **Jaundice:** Hyperbilirubinemia of both conjugated and unconjugated type may be a late feature. In acute hepatic congestion jaundice is severe and liver enzymes are markedly elevated.

### *Effusion*

- **Pleural effusion** develops more commonly on the right side and is due to raised pleural capillary pressure and transudation of fluid into pleural space.
- **Ascites** is due to transudation secondary to raised pressure in the hepatic vein, portal veins and veins draining the peritoneum.
- **Pericardial effusion:** Rare.

### *Renal system*

- Poor renal perfusion leads to oliguria and prerenal azotemia (uremia). Blood urea is usually raised out of proportion to serum creatinine.
- **Urine:** Specific gravity of urine is high, mild proteinuria seen and urinary sodium is low.

### *Cardiac cachexia*

Chronic heart failure is sometimes associated with severe anorexia, marked weight loss (cardiac cachexia), impaired absorption due to gastrointestinal congestion and skeletal muscle atrophy due to immobility.

## **Framingham Criteria for Diagnosis of Heart Failure (Table 7.82)**

The diagnosis of heart failure should not be made on history and clinical findings alone. It requires evidence of cardiac dysfunction (by investigation) and identification of the underlying cause of heart failure in all cases.

*Criteria for Diagnosis of Heart Failure: **One major + two minor***

**Table 7.82** Framingham criteria for diagnosis of heart failure.

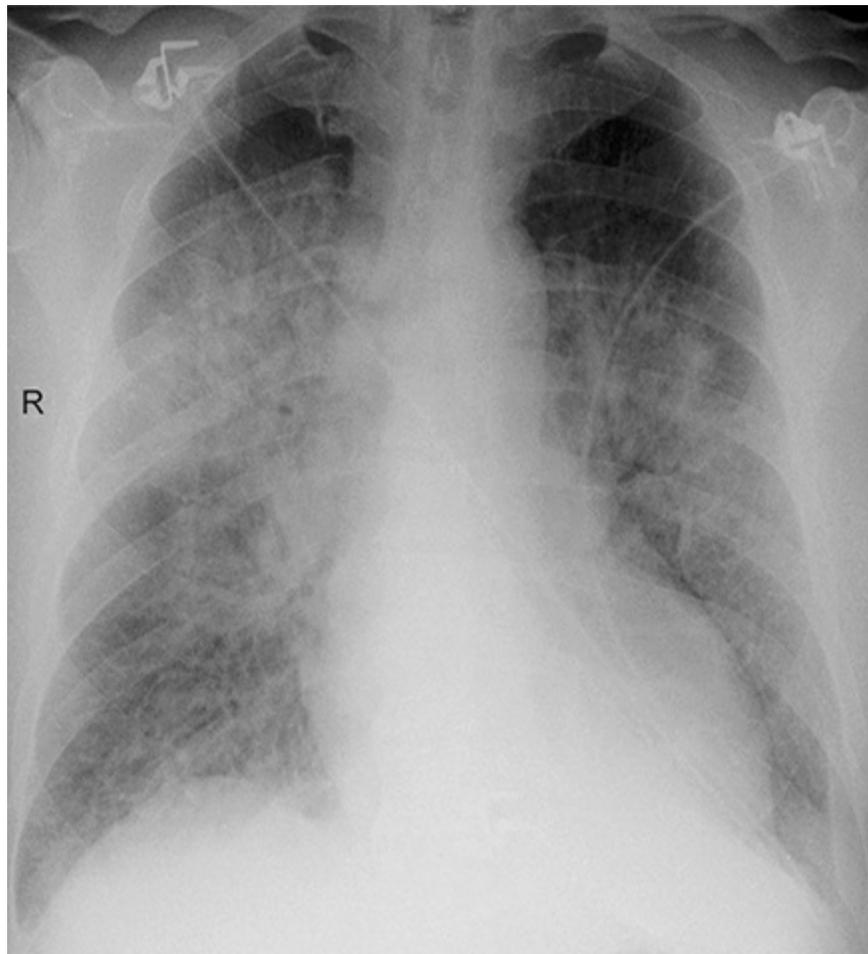

<b>Major</b>	<b>Minor</b>
<ul style="list-style-type: none"><li>• Paroxysmal nocturnal dyspnea</li><li>• Distension of neck vein</li><li>• Rales</li><li>• Cardiomegaly</li><li>• Acute pulmonary edema</li><li>• S<sub>3</sub> gallop</li><li>• Increased venous pressure (&gt;16 cm H<sub>2</sub>O)</li><li>• Positive hepatojugular reflux</li><li>• Weight loss ≥4.5 kg over 5 days treatment</li></ul>	<ul style="list-style-type: none"><li>• Extremity edema</li><li>• Night cough</li><li>• Dyspnea on exertion</li><li>• Hepatomegaly</li><li>• Pleural effusion</li><li>• Vital capacity reduced by one-third from normal</li><li>• Tachycardia (≥120 beats per minute)</li></ul>

## Investigations in Heart Failure

- **Chest X-ray:** It may reveal cardiomegaly. Other findings include phantom tumor (fluid in horizontal or oblique fissures of lungs which disappears after treatment with diuretics), bat's wing appearance (hazy opacification spreading from the hilar regions on both sides (Fig. 7.46), and pleural effusion (bilateral or unilateral).
- **Electrocardiography:** It may reveal previous MI, active ischemia, ventricular hypertrophy (e.g. due to hypertension), atria abnormality, arrhythmias, and conduction abnormalities (e.g. arrhythmia).
- **Echocardiography** is very useful to: (1) determine the etiology, (2) detect any unsuspected valvular heart disease (e.g. occult mitral stenosis), (3) identify patients who will benefit from long-term drug therapy (e.g. ACE inhibitors), (4) assess cardiac chamber dimension (size and shape), ejection fraction, valvular functions, cardiomyopathies and regional wall motion abnormalities and (5) differentiate between systolic and diastolic heart failure.
- **Stress echocardiography:** It helps in assessing the viability in dysfunctional myocardium. Dobutamine stress identifies contractile reserve in stunned or hibernating myocardium.
- **Nuclear cardiology:** Radionucleotide angiography (RNA) is useful for quantify ventricular ejection fraction, single photon emission computed tomography (SPECT) or positron emission tomography (PET) can reveal myocardial ischemia and viability in dysfunctional myocardium.
- **CMR (cardiac MRI):** It helps to assess the viability in dysfunctional myocardium with the use of dobutamine for contractile reserve or with gadolinium for delayed enhancement ('infarct imaging').
- **Cardiac catheterization:** It is useful in the diagnosis of ischemic heart failure (and suitability for revascularization), measurement of pulmonary artery pressure, left atrial (wedge) pressure, left ventricular end diastolic pressure.
- **Cardiac biopsy:** It is useful in the diagnosis of cardiomyopathies (e.g. amyloid) and follow-up of cardiac transplanted patients to assess rejection.
- **Cardiopulmonary exercise testing:** Peak oxygen consumption (VO) is useful in predicting hospital admission and death in heart failure.
- **Ambulatory 24 hour ECG monitoring (Holter):** May be necessary in

patients with suspected arrhythmia. It may be useful in severe heart failure or inherited cardiomyopathy to decide the necessity of defibrillator.

- **Brain natriuretic peptide (BNP) or N-terminal portion of proBNF (NPproBNP)** is elevated in heart failure and highly sensitive for the diagnosis of its diagnosis. It is a marker of risk (**>100 pg/mL**) and is useful in the investigation of patients with breathlessness or peripheral edema (to differentiate cardiac from respiratory cause of acute dyspnea).
- **Blood tests:** Full blood count, liver function tests, serum urea, creatinine and electrolytes, cardiac enzymes in acute heart failure, thyroid function may help to establish the nature and severity of the underlying heart disease and detect any complications.
- **Invasive hemodynamic monitoring:** Useful in selected patients with acute heart failure who have persistent symptoms in spite of empiric standard therapies.

**Fig. 7.46:** Chest X-ray in heart failure showing bat wing appearance.

## Complications in Advanced Heart Failure

- **Renal failure: Cardiorenal syndrome** (poor renal perfusion caused by low cardiac output) may be worsened by therapy [e.g. diuretics, angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers].
- **Hypokalemia:** Due to the result of treatment with potassium-losing diuretics or hyperaldosteronism produced by activation of the renin-angiotensin system and impaired aldosterone metabolism due to congestion of liver.
- **Hyperkalemia:** Due to the effects of drugs which promote renal resorption of potassium (e.g. combination of ACE inhibitors or angiotensin receptor blockers, and mineralocorticoid receptor antagonists).
- **Hyponatremia:** May develop in severe heart failure and is a poor prognostic sign. It may be due to diuretics, inappropriate retention of water (due to high ADH secretion), or failure of the cell membrane ion pump.
- **Hepatic dysfunction:** Due to hepatic venous congestion and poor arterial perfusion.
- **Thromboembolism:** Deep vein thrombosis and pulmonary embolism may develop due to the effects of a low cardiac output and immobility. Systemic emboli may develop in patients with atrial fibrillation or flutter, or with intracardiac thrombus complicating conditions such as mitral stenosis, MI or left ventricular aneurysm.
- **Atrial and ventricular arrhythmias:** Very common and include atrial fibrillation (20%), sudden death (50%) due to a ventricular arrhythmia, ventricular ectopic beats and non-sustained ventricular tachycardia. They may be due to electrolyte changes (e.g. hypokalemia, hypomagnesemia), the underlying heart disease, and the pro-arrhythmic effects of sympathetic activation.

**Q. Write short essay on management of congestive heart failure.**

**Q. Write short note on lifestyle measures in heart failure.**

### Management of Heart Failure

**Aim of treatment:** (1) Relief of symptoms, (2) prevent and control of disease causing cardiac dysfunction and heart failure, (3) retard disease progression and (4) improve quality and length of

life.

### **A. General Lifestyle Advice/Measures**

- **Education of patients and their relatives:** Explanation of nature of disease, about the causes and treatment of heart failure.
- **Measures to prevent heart failure:** Cessation of smoking and illicit drugs, control of hypertension, diabetes and hypercholesterolemia, and pharmacological treatment following myocardial infarction. Identify and treat any factor that aggravates the heart failure.
- **Treatment of the underlying cause of heart failure (e.g. coronary artery disease):** Wherever possible to prevent progression to heart failure.
- **Dietary modifications:** Good general nutrition and maintain desired weight and body mass index. Avoid large meals, foods rich in salt or added salt. Diet low in fat, rich in fruit and vegetables, and increase fiber. Fluid restriction (limited to 1.5 liters) is needed only when heart failure is severe. Alcohol has a negative inotropic effect and should be avoided. Omega-3 polyunsaturated fatty acids reduce mortality and admission.
- **Physical activity, exercise and emotional rest:**
  - **Physical activity and exercise:** Regular low level endurance exercise (e.g. 20–30 minutes walking three or five times/week at 70–80% of peak heart rate) reverses ‘deconditioning’ of peripheral muscle metabolism and is advisable in patients with compensated heart failure. Avoid strenuous isometric activity.
  - **Bed rest:** Reduces the demands on the heart. Bed rest for a few days is for patients with exacerbations of congestive cardiac failure. However, prolonged bed rest may predispose to deep vein thrombosis. This can be avoided by daily leg exercises, low-dose subcutaneous heparin and elastic support stockings.

### **B. Drug Therapy/Management**

- Function of heart can be improved by increasing contractility, reducing preload or afterload. Drugs that reduce preload are used in patients with high end-diastolic filling pressures and pulmonary or systemic venous congestion. Drugs that reduce afterload or increase myocardial contractility are used in patients with signs and symptoms of a low cardiac output.
  - **Diuretic therapy**
    - ◆ In heart failure, diuretics act by increasing the urinary excretion of salt (sodium) and water leading to reduction in blood and plasma volume. Diuretics reduce preload and improves pulmonary and systemic venous congestion. They may also reduce afterload and ventricular volume and increase cardiac efficiency.
    - ◆ Loop diuretics (e.g. furosemide 20–40 mg once or twice) and thiazide diuretics (e.g. hydrochlorothiazide 25 mg once or twice, or metolazone 2.5–5 mg OD) are given to patients with fluid overload.
    - ◆ In severe heart failure, the combination of a loop and thiazide diuretic may be needed. Regular monitoring of serum electrolytes and renal function is necessary because of risk of hypokalemia and hypomagnesemia.
    - ◆ Mineralocorticoid receptor antagonists, such as spironolactone (12.5–25 mg once or twice), are potassium-sparing diuretics and are beneficial in patients having heart failure with severe left ventricular systolic dysfunction.
  - **Angiotensin-converting enzyme inhibitors (ACEI) therapy**
    - ◆ **Mechanism of action:** They prevent the conversion of angiotensin I to angiotensin II. This in turn prevents peripheral vasoconstriction, activation of the sympathetic nervous system and salt and water retention due to aldosterone release. Thus, they interrupt the vicious circle of neurohumoral activation that is characteristic of moderate and severe heart failure.

They also prevent the undesirable activation of the renin-angiotensin system caused by diuretic therapy.

- ◆ **Uses:** ACEI improve survival in patients in all functional classes (NYHA I– IV) and are given to all patients at risk of developing heart failure. They improve effort tolerance and mortality. They can also improve outcome, prevent the onset of overt heart failure in patients with asymptomatic heart failure following myocardial infarction.
- ◆ **Initiation:** Start low dose; if tolerated then gradual increase in few days to weeks to target dose or maximum tolerable dose with regular blood pressure monitoring. Serum creatinine should be measured concomitantly and potassium-sparing diuretics should be discontinued.
- ◆ **Drugs and dosage:** Captopril (6.25 mg thrice till 50 mg thrice a day), enalapril (2.5 mg twice to 10–20 mg twice a day), lisinopril (2.5–5 mg once to 20–40 mg once a day), ramipril (1.25–2.5 mg once till 10 mg once a day).
- **Angiotensin II receptor antagonists (ARA)/blockers therapy**
  - ◆ **Indications:** ARAs are indicated as second line therapy in patients intolerant of ACEI or alternative to ACEI.
  - ◆ **Drugs and dosage:** Losartan (25–50 mg once till 50–150 mg once a day), valsartan, telmisartan, olmesartan (20–40 mg twice till 160 mg twice).
  - ◆ Same initiation and monitoring as ACEI and titration by doubling the dose.
- **Beta-adrenoceptor blocker therapy**
  - ◆ **Indications:** To all patients with current or prior HF and a LVEF  $\leq$ 40% (HF<sub>r</sub>EF) in the absence of a contraindication.
  - ◆ Start low and increased gradually over a 12-week period even during hospitalization.
  - ◆ Drugs and dosage bisoprolol (1.25–2.5 mg once till 10 mg once), carvedilol (3.125 twice till 50 mg twice), metoprolol succinate (12.5 once till 200 mg once).
- **Aldosterone receptor antagonists**
  - ◆ **Indications:** NYHA II-IV, EF  $\leq$ 35%, no contraindication (GFR  $>$ 30, creatinine: 2.5 mg/dL male and 2.0 mg/dL female, K $<$ 5 mg/dL). They improve survival in patients with heart failure.
  - ◆ **Dose:** Spironolactone 12.5–25 mg once till 50 mg daily.
  - ◆ **Monitoring:** Stop all K $^{+}$  supplements, check K $^{+}$  and creatinine 2–3 days after starting then one week and every month for 3 months and every 3 month and when clinically indicated.
  - ◆ **Side effects:** Increase K $^{+}$  (10–15%), gynecomastia or breast pain.
- **Digoxin (Cardiac glycoside)**
  - ◆ Digoxin is a cardiac glycoside that is used in patients in atrial fibrillation with heart failure. It can be used as add on therapy in symptomatic heart failure patients already receiving ACEI and beta blockers. No mortality benefit, only decrease frequency of hospitalizations.
  - ◆ No loading required. Usual dose 0.125–0.25 mg daily (low dose 0.125 mg alternate day if  $>$ 70 years, chronic kidney disease, low lean body mass). Maintain 5–0.9 ng/dL plasma concentration (narrow therapeutic range).
- **Vasodilators and nitrates (Hydralazine Nitrate Combination)**
  - ◆ The combination of hydralazine and nitrates reduces afterload and preload. Their use is limited by pharmacological tolerance and hypotension.
  - ◆ **Indication:** African-American origin, NYHA III-IV, low EF on ACEI and BB, patients intolerant or contraindication of ACEI or ARA (e.g. in severe renal failure).
  - ◆ **Dose:** 37.5 mg hydralazine and 20 mg and isosorbide dinitrate start one tab TID to increase till 2 tabs TID.

- **Ivabradine**
  - ◆ Ivabradine acts on the if inward current in the SA node and reduces the heart rate. It reduces hospital admission and mortality rates in patients with heart.
  - ◆ It is best given to patients who cannot take  $\beta$ -blockers or in whom the heart rate remains high despite  $\beta$ -blockade. It is not useful in patients with atrial fibrillation.
- **Anticoagulation therapy** is indicated in patients with heart failure who are at risk for thromboembolism. These include patients with atrial fibrillation, valvular heart disease, documented left ventricular thrombus or a history of embolic stroke.

### C. Nonpharmacological treatment of heart failure

#### **Q. Write a short note on implantable cardioverter defibrillator (ICD).**

- **Device therapy**
  - **Implantable cardioverter defibrillator (ICD):** Patients with symptomatic ventricular arrhythmias and heart failure have a very bad prognosis. Irrespective of their response to anti-arrhythmic drug therapy, implantation of a cardiac defibrillator improves survival of all these patients. It is indicated in nonischemic or ischemic heart disease (at least 40 days post-MI) with LVEF of  $\leq 35\%$  with NYHA class II or III symptoms or NYHA 1 with EF  $\leq 30\%$  on chronic medical therapy, who have reasonable expectation of meaningful survival for more than 1 year.
  - **Cardiac resynchronization therapy (CRT):**
    - ◆ Indicated for patients who have LVEF of 35% or less, sinus rhythm, left bundle-branch block (LBBB) with a QRS duration of 150 ms or greater, and NYHA class II, III, or ambulatory IV symptoms.
    - ◆ In this, both the LV and RV are paced simultaneously to generate a more coordinated left ventricular contraction and improve cardiac output. It improves symptoms and survival.
- **Coronary revascularization:** Coronary artery disease is the most common cause of heart failure. Patients with angina and left ventricular dysfunction have a higher mortality from surgery (10–20%), but most patients' symptoms and prognosis are improved. Coronary artery bypass surgery or percutaneous coronary intervention may improve function in region of the myocardium that is 'hibernating' because of inadequate blood supply. The 'hibernating' myocardium can be identified by stress echocardiography and specialized nuclear or MR imaging. Before recommending for surgery factors such as age, symptoms and evidence for reversible myocardial ischemia must be considered.
  - **Hibernating myocardium and myocardial stunning**
    - ◆ **Hibernating myocardium** is the reversible left ventricular dysfunction with decreased myocardial perfusion, which is just sufficient to maintain viability of the heart muscle. It is due to an underlying chronic coronary artery disease. Myocardial hibernation is produced due to repetitive episodes of cardiac stunning which may occur, e.g. with repeated exercise in a patient with coronary artery disease. It responds positively to inotropic stress and indicates the presence of viable heart muscle that may recover after revascularization.
    - ◆ **Myocardial stunning** is reversible ventricular dysfunction that persists following an episode of ischemia when the blood flow has returned to normal. This is due to a mismatch between flow and function.
- **Heart (Cardiac) transplantation**
  - Cardiac transplantation is an established and successful treatment of choice for younger patients with severe intractable heart failure, whose life expectancy is  $< 6$  months.
  - **Indications:** Usually reserved for young patients with severe symptoms despite optimal therapy. Most common indications are coronary artery disease and dilated cardiomyopathy.

