- Treatment of the underlying cause (e.g. tuberculosis, uremia, autoimmune disease).
- Bed rest and avoid physical activity.
- **Analgesics:** The pain is usually relieved by oral NSAIDs (high dose aspirin indomethacin or ibuprofen). It also decreases the inflammation in idiopathic or viral pericarditis.
  - **Aspirin** in the dose of 600 mg 4 hourly is the drug of choice for patients with a recent myocardial infarction. Ibuprofen 300–800 mg 3 times daily may also be used. They can be given till pain and pericardial effusion disappears and ESR, CRP values return normal. It usually takes 7 to 10 days.
  - Indomethacin is a more potent anti-inflammatory drug and can be given in the dose of 25 mg 3 times daily. It should be avoided in elderly patients because it can decrease the coronary blood flow.
  - **Colchicine** 0.5 mg twice a day is also effective in combination with NSAIDs.
  - **Corticosteroids** (10–30 mg/day for 2-4 weeks) should be reserved for patients with an immune cause or patients who do not respond to NSAIDs. Because their use is associated with an increased rate of recurrence. Colchicine or corticosteroids reduce the symptoms but does not hasten the cure.
- **Purulent pericarditis:** Antimicrobial therapy, pericardiocentesis and surgical drainage (if required).
- **Indications for hospitalization:** Fever (38 °C), leukocytosis, large pericardial effusion, lack of response to NSAIDs after 1 week of therapy acute trauma, cardiac tamponade, immunosuppressed state, recurrent pericarditis.

## Pericardial Effusion

### Q. Write short essay/note on pericardial effusion and its causes.

**Definition:** Pericardial effusion is an accumulation of fluid within the potential space of the serous pericardial sac.

- Slowly developing pericardial effusions may be asymptomatic. If it develops over a short period, and volume of effusion is large, it may lead to compromisation of ventricular filling leading to embarrassment of the circulation. This is known as cardiac tamponade.

- **Type:** Pericardial effusion may be transudate (hydropericardium), exudate (pyopericardium) or hemopericardium.
- **Etiology:** It commonly develops during an episode of acute pericarditis (refer Box 7.52).

### ***Clinical Signs***

**Symptoms** commonly reflect the underlying pericarditis. Sometimes a sensation of retrosternal oppression may be present.

#### *Signs*

- Cardiovascular examination is normal except if the effusion is large, apex beat/impulse is not palpable (sometimes palpable medial to the left border of cardiac dullness).
- Increase in cardiac dullness on percussion.
- Heart sounds are faint, soft, distant or muffled.
- A pericardial friction rub due to pericarditis may be audible in the early stages. It becomes quieter as fluid accumulates and pushes the layers of the pericardium apart.
- **Ewart's sign:** Rarely, large effusion may compress the base of the left lung. It produces an area of dullness to percussion and tubular breath sounds on auscultation in the left axilla or left base (below the angle of the left scapula) and termed as Ewart's sign.

### ***Investigations***

**Q. Write short note on radiological findings in pericardial effusion.**

- **Chest X-ray:** Shows increased size of the cardiac silhouette, large globular or pear shaped heart or water-bottle appearance with sharp outlines and lucent pericardial fat lines. Typically, the pulmonary veins are not distended Oreo cookie sign/Epicardial fat pad sign.
- **Electrocardiogram:** ECG often shows low voltage QRS complexes (<0.5 mV in limb leads) in the presence of large effusions with sinus tachycardia. Electric alternans characterized by alternation of QRS amplitude or axis between beats) due to a to-and-fro motion of the heart within the fluid-filled pericardial sac may be observed.
- **Echocardiography** is the most useful investigation for demonstrating the

pericardial effusion. It is also useful to monitor the size of the effusion and its effect on cardiac function.

- **Cardiac CT or MRI** is advisable if loculated pericardial effusions are suspected (postcardiac surgery).
- **Pericardial aspiration (pericardiocentesis):** It is aspiration of pericardial fluid effusion with aseptic technique under echocardiographic guidance. A needle is inserted medial to the cardiac apex or below the xiphoid process, directed upwards towards the left shoulder. It is indicated for diagnostic purposes (e.g. tuberculous, malignant or purulent effusion) or for the treatment of cardiac tamponade. Complications of pericardiocentesis include arrhythmias, damage to myocardium and coronary vessels, air embolism, and pneumothorax. The pericardial fluid is can be sent for investigations such as:
  - Cell counts, protein, glucose and LDH to differentiate exudates from transudates, Gram's stains and AFB stain.
  - Cytology for malignant cells
  - Mycobacterium culture
- **Pericardial biopsy** may be advisable if when tuberculosis is suspected and pericardiocentesis is not diagnostic.
- **Other tests:** Depending on the underlying causes, e.g. blood cultures, autoantibody screen.

#### Treatment

- Treat the underlying cause if possible.
- Anti-inflammatory drugs (aspirin or indomethacin). Most effusions resolve spontaneously, but rapid effusion may produce cardiac tamponade.
- **Therapeutic pericardiocentesis:** Indicated to relieve the pressure and a pig-tail catheter drain may be left in temporarily to allow sufficient release of fluid.
- **Pericardial fenestration:** If pericardial effusions accumulate (e.g. malignancy), it may be treated by pericardial fenestration. This procedure consists of creating a window in the pericardium to allow the slow release of fluid into the surrounding tissues. It may be performed either transcutaneously under local anesthetic or by a conventional surgical approach.
- **Intrapericardial instillation of chemotherapeutic agents** may be useful in malignant effusion.

## Cardiac Tamponade

**Q. Write short essay/note on clinical features, signs and management of pericardial tamponade.**

- Cardiac tamponade is the term used for acute heart failure that results from large or rapidly developing pericardial effusion which compresses the heart and impair diastolic filling.
- Minimum amount of pericardial fluid necessary for the development of cardiac tamponade depends on the speed of its accumulation. About 250 mL in rapidly developing effusions and more than 2000 mL in slowly developing effusions.

**Etiology:** Pericardial effusion (refer Box 7.52).

## ***Clinical Features***

### *Symptoms*

- Due to reduced cardiac output: Dyspnea, orthopnea, substernal chest discomfort radiating to neck and jaw.
- Due to systemic venous congestion: Pain in the right upper quadrant and pedal edema in slowly developing cardiac tamponade (subacute tamponade).

### ***Signs***

- Friedreich's sign: Markedly raised jugular venous pressure with sharp rise and y descent.
- Pulsus paradoxus or paradoxical pulse: An exaggeration in the normal variation in pulse pressure seen with inspiration. There is drop in systolic blood pressure of  $\geq 10$  mm Hg. Pulsus paradoxus is the hallmark of cardiac tamponade.

### **Q. Write short note on Kussmaul's sign.**

- *Kussmaul's sign:* Rise in JVP/increased neck vein distension during inspiration.
- *Others:* Reduced cardiac output, hypotension, tachycardia, and oliguria.
- **Beck's triad of hypotension, muffled heart sounds, and elevated jugular venous pressure** remains a useful clue to the presence of severe tamponade.

### ***Investigations***

- *Chest X-ray:* Discussed earlier in pericarditis.

- **Electrocardiogram:** May show sinus tachycardia, reduction in QRS voltage, non-specific ST-T changes and electrical alternans (alternation of QRS complex amplitude or axis between beats).
- **Echocardiography:** A pericardial effusion appears as a lucent separation between parietal and visceral pericardium and shows separation visceral and parietal layers for the entire cardiac cycle.
  - Small effusions are first evident over the posterobasal left ventricle.
  - Early diastolic collapse of the right ventricle and collapse of the right atrium (which occurs during ventricular diastole) are sensitive and specific signs.
  - Right atrial collapse is considered more sensitive.
  - RV collapse more specific for tamponade.

#### Management

- Emergency pericardiocentesis is necessary.
- If patient is hypotensive, as a temporary measure expansion of blood volume by saline, blood, plasma, and dextran.
- Avoid positive pressure mechanic ventilation in acute tamponade because it reduces cardiac filling further.
- Treatment of underlying cause.

## Chronic Constrictive Pericarditis

### Q. Write short essay/note on chronic constrictive pericarditis.

- Constrictive pericarditis is an end stage inflammatory process involving pericardium.
- It is characterized by progressive thickening, fibrosis, and calcification of the pericardium and visceral and parietal pericardium usually becomes adherent resulting in obliteration of the pericardial space. In some cases, the constricting process is formed by the visceral pericardium (epicardium) alone.

**Pathophysiology:** The heart is encased in a solid shell and cannot fill properly. The calcification may extend into the myocardium and may impair myocardial contraction. Following features develop:

- Restricted diastolic filling of the heart by fibrotic pericardium.
- Limitation of venous return to the heart → reduced ventricular filling → inability to maintain adequate preload.

- Filling pressures of the heart tend to become equal in both the ventricles and the atria.
- Systolic function is rarely affected until late in the course of the disease.
- **Preservation of myocardial function in early diastole aids in distinguishing constrictive pericarditis from restrictive cardiomyopathy.**

## ***Etiology (Box 7.53)***

**Box 7.53:** Causes of constrictive pericarditis.

- Idiopathic
- Infectious:
  - **Tuberculosis**
  - Viral especially Coxsackie B
  - Bacterial
  - Fungal
  - Parasitic
  - Postradiotherapy
- Postcardiac surgery
- Post-traumatic
- Neoplastic
- Connective tissue diseases (e.g. rheumatoid arthritis and SLE)
- Toxic/metabolic: Uremia, chylous pericardium, methysergide
- Post myocardial infarction
- Familial

## ***Clinical Features***

- The symptoms and signs are due to:
  - Reduced ventricular filling which is similar to cardiac tamponade (i.e. Kussmaul's sign, Friedreich's sign, pulsus paradoxus—refer pages 521-2).
  - Systemic venous congestion: Symptoms consistent with CCF (especially right-sided heart failure) such as ascites, dependent edema, hepatomegaly and raised JVP.
  - Reduced cardiac output: Inability of the heart to increase stroke volume produces fatigue, hypotension, and reflex tachycardia.
  - Rapid ventricular filling: **Pericardial knock** (occurs 0.09–0.12 second

after A<sub>2</sub>) can be heard in early diastole at the lower left sternal border.