- **Contraindication:** Patients with pulmonary vascular disease due to long-standing left heart failure, complex congenital heart disease (e.g. Eisenmenger’s syndrome) or primary pulmonary hypertension.
- **Ventricular assist devices (VADs)**
  - There is limited supply of donor organs and VADs takes over pumping for the ventricles. Hence, VADs are used as (1) a bridge to cardiac transplantation, (2) potential long-term therapy, (3) short-term restoration therapy following a potentially reversible insult (e.g. viral myocarditis).

Figure 7.47 shows ACC/AHA guidelines (four stages of heart failure and treatment options for systolic heart failure).

### ***Newer Agents in Heart Failure Management***

#### **Q. Discuss newer agents in heart failure management.**

- **Nesiritide (recombinant analog of BNP)**
  - **Actions:** (1) Increase natriuresis, diuresis, and cardiac index. (2) Reduce pulmonary capillary wedge pressure, pulmonary artery pressure, pulmonary vascular resistance, and systemic blood pressure in a dose-dependent manner. (3) Reversal of the deleterious neurohormonal response associated with heart failure. (4) Reduces levels of endothelin 1, aldosterone and norepinephrine.
  - **Advantages:** Does not require ICU admission or invasive monitoring, lower incidence of tachycardia and proarrhythmic effects, and lessen the need for supportive therapies such as diuretics.
- **Endopeptidase inhibitor (ACE + neutral peptidases),** e.g. omapatrilat.
- **Calcium sensitizer:** For example, levosimendan. **Levosimendan** is a novel agent with inotropic properties developed specifically for the management of ADHF (acute decompensated heart failure). It acts by sensitizing troponin C to calcium.
- **Endothelin receptor antagonist:** For example, bosentan, tezosentan. Effective in acute coronary syndromes, acute renal failure and acute heart failure. Indirectly improve contractility while decreasing pulmonary capillary wedge pressure.
- **Vasopressin antagonists (V2 RA):** For example, tolvaptan, lixivaptan, conivaptan. It can be used as adjuvant to diuretic in advanced heart failure.
- **Enoximone:** Type 3 phosphodiesterase inhibitor.
- **Angiotensin receptor-neprilysin inhibitor:** Sacubitril-valsartan for NYHA class II to IV heart failure with reduced ejection fraction.

Management of heart failure based on symptoms, cardiac output and pulmonary capillary wedge pressure is depicted in Figure 7.48.

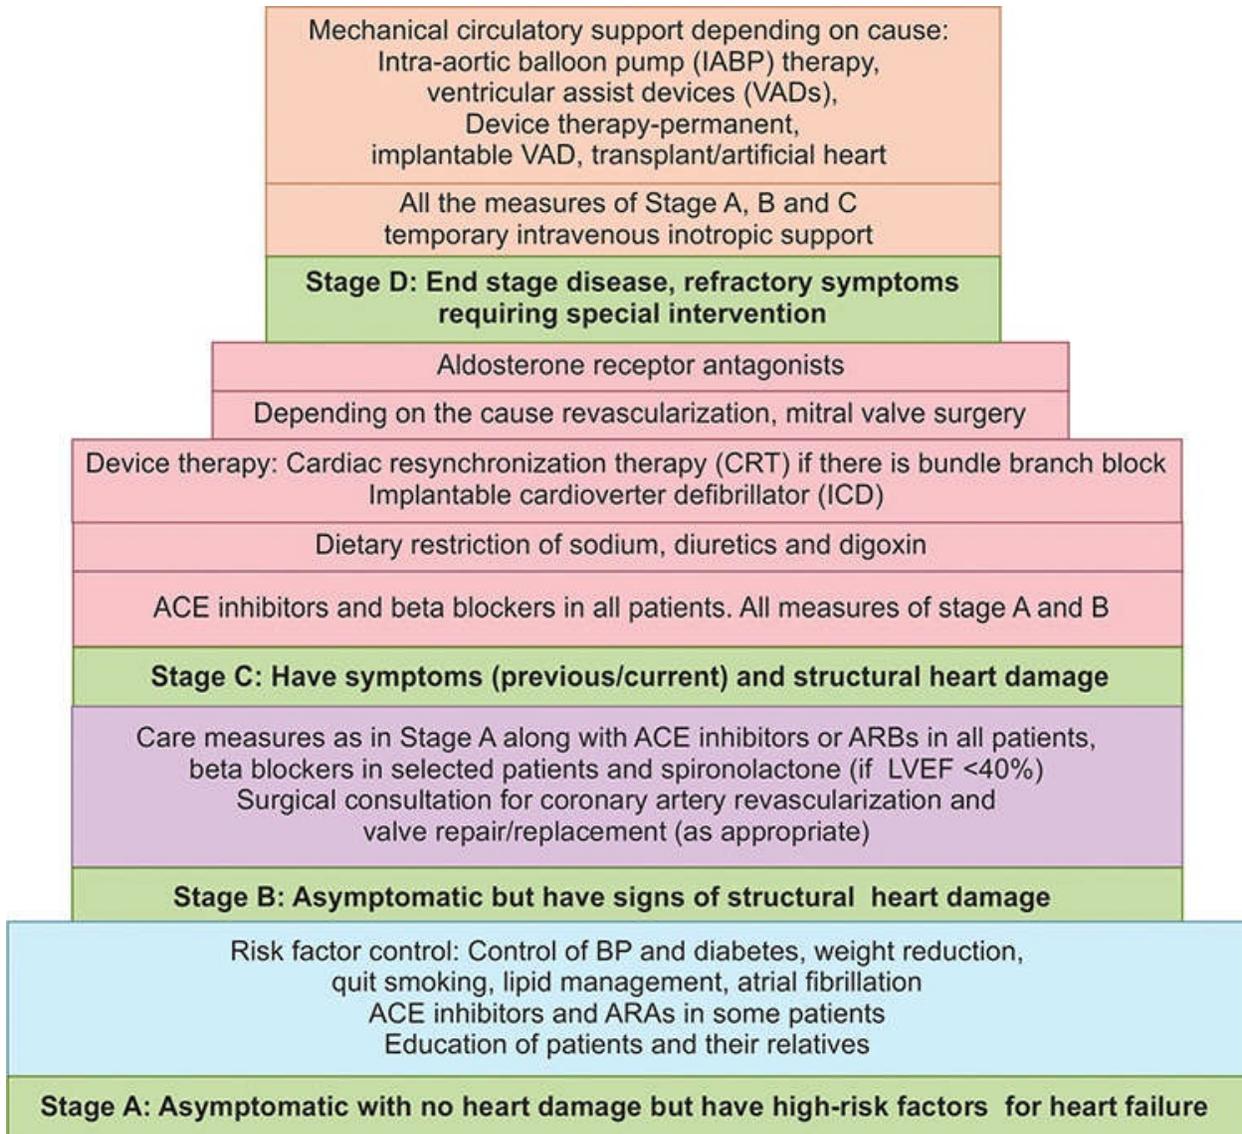

## **Refractory Heart Failure**

### **Q. Write short note on refractory heart failure and its management.**

- Optimal ‘triple therapy’ for patients with chronic congestive heart failure (CHF) includes diuretics, digoxin, and either angiotensin-converting enzyme inhibitors or hydralazine plus nitrates.
- Refractory CHF is defined as symptoms of CHF at rest or repeated

exacerbations of CHF despite ‘optimal’ triple-drug therapy.

- **Management:** It is managed as end stage heart failure, i.e. stage D (Fig. 7.47). Novel agents and nonpharmacological agents can be tried.

**Fig. 7.47:** ACC/AHA guidelines (four stages of heart failure and treatment options for systolic heart failure).

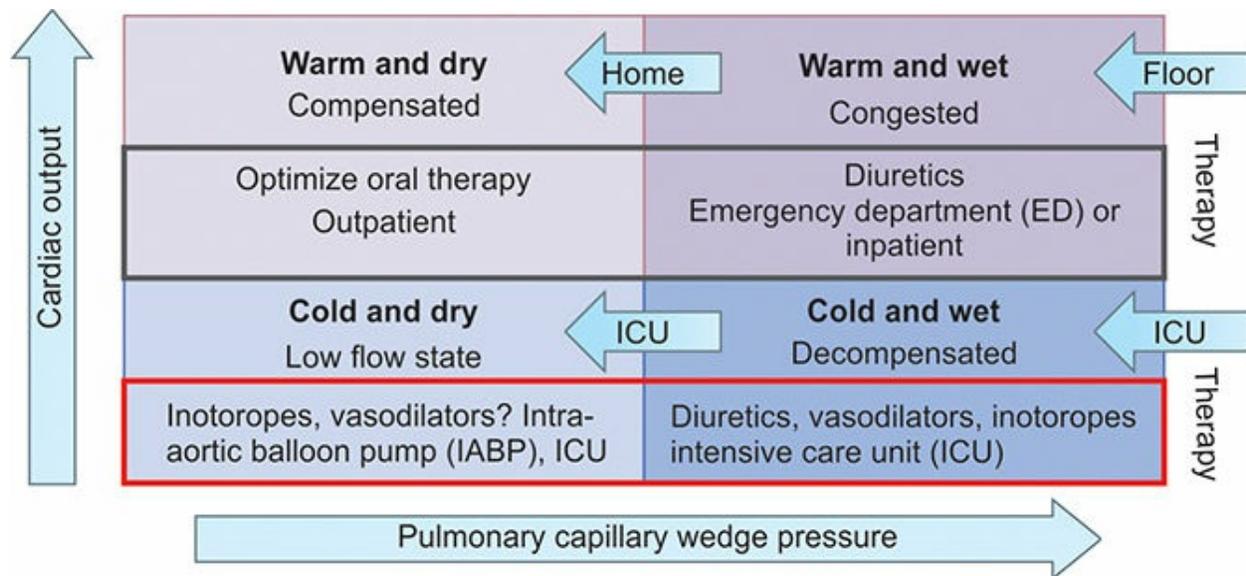

Fig. 7.48: Management of heart failure based on symptoms, cardiac output and pulmonary capillary wedge pressure.

## Brain Natriuretic Peptide

### Q. Write short essay on brain natriuretic peptide (BNP).

- It is called so because it was first discovered in porcine brain. It is a 32-amino acid peptide predominantly secreted by the left ventricles (as a response to left ventricular stretching or wall tension); along with an inactive 76-amino acid N-terminal fragment (NT-proBNP).
- It is activated only after a prolonged period of volume overload. It has an action similar to that of ANP but greater diagnostic and prognostic value as it has a longer half-life.
- **Utility:** Normal values of BNP: <50 pg/mL or <50 ng/L.
  - **Diagnostic and prognostic utility:** BNP levels are raised in conditions associated with left ventricular systolic dysfunction. It is used in the diagnosis of congestive heart failure and useful in patients presenting in the emergency room when the clinical diagnosis of heart failure is uncertain. BNP measurement is used to assess prognosis and monitor response to therapy in patients with heart failure. Raised levels of BNP in heart failure may be associated with an increased risk of death or cardiovascular events.
  - **Other conditions with raised BNP levels:** Renal failure (due to decreased clearance), pulmonary embolism, pulmonary hypertension,

chronic hypoxia, atrial fibrillations, acute myocardial infarction, obese patients and sepsis.

## Pulmonary Edema

**Q. Describe the clinical features, diagnosis and management of acute pulmonary edema.**

**Q. Define pulmonary edema. Enumerate the causes of pulmonary edema.**

**Q. Discuss the etiology, clinical presentation, investigations and management of cardiogenic pulmonary edema. Add a note on the pathophysiology.**

**Q. Discuss the etiology/causes, clinical features, and management of acute left ventricular failure.**

**Q. Define pulmonary edema.**

**Definition:** Pulmonary edema is a condition characterized by accumulation of excess fluid in interstitium and alveoli of the lung as a result of an alteration in one or more of Starling forces.

**Table 7.83** Various causes of pulmonary edema.

<i>Cardiogenic pulmonary edema (CPE)</i>	<i>Non cardiogenic pulmonary edema NCPE [other name of NCPE = ARDS (Acute respiratory distress syndrome)]</i>
<b>Cardiac disorders:</b> Atrial outflow obstruction, LV systolic dysfunction, LV diastolic dysfunction <b>Dysrhythmias</b> <b>LV hypertrophy and cardiomyopathies</b> <b>LV volume overload</b> <b>Myocardial infarction</b> <b>LV outflow obstruction</b>	<b>Direct injury to lung:</b> Chest trauma, pneumonia, pulmonary embolism <b>Indirect injury to lung:</b> Sepsis, multiple transfusions, cardiopulmonary bypass, pancreatitis, toxins <b>Lung injury plus increased hydrostatic pressure:</b> Neurogenic pulmonary edema, high altitude pulmonary edema, re-expansion pulmonary edema

### *Classification and Causes of Pulmonary Edema (Table 7.83)*

**Q. Write short note on the causes of pulmonary edema.**

**Q. Write short essay/note on noncardiac causes of pulmonary edema.**

Pulmonary edema can result from hemodynamic disturbances (hemodynamic or cardiogenic pulmonary edema) or from direct increases in capillary permeability (non-cardiogenic pulmonary edema due to microvascular injury). Based on underlying cause it can be classified as:

- **Cardiogenic pulmonary edema** is defined as a high pulmonary capillary hydrostatic pressure (as estimated clinically from the pulmonary capillary wedge pressure—PCWP) is responsible for abnormal fluid accumulation in alveoli of the lung.
- **Noncardiogenic pulmonary edema** is caused by various disorders in which factors other than elevated pulmonary capillary pressure are responsible for protein and fluid accumulation in the alveoli.

### ***Stages in Development***

- **Interstitial edema:** This is an early stage where edema is limited to interstitium of lung.
- **Alveolar edema:** This occurs later, and characterized by the movement of edema fluid, macromolecules and red blood cells into the alveoli.

### ***Clinical Features of Acute Pulmonary Edema***

#### *Cardiogenic pulmonary edema (CPE)*

- **Clinical features of left heart (acute ventricular) failure:** Extreme breathlessness, shortness of breath orthopnea, and paroxysmal nocturnal dyspnea, anxiety, and feelings of drowning. Cough, pink frothy sputum.
- **Physical findings:**
  - Tachypnea and tachycardia
  - Hypertension
  - Cool extremities may indicate low cardiac output
  - Auscultation reveals fine, crepitations or wheezes
  - **CVS findings:** S<sub>3</sub>, accentuation of pulmonic component of S<sub>2</sub>, jugular venous distention.
  - Patients with (RV) failure may present with hepatomegaly, sustained hepatojugular reflux, and peripheral edema. Change in mental status, caused by hypoxia or hypercapnia.

### *Differences between CPE and NCPE*

- **CPE:** A history of an acute cardiac event is usually present. Physical examination shows an S<sub>3</sub> gallop, jugular venous distention, and crackles on auscultation.
- **NCPE:** They have a warm periphery, a bounding pulse, and no S<sub>3</sub> gallop or jugular venous distention. Definite differentiation is based on pulmonary capillary wedge pressure (PCWP) measurements. The PCWP is generally >18 mm Hg in CPE and <18 mm Hg in NCPE.

### *Unusual Type Pulmonary Edema*

- **Neurogenic pulmonary edema:** Seen in patients with central nervous system disorders and without apparent pre-existing LV dysfunction.
- **Re-expansion pulmonary edema:** Develops after removal of air or fluid that has been in pleural space for some time, post-thoracocentesis. Patients may develop hypotension or oliguria resulting from rapid fluid shifts into lung.
- **High altitude pulmonary edema:** Occurs in young individuals who have quickly ascended to altitudes above 2700 m (8000 feet) and who then engage in strenuous physical exercise at that altitude, before they have become acclimatized. Reversible in less than 48 hours.

### *Investigations*

Same as heart/cardiac failure (refer pages 487-8). ARDS discussed on page 369.

**Q. Write short essay/note on treatment of acute pulmonary edema/acute left ventricular failure.**

**Q. Write short essay/note on treatment of acute pulmonary edema.**

#### **Treatment of acute cardiogenic pulmonary edema**

- **Initial management:** ABCs of resuscitation, i.e. airway, breathing, and circulation.
- Medical treatment of CPE focuses on three main goals:
  1. Reduction of pulmonary venous return (preload reduction).
  2. Reduction of systemic vascular resistance (afterload reduction).
  3. Inotropic support.
- **Oxygenation:** Oxygen should be administered to all patients to keep oxygen saturation at greater than 90%. Methods of oxygen delivery include the use of a face mask [noninvasive ventilation which includes (BiPAP) and (CPAP)], and intubation and mechanical ventilation. Oxygen corrects

hypoxia and positive pressure raises intra-alveolar pressure reducing transudation of fluid.

- **Preload reduction** decreases pulmonary capillary hydrostatic pressure and reduces fluid transudation into the pulmonary interstitium and alveoli. **Nitroglycerin** oral or I/V 10–100 µg/min
- **Diuretics:** They reduce the circulating blood volume and hasten the relief of pulmonary edema. **Intravenous furosemide** has a venodilator action by which it reduces venous return. This effect occurs within a few minutes while diuresis may take 30 minutes.
- **Morphine sulfate:** Morphine 2–5 mg intravenously slowly, and repeated if necessary, reduces anxiety and reduces venous return.
- **Afterload reduction** increases cardiac output and improves renal perfusion, which allows for diuresis in the patient with fluid overload.
  - **ACE inhibitors:** Enalapril 1.25 mg IV or captopril 25 mg sublingually.
  - Angiotensin II receptor blockers.
  - Nitroprusside for 3–4 µg/kg/min IV infusion
- **Inotropic agents:** Dobutamine, dopamine
- **Intra-aortic balloon pumping (IABP)**
  - The IABP is inserted percutaneously through the femoral artery to descending aorta using a modified technique. Fluoroscopy may be used for correct positioning of the balloon, and Helium gas is used to inflate the balloon.
  - The IABP decreases afterload as the pump deflates; during diastole the pump inflates to improve coronary blood flow.
- **Ultrafiltration** is a fluid removal procedure that is particularly useful in patients with renal dysfunction and expected diuretic resistance.
- Correction of precipitating causes, e.g. infection or arrhythmias.
- Treatment of underlying cause.