- Rarely pulmonary venous congestion causing dyspnea, cough, orthopnea.

## **Investigations**

- **ECG:** Rarely normal, nonspecific and highly variable. Atrial arrhythmias are frequent, with atrial fibrillation occurring late in course. Low voltage (<50% cases) and LA enlargement (19–37%).
- **Chest X-ray:** Pulmonary venous congestion and pleural effusions (late in the disease). **Calcified pericardium** is highly suggestive of constrictive pericarditis when present in a patient with constrictive/restrictive physiology.
- **Echocardiography:** **Pericardial thickening better seen through transesophageal echo, normal RV and LV chamber size, LA and RA enlargement, abnormal septal and posterior wall motion, paradoxical septal motion, premature opening of the pulmonic valve and dilated IVC without respiratory variation.**
- **Magnetic resonance imaging/CT scan** can confirm pericardial thickening. Pericardial thickening >4 mm assists in differentiating constrictive disease from restrictive cardiomyopathy, and thickening >6 mm adds even more specific for constriction. Normal pericardial thickness does not exclude pericardial constriction, and the clinical situation must always be taken in account.
- **Cardiac catheterization:** Ventricular pressure initially decreases rapidly (steep y descent on RA pressure waveform tracings) and then increases abruptly to a level that is sustained until systole (the ‘dip-and-plateau waveform’ or ‘square root sign’ seen on RV or LV pressure waveform tracings).

## **Treatment**

- Pericardiectomy (resection of the pericardium) is the only definitive treatment.
- **Pharmacologic therapy**
  - **Steroids** for subacute constrictive pericarditis (before pericardial fibrosis occurs).
  - **Diuretics** to relieve congestion and optimize clinical volume status (may decrease preload to the point of reducing cardiac output).
  - Treatment of the causative disease (e.g. antituberculosis medication).
  - Avoid beta-blockers and calcium channel blockers (CCBs).

# PULMONARY HYPERTENSION

**Q. Write short essay/note on pulmonary hypertension.**

## Definition (WHO)

- Pulmonary hypertension (PH) is defined as an increase in blood pressure in pulmonary circulation (either in the arteries, or both in arteries and veins).
- Normal pressure as measured at right heart catheterization is 14–18 mm Hg at rest and 20–25 mm Hg on exercise. Hemodynamically it is defined as an increase in mean pulmonary arterial pressure to 25 mm Hg at rest.
- Definition may be refined by giving consideration of the pulmonary wedge pressure; the cardiac output and the transpulmonary pressure gradient (mean PAP – mean PWP).

**Table 7.97: WHO classifications of pulmonary hypertension-2008 (Dana point).**

- **Pulmonary arterial hypertension**
  - Idiopathic pulmonary arterial hypertension (IPAH)
  - Familial: BMPR2, ALK 1, unknown
  - Associated with PAH
    - ◆ Connective tissue disease: Scleroderma, SLE, rheumatoid arthritis
    - ◆ Congenital heart disease
    - ◆ Portal hypertension (5–7% of patients)
    - ◆ HIV (0.5% of patients)
    - ◆ Drugs/toxins: aminorex, dexfenfluramine, or fenfluramine-containing products, cocaine, methamphetamine
    - ◆ Others: Hereditary hemorrhagic telangiectasia, hemoglobinopathies, myeloproliferative disorders, splenectomy
  - Associated with venous/capillary involvement
    - ◆ Pulmonary veno-occlusive disease (evidence of pulmonary vascular congestion)
    - ◆ Pulmonary capillary hemangiomatosis
  - Persistent PH of newborn
- **Pulmonary hypertension owing to left heart disease:** Systolic dysfunction, diastolic dysfunction and valvular disease.
- **PH secondary to chronic hypoxemia:** Chronic obstructive lung disease, interstitial lung disease, sleep disordered breathing, alveolar hypoventilation disorders, chronic exposure to high altitude, developmental abnormalities
- **Chronic thromboembolic pulmonary hypertension (CTEPH):** Thromboembolic obstruction of proximal or distal pulmonary arteries

- **Miscellaneous (usually extrinsic compression of pulmonary arteries):** Sarcoidosis, histiocytosis X, lymphangiomyomatosis, compression of pulmonary vessels (adenopathy, tumor, fibrosing mediastinitis, thyroid disorders, glycogen storage disease, Gaucher's disease)

## WHO Classifications of Pulmonary Hypertension (Table 7.97)

**Q. Write short essay/note on causes of pulmonary hypertension.**

### Clinical Features

**Symptoms:** Insidious in onset and is usually diagnosed late. Usual symptoms include exertional breathlessness/dyspnea (60%), fatigue (19%), palpitation and near syncope/syncope (13%), chest pain (7%), palpitations (5%), LE edema (3%), and hoarseness of voice (2%).

**Signs:** These include:

- Cold extremities, peripheral edema, **cyanosis** and rarely clubbing
- Raised jugular venous pulse, prominent v wave if tricuspid regurgitation is present
- Left parasternal lift/heave due to right ventricular hypertrophy.
- Large pulsatile liver
- **Auscultatory signs in pulmonary hypertension (Box 7.54)**
- **Signs of underlying cause**, e.g. interstitial lung disease or cardiac, liver or connective tissue disease.

**Box 7.54:** Auscultatory signs in pulmonary hypertension.

- Pulmonary ejection sound (ES)
- Abnormal second heart sound (S<sub>2</sub>): Loud P<sub>2</sub>, narrow splitting
- Right atrial fourth heart sound (S<sub>4</sub>)
- Right ventricular third heart sound (S<sub>3</sub>)
- Pulmonary ejection systolic murmur (ESM)
- Pulmonary early diastolic murmur (EDM): Graham Steel murmur
- Tricuspid pansystolic murmur (PSM)

### Investigations

- **Chest X-ray**
  - Enlargement of the pulmonary artery and its main branches
  - Peripheral “pruning” of vascular shadows
  - Enlarged right atrium, and right ventricle

- Findings of underlying lung or cardiac pathology
- **Electrocardiogram:** Shows right axis deviation, R/S wave ratio greater than one in lead V1, right bundle branch block (incomplete or complete) and increased P wave amplitude in lead II (due to right atrial enlargement).
- **Echocardiography:** Most useful for detecting pulmonary hypertension and excluding cardiac disease. It shows tricuspid regurgitation, right atrial and ventricular hypertrophy, flattening of interventricular septum, small LV dimension, dilated pulmonary artery and secondary causes (if any).
- **Transthoracic echocardiography:** Doppler assessment of the tricuspid regurgitant jet is a non-invasive method of determining the pressure of pulmonary artery.
- **Right heart catheterization:** Mean PAP pressure at rest >25 mm Hg, with exercise >30 mm Hg, wedge pressure <15 mm Hg.
- **Other tests**
  - Complete blood counts, prothrombin time, partial thromboplastin time and liver function tests.
  - Autoantibodies if autoimmune disease is suspected.
  - HIV-ELISA if the patient has risk factors.
  - Arterial blood gas to exclude hypoxia and acidosis as contributors to pulmonary hypertension.
  - Sleep studies if sleep apnea suspected.
  - Pulmonary function tests to establish airflow obstruction or restrictive lung disease.
  - High-resolution computed tomography of chest to exclude occult interstitial lung disease.
  - Helical CT to detect pulmonary thromboembolism.
  - Ventilation-perfusion scanning to differentiate chronic thromboembolism from primary pulmonary hypertension.

#### Treatment

- Early recognition and treatment of the underlying cause.
- **Medical:** Diuretics mainly to treat edema from right heart failure, digoxin (for atrial tachyarrhythmias), **oxygen** (keep oxygen saturation  $\geq 90\%$ ) and anticoagulants (IPAH) to keep INR 2.0–2.5.
- **PAH specific therapy**

- **Calcium channel blockers:** Indicated in patients who respond to vasodilators during catheterization. High doses required, e.g. nifedipine 240 mg/day, or amlodipine, 20 mg/day.
- **Oral endothelin receptor antagonists (ERAs):** For example, bosentan, sitaxsentan, ambrisentan. Liver function be monitored monthly throughout the duration of use.
  - ◆ Bosentan initiated at 62.5 mg BD for first month and increased to 125 mg BD.
  - ◆ Ambrisentan initiated as 5 mg OD and can be increased to 10 mg daily.
- **Phosphodiesterase type 5 inhibitors (PDE 5-I):** For example, sildenafil, tadalafil, vardenafil. The most common side effect is headache. Effective dose for sildenafil is 20–80 mg TID and for tadalafil is 40 mg OD.
- **Prostaglandins:** For example, epoprostenol (prostacyclin), treprostinil, iloprost, prostacyclin 1P receptor antagonist (Selexipag).
- **Guanylatecyclase stimulant:** For example, riociguat.
- Pneumococcal and influenza vaccination.
- **Surgical therapy**
  - Atrial septostomy (the creation of a right-to-left shunt).
  - Lung transplantation
  - Pulmonary thromboendarterectomy for chronic proximal thromboembolic pulmonary hypertension.

# SUDDEN CARDIAC DEATH

## **Q.** Write a short note on sudden cardiac death.

Sudden cardiac arrest (SCA) and sudden cardiac death (SCD) refer to the sudden cessation of cardiac activity with hemodynamic collapse.

- **Sudden cardiac death** is defined as an unexpected, nontraumatic, natural death due to cardiac causes occurring in a short period (within 1 hour of symptom onset) in an individual with or without any previously identified heart disease but in whom the time and mode of death are unexpected.
- It has four temporal elements: (1) prodromes, (2) onset of terminal event, (3) cardiac arrest, and (4) biologic death.
- Bimodal age distribution with one peak between birth and 6 months of age and another after 65 years of age. It is a male preponderance.

## **Box 7.55:** Causes of sudden cardiac death.

**Coronary artery disease:** Coronary atherosclerosis, developmental anomalies, coronary artery embolism, others (e.g. vasculitis, dissection)

**Myocardial diseases:** Cardiomyopathies, myocarditis and other infiltrative processes, right ventricular dysplasia

**Valvular diseases:** Mitral valve prolapse, aortic stenosis and other forms of left ventricular outflow obstruction, endocarditis

**Conduction system abnormalities:** Wolff-Parkinson-White (WPW) syndrome, Brugada syndrome, long QT syndromes

## Causes (Box 7.55)

### Treatment

- Identifying individuals at high risk of SCD: Combination of factors more useful, most important parameter is left ventricular ejection fraction (LVEF).
- Pharmacological agents
  - Beta blockers, ACEI, amiodarone
  - Revascularization
  - ICD/CRT.

# CARDIAC ARREST

**Definition:** Cardiac arrest is a sudden loss of cardiac pump function which can be reversed by a prompt intervention, without which it leads to death.

## Causes of Cardiac Arrest (Box 7.56)

**Q. Write short note on causes of cardiac arrest.**

**Diagnosis of cardiac arrest (TRIAD):** (1) Loss of **consciousness**, (2) loss of apical and central **pulsations** (carotid, femoral) and (3) **apnea**.

### ECG: Three basic patterns

1. Ventricular tachyarrhythmia: Ventricular fibrillation (VF)/sustained type of pulseless ventricular tachycardia.
2. Ventricular asystole or a brady-asystolic rhythm with an extremely slow rate.
3. Pulseless electrical activity (PEA) previously referred to as electromechanical dissociation.

**Box 7.56:** Causes of cardiac arrest (6 H and 4 T).

- Hypoxia
- Hypotension
- Hypothermia
- Hypoglycemia
- Acidosis ( $H^+$ )
- Hyperkalemia (electrolyte disturbance)
- Cardiac Tamponade
- Tension pneumothorax
- Thromboembolism (pulmonary, coronary)
- Toxicity (e.g. digoxin, local anesthetics, insecticides)

**Q. Write short essay/note on management of cardiac arrest.**

### Management

#### **Chain of Survival**

It refers to the sequence of events that is required to maximize the chances of survival in a patient with cardiac arrest. Survival is most likely if all links in the chain are strong. The chain of survival consists of following links namely:

- Immediate identification of cardiac arrest and activation of the emergency response system (ERS) by a trained individual.
- Immediate CPR with chest compressions.
- Quick defibrillation.
- Effective advanced life support (ALS).
- Integrated post-cardiac arrest care.

**Immediate Identification and Activation of Emergency Response System (ERS)**

- Immediate identification of cardiac arrest: Assessment is of crucial importance. It includes: (1) unresponsiveness (check the individual for a response, gently shake shoulders and ask ‘are you all right?’), (2) no breathing or no normal breathing (i.e. only gasping) and (3) no pulse felt within 10 seconds.
- Activation of ERS: After activation of the ERS, all rescuers should immediately begin CPR.

**Q. Write short essay/note on cardiopulmonary resuscitation (CPR).**

- **Cardiopulmonary Resuscitation (CPR)**

- It provides artificial ventilation and perfusion to the vital organs, particularly heart and brain until spontaneous cardiopulmonary function is restored. It consists of both basic life supports (BLS) and advanced life support (ALS). BLS provides adequate oxygen and perfusion to vital organs (brain and heart) until advanced cardiac life support is available (Table 7.98).

**Table 7.98: Phases of life support and its steps.**

<b>Phases</b>	<b>Steps</b>
Phase-1: Basic life support (BLS)	C = Circulation, A = Airway, B = Breathing
Phase-2: Advance life support (ALS)	D = Drugs, E = ECG, F = Fibrillation
Phase-3: Prolonged life support	Postresuscitation care

**Basic life support (BLS)** consists of maneuver purpose of which is to maintain a low level of circulation until more definitive treatment with advanced life support can be provided.

- **Change from A-B-C to C-A-B:** CPR includes four sequential: **C**irculation, **A**irway and **B**reathing (CAB) and defibrillation. Previously, the sequence used to be **A**irway, **B**reathing and **C**irculation (ABC).
  - **Circulation:** The brain cannot survive for more than 3 minutes without circulation. Hence, start chest compressions immediately for a patient without central pulsations.
    - ♦ **Chest compressions (cardiac massage):**
      - ◇ Place the patient on a hard surface (wooden board).
      - ◇ The palm of one hand is placed in the concavity of the lower half of the sternum 2 fingers above the xiphoid process (avoid xiphisternal junction → fracture and injury). The other hand is placed over the hand on the sternum.
      - ◇ **Shoulders** should be positioned directly over the hands with the **elbows** locked straight and arms extended. Use your upper body weight to compress.
      - ◇ Sternum must be depressed **at least 5 cm** in adults, and **2–4 cm** in children, **1–2 cm** in infants.
      - ◇ **Push hard and push fast.** Must be performed at a rate of 100–120/min.
      - ◇ During CPR the ratio of chest compressions to ventilation should be: single rescuer = 30:2 and in the presence of 2 rescuers, **chest compressions must not be interrupted for ventilation.**
      - ◇ Chest compressions must be continued for 2 minutes before reassessment of cardiac rhythm (2 minutes = equivalent to 5 cycles 30:2).
    - ♦ **Assessment of the adequacy of chest compressions:** Systolic BP = 60–80 mm Hg, diastolic BP (>40 mm Hg) and COP = 30% of normal.
    - ♦ **Complications of chest compressions:** Fractures of rib/sternum, rib separation,

pneumothorax, hemothorax, contusions of lung, lacerations of liver, fat emboli.

- **Airway:** Loss of consciousness usually produces obstruction of airway due to loss of the muscle tone in the airway and falling back of the tongue. Hence, **clear the airway. Basic techniques for airway patency:**
  - ◆ **Head tilt, chin lift:** Place one hand on the forehead and the other on the chin. The head is tilted upwards to displace the tongue anteriorly.
  - ◆ **Jaw thrust method:** In this angles of mandible are grasped with both hands and the mandible is lifted forward.
  - ◆ **Finger sweep:** Sweep out foreign body in the mouth by index finger in unconscious patients and **not in a conscious or convulsing patient.**
  - ◆ **Heimlich maneuver:** Useful to remove the foreign body in a conscious patient. It is done while the patient is standing up or lying down. In this subdiaphragmatic abdominal thrust elevates the diaphragm and expels a blast of air from the lungs that displaces the foreign body. In infants this is performed by a series of blows on the back and chest thrusts.
- **Breathing:** Rescue breathing can be mouth-to-mouth breathing or mouth-to-nose breathing (if there is serious injury of the mouth or it cannot be opened). With the airway open (using the head-tilt, chin-lift maneuver), pinch the nostrils shut for mouth-to-mouth breathing and cover the person's mouth with rescuer making a seal.
  - ◆ **Mouth-to-mouth breathing:** With the airway held open, pinch the nostrils closed, take a deep breath and seal your lips over the patients mouth. Blow steadily into the patient's mouth watching the chest rise as if the patient was taking a deep breath. Volume of each rescue breath should produce visible chest rise.
  - ◆ **Mouth-to-nose breathing:** Seal the mouth shut and breathe steadily through the nose.
  - ◆ **Mouth-to-mouth and nose:** It is used in infants and small children.
- **Assessment of restoration of breathing and circulation:** Contraction of pupil, improved color of the skin, free movement of the chest wall, swallowing attempts and struggling movements.
- **Indications for termination of BLS:** Pulse and respiration returns, emergency medical help arrives, physician declared patient is deceased, in a non-health setting, another indication to stop BLS would be that the rescuer was exhausted and physically unable to continue to perform BLS.
- **Advanced life support (ALS):** The purpose is to restore normal cardiac rhythm by defibrillation when the cause is tachyarrhythmia, or to restore cardiac output by correcting other reversible causes of cardiac arrest. It includes:
  - Circulation by cardiac massage.
  - Airway management by equipment.
  - Breathing by advanced techniques.
  - Defibrillation by manual defibrillator.
  - Drugs.

**Advanced techniques for airway patency:** (1) face mask, (2) oropharyngeal airway, (3) nasopharyngeal airway, (4) laryngeal mask airway, (5) endotracheal intubation, (6) combitube, (7) cricothyrotomy, (8) tracheostomy.

**Advanced breathing:** Expired air contains **16% O<sub>2</sub>** so supplemental 100% O<sub>2</sub> should be used as soon as possible. Successful breathing is achieved by delivery of a tidal volume of **800–1200 mL** in adults at a rate of **10–12 breaths/min** in adults. Advanced techniques include:(1) **Self-inflating resuscitation bag** (Ambu bag), (2) **Mechanical ventilator or in ICU.**

**Advanced circulation**

- It consists of continuation of chest compression and establishing an intravenous access, attaching a cardiac monitor/defibrillator, assessing the rhythm, defibrillation and administering appropriate drugs for rhythm as well as the condition.
- Continuous chest compression is performed at the rate of 100/minute and ventilation is provided at 8–10 breaths/minute (1 breath/6–8 seconds).

### **Rhythm in cardiac arrest**

It may be (1) shockable rhythm (ventricular tachycardia/ventricular fibrillation) and (2) nonshockable rhythm (asystole and pulseless electrical activity).

- Rhythm checks should be performed only after 2 minutes of CPR and not immediately following a defibrillation attempt.

### **Shockable rhythms: Ventricular fibrillation or pulseless ventricular tachycardia (VT).**

**Defibrillation:** Completely depolarize all myocardial cells so SA node can re-establish as pacemaker. Voltage of electricity discharge High from 150 J to 360 J (biphasic) 360 J (monophasic). Continue CPR for 2 minutes and briefly check the monitor for rhythm. If VT/VF persists give second shock and immediately resume CPR and continue for 2 minutes, and repeat this cycle.