## CARDIAC ARRHYTHMIAS

**Q.** Write short note on definition of cardiac arrhythmias.

**Definition:** An abnormality (disturbance) of either rate or electrical rhythm of contraction of the heart is called a cardiac arrhythmia.

- Arrhythmias are usually due to structural disease of the heart but may also occur because of abnormal conduction or depolarization in an otherwise healthy heart.

### Main Types of Arrhythmia

- **Bradycardia:** The heart rate is slow and less than 60/min during the day or less than 50/min at night.
- **Tachycardia:** The heart rate is fast and more than 100/min.

### Sinus Arrhythmia

**Q. Write short essay on sinus arrhythmia.**

- Sinus arrhythmia is a normal physiological phenomenon and involves cyclic changes in the heart rate during breathing. Normal variation (phasic changes) of the heart rate in relation to breathing (during respiration) may occur due to fluctuations of normal parasympathetic nervous system (autonomic) activity/tone. *During inspiration, parasympathetic tone falls and the heart rate increases, and on expiration the heart rate decreases.* This variation is normal, especially in children and young adults.
- The non-respiratory form may occur in diseased hearts and sometimes confused with sinus arrest (also known as ‘sinus pause’).
- Typically sinus arrhythmia results in predictable irregularities of the pulse.
- **Significance:** It is the most common arrhythmia and is manifestation of normal autonomic nervous activity. Absence of this normal variation in heart rate with breathing (sinus arrhythmia) or with changes in posture may be seen in autonomic neuropathy and cardiac failure.

**Treatment** is not usually needed unless symptomatic bradycardia is present.

## Ectopic Beats (Extrasystoles; Premature Beats)

**Q. Write short essay/note on ectopic beats (extrasystoles; premature beats).**

- **Definition:** Ectopic beat is a heartbeat occurring as a result of an impulse originating in an area other than the sinoatrial (SA) node.
- **Classification of ectopic beats** is based on the site of origin of the impulse (ectopic focus).
  - **Supraventricular:** Atrial ectopics, atrial premature beats arising from atrium
  - **Junctional:** Arising from AV junction
  - **Ventricular:** Arising from ventricular muscle
- **Symptoms:** Extra beats, thumping beats or missed beats.
- **Signs:** Irregularity in rhythm, missing of beats, post-ectopic bounding beat and cannon waves on JVP.

### ***Supraventricular Ectopics (Atrial Ectopics; Atrial Premature Beats)***

**Q. Write short essay/note on supraventricular ectopics (atrial ectopics; atrial premature beats).**

- **Atrial premature complexes (APCs)** can be found on 24-h holter monitoring in over 60% of normal adults. They are usually asymptomatic and benign.
- **Causes:** Idiopathic in healthy individuals, anxiety, excessive coffee, tea or tobacco, ischemic and valvular heart disease
- **Electrocardiogram (ECG)** shows early abnormal p waves with a morphology that differs from the sinus p waves. It may be inverted if it originates near the AV node. R-R interval preceding and following the ectopic beat is less than twice the basal R-R interval (i.e. pause following the ectopic is not fully compensated).
- Supraventricular ectopics sometimes may precipitate atrial tachycardia, flutter and fibrillation.

**Treatment:** Treatment is useful only if they cause palpitations. Treatment of the underlying cause. Trigger for paroxysmal supraventricular tachycardias (e.g. alcohol, tobacco, or adrenergic stimulants) should be identified and eliminated. In their absence, mild sedation or beta blocker may be tried.

### ***Ventricular Premature Complexes (VPCs)/ Ventricular Premature Beats (VPB)/Ventricular Ectopics***

**Q. Write short essay/note on ventricular ectopics [ventricular extrasystoles; ventricular premature beats, premature ventricular contractions (PVC)].**

- Of adult males,  $\geq 60\%$  will exhibit VPCs during a 24 hours holter monitoring.
- In patients with previous MI, if frequent ( $>10$  per hour) or complex VPCs are present, they are associated with increased mortality.
- **Causes:** Idiopathic in healthy individuals, excessive tea, coffee and alcohol, acute myocardial infarction, myocardial ischemia, myocarditis, digitals toxicity, hypokalemia, mitral valve prolapse.

#### ***Electrocardiogram***

- These premature beats have wide, bizarre QRS complex, more than 0.12 seconds in duration and usually without a preceding P wave. They arise from an abnormal (ectopic) site in the ventricular myocardium.

- Usually following a premature beat there is complete compensatory pause because the AV node or ventricle is refractory to the next sinus impulse.
- The pause is fully compensated so that the sum R-R intervals preceding and following the ectopic QRS equals double the normal sinus R-R interval.
- When a VPC depolarizes the ventricles at a similar time as a conducted atrial beat, a **fusion beat** is observed.
- The term *bigeminy* refers to a normal complex followed by premature complex; *trigeminy* indicates a premature complex that follows two normal beats; a premature complex that occurs after three normal beats is called *quadrigeminy*. Two successive VPCs are known as a couplet, whereas three successive VPCs are called a triplet. Arbitrarily, three or more successive PVCs are termed *Salvos/ventricular tachycardia*. VPCs having different contours are often called multifocal.

#### Treatment

- In the absence of cardiac disease, isolated asymptomatic VPCs regardless of configuration and frequency, does not require any treatment.
- Beta blockers are useful in symptomatic VPCs that occur mainly in the daytime or under stressful situations and in specific settings such as thyrotoxicosis and mitral valve prolapse.
- Implantable cardiac defibrillator (ICD) placement improve prognosis in patients with inducible VT and LV dysfunction.

## Tachycardia

**Q. Write short note on tachycardia/narrow-complex and wide-complex tachycardia. Write a note on tachycardia.**

**Definition:** Tachycardia is defined as a heart rate of more than 100/minute.

### Classification

- Depending on origin:
  - **Supraventricular tachycardia** is a tachycardias which utilize atrial or AV nodal tissue as part of its mechanism (i.e. originating above the bundle of His)
  - **Ventricular tachycardia:** Originate below the level of bundle of His.
- Depending on QRS complex:
  - **Narrow-complex** (QRS complex <0.12 seconds) tachycardia: Usually tachycardia that originates from or above AV node generally produces

narrow QRS complexes.

- **Wide-complex** (QRS >0.12 seconds) tachycardia: Usually, tachycardias that originate below the AV node produce wide QRS complexes.

**Table 7.84:** Various causes of supraventricular tachycardia (SVT).

<i>Tachycardia</i>	<i>ECG findings</i>
Sinus tachycardia	P wave is similar to sinus rhythm preceding QRS
AV nodal re-entry tachycardia (AVNRT) also referred as paroxysmal SVTs	No visible P wave, or inverted P wave immediately before or after QRS complex
AV reciprocating tachycardia (AVRT) complexes	P wave visible between QRS and T wave
Atrial fibrillation	Irregularly irregular RR intervals and no organized atrial activity
Atrial flutter	Visible flutter waves at 300/min (saw tooth appearance) usually with a 2 : 1 AV conduction
Atrial tachycardia	Organized atrial activity with P wave appear morphological different from sinus rhythm preceding QRS
Multifocal atrial tachycardia	Multiple P wave morphologies ( $\geq 3$ ) and irregular RR intervals
Accelerated junctional tachycardia	ECG similar to AVNRT

## ***Supraventricular Tachycardia***

**Q. What do you understand by the term supraventricular tachycardia? Name various supraventricular tachycardia.**

**Q. Write short note on paroxysmal supraventricular tachycardia (PSVT).**

- Supraventricular tachycardia (SVT) is an arrhythmia and the term commonly used to describe regular tachycardia (heart rate exceeding 100 beats/minute) that arise from the atrium or the atrioventricular junction. Its conduction is via the His–Purkinje system. Hence, on ECG the QRS shape during tachycardia is usually similar to that seen in the same patient during baseline rhythm. Various causes of supraventricular tachycardia are presented in Table 7.84.
- These are usually associated with a narrow QRS complex and are characterized by a re-entry circuit or automatic focus involving the atria. The term SVT is misleading, as, in many cases, the ventricles also form part of the re-entry circuit, such as in patients with AV re-entrant tachycardia.

## ***Sinus Tachycardia***

**Q. Write short note on sinus tachycardia.**

**Definition:** It is characterized by a heart rate of more than 100/minute with normal P waves, P-R interval and QRS complexes.

- If rate-dependent blocks appear or an accessory path is present, there may be widened QRS complexes.
- Causes: It is usually due to an increase in sympathetic activity associated with exercise, emotion, or pregnancy, Pathological causes, include anemia, thyrotoxicosis, anxiety, fever, heart failure, pheochromocytoma, drugs, e.g.  $\beta$ -agonists (bronchodilators) embolism and shock.

### **Treatment**

- Identification and treatment of the underlying cause.
- If the tachycardia produces myocardial ischemia treat with  $\beta$ -blockers.

## ***AV Node Re-entry Tachycardia (AVNRT)***

AVNRT is the most common cause of **paroxysmal supraventricular tachycardia (PSVT)**. AVNRT produces a regular tachycardia with a rate of 120–240/min.

**Mechanism:** AVNRT is due to re-entry in a circuit involving the AV node and there are two functionally and anatomically different right atrial input pathways.

1. Superior ‘fast’ pathway has a longer effective refractory period and conducts faster.
2. Inferior ‘slow’ pathway characterized by a short effective refractory period and slow conduction.

If the atrial impulse occurs early (e.g. an atrial premature beat) when the fast pathway is still refractory, the slow pathway takes over in propagating this atrial impulse to the ventricles. It then travels back through the fast pathway which has already recovered its excitability. Thus, initiating the most common ‘slow fast’, or typical, AVNRT.

### *Clinical features*

- It is common in women than men (F:M = 2:1).
- It usually occurs suddenly without any structural heart disease or obvious provocation. However, exertion, coffee, tea and alcohol may aggravate or induce the arrhythmia.
- Episodes/attack may last from a few seconds to many hours and may stop spontaneously or may continue indefinitely until medical intervention.
- During the attack, the patient is usually aware of a rapid, very forceful, regular heart beat and may experience chest discomfort, lightheadedness or breathlessness. Sometimes polyuria (due to the release of atrial natriuretic peptide) may develop.

**ECG:** Usually shows a tachycardia at a rate of 140–240/minute with normal regular QRS complexes. Occasionally, the QRS complexes will show typical bundle branch block.

### **Management**

- Treatment is not always required.
- Episode/attack may be terminated in patients without hypotension by **carotid sinus pressure or by the Valsalva maneuver**.
- If these maneuvers are unsuccessful, **adenosine** (3–12 mg rapidly IV in incremental doses until tachycardia stops) or **verapamil** (5 mg IV over 1 min) will restore sinus rhythm in most of the

patients. Intravenous  $\beta$ -blocker or flecainide may be helpful.

- Rarely, when there is severe hemodynamic compromise, the tachycardia should be terminated by DC cardioversion.
- Recurrent SVT: Catheter ablation will permanently prevent SVT in more than 90% of cases.

## Atrial Fibrillation

**Q. Discuss the etiology, pathophysiology, clinical features, complications, diagnosis and management of atrial fibrillation.**

### *Definition*

- Atrial fibrillation (AF) is an arrhythmia characterized by disorganized atria and produces multiple atrial foci fire impulses at a rate of 350–600/minute. There is no atrial contraction but only fibrillation. The ventricles respond at irregular intervals, usually at a rate of 100–140/minute.
- It is the most common cause of sustained cardiac arrhythmia.

### *Etiology (Table 7.85)*

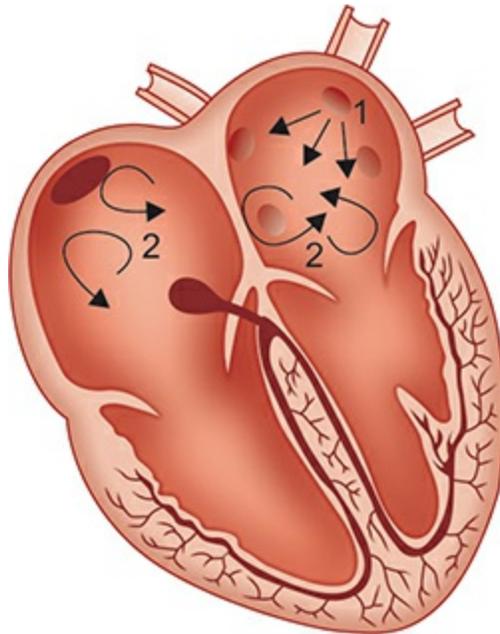

Any condition that raises the atrial pressure, increases atrial muscle mass, causes atrial fibrosis, or inflammation and infiltration of the atrium, may produce atrial fibrillation. Many genetic (gene defects linked to chromosomes 10, 6, 5 and 4) and systemic causes also may be responsible for atrial fibrillation.

### *Mechanisms of Atrial Fibrillation (Fig. 7.49)*

- AF is a complex arrhythmia. It is characterized by (1) abnormal automatic firing at a rate of 350–600/minute and (2) the presence of multiple interacting re-entry circuits looping around the atria.
- Episodes of atrial fibrillation are initiated by rapid bursts of depolarizing automatic ectopic beats arising from conducting tissue in the pulmonary veins or from diseased atrial tissue. The atria respond electrically at this rapid rate. Many of them reach the AV node during its refractory period, and hence not conducted.
- AF becomes maintained by continuous, rapid (300–600/min) activation of the atria by multiple re-entrant conduction within the atria or sometimes because of continuous ectopic firing. Re-entry occurs in enlarged atria or in which conduction is slow (occurs in many forms of heart disease).

**Table 7.85** Causes of atrial fibrillation.

<b>Cardiac</b>	<b>Noncardiac</b>
<ul style="list-style-type: none"><li>• Hypertensive heart disease</li><li>• Valvular heart disease (e.g. rheumatic heart disease)</li><li>• Ischemic heart disease</li><li>• Heart failure</li><li>• Cardiomyopathy</li><li>• Pericarditis</li><li>• Congenital heart disease</li><li>• Postcardiac surgery</li></ul>	<ul style="list-style-type: none"><li>• Pulmonary: Pneumonia, COPD, pulmonary embolism</li><li>• Hyperthyroidism/thyrotoxicosis</li><li>• Excess catecholamine/sympathetic activity</li><li>• Drugs and alcohol</li><li>• Significant electrolyte imbalance</li></ul>
<b>Lone atrial fibrillation</b>	<b>Reversible/transient AF</b>
<ul style="list-style-type: none"><li>• Younger patients &lt;60</li><li>• No underlying cause</li><li>• Usually not much symptoms</li><li>• Normal heart structure</li><li>• No associated co-morbidities</li></ul>	<ul style="list-style-type: none"><li>• Acute upper respiratory tract infections (URTI), chest infection AMI, pericarditis, thyrotoxicosis, pulmonary embolism, after CABG, holiday heart syndrome</li></ul>

**Fig. 7.49:** Mechanisms of atrial fibrillation. (1) Ectopic beats, originating from the pulmonary veins usually trigger atrial fibrillation. (2) Re-entry within the atria maintains atrial fibrillation.

## ***Clinical Features***

### ***Symptoms***

Usual symptoms include palpitations, fatigue, syncope, angina and symptoms

of cardiac failure and thromboembolism.

### *Cardinal signs*

- Irregularly irregular pulse, varying volumes of pulse, pulse deficit (apex pulse deficit)
- Blood pressure: Hypotension, mean of three recordings to be taken
- Absence of a waves on JVP.
- Varying intensity of the first heart sound, disappearance of the fourth heart sound and disappearance of the PSA of the mid-diastolic murmur of mitral stenosis (MS) in a few.

### *Investigations*

#### **Q. Write short note on ECG changes in atrial fibrillation.**

- Electrocardiogram (Box 7.49)
- 2D ECHO to look for LA size, thrombus, LV function
- Holter monitoring: For paroxysmal AF
- Exercise stress test: Ischemic heart disease (IHD)
- Catheterization: Before ablation
- Thyroid function tests and serum electrolytes in all patients.
- Chest X-ray
- Fasting lipid profile.

#### **Box 7.49:** ECG changes in atrial fibrillation.

- No clear P waves
- Fine very irregular, disorganized atrial fibrillatory or F waves, coarse fibrillary waves indicate LAE.
- F waves: Several independent re-entrant wavelets within atria, which may be fine or coarse
- Atrial rate: 350–500 bpm
- **Ventricular rate:** Irregularly irregular, conduction of AV node
- **QRS complexes:** Rhythm is rapid and irregular, narrow/broad. Broad-BBB, aberrant conduction, pre-excitation
- Long R-R interval is followed by short R-R intervals. Atrial impulse may find the RBBB still refractory. **Ashman phenomenon** is characterized by wide QRS complexes with a short cycle following long cycle commonly seen in ASD.

#### **Q. Write short note on complications of atrial fibrillation.**

**Complications:** Thromboembolism, precipitation/worsening of cardiac failure, syncope, hypotension, angina, precipitation of pulmonary edema in mitral stenosis.

## **Management/treatment**

### **Goals of management**

- Hemodynamic stabilization
- Heart rate control or restoration of sinus rhythm.
  - Minimize symptoms associated with excessive heart rates.
  - Prevent tachycardia-associated cardiomyopathy.
- Prevention of recurrent AF
- **Reduction of the risk of thromboembolism:** Anticoagulation prevents embolic complications.
- **Treatment of underlying cause:** When atrial fibrillation develops as a complication of acute precipitating event (e.g. alcohol toxicity, chest infection, pulmonary embolism or hyperthyroidism), the provoking primary disorder/ cause should be effectively treated. It will often restore sinus rhythm.

### **Strategies for the acute management of AF:**

- **Ventricular rate control** is achieved by drugs which block the AV node.
- **Cardioversion ( $\pm$  anticoagulation): Cardioversion** is procedure by which an abnormally fast heart rate (tachycardia) or cardiac arrhythmia is converted to normal rhythm using electricity or drugs. Cardioversion is achieved electrically by DC shock or medically antiarrhythmic drug either by intravenous infusion (e.g. flecainide, propafenone, vernakalant or amiodarone) or orally (flecainide or propafenone). Oral agent is administered to a particular patient who is previously tested in hospital and found to be safe ('pill in pocket 'approach).

### **Long-term management of atrial fibrillation**

Clinical classification of atrial fibrillation is presented in Table 7.86.