### **Drugs:**

- **Adrenaline:** Given as a **vasopressor**  $\alpha$ -1 effect (not as an inotrope). **Dose is 1 mg (0.01 mg/kg) IV every 4 minutes** (alternating cycles) while continuing CPR.
  - Given: (1) Immediately in nonshockable rhythm (non-VT/VF), (2) In VF or VT given after the 3rd shock.
  - **Repeated** in alternate cycles (every 4 minutes).
  - Once adrenaline → always adrenaline.
- **Amiodarone:** Given in shockable rhythm **after the 3rd shock**. If unavailable give **lidocaine** 100 mg IV (1–1.5 mg/kg). **Dose is 300 mg IV bolus** (5 mg/kg).
- **Vasopressin (ADH):** 40 IU single dose once.
- **Magnesium:** Given (1) VF/ VT with hypomagnesemia, (2) Torsade de pointes, (3) Digoxin toxicity. **Dose is 2 g IV.**
- **Calcium:** **Dose is 10 mL of 10%** calcium chloride IV.
  - **Indications:** PEA caused by hyperkalemia, hypocalcemia, hypermagnesemia, and overdose of calcium channel blockers.
  - Calcium solutions and  $\text{NaHCO}_3$  should not be given simultaneously by the same route.
- **Thrombolytics:** Fibrinolytic therapy is considered when cardiac arrest is caused by proven or suspected **acute pulmonary embolism**. If a fibrinolytic drug is used in these circumstances consider performing CPR for at least 60–90 minutes before termination of resuscitation attempts. Example: Alteplase, tenecteplase (old generation: streptokinase).
- **Sodium bicarbonate:** Used in (1) severe metabolic acidosis ( $\text{pH} < 7.1$ ), (2) life-threatening hyperkalemia, (3) tricyclic antidepressant overdose.
  - Dose: (half correction)  $1/2$  base deficit  $\times$   $1/3$  body weight
  - Adverse drug reactions: (1) Increases  $\text{CO}_2$  load, (2) inhibits release of  $\text{O}_2$  to tissues, (3) impairs myocardial contractility and (4) causes hyponatremia.
- **Atropine:** Its routine use in **pulseless electrical activity** (PEA) and asystole is not useful. **Indicated** in sinus bradycardia or AV block causing hemodynamic instability. **Dose is 0.5 mg IV.** Repeated up to a maximum of 3 mg (**full atropinization**).

### **Nonshockable rhythms: Pulseless electrical activity (PEA) and asystole.**

- PEA is characterized by cardiac electrical activity in the absence of any palpable pulse. They

usually have some very weak mechanical myocardial contractions and does not produce a detectable pulse.

- Start CPR. Begin with chest compressions, and continue for 2 minutes before the rhythm check is repeated.
- Give 1 mg adrenaline IV immediately and re-check rhythm after 2 minutes of CPR.
- If PEA or asystole persists, continue CPR and re-check rhythm every 2 minutes. Administer adrenaline every 3–5 minutes. Do not give atropine.
- Check rhythm. If it shows change, check for pulse. If pulse appears, start post-resuscitation care. If there is still no pulse, continue CPR with rhythm check every 2 minutes and adrenaline every 3–5 minutes. If the rhythm develops into VF/VT, defibrillate the patient.

**IV fluids:** Infuse fluids rapidly if hypovolemia is suspected. Use **normal saline** (0.9% NaCl) or **Ringer's** solution. **Avoid dextrose** which is redistributed away from the intravascular space rapidly and causes hyperglycemia which may worsen neurological outcome after cardiac arrest. Dextrose is indicated only if there is **documented hypoglycemia**.

#### **Postresuscitation care**

- Maintain adequate airway and support breathing.
- Continue cardiac monitoring.
- Vasoactive medications (norepinephrine, dobutamine and epinephrine) and IV fluids to support circulation.
- Avoid hyperthermia, hyperglycemia (maintain blood sugar <200 mg/dL).
- Treating the precipitating cause of cardiac arrest.

## Syncope

**Q. Write short essay/note on cardiac syncope/syncope.**

**Definition:** Syncope is defined as a transient loss of consciousness due to inadequate cerebral blood flow with loss of postural tone.

- It is associated with loss of postural tone, with spontaneous return to baseline neurologic function without any resuscitative efforts.
- **Presyncope** is the term used for lightheadedness in which the individual thinks he/she may black out.
- **Classical vasovagal syncope:** Syncope triggered by emotional or orthostatic stress such as venipuncture (experienced or witnessed), painful or noxious stimuli, fear of bodily injury, prolonged standing, heat exposure, or exertion.

**Mechanism:** Global hypoperfusion of cerebral cortices or focal hypoperfusion of the reticular activating system.

- About 1/3 of individuals may develop a syncopal episode during their lifetime.
- Its incidence increases with age (sharp rise at age 70 years).

- Cardiac syncope has a high incidence (about 24%) of subsequent cardiac arrest.

**Table 7.99: Causes of syncope.**

#### Cardiac causes

- **Cardiac arrhythmias:** Ventricular tachycardia, paroxysmal supraventricular tachycardia, long QT syndrome, Brugada syndrome, bradycardia (Mobitz type II or 3rd degree heart block)
- **Structural cardiac or cardiopulmonary disease:** Cardiac valvular disease (AS, MS, PS), obstructive cardiomyopathy, atrial myxoma, acute aortic dissection, pericardial disease/tamponade, pulmonary embolus/pulmonary hypertension, acute myocardial infarction/ischemia

#### Noncardiac causes

- **Neurocardiogenic syncope ‘vasovagal or vasodepressor syncope’:** Classical vasovagal syncope, situational syncope, carotid sinus syncope, glossopharyngeal neuralgia, micturition syncope
- **Orthostatic hypotension:** Autonomic failure which may be primary (e.g. pure autonomic failure, multiple system atrophy, Parkinson’s disease with autonomic failure) or secondary (e.g. diabetic neuropathy)
- **Neurovascular syncope:** Vascular steal syndromes

### ***Causes of Syncope (Table 7.99)***

**Causes of nonsyncopal attacks (Box 7.57):** Episodes that may be confused with syncope include disorders without impairment of consciousness and disorders with partial or complete loss of consciousness.

#### **Box 7.57: Causes of nonsyncopal attacks.**

- **Seizures.**
- **Metabolic or toxic abnormalities:** Hypoglycemia and encephalitis rarely syncope.
- **Neurologic syncope:** Subarachnoid hemorrhage, transient ischemic attack, complex migraine headache.
- **Psychiatric syncope**
- **Drug induced loss of consciousness:** Drugs of abuse and alcohol.

### ***Investigations***

- **Electrocardiogram (ECG):** Factors that suggests arrhythmia-induced syncope are prolonged intervals (QRS, QTc), severe bradycardia, pre-excitation, evidence of myocardial infarction.
- Holter monitoring
- Echocardiography

- Neurological: CT brain and MRI, EEG
- Laboratory evaluation: FBC and hematocrit, RBS, electrolytes, pregnancy test.
- Head up tilt table test.

## COR PULMONALE

**Q. Discuss the etiology, pathogenesis, clinical features, investigations and management of chronic cor pulmonale.**

- Cor pulmonale is a Latin word means ‘pulmonary heart’ and is defined as **symptoms and signs of fluid overload secondary to lung disease.**
- Cor pulmonale is a disease of the right ventricle characterized by its hypertrophy and dilation with or without failure secondary to diseases directly affecting the lung parenchyma, pulmonary vasculature, chest bellows or central. This excludes pulmonary alterations produced due to diseases that primarily affect the left side of the heart (e.g. congenital heart diseases).

### Types of Cor Pulmonale

**Q. Write short essay/note on types and causes of cor pulmonale.**

**Q. Write short essay/note on acute cor pulmonale.**

According to rate of development: Acute or chronic.

- **Acute cor pulmonale** develops due to a sudden increase in right ventricular pressure. It usually follows **acute massive pulmonary embolism** that is sufficient enough to obstruct more than 60% of pulmonary circulation. It leads to acute pulmonary hypertension, acute right ventricular dilatation and failure. Other example is acute respiratory distress syndrome.
- **Chronic cor pulmonale:** It can be further divided hypoxic type or vascular obliterans type.
  - **Hypoxic subtype:** Chronic obstructive pulmonary disease (COPD) is the most common disease associated with hypoxic subtype.
  - **Obliterans subtype:** Most common process associated with this subtype is pulmonary thromboembolic disease.

## Box 7.58: Causes of cor pulmonale.

**Diseases of lung:** Chronic obstructive pulmonary disease (COPD, e.g. chronic bronchitis and emphysema), pulmonary tuberculosis, interstitial lung disease, high altitude dwelling, cystic fibrosis, pleural fibrosis

**Diseases of pulmonary circulation:** Recurrent pulmonary thromboembolism, primary pulmonary hypertension, collagen vascular diseases, chronic liver disease

**Diseases of thorax:** Kyphoscoliosis, neuromuscular diseases, sleep apnea syndrome, obesity

**Diseases of respiratory control:** Brainstem lesions, central sleep apnea—Ondine's curse.

## Etiology (Box 7.58)

### Clinical Features

Usually the signs and symptoms are minimal except in the advanced stage. Mostly the clinicians focus on the disease producing cor pulmonale rather than on cor pulmonale itself.

### Symptoms

- **Similar to those of right side heart failure:** Fatigability, dyspnea on exertion, syncope, chest pain, palpitation, abdominal distension, edema of the lower extremity, exercise-induced peripheral cyanosis and excessive daytime somnolence.

### Signs

- Pedal edema
- Accentuated A wave of the jugular venous pulsations and prominent jugular V wave, indicating the presence of tricuspid regurgitation.
- Palpable left parasternal lift.
- Accentuated pulmonic component of the second heart sound, right sided S<sub>4</sub> heart sound, ejection systolic murmur in the pulmonary area. In addition there may be pansystolic murmur of tricuspid regurgitation or early-diastolic murmur of pulmonary regurgitation.
- **Overt right side heart failure:** In a patient with chronic cor pulmonale reveal following signs:
  - Increasing peripheral edema
  - Jugular venous pressure: Raised and hepatojugular reflux positive
  - Tender hepatomegaly and enlargement of heart
  - Right ventricular third heart sound and a gallop rhythm, and right sided

fourth heart sound.