Long-term management of persistent atrial fibrillation has two options:

1. **Rhythm control** is an attempt to restore and maintain normal sinus rhythm by antiarrhythmic drugs plus DC cardioversion plus oral anticoagulation.
  - **Pharmacological cardioversion:** By quinidine, ibutilide, flecainide, propafenone or amiodarone. The dose of amiodarone 5–7 mg/kg intravenously over 1 hour followed by 1.2–1.8 g/24-hour infusion.
  - **Electric cardioversion:** If there is failure of medical cardioversion, electric cardioversion is done after 3 weeks of warfarin therapy which is continued further for another 4 weeks after cardioversion. Anticoagulation is to be given to these patients.
2. **Rate control:** If sinus rhythm cannot be restored, treatment is aimed to control the ventricular rate to less than 100/minute and to prevent embolic complications. This is achieved by AV nodal slowing agents plus oral anticoagulation.
  - Calcium channel blockers (calcium antagonists)
    - **Verapamil:** 5–10 mg intravenously over 2 minutes. If required repeat in 30 minutes.
    - **Diltiazem:** 10 mg intravenously over 2 minutes. If required repeat same dose in 15 minutes. An infusion at 10–15 mg/hour is started to maintain ventricular rate below 100/minute.
  - **$\beta$ -blockers:** Propranolol 1 mg intravenously over 2 minutes. Dose is repeated every 5 minutes up to a maximum of 5 mg.
  - **Digoxin:** 0.25–0.5 mg intravenously, then 0.25 mg after 4–6 hours and another after 12 hours. At

present less commonly used.

- **Amiodarone:** 150 mg over 10 minutes followed by 1 mg/minute over 6 hours and then 0.5 mg/minutes for next 18 hours. Adverse effects include: hepatic toxicity (hepatitis that can progress to cirrhosis), pulmonary toxicity (cough and dyspnea), thyroid dysfunction (hypothyroidism, hyperthyroidism), sun sensitivity and ocular symptoms.

**Prevention of recurrence:**

- After restoring the sinus rhythm (either by electric or pharmacological cardioversion), recurrence is prevented by quinidine, amiodarone or dronedarone (safer than amiodarone).
- When cardioversion is unsuccessful or if atrial fibrillation is likely to recur, following treatment is given:
  - Allow the patient to remain in atrial fibrillation but reduce the ventricular rate by digitals, diltiazem, verapamil or propranolol.
  - **Chronic anticoagulation**
  - Reduction in stroke risk; by warfarin or antiplatelet agents.

**Reduction of the risk (prevention) of thromboembolism (Anticoagulation)**

One of the complications of atrial fibrillation is embolism. First step is to determine the need for anticoagulation. A scoring system known as **CHA<sub>2</sub>DS<sub>2</sub>-VASc** (Table 7.87) is used to assess the risk of embolism.

**Indications:** Atrial fibrillation in patients with rheumatic mitral stenosis or with mechanical prosthetic heart valve. Other indications include:

- Transesophageal echocardiography should be done in patients with atrial fibrillation to exclude an atrial thrombus.
  - If no atrial thrombi: Heparin is given before cardioversion (if conversion to sinus rhythm) and followed by warfarin for 4 weeks.
  - If atrial thrombi present: Warfarin is given for 3 weeks prior to cardioversion and is continued for another 4 weeks after cardioversion.
- If cardioversion is unsuccessful and patient remains in atrial fibrillation, long-term warfarin should be given.

**Anticoagulants:** With warfarin, the INR should be maintained between 2.0 and 3.0 (2.5 and 3.5 in case of underlying valvular lesion). Newer oral anticoagulants include dabigatran (a direct thrombin inhibitor in the dose of 150 mg BID), apixaban (5 mg BID), and rivaroxaban (20 mg OD).

**Aspirin:** In the dose of 325 mg/day may be used as an alternative to warfarin when patient is allergic to warfarin or is contraindicated, patient <75 years of age with no previous stroke or transient ischemic attack without hypertension, diabetes or heart failure.

**Radiofrequency ablation (RF) ablation therapy:** Indications are:

- Very symptomatic patients who refuse antiarrhythmic drug therapy.
- Young patients where only effective antiarrhythmic drug is amiodarone.
- Patients with significant bradycardia for whom antiarrhythmic drug therapy will require pacemaker.
- **Surgical procedure for AF** is the 'cut-and-sew' maze procedure.

**Table 7.86** Clinical classification of atrial fibrillation and choice of treatment.

<b>Terminology</b>	<b>Clinical features</b>	<b>Treatment</b>
Initial event (first detected episode)	Symptomatic/asymptomatic. Onset unknown	Rhythm/rate control
Paroxysmal (may be vagotonic AF or adrenergic AF)	Intermittent episodes that stops spontaneously (self-termination) within 7 days and most often <48 hours	Rhythm control. Vagotonic AF responds to digitalis, disopyramide while beta blockers are helpful for adrenergic AF
Persistent	Prolonged, not self-terminating, lasting >7 days which requires termination by electrical or chemical cardioversion	Rhythm/rate control
Permanent ('accepted')	Not spontaneously terminated or terminated but relapsed, no cardioversion attempt	Rate control

*Note:* Atrial fibrillation may be asymptomatic and the first detected episode should not be considered as the true onset.

**Table 7.87:** CHA<sub>2</sub>DS<sub>2</sub>-VASc stroke risk scoring system for non-valvular atrial fibrillation.

<b>Risk factor</b>	<b>Score</b>	
<b>C:</b> Congestive heart failure	1	<b>0 points: Low-risk</b> (no prophylaxis required) <b>1–2 points: Moderate-risk</b> (oral anticoagulant or aspirin recommended) <b>&gt;3 points: High-risk</b> (oral anticoagulant recommended)

<b>S<sub>2</sub>:</b> Prior stroke or TIA	2	
<b>V:</b> Vascular disease	1	
<b>A:</b> Age 65–74 years old	1	
<b>Sc:</b> Sex category (female)	1	

## Atrial Flutter

**Q.** Define atrial flutter. Discuss the causes, electrocardiographic features and management of atrial flutter.

**Definition:** Atrial flutter is a cardiac arrhythmia usually characterized by an organized, regular, rapid atrial rate between 250–350/minute. The ventricles respond to every second, third or fourth beat (2:1, 3:1 or 4:1 AV block).

## Common Causes

- **Cardiac causes:** Organic heart diseases (e.g. ischemic, rheumatic, congenital), pericarditis, following open heart surgery (1st week).
- Acute respiratory failure.

**ECG:** Characteristic saw-toothed flutter waves ('F' waves) between QRS complexes. QRS complexes are regular.

### Management

- **Restoration to sinus rhythm:** Treatment of a symptomatic acute paroxysm is direct electrical cardioversion. Atrial flutter of more than 1–2 days should be treated similar to atrial fibrillation and anticoagulated for 3 weeks prior to cardioversion.
- **Control of ventricular rate:** By using digoxin,  $\beta$ -blockers or verapamil/diltiazem followed by conversion to sinus rhythm using quinidine, amiodarone, disopyramide or flecainide.
- **Prevention of recurrences:** Recurrent paroxysms can be prevented by class III antiarrhythmic agents (refer Table 7.91) such as quinidine, amiodarone, disopyramide or flecainide. Treatment of choice for patients with recurrent atrial flutter is catheter ablation.
- **Prevention of stroke:** Risk of stroke is similar to that of atrial fibrillation and the management is almost identical but anticoagulants may be stopped earlier after successful ablation.

## Wolff-Parkinson-White Syndrome (WPW Syndrome)

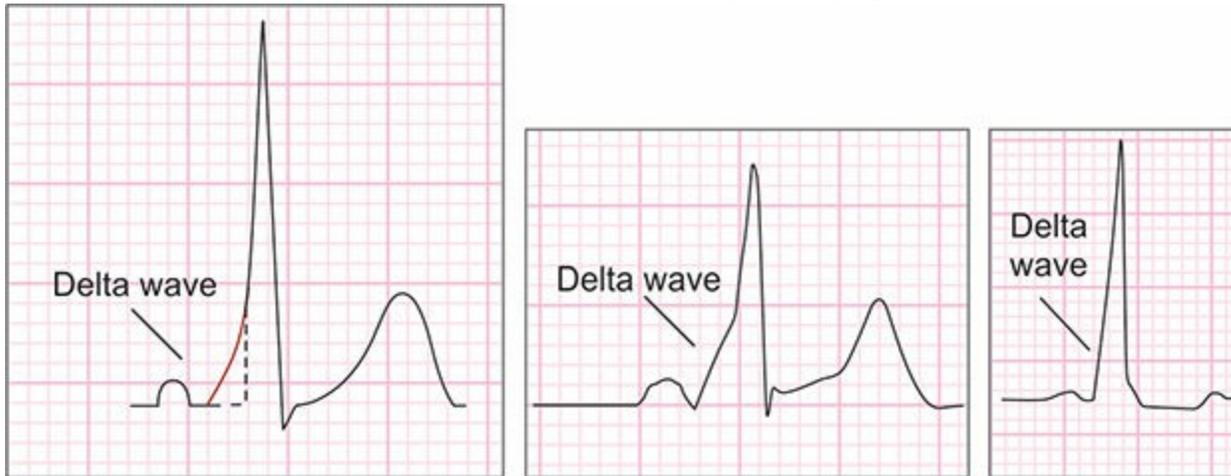

**Q. Write short essay on Wolff-Parkinson-White (WPW) syndrome.**

Wolff-Parkinson-White (WPW) syndrome is an extra electrical (accessory) pathway (Bundle of Kent) between atria and ventricles and causes tachycardia.

**Accessory pathways:** Extra electrical pathway consists of an abnormal band of rapidly conducting fibers which connects the atria and ventricles. These conducting fibers resemble Purkinje tissue, in that they conduct very rapidly and are rich in sodium channels. Accessory pathways may be of two types.

1. **Concealed accessory pathway:** About 50% of cases, this pathway only conducts in the retrograde direction (from ventricles to atria) and thus does not change the appearance of the ECG in sinus rhythm. It is called as a concealed accessory pathway.
2. **Manifest accessory pathway:** In remaining 50%, the pathway conducts anterograde direction (from atria to ventricles). Thus, AV conduction in sinus rhythm is mediated via both the AV node and the accessory pathway and distorts the QRS complex. Premature ventricular activation via this pathway shortens the PR interval and produces a 'slurred' initial deflection

of the QRS complex, and is called a delta wave. This manifests as accessory pathway. Because AV node and accessory pathway have different conduction speeds and refractory periods, a re-entry circuit can develop, producing tachycardia. When this is **associated with symptoms, it is termed as Wolff–Parkinson–White (WPW) syndrome.**

**Fig. 7.50:** ECG findings in Wolff-Parkinson-White (WPW) syndrome.

**ECG (Fig. 7.50):** During tachycardia is indistinguishable from that of AVNRT.

- Short PR interval (<0.12 sec)
- Slurred upstroke of the QRS complex (Delta wave)
- Wide QRS complex.

**Complications:** Atrial flutter, atrial fibrillation, supraventricular tachycardia, ventricular tachycardia, ventricular fibrillation and death.

#### Treatment

- Carotid sinus pressure or intravenous adenosine used for termination of the tachycardia.
- Acute episodes of PSVT in Wolff-Parkinson-White (WPW) syndrome are treated similar to that of PSVT.
- Life-threatening atrial fibrillation is treated as an emergency with DC cardioversion.
- In non-life-threatening atrial fibrillation (AF), lidocaine (3–5 mg/kg) or procainamide (15 mg/kg) administered IV over 15–20 minutes will usually show the ventricular response. Ibutilie can also be used.
- *Avoid IV verapamil and digitalis in WPW and AF*, because they can increase ventricular response (by shortening the refractory period of accessory pathway). Beta blockers are of no use in controlling ventricular response during AF when conduction proceeds over the bypass tract.
- Catheter ablation of bypass tracts is possible in >90% of the patients and is the treatment of choice in patients with symptomatic arrhythmias. Surgical ablation may be required in an occasional patient in whom catheter ablation fails.

## Sick-Sinus Syndrome

### **Q. Write short essay on sick-sinus syndrome.**

- It comprises a number of abnormalities namely sinus bradycardia, sinus arrest, combinations of sinoatrial and AV blocks, tachycardia-bradycardia and supraventricular tachycardia.
- Characterized by sinus node dysfunction with an atrial rate inappropriate for physiologic requirements.
- **Cause:** Usually due to ischemia, fibrosis, drug induced or autonomic dysfunction.

### ***Clinical Features***

- Majority are asymptomatic.
- Clinical features are due to cerebral hypoperfusion and reduced cardiac output. These include syncope, palpitations and dizziness. There may be symptoms caused due to worsening of underlying conditions (e.g. congestive heart failure, angina pectoris, and cerebrovascular accident).
- A slow heart rate, fever, left ventricular failure or pulmonary edema suggests sick-sinus syndrome.

**Treatment** of recurrent symptomatic bradycardia or prolonged pauses by implantation of a permanent pacemaker.

## Ventricular Tachycardia (VT)

### **Q. Write short essay on ventricular tachycardia.**

- **Most common cause of wide complex tachycardia (80%).**
- VT heart rate is 100–200 bpm and if more than rate >220 bpm it is ventricular fibrillation (VF).
- Major cause of morbidity and mortality in patients with structural heart disease.
- Major cause of sudden cardiac death –60% cases on holter monitoring.
- Relatively organized tachyarrhythmias with discrete QRS complexes.
- Recurrence is more common in less than one year of onset.
- The occurrence of three or more VPC complexes with a rate of > 120 bpm in succession is called as VT.

**Table 7.88: Causes of ventricular tachycardia.**

<ul style="list-style-type: none"><li>• Ischemic heart disease: Acute MI, after chronic infarction</li><li>• Dilated cardiomyopathy</li><li>• Hypertrophic cardiomyopathy</li><li>• Post CABG, post TOF surgery</li><li>• Idiopathic</li><li>• Specific etiology—genetic</li></ul>	<b>Reversible causes of VT</b> <ul style="list-style-type: none"><li>• Hypoxia</li><li>• Hyperthyroidism, catecholamines</li><li>• Electrolyte abnormalities: Hypokalemia, hypomagnesemia, hypocalcemia, metabolic acidosis</li><li>• Drugs, alcohol, starvation</li></ul>
--	--

### ***Types of VT***

- **Non-sustained VT** is termination of VT by self less than 30 seconds.
- **Sustained VT** is presence of VT for >30 seconds or hemodynamically unstable but terminated in less than 30 seconds.
- **Slow VT:** Heart rate >100 < 120 bpm.
- **Pulseless VT:** VT with hemodynamic collapse that requires DC cardioversion.
- **Refractory VT:** VT that does not revert to sinus rhythm on medication use or use of three shocks.
- **VT storm:** Repeated VT episodes requiring the DC shocks/ICD shocks.

**Table 7.89: Clinical features of ventricular tachycardia.**

<ul style="list-style-type: none"><li>• Asymptomatic</li><li>• May have palpitations-transient/sustained</li><li>• Chest pain: Angina</li><li>• Syncope/dizziness</li></ul>	<ul style="list-style-type: none"><li>• Presyncope</li><li>• Cannon a waves</li><li>• Absent pulse</li><li>• Hypotension</li><li>• Variable S<sub>1</sub></li></ul>
---	---

### ***Etiology (Table 7.88)***

Re-entry is the most common mechanism.

### ***Clinical Features (Table 7.89)***

### ***Diagnosis***

- ECG: 12 lead with long rhythm strip of lead II.
- 24 hour holter monitoring in case of transient episode.
- 2D echo for the etiology.

- Routine investigations, serum electrolytes, calcium, magnesium, ABG.

#### Treatment

- **Prompt restoration of sinus rhythm** followed by prophylactic therapy.
- **Hemodynamically unstable patients: Synchronized DC** cardioversion is the treatment of choice (if systolic BP is below 90 mm Hg).
- **If the patient is stable and arrhythmia is well tolerated:** With preserved left ventricular function **IV procainamide** 50 mg/min. In presence of left ventricular dysfunction, **IV 150 mg amiodarone** given as a bolus, followed by a continuous infusion. **IV lidocaine** can be used but may depress left ventricular function, causing hypotension or acute heart failure.
- **Correction of electrolyte or acid-base imbalance**, e.g. hypokalemia, hypomagnesemia, acidosis and hypoxemia.
- **Prevention of VT:** Beta-blockers reducing ventricular automaticity and amiodarone can be added if additional control is needed. Do not use class Ic anti-arrhythmic drugs in patients with coronary artery disease or heart failure because they depress myocardial function and can be proarrhythmic (increases the possibility of a fatal arrhythmia).
- **Implantable cardiac defibrillator** is the absolute indication in presence of LVEF <30% and is recommended for patients with high risk of arrhythmic death (e.g. poor left ventricular function, or associated with hemodynamic compromise). Rarely, surgery (e.g. aneurysm resection) or catheter ablation may be required for patients with VT associated with a myocardial infarct scar.

## Torsades De Pointes

- A special type of ventricular tachycardia (VT) characterized by **polymorphic QRS complexes that change in amplitude and cycle length**, giving the appearance of oscillations around the baseline. This is associated with QT prolongation.
- **QT prolongation** may result from electrolyte disturbances (particularly hypokalemia and hypomagnesemia), antiarrhythmic drugs (quinidine), phenothiazines, tricyclic agents, and bradyarrhythmias. It may be due to congenital long QT syndrome (Andersen-Tawil syndrome, Romano-Ward syndrome, Jervell and Lange-Nielsen syndrome).
- The electrocardiographic hallmark is polymorphic VT preceded by marked QT prolongation, often in excess of 0.60 second.

#### Treatment

- Correct electrolyte abnormalities or underlying cause.
- Intravenous **magnesium** (8 mmol over 15 minutes, then 72 mmol over 24 hours) should be given in all patients.
- Avoid class IA and class III antiarrhythmic agents.
- Lidocaine does not prolong QT interval. Isoproterenol bridge before temporary pacemaker. Phenytoin 100 mg every 5 minutes maximum dose of 500 mg.
- Temporary pacemaker

- Beta blockers (BBs) to be used to prevent syncope in patients with congenital QTc prolongation syndrome.

## Brugada Syndrome

- Named by the Spanish cardiologists Pedro Brugada and Josep Brugada.
- Major cause of **sudden unexpected death syndrome** (SUDS), and is the most common cause of sudden death in young men without known underlying cardiac disease in Thailand and Laos.
- Genetic abnormality of the cardiac **sodium channels**, leading to ventricular tachycardia and/or sudden cardiac death.
- Hereditary: 60% of Brugada patients have a family history of SCD. Mutations of SCN5a genes resulting in diminished inward sodium current in the region of the RV outflow tract epicardium appear responsible for this syndrome.
- The large potential difference between the normal endocardium and rapidly depolarized RV outflow epicardium gives rise to **ST segment elevation in V<sub>1</sub> to V<sub>3</sub>** in sinus rhythm and predisposes to local re-entry and life-threatening ventricular arrhythmias in the absence of structural heart disease.
- Arrhythmias frequently occur during sleep. Affects relatively young and predominant in males.

### Treatment

- No benefit from beta blockers.
- Implantable cardiac defibrillator (ICD) treatment to manage recurrences. A history of syncope spontaneous ST segment elevation and inducibility of VT with programmed stimulation may identify family members also at risk of SCD who warrant prophylactic ICD therapy.

## Ventricular Fibrillation

**Q. Write short note/essay on causes, diagnosis and treatment of ventricular fibrillation.**

- Characterized by very rapid, irregular and uncoordinated movement of the ventricles with no mechanical effect.
- Patient is pulseless and becomes rapidly unconscious, and respiration ceases (cardiac arrest).
- ECG: Shows shapeless/bizarre, rapid oscillations.

- Ventricular fibrillation rarely reverses spontaneously.

**Treatment:** Electrical defibrillation.

## Atrioventricular Blocks

**Q. Discuss the causes, clinical features and management of atrioventricular blocks and AV conduction disturbances.**

**Heart block or conduction block** may develop at any level in the conducting system. Block in either the AV node or the His bundle produces AV block, whereas block lower in the conduction system results in bundle branch block.

**Types:** Atrioventricular block consists of three forms: (1) first degree AV block, (2) second degree AV block and (3) third degree (complete) AV block.

### ***First Degree Atrioventricular (AV) Block***

- In this type of block AV conduction is delayed.
- ECG shows simple prolongation of the PR interval to  $>0.22$  seconds. Every atrial depolarization is followed by conduction to the ventricles but occurs with delay. So, all the P waves are conducted and the QRS is normal as the delay is most often in the AV node.

### ***Second Degree Atrioventricular (AV) Block***

In this type of AV block, dropped beats occur because some impulses from the atria fail to conduct to the ventricles.

#### *Types*

- **Mobitz type I second-degree AV block** (Wenckebach block phenomenon): Characterized by progressive slowing of AV conduction until it is totally blocked. ECG shows progressive lengthening of successive PR intervals until a P wave fails to conduct (culminating in a dropped beat).
- **Mobitz type II second-degree AV block:** In this type, the PR interval remains constant but some atrial impulses (P waves) are not conducted. It occurs when a dropped QRS complex is not preceded by progressive PR interval prolongation. The QRS complex is usually wide ( $>0.12$  s).
- **2: 1 or 3: 1 (advanced) block:** Occurs when every second or third P wave

conducts to the ventricles. The block is defined by a ratio in which the first digit represents the total number of P waves, and the second digit represents the number of P waves conducted (i.e. the number of QRS complexes). This form of second degree block is neither Mobitz I nor II.

### ***Third-degree (Complete) Atrioventricular Block***

#### **Q. Write short essay on complete heart block.**

Complete heart block occurs when all the atrial activities fails to conduct (AV conduction fails completely) to ventricles and both the atria and ventricles beat independently (AV dissociation). In this ventricular activity (and the life) is maintained by spontaneous escape rhythm arising in the AV node or bundle of His (narrow QRS complexes) or the distal Purkinje tissues (broad QRS complexes). Distal escape rhythms are slower and less reliable. Causes of complete heart block are listed in Box 7.50.

#### **Box 7.50:** Causes of heart block.

##### **Congenital**

##### **Acquired**

- Myocardial ischemia or infarction
- Idiopathic fibrosis
- Inflammation
  - Acute (e.g. aortic root abscess in infective endocarditis)
  - Chronic (e.g. sarcoidosis, Chagas' disease)
- Trauma (e.g. intracardiac surgery)
- Drugs (e.g. digoxin intoxication,  $\beta$ -blocker)
- Tumors and infections involving the conducting system
- Infections: Rheumatic autoimmune disease, neuromuscular diseases
- Lev's disease
- Lenegre's disease

#### ***Clinical features of complete heart block***

- Regular (except in congenital complete AV block), high volume slow pulse (25–50/minute) which does not vary with exercise. Usually there is a compensatory increase in stroke volume and produces a large-volume pulse.
- Irregular cannon waves on JVP in the neck.
- Stokes- Adams attacks

- Varying intensity of first heart sound.

**ECG:** Constant P-P and R-R intervals, complete AV dissociation (i.e. the atria and ventricles beat independently) and there is no relation between the P waves and the QRS complexes.

## Adams-Stokes Attacks (Stokes-Adams-Morgagni Attacks)

**Q. Write short essay on Adams-Stokes attacks (Stokes-Adams-Morgagni attacks) and their clinical features.**

Stokes-Adams attack is characterized by a recurrent episode of sudden loss of consciousness unrelated to posture with or without convulsions due to a disorder of heart rhythm in which there is bradycardia or absent pulse.

### *Etiology*

Episodes of ventricular asystole may complicate intermittent high-grade AV block (Mobitz type II or complete heart block), profound bradycardia or ventricular standstill. Sinus disease and neurocardiogenic syncope may produce similar symptoms.

### *Clinical Features*

- **Prodrome** preceding the attack may be observed in few patients.
- **Sudden loss of consciousness:** Patient may fall to the ground with sudden loss of consciousness without warning and results in collapse. During the attack, patient is pale with a death-like appearance and deeply unconscious. The pulse is usually very slow or absent. Recovery is rapid and after a few seconds the patient recovers consciousness with characteristic flush as the heart starts beating again and pulse quickens.
- Occasionally, brief anoxic generalized convulsions/seizures and death may occur if there is prolonged asystole or severe prolonged bradycardia (more than 10 seconds) causing cerebral hypoxia/ischemia. Prolonged bradycardia may produce cyanosis.
- Usually there are no sequelae, but patients may injure themselves due to the sudden fall.

**Treatment of heart block:** (1) removal of offending agent, (2) injection atropine/injection isoprenaline if symptomatic, and (3) Pacemaker insertion.

## Therapeutic Procedures

## ***Defibrillation and Cardioversion***

**Q. Write short note on defibrillation and cardioversion.**

### *Introduction*

- By the passage of sufficiently large electrical current (from an external source) through the heart, it can be completely depolarized. This will interrupt any arrhythmia and produce a short period of asystole and is usually followed by the resumption of normal sinus rhythm.
- **Cardioversion** is a procedure by which an abnormally fast heart rate (tachycardia) or cardiac arrhythmia is converted to a normal rhythm using electricity (defibrillation) or drugs.

### *Defibrillation*

- In this technique ventricular fibrillation is converted to sinus rhythm by defibrillators which deliver direct current (DC). When the defibrillator is discharged, a high-voltage field electric shock of short duration is delivered to the heart. This electric shock envelopes the heart and depolarizes the myocardium which causes an organized heart rhythm to emerge.
- **Method:** Defibrillators deliver a DC, high-electrical energy, short-duration shock through two large electrodes or paddles coated with conducting jelly or a gel pad. One electrode is positioned over the upper right sternal edge and the other over the cardiac apex. Present-day modern units deliver a biphasic shock. Advantage is that the shock polarity is reversed during mid-shock and this decreases the total shock energy needed to depolarize the heart.

### *DC cardioversion (DCC)*

- **Transthoracic electric shock:** It is used to convert sinus rhythm in tachyarrhythmias which do not respond to medical treatment or that are associated with hemodynamic compromise (e.g. hypotension, worsening heart failure).
- **Precautions:**
  - A short acting general anesthetic or powerful sedation is used in elective cardioversion.
  - Withdraw digitalis therapy at least 36 hours before cardioversion.

- Patients with long-standing (>48 hours) atrial fibrillation or flutter should be anticoagulated adequately for at least 3 weeks before cardioversion to reduce the risk of embolization.
- Levels of cardiac enzyme may rise after a cardioversion.
- **Difference between defibrillation and cardioversion:** A nonsynchronous shock is used to defibrillate and accidental defibrillation (in patient who do not need it) may itself precipitate ventricular fibrillation. A synchronized shock (i.e. one delivered during the QRS complex) is used for all cardioversions except for very rapid ventricular tachyarrhythmias, such as ventricular flutter or VF.
- **Indications for DCC:** Ventricular fibrillation, sustained ventricular tachycardia, atrial fibrillation/flutter and supraventricular tachycardia.

## Cardiac Pacemakers

**Q. Write short note on types of cardiac pacemakers and its indications.**

### Temporary Pacing

- It involves delivery of an electrical impulse into the heart to initiate depolarization and to trigger cardiac contraction.
- **Indication:** Transient AV block, arrhythmias complicating acute MI or cardiac surgery, to maintain the rhythm in other situations of reversible bradycardia (i.e. due to metabolic disturbance or drug overdose), or as a bridge to permanent pacing.

**Table 7.90:** Indication of permanent pacing.

- Acquired AV block in adults
  - Complete heart block associated with any one of the following:
    - ◆ Symptomatic bradycardia
    - ◆ CHF
    - ◆ Asystole >3 second
    - ◆ Escape rate <40 beats per minute
    - ◆ Post AV junction ablation, myotonic dystrophy.
  - Second degree AV block with symptomatic bradycardia
  - Atrial fibrillation, atrial flutter, or rare cases of supraventricular tachycardia with complete heart block, bradycardia or any of the conditions listed under above.
- After myocardial infarction
  - Persistent advanced second-degree AV block or complete heart block with block in His Purkinje system.

- Transient advance AV block with associated bundle branch block
- Bifascicular trifascicular block
  - Bifascicular block with intermittent complete heart block associated with symptomatic bradycardia
  - Bifascicular or trifascicular block with intermittent type II second-degree AV block without symptoms
- Sinus node dysfunction with documented symptomatic bradycardia: Commonest indication of pacing
- Hypersensitive carotid sinus, recurrent syncope associated with clear, spontaneous events provoked by carotid sinus stimulation.

**Transvenous pacing:** It is done in patients with symptomatic bradycardias. In this procedure under the guidance of cardiac fluoroscopic imaging, a thin (French gauge 5 or 6), bipolar pacing electrode wire is inserted via an internal jugular vein, a femoral vein or a subclavian vein and is positioned at the apex of right ventricle. The electrode is connected to an external pacemaker with an adjustable energy output and pacing rate usually about 60–80/minute.

- **Complications:** Pneumothorax, brachial plexus or subclavian artery injury, local infection or septicemia (usually *Staphylococcus, aureus*), and pericarditis.

**Transcutaneous pacing** is performed in selected patients with asymptomatic bradycardia or conduction abnormalities. It may be lifesaving for patients with cardiac arrest precipitated by bradycardia. This method consists of depolarizing the myocardium by current flow between two large adhesive electrodes positioned anteriorly and posteriorly on the chest wall.

### *Permanent pacing*

Pacing electrodes (leads) can be placed via the subclavian or cephalic veins and are designed to both pace and sense either the ventricles or the atria or more commonly, both chambers.

*Indication for permanent pacing (Table 7.90)*

## **Antiarrhythmic Drugs (Table 7.91)**

**Q. Write short essay on antiarrhythmic drugs.**

***Therapy of Various Arrhythmias (Table 7.92)***

### **Amiodarone**

**Q. Write short note on amiodarone and its use in clinical practice.**

Amiodarone is an unusual iodine containing highly lipophilic long-acting antiarrhythmic drug.

**Table 7.91:** Vaughan-Williams classification of antiarrhythmic drugs.

<i>Class</i>	<i>Mechanism of action</i>	<i>Examples</i>
I. Na <sup>+</sup> channel blocker	Change the slope of phase 0	Ia: Quinidine, diisopyramide, procainamide, moricizine Ib: Lidocaine, phenytoin, Mexiletine Ic: Flecainide, propafenone
II. β blocker	↓ heart rate and conduction velocity	Propranolol, metoprolol, esmolol, acebutolol
III. K <sup>+</sup> channel blocker	↑ action potential duration (APD) or effective refractory period (ERP)	Amiodarone, sotalol, bretylium, dronedarone
	Delay repolarization	Vernakalant, azimilide, tedisamil
IV. Ca <sup>++</sup> channel blocker	Slowing the rate of rise in phase 4 of SA node.	Verapamil, diltiazem
Others		Adenosine, magnesium, digitalis

**Table 7.92** Various types of arrhythmias and their therapy.

<i>Arrhythmias</i>	<i>Acute therapy</i>		<i>Chronic therapy</i>	
	<i>First choice</i>	<i>Alternatives</i>	<i>First choice</i>	<i>Alternatives</i>
Atrial fibrillation/atrial flutter	Esmolol	Verapamil,	Digoxin	Propranolol
Paroxysmal supraventricular tachycardia (PSVT)	Adenosine	Esmolol, diltizem, verapamil	Digoxin, verapamil, propranolol	Propafenone
Ventricular tachycardia (VT)	Lidocaine Cardioversion	Procainamide, mexiletine, amiodarone	Amiodarone Dofetilide	Mexiletine, propranolol, propafenone
Torsades de pointes	Pacing	Isoprenaline, magnesium	Propranolol	Pacing
Ventricular fibrillation (VF)	Electrical defibrillation	Lidocaine, amiodarone	Amiodarone	Procainamide, dofetilide
Wolff-Parkinson-White (WPW) syndrome	Cardioversion	Amiodarone, propafenone, procainamide	Amiodarone, propranolol	Quinidine, propafenone

**Indications:** Useful in wide range of ventricular and supraventricular

arrhythmias.

- Resistant ventricular tachycardia/pulseless VT
- Recurrent ventricular fibrillation
- To maintain sinus rhythm in atrial flutter when other drugs have failed. For patients with heart failure or left ventricular hypertrophy only amiodarone is recommended.

**Duration of action:** Long. Hence suitable for long-term prophylactic therapy

**Adverse reactions:** These are dose-related and increase with duration of therapy. These reactions include fall in blood pressure, bradycardia, and myocardial depression on IV injection and on drug cumulation. Nausea, gastrointestinal upset with oral medication, Photosensitization and bluish skin discoloration pigmentation may develop in about 10% of patients. Pulmonary alveolitis and fibrosis are serious adverse reactions. Cirrhosis occurs uncommonly. Neurologic dysfunction, and hyperthyroidism (1–2%) or hypothyroidism (2–4%) can be seen.

**Dose:**

- Oral 400–600 mg/day for few weeks, followed by 100–200 mg for maintenance therapy.
- Slow IV injection of 100–300 mg (5 mg/kg) over 30–60 minutes.

## DISEASES OF THE MYOCARDIUM

### Myocarditis

**Q. Write short essay/note on acute myocarditis.**

- Acute myocarditis is an acute inflammatory disease of the myocardium (heart muscle).
- Myocarditis may present with a wide range of symptoms, ranging from mild dyspnea or chest pain that resolves without specific therapy to cardiogenic shock and death.
- Major long-term sequelae of myocarditis is DCM (dilated cardiomyopathy) with chronic heart failure.
- Three distinct forms of inflammatory cardiomyopathy (myocarditis associated with cardiac dysfunction) are recognized: Idiopathic,

autoimmune and infectious.

## ***Etiology (Table 7.93)***

**Table 7.93: Causes of myocarditis.**

### **Infections**

- **Viral:** Most common cause. Coxsackie A and B, influenza, HIV, dengue virus, parvovirus B19, hepatitis C, Epstein-Barr virus
- **Bacterial:** Diphtheria, *Staph. aureus*, *Mycoplasma pneumoniae*
- **Protozoal:** Trypanosomiasis (*Trypanosoma cruzi*), toxoplasmosis
- **Spirochetal:** Lyme disease (*Borrelia burgdorferi*)
- **Fungal**

### **Toxic**

- **Direct injury:** Drugs (e.g. cocaine, lithium and anti-cancer drugs, such as doxorubicin)
- **Hypersensitivity reactions** and associated myocarditis:
  - Drugs: Penicillins and sulfonamides
  - Lead and carbon monoxide
  - Others: Bee venom, wasp venom, scorpion venom, snake venom

**Autoimmune** conditions: Systemic lupus erythematosus and rheumatoid arthritis

**Others:** Acute rheumatic fever, chemical agents, radiation, giant cell myocarditis (thymoma, Crohn's disease)

**Q. Write short essay/note on causes of myocarditis.**

## ***Clinical Features of Myocarditis***

- Range from an asymptomatic or present with fatigue, palpitations, chest pain, dyspnea and fulminant congestive cardiac failure depending on the type of myocarditis.

**Classification:** Depending on the clinical presentations, myocarditis can be classified into four groups:

1. **Fulminant myocarditis:** Has abrupt onset and follows a viral prodrome (fever, chills, myalgia and constitutional symptoms) or influenza-like illness, and produces severe acute heart failure or cardiogenic shock. Prognosis is good.
2. **Acute myocarditis:** It presents with heart failure, acute myocardial infarction or sudden cardiac death. It may progress to dilated cardiomyopathy and chronic heart failure. More common in children/teenagers.

3. **Chronic active myocarditis:** It is rare and have insidious onset. It is seen in older adults and microscopically shows chronic inflammation of the myocardium.
4. **Chronic persistent myocarditis:** It shows focal myocardial infiltrates and cause chest pain and arrhythmia without causing ventricular dysfunction.

**Physical examination** may be normal or present with soft muffled heart sounds, a prominent third sound, inappropriate tachycardia, arrhythmias including conduction blocks, signs of congestive heart failure and pericardial friction rub (associated with pericarditis).

### ***Investigations***

- **Chest X-ray:** May show mild cardiac enlargement.
- **ECG** changes are common but nonspecific. May show standard T wave abnormalities and arrhythmias. Heart block may develop in diphtheritic myocarditis, Lyme disease and Chagas' disease.
- **Cardiac enzymes:** Biochemical markers of myocardial injury such as troponin I and T, creatine kinase may be raised during the early phases.
- **Echocardiography:** May show left ventricular dysfunction, and global hypokinesia with or without pericardial effusion.
- **Cardiac magnetic resonance imaging:** MRI may show myocardial inflammation or infiltration. May show increased myocardial T<sub>2</sub> signal on inversion recovery sequence and delayed contrast enhancement after gadolinium-DTPA infusion.
- **Viral antibody titers:** May be increased.
- Endomyocardial biopsy is sometimes useful to confirm the diagnosis and may show acute inflammation. Although controversial, still the current gold-standard test for diagnosis. It should be considered when there is suspicious of giant cell myocarditis, hypersensitivity/eosinophilic myocarditis, and cardiac involvement in a systemic disease.
- **Viral RNA, DNA:** Genome by polymerase chain reaction (PCR) or in situ hybridization.
- **Blood:** Leukocytosis, elevated ESR or eosinophilia.

**Complications:** Ventricular arrhythmia, heart block, congestive heart failure, acute pericarditis, progression to chronic myocarditis or chronic dilated cardiomyopathy (e.g. Chagas disease).

## Management

- Identify, treat, eliminate or avoid the underlying cause.
- Prolonged bed rest during the acute phase of the illness and restriction of physical activities for 6 months (till ECG is normal). Because physical activities can induce potentially fatal ventricular arrhythmias.
- Treatment of heart failure with diuretics, ACE inhibitors/AII receptor antagonists,  $\beta$ -blockers, spironolactone  $\pm$  digoxin. Arrhythmias are treated by amiodarone and  $\beta$ -blockers. Digoxin should be used with caution.
- **Antibiotics:** Specific antimicrobial therapy if a causative organism has been identified.
- NSAIDs should not be given in the acute phase but may be given in the late phase.
- Corticosteroids and immunosuppressive agents use is controversial.
- **Immunoglobulin:** High-dose intravenous immunoglobulin appears to hasten the resolution of the left ventricular dysfunction and improved survival.
- Refractory patients may rarely need cardiac transplantation or temporary circulatory support (with a mechanical ventricular assist device).