## Investigations

- **Chest X-ray**
  - Enlarged pulmonary artery and right ventricle, distended azygous or other central vein.
  - In pulmonary embolism Westermark sign ‘oligemia of lung lobe or entire lung’. Hampton’s hump ‘wedge-shaped opacity’
  - In COPD anterior-posterior diameter increased, diaphragm flattened, honeycombing and hyperlucency of lung.
- **Electrocardiogram:** Right axis deviation, P pulmonale (large P wave) in the inferior and anterior leads ‘right atrial enlargement’, right bundle branch block, right precordial T-wave inversions, delayed intrinsicoid deflection of right precordial leads, RVH, S1 Q3 T3 pattern and QR pattern in lead V1 or V3R.
- Arterial blood gas analysis: Hypoxia, hypercapnia.
- BNP: Used as biomarker for pulmonary hypertension in COPD patients.
- Echocardiography: Hypertrophy and dilatation of right ventricle.
- Others: CECT/HRCT chest, nuclear scan for detecting pulmonary embolism, rarely right heart catheterization.

### Management of Chronic Cor Pulmonale

These include (1) general measures, (2) additional measures in cor pulmonale due to COPD and (3) surgical treatment.

- **General measures**
  - **Nonpharmacological treatment:**
    - ◆ Oxygen therapy.
    - ◆ Phlebotomy.
    - ◆ Noninvasive positive pressure ventilation (NIPPV).
  - **Pharmacological treatment:**
    - ◆ Diuretics.
    - ◆ Anticoagulation.
    - ◆ Vasodilators
- **Treatment to decrease pulmonary hypertension** (refer page 524)
  - Treatment of underlying disease.
  - Oxygen therapy is the most important treatment for reducing pulmonary hypertension. The long-term oxygen therapy retards its progression of pulmonary hypertension and oxygen therapy should be started if the arterial oxygen tension is 55 mm Hg or less.
- **Treatment of right heart failure**

- Restriction of salt intake
- Digoxin: Role not clear
- Diuretics
- **Chronic anticoagulation** with Warfarin may benefit patients with cor pulmonale due to thrombo-occlusive pulmonary disease.
- **Surgical treatment**
  - Pulmonary embolectomy: If pulmonary emboli are not resolved.
  - Heart lung transplantation: For primary pulmonary hypertension.

## DISEASES OF VESSELS

### Aortic Aneurysms

**Q. Write short note on aneurysm of aorta.**

**Definition of aneurysm:** It is an abnormal permanent focal dilatation of a blood vessel/artery to 1.5 times its normal diameter.

#### *Classification of Aortic Aneurysm*

**Q. Write short note on classification of aortic aneurysms and its common causes.**

- **Depending on the gross appearance:** (1) Fusiform aneurysm and (2) saccular aneurysm, (3) cylindrical and (4) arterial dissection.
- **Depending on the sites/region involved:** (1) Thoracic part of aorta, (2) ascending aorta, (3) arch of aorta, (4) descending aorta, (5) abdominal aorta (commonest site is infrarenal portion).
- **Depending on the etiology:** Atherosclerosis (commonest cause), cystic medial necrosis, syphilis (aneurysm of ascending aorta), rheumatic aortitis, and trauma.

### Aortic Dissection

**Q. Write short note on aortic dissection.**

**Definition:** Aortic dissection develops when **blood from the aortic lumen enters into the aortic wall** through a breach in the integrity of the aortic wall.

- Blood enters the media, split it into two layers and travels along the layers of the media creating a ‘false blood-filled lumen’ alongside the existing or

‘true lumen’.

- Usually, the false lumen re-enters the true lumen, producing a double-barreled aorta. However, it may rupture into the surrounding structures (e.g. left pleural cavity, pericardium) with fatal consequences.
- Dissection may damage aortic valve and compromise the branches of the aorta.
- Affects males more than females during 5th to 7th decades. Men/Female ratio 2:1 to 5:1. Proximal dissection peak age is 50–55 years and distal dissection peak age is 60–70 years.
- Dissection in younger patients is usually associated with Marfan’s syndrome, pregnancy or trauma.

### **Box 7.59:** Predisposing factors for aortic dissection.

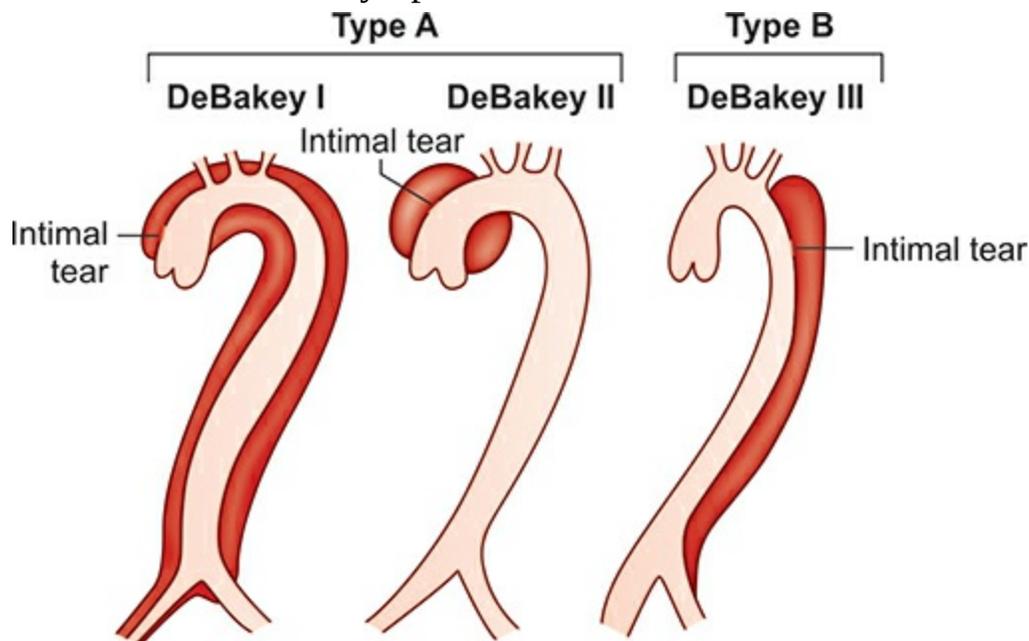

- **Systemic hypertension** (~80%)
- **Aortic diseases:** Aortic atherosclerosis, dilatation, nonspecific aneurysm, arteritis, coarctation, bicuspid aortic valve. Previous aortic surgery (e.g. CABG, aortic valve replacement)
- Trauma
  - Direct iatrogenic, e.g. cardiac catheterization, intra-aortic balloon pumping
  - Indirect trauma, e.g. sudden deceleration
- Hereditary connective tissue diseases, e.g. Marfan syndrome, Ehler-Danlos syndrome
- Chromosomal aberrations: Turner’s syndrome, Noonan’s syndrome
- Others: Third trimester of pregnancy or first stage of labor, giant cell arteritis, Behçet’s disease, and syphilis

### ***Predisposing Factors (Box 7.59)***

#### ***Classification (Fig. 7.54)***

- **Stanford anatomical classification**
  - **Type A dissections (66%):** Dissection involving either both the ascending and descending aorta or only the ascending aorta (types I and II of the DeBakey classification). It is more common but dangerous.
  - **Type B dissections:** They have dissection limited to descending aorta (usually begin distal to the subclavian artery) and do not involve the ascending part and (DeBakey type III).
- **DeBakey classification** (Fig. 7.54)
  - Type I: Involves ascending to descending aorta

- Type II: Limited to ascending or arch of aorta
- Type III: Involves descending aorta only.
- **According to the timing of diagnosis** from the initial onset of symptoms:
  - **Acute** diagnosis is made <2 weeks of symptoms
  - **Subacute** 2–8 weeks of symptoms
  - **Chronic** >8 weeks of symptoms.

**Fig. 7.54:** Classification of aortic dissections. Type A (proximal) involves the ascending aorta (DeBakey I and II). Type B (distal or DeBakey III) dissections arise beyond the subclavian artery.

## ***Clinical Features***

### *Symptoms*

- Sudden (abrupt) onset of severe, tearing, migratory pain, beginning in the anterior chest, radiating to the back between the scapulae (interscapular area), and moving downward as the dissection progresses. Pain may be misdiagnosed as that of myocardial infarction. Usually anterior chest pain develops when there is involvement of the ascending aorta, pain is intrascapular when descending aorta is involved. Collapse is common.
- **Others:** Syncope, dyspnea, weakness, hypertension or hypotension.

### *Signs*

- **Asymmetry of pulses and blood pressure:** It may produce asymmetry of the brachial, carotid or femoral pulses and blood pressure.

- **Signs of aortic regurgitation.**
- **Signs of occlusion of branches of aorta:** It may occlude orifices of branches of aorta and cause MI (coronary), stroke (carotid) paraplegia (spinal), mesenteric infarction with an acute abdomen (celiac and superior mesenteric), renal failure (renal) paraplegia (spinal cord) and ischemia of limb (usually leg).
- **Others:** Pulmonary edema, hemopericardium, cardiac tamponade.

### ***Investigations***

- **Chest X-ray:** May show widening/broadening of superior mediastinum and distortion of the aortic 'knuckle' but these may be absent in 10% of cases. A small left-sided pleural effusion may be found.
- **Electrocardiogram:** ECG may show left ventricular hypertrophy in patients with hypertension (33% of cases). ECG is necessary to rule out any ischemic changes or MI. Rarely changes of acute MI (usually inferior) may be evident.
- **Doppler echocardiography:** It may reveal aortic regurgitation, and dilated aortic root.
- **Transesophageal echocardiography (TEE):** May be useful since it can show images of the first 3–4 cm of the ascending aorta (sensitivity 98–99% and specificity 94–95%).
- **CT and MRI angiography:** Highly (98–100%) specific and sensitive MRI is the gold standard for diagnosis.

### **Management/Treatment**

Mortality rate of acute aortic dissection if untreated is 1–5% /hour and 90% within 3 months. Hence urgent treatment is needed.