## Cardiomyopathy

### **Q. Define and classify cardiomyopathy.**

### **Definition**

Cardiomyopathies are a heterogeneous group of diseases of the myocardium that affects the mechanical or electrical function of the heart.

- The term cardiomyopathy should be restricted to the conditions which primarily affect the myocardium. It does not include myocardial involvement due to congenital, acquired valvular, hypertensive, and coronary arterial or pericardial abnormalities.
- *Etiology:* They can be genetic/inherited or have infective, toxic causes or idiopathic.

### **Classification**

Cardiomyopathies may be classified according to a variety of criteria, including the underlying genetic basis of dysfunction. Two fundamental forms of cardiomyopathy (Box 7.51) are:

1. *Primary cardiomyopathy:* Consists of heart muscle disease predominantly involving the myocardium and/or of unknown cause.
2. *Secondary cardiomyopathy:* Consists of myocardial disease of unknown cause or cardiomyopathy associated with systemic disease (e.g. chronic alcohol use, amyloidosis).

**Box 7.51:** Etiologic classification of cardiomyopathy.

**Primary cardiomyopathy**

- Idiopathic (D, R, H)
- Familial (D, R, H)
- Eosinophilic endomyocardial fibrosis (R)
- Endomyocardial fibrosis (R)

**Secondary cardiomyopathy**

- *Infective (D):* Viral, bacterial, fungal, protozoal, metazoal, rickettsial, spirochetal myocarditis.
- *Metabolic (D):* Familial storage disease (D, R): Glycogen storage disease, mucopolysaccharidosis, hemochromatosis, Fabry’s disease
- *Deficiency (D):* Electrolytes, nutritional
- *Autoimmune disease:* Systemic lupus erythematosus, polyarteritis nodosa, rheumatoid arthritis
- *Infiltrations and granulomas diseases (R, D):* Amyloidosis, sarcoidosis, malignancy
- *Neuromuscular:* Muscular dystrophy, myotonic dystrophy, Friedrich’s ataxia (H, D)
- *Sensitivity and toxic reaction (D):* Alcohol, drugs, radiation
- Peripartum heart disease Takotsubo (stress) cardiomyopathy

D, dilated cardiomyopathy; H, hypertrophic cardiomyopathy; R, restrictive cardiomyopathy

**Clinical Classification of Cardiomyopathy (Fig. 7.51 and Table 7.94)**

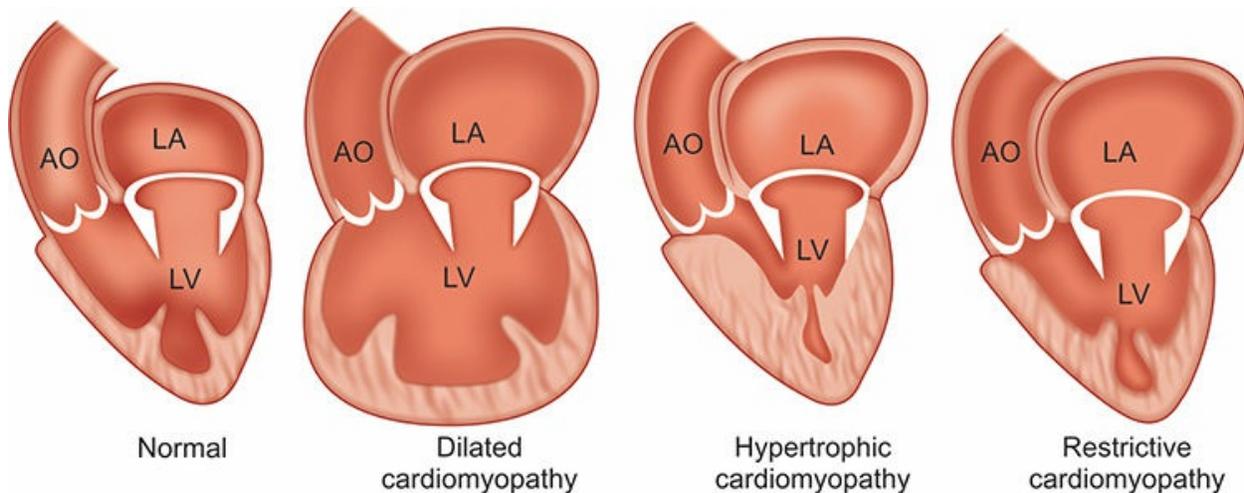

**Table 7.94:** Salient features of three major clinical types of cardiomyopathies.

<b>Functional type (Left ventricular ejection fraction)</b>	<b>Abnormality</b>		<b>Dysfunction</b>
	<b>Structural</b>	<b>Functional</b>	
Dilated/congestive (<40%)	Dilatation of ventricle	Poor ventricular contraction	Systolic dysfunction
Hypertrophic (50–80%)	Hypertrophy of left ventricle generalized or involves the upper portion of interventricular septum	Impairment of ventricular filling and left ventricular ejection due to outflow tract obstruction	Predominantly diastolic dysfunction
Restrictive/obliterative (45–90%)	Small ventricle with” stiff wall”	Impairment of ventricular filling	Diastolic dysfunction

**Dilated (Congestive) Cardiomyopathy (DCM)**

**Q. Write short essay/note on dilated cardiomyopathy (congestive cardiomyopathy).**

- DCM is characterized by dilatation/enlargement of the ventricular chambers and systolic dysfunction (impaired contraction of left and/or right ventricular) with preserved wall thickness.
- Left ventricular mass is increased but thickness of wall is normal or reduced. Dilatation of the valve rings may cause functional incompetence of mitral and tricuspid valves.
- Most common of all cardiomyopathies.
- Responsible for about one in three cases of heart failure and third most common cause of heart failure.

**Fig. 7.51:** Clinical classification of cardiomyopathy.  
(AO: aorta; LA: left atrium; LV: left ventricle)

### *Etiology*

- **Familial DCM:** One-fifth to one-third of patients has familial forms of DCM. It is inherited as an autosomal dominant disorder and is associated with more than 20 varieties of single-gene mutations. Most of these mutations involve genes encoding the cytoskeleton of the myocyte (dystrophin, lamin A and C, emerin and metavinculin). Most of the X-linked inherited skeletal muscular dystrophies (e.g. Becker and Duchenne) are associated with cardiomyopathy.
- **Sporadic DCM:** Causes include:
  - **Myocarditis:** Coxsackie, adenoviruses, HIV, bacteria, fungal, mycobacteria, parasitic (Chagas disease)

- **Toxins:** Alcohol, chemotherapy (e.g. adriamycin, trastuzumab, cyclophosphamide), metals (cobalt, lead, mercury, arsenic)
- Autoimmune diseases (SLE, systemic sclerosis, dermatomyositis)
- **Endocrine:** Diabetes mellitus, thyrotoxicosis, hypothyroidism
- **Neuromuscular:** Muscular dystrophies, Friedrich's ataxia, myotonic dystrophy

### *Clinical features*

- It is three times more common in men than women and the peak incidence is in middle age.
- Symptoms may be gradual in onset or may cause sudden cardiac death due to arrhythmias. Thromboembolism, conduction defects and sporadic chest pain may be present.
- **Symptoms/signs of heart failure**
  - Fatigue and weakness
  - Pulmonary congestion (left heart failure), dyspnea (rest, exertional, nocturnal), orthopnea.
  - Systemic congestion (right heart failure), edema, nausea, abdominal pain, nocturia.
  - Low cardiac output
  - Hypotension, tachycardia, tachypnea
  - Narrow pulse pressure
  - Elevated jugular venous pressure (JVP)
  - **Arrhythmia:** Atrial fibrillation, conduction delays, complex PVCs, sudden death.

### *Investigations*

- **Chest X-ray:** Generalized enlargement of heart, CHF
- **Electrocardiogram:** ECG shows tachycardia, conduction abnormalities (AV block, LBBB), diffuse nonspecific ST segment and T wave changes, arrhythmias (i.e. atrial fibrillation, ventricular premature contractions or ventricular tachycardia)
- **24-hour Holter monitor:** If lightheadedness, palpitation, syncope
- **Echocardiogram, CTI, CMRI:** Show left ventricular dilation with normal or minimally thickened or, thinned walls, global hypokinesia, low

EF

- Elevated BNP
- Cardiac catheterization to rule out coronary artery disease
- Myocardial biopsy, rarely necessary.

#### **Treatment**

- *Control and conventional management of heart failure:* Salt restriction, fluid restriction and initiate standard treatment of heart failure. Medical therapy consists of ACE inhibitors, diuretics, digoxin and hydralazine/nitrate combination. L-carnitine, antioxidants and chelating agents have been tried.
- Anticoagulation prophylaxis
- Implantation of a cardiac defibrillator and/or cardiac resynchronization therapy in some patients.
- Cardiac transplantation in certain patients.

**Prognosis:** Majority particularly >50 years die within 4 years of onset. Spontaneous improvement or stabilization occurs in 25% of cases. Death is due to progressive heart failure, ventricular tachycardia. SCD is a constant threat.

### ***Alcoholic Cardiomyopathy***

- Individuals who consumes >90 g/day of alcohol for many years.
- Clinical picture resembling idiopathic or familial DCM.
- Partially genetically predetermined (ALDH2).
- Abstention may halt the progression or may even reverse.

### ***Peripartum Cardiomyopathy***

- Cardiac dilatation with CHF develops during last trimester or within 6 months of delivery.
- Typically present in multiparous of age >30 years.
- Unknown cause
- Inflammatory myocarditis, immune activation, multiple gestations have been incriminated.
- Symptoms, signs and management are that of IDCM
- Further pregnancy should be discouraged.

### ***Hypertrophic Cardiomyopathy***

**Q. Write short essay/note on hypertrophic cardiomyopathy (HCM).**

- HCM is characterized by left ventricular hypertrophy, typically of a non-dilated chamber, without any obvious cause.
- Two significant features are:
  - **Asymmetric myocardial hypertrophy** of the left ventricle with greater hypertrophy of the interventricular septum.
  - A dynamic left ventricular outflow tract pressure gradient, related to narrowing of the sub aortic area which may produce LV outflow tract obstruction.
- It is familial and transmitted as an autosomal dominant trait.

*Clinical features*

- *Asymptomatic*: Echocardiographic finding only and family history may be positive.
- *Symptomatic*: Dyspnea in 90%. Other symptoms include effort-related such as angina and breathlessness, arrhythmia and sudden death.

*Signs*

- Rapidly rising carotid pulse ('jerky' 'spike and dome')/bisferiens pulse (two systolic peaks).
- Double apical impulse.
- Reversed pulsus paradoxus on arterial pulse with Bernheim a wave in JVP.
- Harsh ejection systolic murmur best heard at the lower-left sternal border as well as the apex due to left ventricular outflow tract obstruction. This murmur increases during standing and Valsalva maneuver (which reduce ventricular preload) but decreases during squatting and sustained hand grip (which increase afterload), and also by leg rising (which increases preload).
- Pansystolic murmur at mitral area due to mitral regurgitation.

*Investigations*

- *Electrocardiogram*: Abnormal in 85–90% of cases. Shows left ventricular hypertrophy, abnormal ST-Ts, giant T-wave inversions, abnormal Q' waves, bundle branch block (BBB).
- *Chest X-ray*: Normal or shows mild-to-moderate cardiac enlargement.

- Echocardiography is diagnostic. Increased LV wall thickness  $\geq 15$  mm, **systolic anterior motion** (SAM) of the mitral valve and dynamic LV outflow tract obstruction.
- Genetic testing for evaluation of family members.

#### **Treatment**

- *Avoid:* Dehydration, digitalis, diuretics, dihydropyridines, and vasodilators.
- *Drug therapy:* Beta-adrenergic blockers, calcium-channel blockers (verapamil, diltiazem, etc.), disopyramide and anti-arrhythmics (amiodarone).
- Implantable cardiac defibrillator (ICD).
- Myectomy (partial surgical resection of septum) may improve outflow tract obstruction.
- Iatrogenic infarction of the basal septum (septal ablation) using a catheter delivered alcohol solution.
- Transplantation.

#### *Prognosis*

- Risk of SCD higher in children. Clinical deterioration usually is slow.
- Poor prognosis in males, young age of onset, family history of SCD, history of syncope, exercise induced hypotension (worst).
- Progression to DCM occurs in 10–15%.

### ***Restrictive (Obliterative) Cardiomyopathy***

#### **Q. Write short essay/note on restrictive cardiomyopathy (obliterative cardiomyopathy).**

- Rare condition in which ventricular filling is impaired because of the stiff ventricles. Hallmark is an abnormal diastolic function.
- It resembles constrictive pericarditis, and it is important to differentiate because constrictive pericarditis is an operable disease.
- Much less common than DCM or HCM outside the tropics, but frequent cause of death in Africa, India, South and Central America and Asia primarily because of the high incidence of endomyocardial fibrosis in those regions.

#### ***Causes***

- Idiopathic
- *Myocardial:*
  - *Noninfiltrative:* Idiopathic, scleroderma

- *Infiltrative*: Amyloidosis, sarcoidosis, Gaucher's disease, Hurler disease
- Storage disease: Hemochromatosis, Fabry disease, glycogen storage diseases.
- *Endomyocardial*: Tropical endomyocardial fibrosis, hypereosinophilic syndrome, carcinoid, metastatic malignancies, radiation, anthracycline drugs.

### *Clinical features*

- Symptoms of right and left heart failure. Exercise intolerance, dyspnea, peripheral edema, ascites and enlarged tender liver.
- Systemic embolism may develop in about 25% cases.
- Jugular venous pressure may be raised with diastolic collapse and positive Kussmaul's sign.
- Mild cardiac enlargement, the cardiac apex is easily palpable, and a mitral regurgitation murmur may be heard (not found in constrictive pericarditis).
- Heart sounds are soft and third and fourth heart sounds may be heard.

### *Investigations*

- **Electrocardiogram**: Shows non-specific ST-T wave changes, low voltage, arrhythmias
- **Chest X-ray**: Shows mild cardiomegaly.
- **Doppler echocardiography**: Abnormal mitral inflow pattern, symmetrically thickened LV walls and systolic dysfunction, prominent E wave (rapid diastolic filling), reduced deceleration time (increased left atrial pressure).
- **Cardiac MRI and CT**: Show symmetrically thickening of left ventricle wall, and normal or slightly reduced ventricular volumes and systolic function. These findings are useful in differentiating it from constrictive pericarditis.
- **Cardiac catheterization**: Shows increased ventricular filling pressures with dip-and-plateau pattern.

### **Treatment**

- No satisfactory medical therapy.
- Drug therapy must be used with caution.
  - Diuretics for extremely high-filling pressures.

- Chronic anticoagulation is often recommended.
- Vasodilators may decrease filling pressure.
- Calcium-channel blockers to improve diastolic compliance.
- Digitalis and other inotropic agents are not indicated.
- Transplantation may be indicated.

**Table 7.95: Classification of congenital heart diseases.**

<i>Acyanotic</i>	<i>Cyanotic</i>
<b>With (left to right) shunts</b> <ul style="list-style-type: none"> <li>• Ventricular septal defect</li> <li>• Atrial septal defect</li> <li>• Patent ductus arteriosus</li> </ul> <b>Without shunts (obstructive lesions)</b> <ul style="list-style-type: none"> <li>• Aortic stenosis</li> <li>• Coarctation of aorta</li> </ul>	<b>With (right to left) shunts</b> <ul style="list-style-type: none"> <li>• Tetralogy of Fallot</li> <li>• Tricuspid atresia</li> <li>• Ebstein's anomaly</li> <li>• Transposition of great vessels</li> <li>• Truncus arteriosus</li> </ul> <b>Without shunts (obstructive lesions)</b> <ul style="list-style-type: none"> <li>• Pulmonary stenosis</li> </ul>

## CONGENITAL HEART DISEASES

**Q. Write short note on:**

- **Common congenital heart diseases seen in adults.**
- **Enumerate cyanotic heart diseases.**

Congenital heart disease (CHD) is the most common group of structural malformations in children. CHD occurs in 8 per 1000 infants. About 1 in 10 stillborn infants have a cardiac anomaly.

### Classification of Congenital Heart Diseases

Classification of congenital heart diseases is summarized in Table 7.95.

#### Acyanotic Congenital Heart Diseases

##### *Persistent Ductus Arteriosus (Patent Ductus Arteriosus, PDA)*

**Q. Write short essay on persistent ductus arteriosus (patent ductus arteriosus).**

##### *Etiology*

Rubella infection during the first trimester of pregnancy and fetal valproate syndrome is associated with a high incidence of PDA. **Patent (persistent)**

**ductus arteriosus (PDA)** is a congenital anomaly in which the **ductus arteriosus remains open after birth**. This produces a persistent communication between the proximal left pulmonary artery and the descending aorta. Since the pressure in the aorta is higher than that in the pulmonary artery, it produces a continuous arteriovenous left to right shunt the volume of which depends on the size of the ductus. About 50% of the left ventricular output is recirculated through the lungs, with a consequent increase in the work of the heart. PDAs may occur as an **isolated anomaly** (about 90%), **or associated with** other abnormalities such as **VSD, coarctation of the aorta, or pulmonary or aortic valve stenosis**.

### *Clinical features*

#### *Symptoms*

- More common in females with female to male ratio of about 2:1.
- When the shunt is small, then it may be asymptomatic for years.
- If the shunt is moderate-to-large, there is retardation of growth and development. It produces left heart volume overload. Cardiac failure may develop producing dyspnea. In some cases, it may raise pulmonary artery pressure resulting in pulmonary hypertension and Eisenmenger's syndrome.

#### **Q. Write short essay on differential cyanosis.**

**Persistent ductus with reversed shunting:** When the pulmonary vascular resistance increases, pulmonary artery pressure may rise until it equals or exceeds aortic pressure. Then the shunt through the patent ductus arteriosus may reverse causing Eisenmenger's syndrome. Patients with Eisenmenger's syndrome are cyanotic and may have **differential cyanosis**. It is characterized by cyanosis and clubbing of the toes but not the fingers because the right-to-left ductal shunting is distal to the subclavian arteries.

#### *Signs*

#### **Q. Write short essay on cardiac findings in patent ductus arteriosus.**

- **Bounding pulse:** Pulses are increased in volume.
- **Apex beat** is shifted down and out and hyperdynamic.
- PDA produces a characteristic **continuous harsh murmur known as 'machinery-like'/Gibson's murmur**. It is heard with late systolic

accentuation and maximal in the first left intercostal space below the clavicle and frequently accompanied by a continuous thrill at the upper-left sternal edge. However, in a large PDA when pulmonary hypertension develops the murmur becomes softer.

- First heart sound is loud (due to loud mitral component).
- Graham Steell murmur of pulmonary hypertension will be present.

### *Investigations*

- **Chest X-ray** shows enlargement of the pulmonary artery with increased vascular markings (plethoric fields).
- **ECG** is usually normal with smaller ductal shunts. It may demonstrate left atrial enlargement, left ventricular hypertrophy, sinus tachycardia or atrial fibrillation in patients with moderate or large shunts.
- **Echocardiogram and color Doppler** shows PDA and the amount of blood flow through the ductus arteriosus.
- **Magnetic resonance imaging and computed tomography:** It can assess the degree of calcification, which is important, if surgical therapy is considered.

**Complications:** Cardiac failure, hypertensive pulmonary vascular disease, endarteritis, paradoxical embolism.

### **Management**

- Small ductus arteriosus may predispose to endarteritis and ductus closure should be done unless clinically silent.
- Ductus closure is indicated for any child or adult who is symptomatic from significant left-to-right shunting through the PDA.
- Transcatheter-occluding devices (e.g. coils, buttons and umbrellas) are increasingly used.
- Video-assisted thoracoscopic clip closure.
- Surgical ligation or division of the PDA remains the treatment of choice for the rare very large ductus arteriosus.
- Symptomatic patients with PDA usually improve with a medical regimen of diuretics, digoxin and angiotensin-converting enzyme inhibition, antidysarrhythmia medications with anticoagulation may be useful in patients with atrial fibrillation or flutter.
- **Pharmacological treatment in the neonatal period:** In the first week of life, if the ductus is patent; a prostaglandin synthetase inhibitor (e.g. indomethacin or ibuprofen) may be used to induce its closure. However, if there is an impaired lung perfusion (e.g. severe pulmonary stenosis and left-to right shunt through the ductus), the ductus must be kept open with prostaglandin treatment to improve oxygenation.

## ***Coarctation of Aorta***

**Q. Write short essay on coarctation of aorta.**

Coarctation of the aorta (COA) is narrowing of the lumen of the aorta at the region or just distal to the insertion of the ductus arteriosus distal to (just below) the origin of the left subclavian artery.

**Etiology:** It is congenital heart disease associated with other abnormalities, such as bicuspid aortic valve (80% of cases) and 'berry' aneurysms in the circle of Willis, Turner's syndrome. Other lesions that may be associated include patent ductus arteriosus, ventricular septal defect and patent ductus arteriosus, mitral stenosis or regurgitation.

**Types:** Two classic forms.

1. **Infantile (preductal) form:** Characterized by tubular hypoplasia of the aortic arch proximal to a patent ductus arteriosus. It produces symptoms in early childhood.
2. **Adult (postductal) form:** Shows narrowing of the aorta, opposite the closed ductus arteriosus (ligamentum arteriosum) distal to the arch vessels.

*Clinical features*

*Symptoms*

- It is twice common in men compared to women.
- It may present as cardiac failure in the newborn but often asymptomatic for many years when detected in older children or adults.
- May present with headaches and epistaxis/nosebleeds due to hypertension proximal to the coarctation.
- Occasionally present with weakness or cramps/ Claudication in the legs and cold legs due to decreased blood flow to the lower part of the body limbs.

*Signs*

**Q. Write short note on radiofemoral delay and Suzman's sign.**

- **Pulse:** The femoral pulses and pulses in the lower limbs are weak, delayed (radiofemoral delay) in comparison with the radial pulse. If coarctation is proximal to the left subclavian artery, asynchronous radial pulses in right and left arms are observed. Prominent pulsations in the neck. In severe coarctation, pulses are poor.
- **BP:** It is raised in the upper limbs, but normal/low in the legs (difference >20 mm Hg).

- *Heart sounds and murmurs:*
  - *Ejection systolic murmur (ESM):* Systolic murmur is heard posteriorly, over the spine due to coarctation.
  - Systolic or continuous murmurs over lateral thoracic wall due to collaterals.
  - An ejection click and systolic murmur in the aortic area, if associated with bicuspid aortic valve. Heaving apical impulse.
- **Bruits:** Aortic narrowing causes formation of collaterals mainly in the periscapular, internal mammary and intercostal arteries, and may produce localized bruits.
- **Suzman's sign:** It is characterized by dilated, tortuous, pulsatile arteries around the scapulae and intercostals regions in the back. It is seen better when the patient bends forwards with hands hanging down.
- **Corkscrew-shaped retinal arteries.** Absence of papilledema despite high BP.

### *Investigations*

- **Chest X-ray:** In early childhood, it is often normal. Later, it may show post-stenotic dilatation of aorta and indentation of the descending aorta at the site of the coarctation. This produces an aorta shaped like a '**figure 3**' (due to combination of dilated left subclavian artery above, stenosed, coarcted segment in the middle and dilated poststenotic aorta below in the upper right mediastinum. Tortuous and dilated collaterals may erode the undersurfaces of the ribs producing notching of the under-surfaces of the posterior ribs ('**rib notching**' or '**Dock'sign**') extending from third to ninth ribs. It may be unilateral or bilateral, and found only after 6 years of age.
- **CT, MRI and CMR scanning** is the best imaging method to accurately demonstrate the coarctation and quantify flow.
- **ECG:** May demonstrate left ventricular hypertrophy.
- **Echocardiography** sometimes shows the coarctation and other associated anomalies. It confirms left ventricular hypertrophy.

**Complications:** Hypertension, left ventricular/congestive heart failure, infective endocarditis (at the site of coarctation, bicuspid aortic valve or collateral channels), cerebral hemorrhage due to rupture of Berry aneurysm and rupture or dissection of aorta.

### Treatment

- If untreated, death may occur due to complications (e.g. left ventricular failure, dissection of the aorta or cerebral hemorrhage).
- Treat hypertension and congestive heart failure. Avoid ACE inhibitors and angiotensin II receptor antagonists because they may lead to inadequate perfusion of lower-body and may precipitate renal failure.
- *Surgical correction:* Intervention is needed if there is a peak–peak gradient across the coarctation of >20 mm Hg and/or proximal hypertension. In neonates surgical repair is required. In older children and adults, balloon dilatation and stenting or surgery is advisable. Recurrence of stenosis may occur as the child grows. A balloon dilatation is preferred for recoarctation (sometimes stenting).

## *Atrial Septal Defect*

### **Q. Write short essay on atrial septal defect.**

An atrial septal defect (ASD) is an abnormal, fixed opening in the atrial septum. It is due to incomplete formation of the atrial septum.

#### *Types of ASD*

- **Ostium secundum** defects (75–85% of ASDs) are located in the region of the midseptum (fossa ovalis).
- **Ostium primum (atrioventricular septal)** defects (10–15%) are located in the lower portion of the atrial septum.
- **Sinus venosus** defects:
  - **Superior sinus venosus type defect (5–10%):** Defects are located in the superior part of the septum near the orifice of the superior vena cava (SVC).
  - **Inferior sinus venosus (IVC) type defect (1%):** Defects are located on the inferior part of the septum near the inferior vena cava (IVC) entry point.
- **Coronary sinus (1%)** septal defect (in which a defect between the coronary sinus and the left atrium allows a left-to-right shunt to occur through an ‘unroofed’ coronary sinus).

#### *Hemodynamics*

In ASD flow of blood is between the left and right atria. Normal RV is more compliant than the LV and initially a large volume of blood shunts through the atrial defect from the left atrium to right atrium and then to right ventricle. This increases right ventricular output and markedly increased pulmonary

blood flow through the pulmonary arteries. As a result, there is progressive enlargement of right atrium, right ventricle and pulmonary arteries. Eventually, pulmonary hypertension develops and sometimes reversal of the shunt from right to left (tend to occur later in life).

### *Clinical Features*

#### *Symptoms*

- ASDs are often **asymptomatic till adulthood**.
- Two to three times more common in women than in men.
- Symptoms include easy fatigability, recurrent chest infection, exertional dyspnea, palpitations related to arrhythmias (especially atrial fibrillation), platypnea-orthodeoxia-dyspnea with standing, relieved by restand cardiac failure.
- *After 40 years*: Deterioration due to atrial fibrillation, increased left to right shunt due to hypertension and coronary artery disease (CAD) which decrease left ventricular (LV) compliance.

#### *Signs*

- **Pulse**: No variation in rate or volume with Valsalva, irregularly irregular pulse with AF.
- **JVP**: (1) a and v waves have equal height that is reflection of LA waves and (2) a wave becomes taller when pulmonary hypertension develops or associated mitral stenosis (MS).
- Systolic pulsations in second and third left intercostals space due to dilated pulmonary artery.
- Characteristic physical signs due to the volume overload of the right ventricle:
  - **S2- wide fixed split**: *Wide, fixed splitting of the second heart sound (S<sub>2</sub>).*
    - ◆ *Wide due to (1) increased RV ejection time (delay in right ventricular ejection) and (2) increased pulmonary hangout interval.*
    - ◆ *Fixed because the atrial septal defect equalizes left and right atrial pressures throughout the respiratory cycle.*
  - A systolic flow murmur over the pulmonary valve not due to atrial septal defect.
  - Diastolic flow murmur over the tricuspid valve may be heard in

children with a large shunt.

- $S_1$ -loud and  $P_2$  is loud (due to increased recoil of the dilated PA and close proximity of dilated PA to chest wall).
- Ventricular heave/parasternal impulse present.

### *Investigations*

- **Chest X-ray (Fig. 7.52):** It shows enlargement of the heart (right atrium, right ventricle) and prominent pulmonary arteries (Jug handle appearance) with pulmonary plethora. Hilar dance on fluoroscopy is characteristic.
- **ECG:** Incomplete right bundle branch block (RBBB due to right ventricular depolarization) and right axis deviation (due to dilatation of the right ventricle). Ostium primum defects may show left axis deviation.
- **Echocardiography:** May show hypertrophy and dilatation of the right heart and pulmonary arteries.
- Subcostal views with 2D and color Doppler demonstrates the ASD and helps in calculation of the left right shunt (QP: QS ratio).
- **CMR and CT** helps to assess for anomalous pulmonary venous drainage.
- **MRI:** Can be used to identify size and location of defect, A major advantage of MRI is the ability to quantify right ventricular size, volume, and function along with the ability to identify the systemic and pulmonary venous return.
- **Cardiac catheterization:** In non-restrictive ASD, pressure gradient between atria is less than 3 mm Hg.

**Complications:** Congestive heart failure (in neonates), paradoxical embolism, atrial fibrillation. Others include pulmonary hypertension (late), Eisenmenger's syndrome (very late) and very rarely infective endocarditis.

**Fig. 7.52:** Chest X-ray of atrial septal defect showing jug handle appearance.

### **Management**

- Prompt treatment of respiratory infections.
- Indications for intervention
  - ASD with significant left to right shunting resulting in right atrial/ventricular enlargement irrespective of symptoms.
  - Atrial septal defects in which pulmonary flow is increased 50% above systemic flow (i.e. flow ratio of 1.5 : 1).
  - Thromboembolic events.
- **Contraindications to surgery:** Severe pulmonary hypertension and shunt reversal.
- **Surgical options available are:**
  - Median sternotomy with direct closure of small to moderate defect.
  - Larger defects closed with autologous pericardium or synthetic patches like polyester polymer (Dacron) or polytetrafluoroethylene (PTFE).
  - Surgical closure of the defect is done in patients above 3 years of age, provided there are no signs of pulmonary hypertension and the pulmonary flow is 50% more than the systemic blood flow ( $Q_p:Q_s > 1.5/1$ ).
  - A transcatheter septal clamshell device closure may be used for most secundum ASDs (if

suitable size).

- Uncorrected ASD does not require antibiotic prophylaxis for endocarditis unless other high-risk conditions are present (refer infective endocarditis on page 481).

**Prognosis:** Long-term prognosis thereafter is excellent after surgical intervention.

### *Patent Foramen Ovale*

#### **Q. Write short note on patent foramen ovale.**

- It may be found in >25% of adult population and is hemodynamically insignificant.
- Usually asymptomatic but may be associated with paradoxical emboli and increased incidence of embolic stroke.

### *Ventricular Septal Defect*

#### **Q. Write short essay on ventricular septal defect.**

Ventricular septal defect (VSD) is the most common congenital heart disease (2 per 1000 live births).

#### *Etiology*

- Congenital ventricular septal defect are due to incomplete septation of the ventricles. Embryologically, the interventricular septum has two portions namely (1) a membranous and (2) a muscular portion (which is further divided into inflow, trabecular and outflow portions). Most congenital ventricular defects are 'perimembranous', i.e. at the junction of the membranous and muscular portions. Congenital ventricular septal defect may be isolated or may be associated with other congenital heart disease.
- **Causes of acquired ventricular septal defect:** Ventricular septal rupture as a complication of acute MI, infective endocarditis or rarely from trauma/cardiac catheterization.

#### *Hemodynamic consequences*

- Left ventricular pressure is higher than right ventricle. Therefore, blood flows from left to right ventricle and this causes a volume overload of the right ventricle and increased pulmonary blood flow.
- The shunt volume in a VSD depends on the shunt size of the defect and the pulmonary vascular resistance. If the defect is large (at a later stage),

large volumes of blood flows through the pulmonary vasculature leading to pulmonary hypertension. When the right ventricular pressure becomes higher than left, the blood starts to shunt from right to left leading to Eisenmenger's complex. It is characterized by cyanosis.

### *Clinical features*

#### *Symptoms*

- Symptoms depend on the size of the defect and severity the shunt.
- In patients with large VSD, symptoms develop soon after birth. It includes dyspnea, repeated pulmonary infection, hepatomegaly, sweating, and failure to thrive. Irreversible pulmonary vascular disease after 1–2 years of age.
- Some children with isolated VSD develop subpulmonic stenosis: Patient not at risk of pulmonary vascular disease.

#### *Signs*

#### **Q. Write short note on Maladie de Roger.**

- Pulse pressure is relatively wide.
- Murmur:
  - Blood flow from the high-pressure left ventricle to the low-pressure right ventricle during systole produces a **pansystolic murmur (PSM)**. It is usually heard best at the left sternal edge (3rd, 4th and 5th intercostal space) and radiates all over the precordium.  $S_1$  and  $S_2$  are masked by a pansystolic murmur.
  - **A small defect usually produces a loud PSM murmur (maladie de Roger)** presenting in older children when there is no other hemodynamic disturbance.
  - **Large defect produces a softer murmur**, especially when the right ventricular pressure is raised. This can be detected immediately after birth, while pulmonary vascular resistance is high, or when the shunt is reversed as in Eisenmenger's syndrome.
- Precordium is hyperkinetic with a systolic thrill at left sternal border (LSB).
- Prominent parasternal pulsation, tachypnea and indrawing of the lower ribs on inspiration.

- Mortality—27% by 20 years and 69% by 60 years.

### *Investigations*

- **Chest X-ray:** Shows cardiomegaly proportional to the volume overload. Mainly LV, LA and RV enlargement. Increased pulmonary blood flow, PAH.
- **Electrocardiogram:** May show right/left or combined ventricular hypertrophy. RBBB is common. **Katz Watchtel sign**, i.e. large equiphasic QRS in  $V_2$ - $V_4$  suggestive of biventricular hypertrophy.
- **Doppler echocardiography** is useful to determine location of VSD, morphology of LV outflow, aortic valve involvement.
- **Cardiac catheterization** to assess pulmonary vascular resistance in complicated VSD.

**Complications:** These include congestive heart failure, pulmonary hypertension, Eisenmenger's syndrome, right ventricular outflow tract obstruction, infective endocarditis.

### *Natural history*

- Spontaneous closure occurs in about 40% of cases.
- Development of RVOT obstruction/infundibular stenosis (*Gasul's transformation*) may occur in 5% of the defects. Though patient requires surgery, it prevents development of pulmonary vascular obstructive disease.
- Aortic insufficiency develops in approximately 5% of patients. This may either be related to prolapse of an aortic valve cusp into VSD or lack of support to the aortic root.

### **Management**

- **Small VSD:** No medication or surgery needed if asymptomatic. About 75–80% closes by 2 years and it needs observation.
- **Cardiac failure in infancy:** It is initially managed with digoxin and diuretics. If failure persists surgical repair of the defect should be performed.
- **Moderate/large VSD:** Repair by intervention
  - Large hemodynamically significant VSD: L to R shunting with  $Q_p/Q_s \geq 2:1$ , even if asymptomatic, ideally before 1 year.
  - Growth failure, unresponsive to medical therapy is an indication for surgery.
- Surgical closure is contraindicated in fully developed Eisenmenger's syndrome. These patients may be treated by heart–lung transplantation.

## ***Eisenmenger's Syndrome***

### **Q. Write short essay on Eisenmenger's syndrome.**

Eisenmenger syndrome characterized by an untreated congenital cardiac defect with intracardiac communication that leads to pulmonary hypertension, reversal of flow, and cyanosis.

- It develops as a consequence of the reversal of a left-to-right shunt to a right-to-left shunt. It develops in patients with congenital heart disease such as patent ductus arteriosus (PDA), ventricular septal defect (VSD), and atrial septal defect (ASD).
- VSD Eisenmenger is called as Eisenmenger complex.

### *Clinical features*

#### *Symptoms*

Dyspnea, fatigue, dizziness and syncope.

#### *Signs*

- **Central cyanosis and clubbing:** It develops due to the mixing of deoxygenated blood with oxygenated blood. It is generalized in ASD and VSD reversal, whereas it is differential (only lower limbs) in PDA with reversal.
- Signs of pulmonary hypertension and its sequelae (refer 'pulmonary hypertension').
- **Heart sounds:** S<sub>2</sub> is loud with palpable P<sub>2</sub>.
  - In ASD with reversal: S<sub>2</sub> fixed but narrowly split
  - In VSD with reversal: S<sub>2</sub> single
  - In PDA with reversal: S<sub>2</sub> mobile but narrowly split
  - Right ventricular S<sub>4</sub> and pulmonary ejection click appear.
- **Murmurs:** The murmurs of the underlying cause (ASD, VSD, PDA) decrease in intensity, duration and finally disappear with the development of Eisenmenger's syndrome. Early diastolic murmur at pulmonary area and pansystolic murmur of TR appear.

**Complications:** Right heart failure, infective endocarditis, pulmonary infections, severe hemoptysis, secondary polycythemia, pulmonary thrombosis with infarction, brain abscess, cerebral stroke and ventricular

arrhythmias.

#### **Treatment**

- Surgical correction of underlying defect (refer treatment of ASD, VSD and PDA).
- Do not advise vasodilator therapy using calcium channel blockers. It causes systemic vasodilatation and increases right-to-left shunt.
- Long-term oxygen inhalation may be useful to relieve symptoms.
- Phlebotomy when hyperviscosity syndrome develops due to polycythemia.
- Heart-lung transplantation is the only curative treatment.
- Relief of symptoms: By drugs such as prostanoids (e.g. epoprostenol, iloprost, treprostinil), endothelin receptor antagonists (e.g. bosentan) and phosphodiesterase-5 inhibitors (e.g. sildenafil, tadalafil).