- **Goal: Reduction of systolic blood pressure (100–120) and diminution of dp/dt** (reflects force of LV ejection) through use of a beta blocker. Therapy is targeted to halt the progression of the dissection. The course of the tear rather than the tear itself leads to compromise of vasculature or rupture.
- **Initial medical management consists of control of pain and antihypertensive treatment.** About 50% of patients are hypertensive and they are given urgent antihypertensive medication to reduce systolic blood pressure to below 120 mm Hg. This may be achieved by
  - Intravenous beta-blockers (e.g. labetalol, metoprolol) and vasodilators (GTN).
  - Intravenous calcium channel blockers (e.g. verapamil or diltiazem) are used if  $\beta$ -blockers are contraindicated.
  - If the above drugs fail to control BP adequately, sodium nitroprusside may be given.
- **Type A dissections need emergency surgery** to replace the ascending aorta (arch replacement) if fit enough, because medical management has a high mortality (50% within 2 weeks).

- Better prognosis with **type B dissections** and have a survival of 89% at 1 month. They are initially treated medically unless they develop complications such as actual or impending external rupture, or vital organ (gut, kidneys) or limb ischemia. In these patients very high morbidity and mortality rate associated with surgery.
- **Surgical therapy:** Percutaneous or minimal access endoluminal repair and involves either 'fenestrating' (perforating) the intimal flap or endovascular implantation of a stent graft placed from the femoral artery.

**Cause of death:** Acute aortic regurgitation, major branch vessel obstruction, aortic rupture (into pericardium, left pleural cavity, or mediastinum).

## Marfan's Syndrome

**Q. Write short note on Marfan's syndrome and its clinical features.**

It is an autosomal dominant disorder of connective tissue characterized by mutations in the *fibrillin* gene on chromosome 15.

### Systems affected

- **Cardiovascular system:** Weakening of the media of the aortic root cause dilatation (Fig. 7.55D), regurgitation and dissection. Mitral valve prolapse, mitral regurgitation.
- **Skeletal system:** Tall stature, arachnodactyly, wrist (Fig. 7.55A) and/thumb sign (Fig. 7.55B), joint hypermobility, scoliosis, chest deformity and high arched palate (Fig. 7.55C).
- **Eyes:** Dislocation of the lens (superior and temporal).

**Figs. 7.55A to D:** Features of Marfan's syndrome: (A) Wrist sign with right pneumothorax on intercostal drainage;(B) Thumb sign; (C) High arched palate; (D) Chest X-ray showing aortic root dilatation.

**Investigations:** Chest X-ray (Fig. 7.55D), echocardiography, MRI or CT may detect aortic dilatation.

**Treatment:**  $\beta$ -blockers reduces the rate of aortic dilatation and risk of rupture. Elective replacement of the ascending aorta: in patients with progressive aortic dilatation.

## RAYNAUD'S PHENOMENON AND RAYNAUD'S DISEASE

### Q. Write short note on Raynaud's phenomenon, its causes and Raynaud's disease.

- **Raynaud's phenomenon:** Chronic episodic attacks of digital ischemia due to spasm of the digital arteries usually precipitated by exposure to cold or emotional stress and relieved by heat. An underlying disease or cause is present and most commonly connective tissue disease such as systemic sclerosis. If there is no underlying cause, it is termed **Raynaud's disease** (primary or idiopathic Raynaud's phenomenon).
- Affects 5–10% of population.

**Table 7.100: Causes of Raynaud's phenomenon (Secondary Raynaud's).**

<b>Connective tissue disease and vasculitis</b> , e.g. systemic sclerosis, SLE, rheumatoid arthritis, Sjögren's syndrome, Mixed connective tissue disease	<b>Hematological disease</b> , e.g. cryoglobulinemia, cold agglutinins, paroxysmal hemoglobinuria, Waldenström's macroglobulinemia
<b>Obstructive arterial disease</b> , e.g. atherosclerosis, thromboangiitis obliterans (TAO) (Buerger's disease)	<b>Neurological disease</b> , e.g. thoracic outlet syndrome (cervical rib), carpal tunnel syndrome
<b>Trauma or vibration:</b> Reflex sympathetic dystrophy, vibration exposure, arteriovenous fistula	<b>Miscellaneous</b> , e.g. paraneoplastic syndrome, chronic renal failure, primary pulmonary hypertension
<b>Drugs and toxins</b> , e.g. Ergot, $\beta$ -blockers, methysergide	

### Causes of Raynaud's Phenomenon (Table 7.100)

#### Clinical Features

- **Characterized by sequential color changes:** White (pallor due to vasospasm), >blue (cyanosis due to deoxygenated blood) > and red (rubor due to reactive hyperemia). Pallor is essential for diagnosis.
- **Age of onset and gender:** Usually less than 40 years of age, but it may

occur over this age. F: M = 5:1. However, in secondary cases it depends on the underlying disease, and is not restricted to female sex.

- Raynaud's phenomenon usually involves the hands and less common in the feet. Rarely, involves nose, ear lobe, tongue, etc.
- **Typical attack** is characterized by sudden attack of pallor in one or more digits, followed after a few minutes by cyanosis or/and sometimes by erythema. Attacks are usually precipitated by cold (either local or of the whole body), by pressure or by psychological stimuli. Episodes may occur infrequently or many times each day.
  - **Primary Raynaud's:** Usually bilateral, symmetrical and involves several digits (fingers).
  - **Secondary Raynaud's:** Involves only one or a few digits and asymmetry is not unusual.
- **Severe cases:** Usually seen in secondary type and may be complicated by:
  - Telangiectasias of the nail fold
  - Thinning and ridging of the nail
  - Atrophy or sclerosis of the fingers (sclerodactyly).
  - **Skin necrosis:** Rare in primary Raynaud's phenomenon but not uncommon in secondary Raynaud's phenomenon and may lead to destruction of the digits.

## Investigations

- Blood test
  - Complete blood count, ESR, urinalysis
  - Patient with ANA, specific antigen like Sm antigen or topoisomerase or centomere or DsDNA to rule out SLE or scleroderma.
- **Chest X-ray:** To look for cervical rib or evidence of ILD.
- **Specific test:** Nail fold capillary microscopy procedure differentiates primary from secondary Raynaud phenomenon. Patients with connective tissue diseases may have enlarged deformed capillary loops surrounded by avascular areas.

## Treatment

### *General measures*

- Lifestyle modifications to minimize exposure to cold.
- Patient's education to recognize and terminate attacks promptly by returning to a warmer

environment and applying local heat to hands (e.g. by placing their hands in warm water or by using a hair dryer).

- Cessation of smoking because nicotine induces cutaneous vasoconstriction.
- Stress modification and social support to minimize vasoconstriction induced by hyperactivity of sympathetic nervous system.
- Treatment of underlying cause.
- **Drugs:** Calcium channel blockers (e.g. nifedipine, amlodipine), sildenafil, prostaglandin analogues (e.g. ilaprost), bosentan, losartan, topical glyceryl trinitrate.
- **Sympathectomy:** Patients with refractory, disabling attacks or with an acutely ischemic digit that is unresponsive to other measure.

## CIRCULATORY FAILURE: SHOCK

**Q. Write short note/essay on:**

- **Septic shock, SIRS and sepsis (refer chapter 4).**
- **Anaphylactic shock (refer pages 1129-31) and neurogenic shock (refer page 534).**
- **Management of septic shock (refer pages 212-4).**

### Definition

**Q. Define acute circulatory failure/shock.**

- Shock (acute circulatory failure, low-output state) is defined as a state with impaired cardiac pump, circulatory system, and/or volume that can lead to compromised blood flow to tissues.
- Kumar and Parrillo (1995): Shock is a state in which profound and widespread reduction of effective tissue perfusion leads first to reversible, and then if prolonged, to irreversible cellular injury.

### Classification and Causes (Table 7.101)

**Q. Write short note/essay on classification and causes of shock.**

**Q. Causes of cardiogenic shock.**

**Table 7.101: Classification and causes of shock.**

<i>Type of shock and insult</i>	<i>Causes</i>	<i>Physiologic effect</i>	<i>Compensation</i>
<b>Cardiogenic:</b> Heart fails to pump blood out	Myocardial infarction (MI), arrhythmia, aortic stenosis,	Decreased cardiac output	Baroreceptor mechanism.

	mitral regurgitation, myocarditis, rupture of papillary muscle, right ventricular infarction with excessive diuretic therapy		Increased systemic vascular resistance. Increased heart rate and contractibility
<b>Obstructive:</b> Heart pumps well, but the outflow is obstructed	Extracardiac obstructive causes such as pericardial effusion, tension pneumothorax, tamponade, acute massive pulmonary embolism		
<b>Hypovolemic:</b> Heart pumps well, but <b>not enough blood volume</b> to pump	Hemorrhage, fluid loss (vomiting, diarrhea, burns)		
<b>Distributive:</b> Heart pumps well, but there is <b>peripheral vasodilation</b>	Septic, anaphylactic, and neurogenic shock Pancreatitis, burns, multi-trauma via activation of the inflammatory response	Reduced systemic vascular resistance	Increased cardiac output. Increased heart rate and contractibility. No change in neurogenic shock

## Stages of Shock (Table 7.102)

**Table 7.102: Stages of shock.**

<i>Stage</i>	<i>Pathophysiology</i>	<i>Clinical findings</i>
Insult (initial stage)	Example: Splenic rupture with blood loss	
Preshock (compensatory stage)	Hemostatic compensation Mean arterial blood pressure (MAP) = Reduced. Decreased cardiac output is compensated by increase in heart rate and systemic vascular resistance.	MAP is maintained Heart rate will be increased Extremities will be cool due to vasoconstriction.
Shock (progressive stage)	Compensatory mechanisms fail	MAP is reduced. Tachycardia, dyspnea, restlessness
End organ dysfunction (refractory stage)	Cell death and organ failure	Decreased renal function, liver failure, disseminated intravascular coagulopathy, death

## Pathogenesis of Various Types of Shock (Flowchart 7.6)

### Clinical Features (Table 7.103)

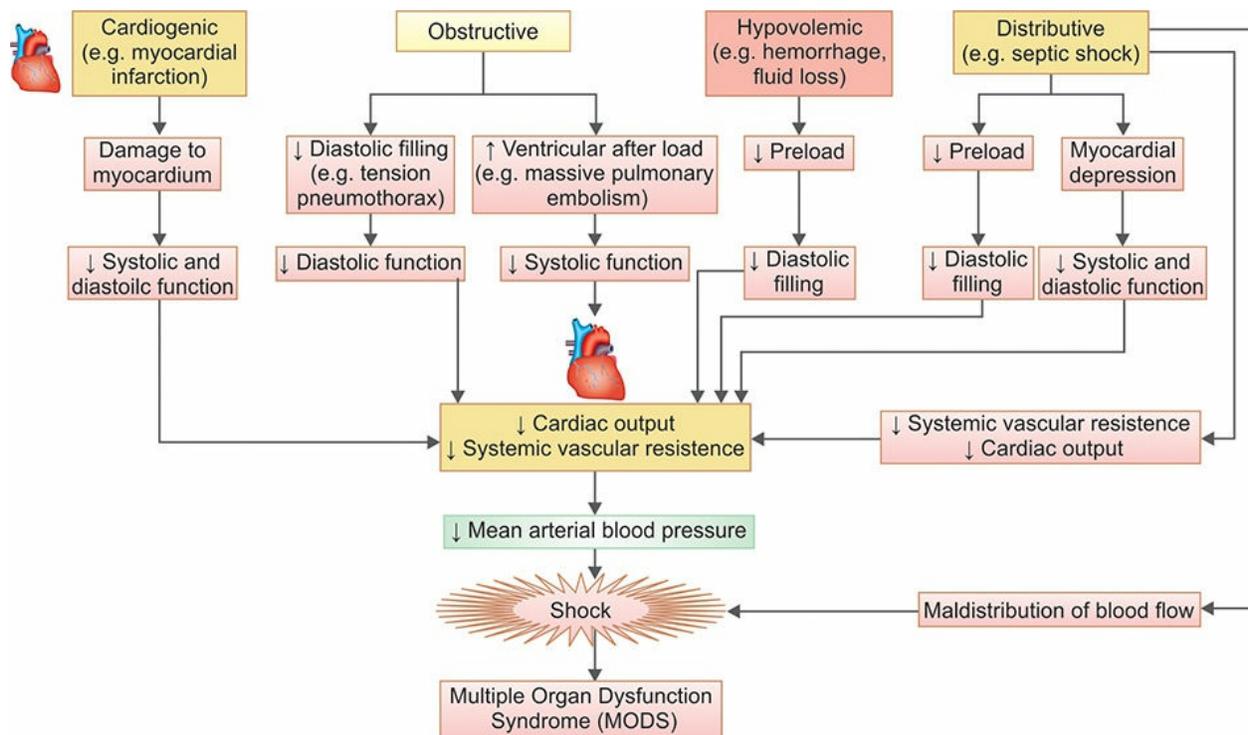

**Q. Write short notes on hypovolemic shock.**

**Types of Shock**

• **Neurogenic shock**

- Neurogenic is the rarest form of shock. Caused by the loss of sympathetic control of resistance vessels resulting in massive dilatation of arterioles and venules.
- A type of distributive shock that results from the loss or suppression of sympathetic tone.
- Causes massive vasodilatation in the venous vasculature → venous return to heart → cardiac output.
- Most common cause is spinal cord injury above T6.

**Flowchart 7.6:** Pathogenesis of various types of shock.

**Table 7.103:** Clinical features of various types of shock.

	<i>Hypovolemic shock</i>	<i>Distributive shock</i>	<i>Cardiogenic shock</i>	<i>Obstructive shock</i>
Heart rate	Increased	Increased (normal in neurogenic shock)	Increased or decreased	Increased

Jugular venous pressure (JVP)	Low	Low	High	High
Blood pressure	Low	Low	Low	Low
Skin	Cold	Warm (cold in severe shock)	Cold	Cold
Capillary refill	Slow	Slow	Slow	Slow

- **Sepsis** (discussed in Chapter 4)
  - **Sepsis syndrome:** SIRS with confirmed infectious process associated with organ failure or hypotension
  - Two phases:
    - ◆ **‘Warm’ shock-early phase:** Hyperdynamic response, vasodilation
    - ◆ **‘Cold’ shock-** late phase: Hypodynamic response
  - Decompensated state
- **Anaphylactic shock** (discussed in Chapter 20)
  - A type of distributive shock that results from widespread systemic allergic reaction to an antigen.
  - Differences between anaphylactic shock and anaphylactoid shock (Table 7.104).
  - This hypersensitive reaction is **life-threatening**.
- **Cardiogenic shock.**
  - The impaired ability of the heart to pump blood. Pump failure of the right or left ventricle.
  - Most common cause is left ventricular myocardial infarction (anterior). Occurs when > 40% of ventricular mass damage.
  - Mortality rate is 80% or more.

**Table 7.104:** Differences between anaphylactic shock and anaphylactoid shock.

<i>Anaphylactic shock</i>	<i>Anaphylactoid shock</i>
<ul style="list-style-type: none"> <li>• Insect envenomations</li> <li>• Antibiotics (beta-lactams, vancomycin, sulfonamides)</li> <li>• Heterologous serum (anti-toxin, anti-sera)</li> <li>• Blood transfusion</li> <li>• Immunoglobulins (esp. IgA deficient)</li> </ul>	<ul style="list-style-type: none"> <li>• Ionic contrast media</li> <li>• Protamine</li> <li>• Opiates</li> <li>• Polysaccharide volume expanders (dextran, hydroxyethyl starch)</li> <li>• Muscle relaxants</li> </ul>

- Egg-based vaccines
- Latex

- Anesthetics

## Q. Write short note/essay on management of shock.

### Management of Shock

Goal of management: (1) Treat reversible causes, (2) protect ischemic myocardium and (3) improve tissue perfusion.

#### *Patient Monitoring*

- Initial assessment (ABC)
- Airway:
  - Does patient have mental status to protect airway?
  - Glasgow Coma Scale (GCS) less than 'eight' means 'intubate'
  - Airway is compromised in anaphylaxis.
- **Breathing:** If patient is conversing with you, airway (A) and breathing (B) are fine, place patient on oxygen.
- **Circulation:** Vitals (heart rate and blood pressure), 2 large bore IV, start fluids (careful if cardiogenic shock), put on continuous monitor.
  - In a trauma, perform ABCDE, not just ABC.
- **Deficit or Disability:**
  - Assess for obvious neurologic deficit.
  - Moving all four extremities—Yes/No Pupils-Reaction
  - Glasgow Coma Scale (M6, V5, E4).
- **Exposure:** Remove all clothing on trauma patients.

#### *General Measures*

- Optimize oxygen content
  - Hemoglobin: Check if appears pale or anemic, check coagulation status.
  - SaO<sub>2</sub>: Just a pulse oximeter tells you the SpO<sub>2</sub>. Check SaO<sub>2</sub> on ABG.
- Optimize cardiac output
  - Cardiac output (CO) = Stroke volume (SV) x Heart rate (HR)
  - Stroke volume depends on preload, contractility and afterload
    - ◆ Preload: Look at response to fluid bolus.
      - ◇ If improves BP could be suggestive of decreased preload (volume) and a reasonable contractility.
      - ◇ If no improvement or worsening BP could be suggestive of a contractility problem or excess preload (volume) situation.
      - ◇ Look at CVP
    - ◆ Contractility
      - ◇ Check any history suggestive of ischemic disease or CCF.
      - ◇ Check ECHO and ECG.
      - ◇ A high systolic pressure could be suggestive of good contractility.
    - ◆ Afterload
      - ◇ Check ECHO if suggestive of any obstructive features.
      - ◇ If peripheries cold could indicate increased vascular resistance.

- ◇ If peripheries warm could indicate vasodilation and decreased vascular resistance.
- ◇ A low diastolic blood pressure could indicate low vascular resistance.
- ◇ A high diastolic blood pressure could indicate increased vascular resistance.

- **Heart rate**

- If low, 2 possible interventions namely electric pacing or pharmacological intervention.
- If high, 2 possible interventions namely electric cardioversion/defibrillation or pharmacological intervention.

**Optimize Blood Pressure**

**Q. Write short note/essay on sympathomimetic amines and vasopressor agents in shock.**

- **Vasopressors and inotropes (sympathomimetic amines and vasopressin)(Table 7.105)**

- Dobutamine alone is useful to augment cardiac output if arterial pressure is near-normal. Otherwise, a combination of dopamine and dobutamine is preferred initial sympathomimetic agents.
- Vasopressin
  - ◆ Vasopressin constricts vascular smooth muscle directly via V1 receptors, and also increases responsiveness of the vasculature to catecholamines.
  - ◆ Vasopressin may also increase blood pressure by inhibition of vascular smooth muscle nitric oxide production.
- **Milrinone** can be used to increase cardiac contractility.
- **Steroids** can be used in specific types as septic shock.

**Treatment of Underlying Cause**

- **Hypovolemic Shock**

- Rapid replacement of blood, colloid, or crystalloid.
- Identify source of blood or fluid loss and treat it. Endoscopy/colonoscopy or angiography.

**Table 7.105: Common sympathomimetic amines used in shock.**

<b>Sympathomimetic amine (receptor activated) and dose</b>	<b>Actions</b>
<b>Dopamine:</b> (Dopaminergic+ $\alpha$ + $\beta_1$ ) • 0.2–1 mg/minute	Vasodilation of renal, mesenteric, cerebral and coronary vessels Increase myocardial contraction, heart rate and cardiac output. Rise in systolic blood pressure
<b>Dobutamine:</b> ( $\beta_1$ ) • 2–8 $\mu$ g/kg/minute	Marked increase in myocardial contraction, minimal increase in heart rate and minimal peripheral vessels vasodilatation
<b>Noradrenaline:</b> ( $\alpha$ + $\beta_1$ ) • 2–8 $\mu$ g/minute	Increased myocardial contraction, heart rate, cardiac output, and rise in blood pressure Vasoconstriction in skin, muscle and splanchnic beds. Coronary vasodilation
<b>Adrenaline:</b> ( $\alpha$ + $\beta_1$ + $\beta_2$ ) • 1–8 $\mu$ g/kg/minute	Increased myocardial contraction, heart rate and cardiac output. Rise in mean blood pressure Vasoconstriction in most except skeletal muscles and coronary arteries. Vasodilatation in skeletal muscles and coronary arteries

<b>Isoproterenol:</b> ( $\beta_1 + \beta_2$ ) <ul style="list-style-type: none"> <li>• 5–10 <math>\mu\text{g}/\text{minute}</math></li> </ul>	Increased myocardial contraction, heart rate cardiac output and rise in systolic blood pressure Vasodilatation mainly in skeletal muscles
<b>Phenylephrine:</b> ( $\alpha_1$ ) <ul style="list-style-type: none"> <li>• 30–60 <math>\mu\text{g}/\text{minute}</math></li> </ul>	Vasoconstriction

**Box 7.60:** Management of cardiogenic shock.

**Left ventricular infarction**

- Intra-aortic balloon pump (IABP)
- Cardiac angiography
- Revascularization: Angioplasty, coronary bypass

**Right ventricular infarction**

- Fluid and inotropes with PA catheter monitoring

**Mechanical abnormality**

- Echocardiography
- Corrective surgery.

**Q. Write short note on management of cardiogenic shock.**

**Cardiogenic Shock (Box 7.60)**

*Extra-cardiac obstructive shock*

- Pericardial tamponade: Pericardiocentesis and surgical drainage (if needed).
- Pulmonary embolism
  - Heparin
  - Ventilation/perfusion lung scan
  - Pulmonary angiography
  - Consider: Thrombolytic therapy, embolectomy at surgery.

*Septic shock*

- Identify site of infection and drain, if possible.
- Antimicrobial agents (key rules).
- ICU monitoring and support with fluids, vasopressors, and inotropic agents.

**Management of neurogenic shock**

- Hypovolemia: Treat with careful fluid replacement for BP < 90 mm Hg, UO < 30 cc/hr.
- Observe closely for fluid overload
- Vasopressors may be needed.
- Hypothermia: Warming. Avoid large swings in patient's body temperature.
- Treat hypoxia
- Maintain ventilatory support.
- Alpha agonist to augment tone if perfusion still inadequate
  - Dopamine (>10  $\mu\text{g}/\text{kg}$  per min)
  - Ephedrine (12.5–25 mg IV every 3–4 hour)
- Treat bradycardia with atropine 0.5–1 mg doses to maximum 3 mg, may need transcutaneous or transvenous pacing temporarily.

# PULMONARY EMBOLISM AND VENOUS THROMBOSIS

## Pulmonary Embolism (PE)

**Q. Discuss the etiology, clinical features, investigations, diagnosis and management of pulmonary thromboembolism and pulmonary infarction.**

### *Definition*

- **Pulmonary embolism** (pulmonary thromboembolism—PTE) is defined as an embolism in which emboli occlude pulmonary arterial tree (pulmonary artery or its branches). Pulmonary embolism is the second most common cause of unexpected death in most age groups. It accounts for about 15% of all postoperative deaths. Present in 60–80% of patients with DVT, more than 50% of them are asymptomatic.
- **Pulmonary infarction:** It is ischemic necrosis of lung tissue following embolic occlusion. It develops in less than 10% of cases of pulmonary embolism. They are more common in patients with an underlying cardiac or pulmonary disease.

### *Source of Emboli*

Pulmonary embolism usually results from dislodgement of venous thrombi and the source of these emboli are as follows:

- **Thromboemboli**
  - **Deep leg veins:** DVTs are the source in more than 95% of cases of pulmonary emboli. Deep leg veins include popliteal, femoral or iliac veins. Other source of thromboemboli is from pelvic veins, abdominal veins and vena cava.
  - **Other sites:** Rarely, source of emboli may be right atrium or right ventricle.
- **Other nonthrombotic emboli:** They are rare and include septic emboli (from endocarditis involving the tricuspid or pulmonary valves), tumor emboli (especially choriocarcinoma), fat (long bone fractures), air,

amniotic fluid emboli and foreign material during **iv** drug use.

**Table 7.106:** Risk factors (predisposing factors) for venous thrombosis and embolism.

**Primary (genetic)**

- **Deficiency of antithrombotic (anticoagulant) factors** (e.g. Antithrombin III deficiency, protein C and S deficiency)
- **Increased prothrombotic factors** (e.g. activated protein C (APC) resistance (factor V mutation/ factor Va/ factor V Leiden).

**Secondary (acquired)**

- **Surgery:** Major abdominal/pelvic, hip/knee surgery, postoperative intensive care
- **Obstetrics:** Pregnancy, postpartum
- **Cardiorespiratory disease:** COPD, congestive cardiac failure
- **Lower limb conditions:** Fracture, varicose veins
- **Malignancy:** Abdominal/pelvic, advanced/disseminated cancers, concurrent chemotherapy
- **Antiphospholipid antibody syndrome**
- **Miscellaneous:** Increasing age, prolonged bed rest, prolonged immobilization, trauma

### ***Causes and Risk Factors (Table 7.106)***

**Q. Write short essay/note on the predisposing causes of pulmonary embolism.**

**Q. Write short note on Virchow's triad.**

**Virchow's triad:** It consists of three factors that predispose to thrombus formation and includes (1) endothelial injury, (2) altered blood flow and (3) hypercoagulability. These factors favor the adhesion of platelets at the site of endothelial damage. These platelets undergo aggregation and release factors which generate thrombin generation. Venous thrombi form and flourish in the presence of stasis and hypercoagulability.

### ***Pathological Consequences***

**Embolization:** The deep venous thrombi may detach from their site of formation. These emboli pass to the vena cava, right atrium and right ventricle, and finally lodge in the pulmonary arterial circulation. In the lung they produce acute pulmonary embolism.

- **Acute massive pulmonary embolism:** When emboli lodges in the main pulmonary artery (may result in death). Massive pulmonary embolism

shows 60% or more obstruction of the pulmonary circulation. Massive PE accounts for 5–10% of cases.

- **Pulmonary infarction:** It results from embolism to smaller pulmonary arteries. Most (about 75%) small pulmonary emboli do not produce infarcts. However, in the patients with congestive heart failure or chronic lung disease an embolus can cause infarction.
- **Pulmonary hemorrhage:** Obstruction of medium-sized pulmonary arteries by emboli and subsequent rupture of these vessels can result in pulmonary hemorrhage.
- **Pulmonary hypertension:** Multiple recurrent pulmonary emboli → may cause mechanical blockage of the arterial bed → result in chronic pulmonary hypertension → right ventricular failure.

### ***Clinical Features of Pulmonary Embolism and Pulmonary Infarction***

- Dyspnea (75–85%), pleuritic chest pain (57–87%), cough (40–53%), hemoptysis, syncope, similar to obstructive lung disease (chronic).
- **Massive pulmonary embolism:** Rarer condition characterized by sudden collapse because of an acute obstruction of the right ventricular outflow tract. Symptoms include collapse/hypotension, unexplained hypoxia, engorged neck veins. Acute right heart failure (acute cor pulmonale).

#### *Physical findings*

- Patient may be normal.
- There may be tachypnea (respiratory rate >16/min) in 96% of cases, rales (58%), accentuated second heart sound (53%), tachycardia (heart rate >100/min), fever (temperature >37.8 °C), diaphoresis, S<sub>3</sub> or S<sub>4</sub> gallop.
- Other clinical signs and symptoms suggesting thrombophlebitis, lower extremity edema, cardiac murmur, cyanosis and clinical evidence of DVT may be present.

### ***Wells Scoring System (Box 7.61)***

**Box 7.61:** Wells scoring system for the diagnosis of pulmonary embolism (PE).

- 
- Clinically suspected DVT: 3.0 points

- Alternative diagnosis is less likely than PE: 3.0 points
- Tachycardia (heart rate > 100): 1.5 points
- Immobilization ( $\geq$  3d)/surgery in previous four weeks: 1.5 points
- History of DVT or PE: 1.5 points
- Hemoptysis: 1.0 point
- Malignancy (with treatment within six months) or palliative: 1.0 point

Score > 4-PE likely. Consider diagnostic imaging and score 4 or less-PE unlikely.

## Diagnosis

### Q. Write short essay/note on diagnosis of pulmonary embolism.

Pulmonary embolism is the Great Masquerader. Its symptoms and signs are nonspecific and the diagnosis is difficult. Not all leg pain is due to deep vein thrombosis and not all dyspnea is due to pulmonary embolism. Pulmonary embolism should be considered if a patient has pleuritic chest pain, hemoptysis or dyspnea that is out of proportion to the size of pleural effusion.

#### • Nonimaging Diagnostic Modalities

##### Blood tests

- **Pulmonary infarction:** It results in polymorphonuclear leukocytosis, raised erythrocyte sedimentation rate (ESR) and raised lactate dehydrogenase levels in the serum.
- **D-dimer assay:** D-dimer is a specific degradation product produced during the breakdown of endogenous fibrin (fibrinolysis) by plasmin. It is best screening test for PE or DVT. Its significance are:
  - ◆ **Raised D-dimer:** The quantitative raise in plasma D-dimer [measured by enzyme-linked immunosorbent assay (ELISA)] indicates the presence of DVT or PE or clinically ineffective thrombolysis. The sensitivity of the D-dimer is >80% for DVT (less sensitive than for PE because the size of DVT thrombus is smaller) and >95% for PE. However, raised D-dimer is not specific, because it may be also raised in other conditions (e.g. myocardial infarction, pneumonia, sepsis, cancer, postoperative state and during second or third trimester of pregnancy). It has no role in hospitalized patients because levels are usually raised due to systemic illness. A positive test or normal test in high-risk patients requires further specific diagnostic tests such as Doppler of legs for deep vein thrombosis, spiral CT pulmonary angiography (CT-PA), perfusion scanning of

the lungs and pulmonary angiography.

- ◆ **Normal D-dimer:** If D-dimer is normal, it rules out the diagnosis of embolism (unless patient has a high-risk of PTE clinically).
- **Electrocardiogram (