## **Cyanotic Congenital Heart Diseases**

### ***Tetralogy of Fallot***

**Q. Write short essay on Fallot's tetralogy or Tetralogy of Fallot (TOF).**

It is the most common congenital cyanotic heart disease in adults (75%). It consists of four features (Fig. 7.53A):

1. Ventricular septal defect usually large and similar in aperture to the aortic orifice.
2. Pulmonary stenosis: Right ventricular outflow tract obstruction mostly subvalvular (infundibular) but may be valvular, supra-valvular or a combination of these.
3. Overriding of dextroposed aorta
4. Right ventricular hypertrophy

Presence of ASD along with TOF is known as **pentalogy of Fallot**.

#### ***Etiology***

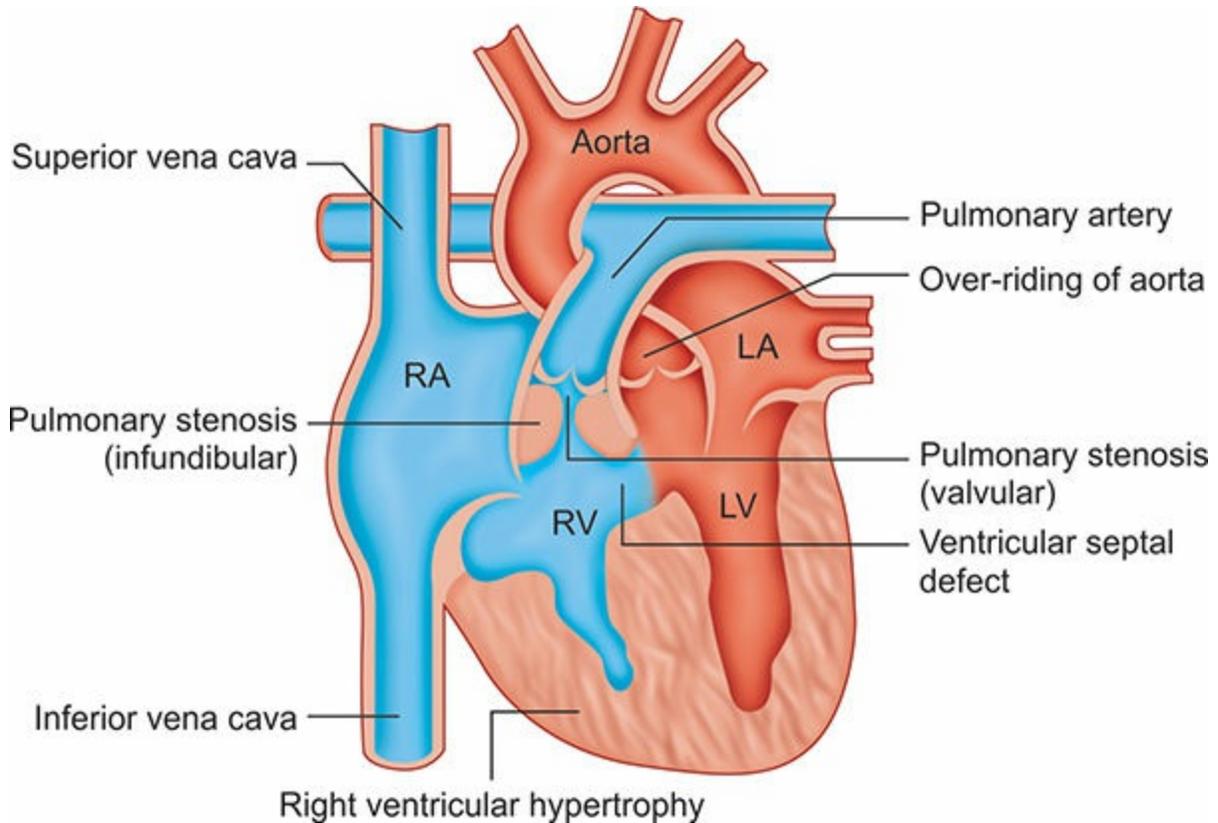

- It occurs in about 1 in 2000 births and is the most common cause of cyanosis in infancy after the first year of life.
- It is due to abnormal development of the bulbar septum that separates the ascending aorta from the pulmonary artery.

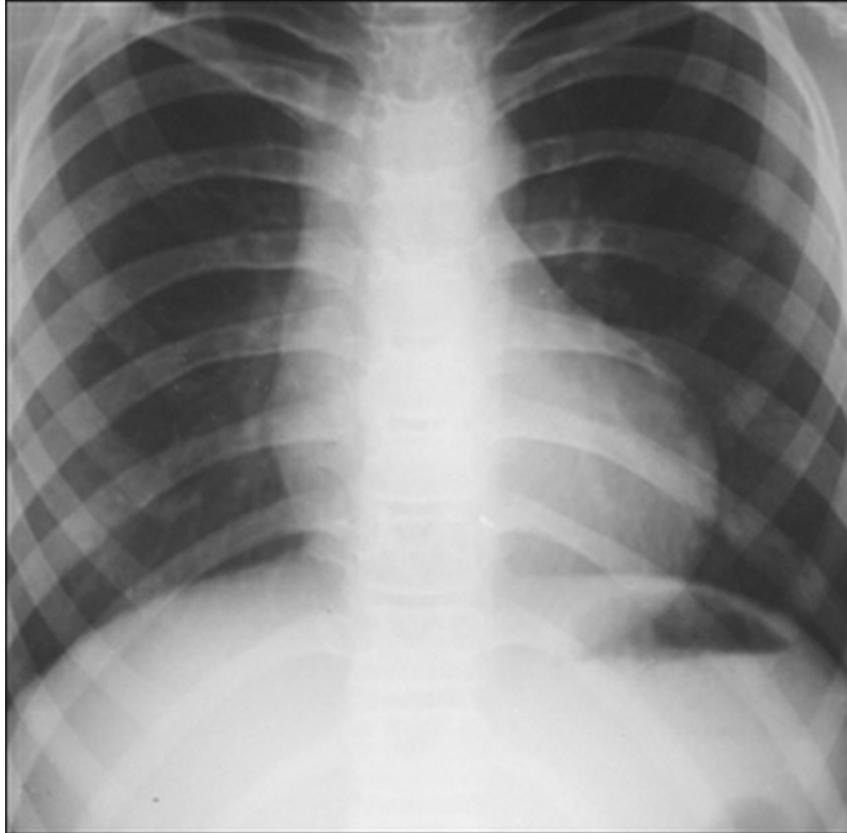

#### ***Pathophysiology***

- When RV and LV pressures become identical, there is little or no left to right shunt. Hence, VSD is silent.
- Right ventricle empties into pulmonary artery across pulmonic stenosis

producing ejection systolic murmur. Hence, the more severe the pulmonary stenosis, more is the left to right shunt and less is the flow into the pulmonary artery and the ejection systolic murmur is shorter.

- When tetralogy causes elevation of right ventricular pressure, right-to-left shunting of cyanotic blood across the ventricular septal defect occurs.
- Congestive failure usually does not develop because right ventricle is effectively decompressed by ventricular septal defect.

**Figs. 7.53A and B:** (A) Diagrammatic representation of tetralogy of Fallot. Four components are: (1) ventricular septal defect; (2) subpulmonic stenosis/pulmonary valvular stenosis; (3) aorta overriding the VSD and (4) right ventricular hypertrophy; (B) X-ray shows an abnormally small pulmonary artery, large right ventricle and a 'boot-shaped' heart.

### *Clinical Features*

#### *Symptoms*

- Symptoms depend on the severity of pulmonary stenosis and may present any time after birth.
- Paroxysmal attacks of dyspnea, anoxic spells, predominantly after waking up. Child cries becomes blue (cyanosis due to increased right sided pressures, resulting in a right to left shunt), lose consciousness and may develop convulsion. Frequency varies from once a few days to many attack everyday.
- Squatting is common
- **Fallot's spell ('tet spell')**: It is lethal, unpredictable, episodes in which the child suddenly becomes increasingly cyanosed usually during feeding, crying, fever or exercise and may become apnoeic and unconscious. This is because of spasm of the subpulmonary muscle (infundibular septum),

systemic vasodilatation producing increased right-to-left shunting across VSD and acute increase right ventricular outlet obstruction.

- Progression of spell may lead to metabolic acidosis which further reduces systemic resistance and increases pulmonary vascular resistance. This can cause sudden death.
- **Fallot's spell** can be relieved by increasing systemic/peripheral resistance. This diminishes (reduces) right-to-left shunting, increases systemic venous return and increases pulmonary blood flow. Example of postural maneuver that increases peripheral/systemic resistance is sitting posture/squatting (Fallot sign).
- Adults have growth retardation, fatigue and dyspnea on exertion but cyanotic spells are not usual. Secondary polycythemia due to chronic hypoxia and can produce thrombotic strokes.

### *Signs*

- **Combination of cyanosis with a loud ejection systolic murmur:** In the pulmonary area (as for pulmonary stenosis) is the most characteristic feature. The ejection systolic murmur is heard in the second and third left intercostal spaces and is due to pulmonary outflow obstruction. Intensity and duration of ejection systolic murmur is inversely proportional to severity of right ventricular outflow tract obstruction. However, cyanosis may not be seen in the newborn or in patients with only mild right ventricular outflow obstruction ('acyanotic tetralogy of Fallot').
- **Second heart sound:** Pulmonary obstruction results in delayed  $P_2$  and  **$P_2$  become soft or inaudible** (too soft to be heard). Since  $P_2$  is inaudible, hence  $S_2 = A_2$  ( $S_2$  is single loud second heart sound).
- Aorta is displaced anteriorly too,  $A_2$  becomes loud. Ascending aorta in TOF is large, results in an aortic ejection click.
- Other signs include clubbing, parasternal heave, systolic thrill.

### *Investigations*

- **Chest X-ray (Fig. 7.53B):** Shows an abnormally small pulmonary artery, large right ventricle and a 'boot-shaped' heart ("Coeur en Sabot").
- **ECG:** Shows right ventricular hypertrophy.
- **Echocardiography:** It is diagnostic and highly sensitive. It shows that the aorta is not continuous with the anterior ventricular septum.

- Cardiac catheterization is rarely required.

**Complications:** These include (1) intravascular thrombosis, cerebrovascular accidents and embolism secondary to polycythemia, (2) brain abscess and (3) infective endocarditis.

#### Treatment

- **Definitive management:** Consists of total correction of the defect by surgical means (relief of the pulmonary stenosis and closure of the ventricular septal defect) in infants and children prior to 5 years of age.
- **Blalock–Taussig shunt:** It is a shunt/anastomosis between a subclavian artery and pulmonary artery on the same side. In babies with severely hypoplastic pulmonary arteries (severe pulmonary stenosis), initially palliation in the form of a Blalock–Taussig shunt may be performed. This increases pulmonary blood flow and pulmonary artery development, and may facilitate later definitive correction.
- Treatment of cyanotic spells:
  - Patient is asking to assume squatting (knee-to-chest) position.
  - Oxygen administration
  - Intravenous fluids to increase venous return.
  - Morphine IV in the dose of 0.1 mg/kg reduces the release of catecholamines. This increases the period of right ventricular filling.
  - Propranolol IV in the dose of 0.01 mg/kg followed by oral dose of 3–5 mg/kg/day in divided doses.
- **Antibiotic prophylaxis for prevention of endocarditis.**

### Ebstein Anomaly

- Ebstein's anomaly is a cyanotic congenital heart disease that is characterized by abnormalities of the tricuspid valve and atrialization of right ventricle. It is associated with maternal lithium consumption.
- **Clinical features:** Patients present with episodic tachyarrhythmia's (associated WPW syndrome) and cyanosis. They are prone to develop paradoxical embolism, brain abscess and sudden cardiac death.
- On examination, there is central cyanosis and clubbing, prominent a waves in JVP and hepatomegaly. On auscultation patient will have a split first heart sound, split second heart sound, S<sub>3</sub> and S<sub>4</sub>. Pansystolic murmur of TR is present.
- ECG reveals right axis deviation, 'Himalayan' giant P waves, RBBB, pre-excitation pattern. CXR reveals gross cardiomegaly often called as wall to wall heart or the box heart.
- Doppler echocardiography is diagnostic.

### Management

Medical management include treatment of arrhythmias, embolism and nitric oxide. Surgical repair includes tricuspid replacement, selective plication of the atrialized right ventricle and closure of intracardiac shunt (Danielson repair, Carpentier technique).

**Prognosis:** After total surgical correction is good (especially if the operation is performed in childhood). About 66% live to one year, 49% to 3 years, and 24% to 10 years.

### Box 7.52: Common causes of pericarditis.

- Idiopathic
- Infections
  - Viral (Coxsackie A and B, Echovirus, HIV)
  - Pyogenic (**Pneumococcus, Staphylococcus, Legionella**)
  - Tuberculosis: Most common cause in India
  - Fungal (Histoplasmosis, Candida)
  - Syphilis, parasitic
- Acute myocardial infarction
- Metastatic neoplasm
- Hypothyroidism
- Radiation therapy (up to 20 years earlier)
- Chronic renal failure
- Connective tissue disorder (RA, SLE)
- Drug reaction (Procainamide, hydralazine)
- Autoimmune following heart surgery and MI (Dressler's syndrome)
- Trauma

## DISEASES OF THE PERICARDIUM

### Acute Pericarditis

**Q.** Write short essay/note on:

- **Acute pericarditis.**
- **Causes and management of pericarditis.**

**Definition:** Acute pericarditis is defined as an acute inflammation of the pericardium.

### *Etiology*

**Q. Write short note on causes of pericarditis.**

Various common causes of pericarditis are listed in Box 7.52.

### ***Classification***

- **Depending on the duration:** Pericarditis is classified as acute (<6 weeks), subacute (6 weeks to 6 months) and chronic (>6 months).
- **Depending on the nature of inflammation:** Pericarditis may be associated with pericardial effusion and also may coexist with myocarditis. Depending on the nature of pericardial inflammation, it may be classified as serous, hemorrhagic or purulent pericarditis.
  - *Fibrinous pericarditis:* Fibrinous exudate may heal and form varying degrees of adhesion formation.
  - *Serous pericarditis:* Produces a large effusion of turbid, straw colored fluid with high protein content.
  - Hemorrhagic pericarditis is usually due to malignant disease (e.g. carcinoma of the breast or bronchus, and lymphoma).
  - *Purulent pericarditis:* May develop as a complication of septicemia, by direct spread from an intrathoracic infection, or from a penetrating injury.

### ***Clinical Features***

#### ***Pericardial Pain***

- Pericardial inflammation produces characteristic pericardial pain. It is sharp, retrosternal (central) chest pain which radiates to the shoulders and neck. Radiation of pain to trapezius muscle ridges is a feature that favors pericardial pain.
- Pain may be steady and constrictive. Typically aggravated by deep breathing, movement, and a change of position /lying down, coughing exercise and swallowing.
- Typically relieved by sitting up and leaning forward.

#### ***Nonspecific Symptoms***

- Low-grade fever, and malaise. Myocarditis may be associated with pericarditis.
- Large pericardial effusion can compress adjacent bronchi and lung and

produce dyspnea (Ewart's sign).

### *Pericardial Friction Rub*

- Pericardial friction rub is a high-pitched superficial scratching or crunching sound, produced by movement of the inflamed pericardium. It is diagnostic of pericarditis.
- Best heard by applying firm pressure with the diaphragm of stethoscope at the lower left sternal edge at the end of expiration with the patients sitting upright and leaning forward. Usually heard in systole but may also be audible in diastole.
- It has a 'to-and fro', leathery quality. It is usually transitory, repeatedly disappearing and re-appearing.
- **Three phase:** Classical pericardial friction rub has three phases corresponding to movement of heart during three phases of cardiac cycle namely (1) atrial systole, (2) ventricular systole and (3) ventricular diastole (rapid ventricular filling during early diastole). However, in some it may be heard as only one (monophasic) or two (biphasic) rubs.

### *Other Features*

- **Pulsus paradoxus** (paradoxical pulse) is characterized by weakness/disappearance of arterial pulse during inspiration.
- **Cardiac tamponade:** Characterized by the accumulation of pericardial fluid under pressure.
- **Constrictive pericarditis:** Results from scarring and consequent loss of elasticity of the pericardial sac. Typically pericardium is thicker than normal and shows chronic inflammation, sometimes with calcification.
- **Effusive-constrictive pericarditis:** Characterized by constrictive physiology with a coexisting pericardial effusion, usually with tamponade.

### *Investigations*

- **Blood:** Leukocytosis (bacterial pericarditis) or lymphocytosis (viral pericarditis) and raised ESR.
- **Cardiac enzymes (CPK-MB, troponin T):** Normal unless associated with myocarditis.
- **Electrocardiogram:** ECG is diagnostic and changes may be found over the affected area, which may be widespread. These are as follows:

- Widespread **concave upwards (saddle shaped/smiling face) ST elevation** in multiple leads (particularly leads I, II, aVL, aVF and V1-V3) and reciprocal ST depression in leads aVR and V.
- **PR segment depression** is a characteristic feature of acute pericarditis.
- The above changes evolve over time and later followed by resolution of the ST elevation, T wave flattening/inversion (due to myocarditis) and finally T wave normalization.
- Finally ECG becomes normal.
- When there pericardial effusion QRS voltage is reduced. Electrical alternans is seen with effusion.

### *Differential Diagnosis*

- **Myocardial infarction (Table 7.96):** The early ECG changes observed in pericarditis should be differentiated from the ST elevation observed in myocardial infarction (limited to the infarcted area, e.g. anterior or inferior). Most reliable feature may be the ratio of ST segment elevation (in millimeters) to T-wave amplitude in lead V6; ratio > 0.24.
- **Chest X-ray:**
  - May be normal in pericarditis without effusion. Stenciled borders of heart.
  - Rapid increase in the size of the cardiac shadow (cardiomegaly-pear-shaped) may be seen in pericarditis with effusion. (money bag/water-bottle appearance). Oreo cookie sign/epicardial fat pad sign can be seen on lateral X-ray chest.
- **Echocardiography** used for confirmation of the pericardial effusion.
- **CT and cardiac MR** may be useful when there is thickening (>4 mm) or inflammation of pericardium and myocardium.
- **Paracentesis:** Diagnostic paracentesis is performed when there is pericardial effusion.

**Table 7.96:** Differences in ECG changes between acute pericarditis and acute ST-elevation myocardial infarction.

<i>ECG finding</i>	<i>Acute pericarditis</i>	<i>Acute ST-elevation MI</i>
Shape of ST-segment	Concave upward	Convex upward
Reciprocal ST-segment changes	–	+

Location of ST-segment changes	Diffuse (except aVR and V <sub>1</sub> )	Depends on coronary artery affected
Q waves	–	+
Depression of PR-segment	+	–
Concomitant presence of ST and T changes	– (T wave inversion occurs after ST segments have normalized)	+

### Q. Write short note on management of pericarditis.

#### Treatment
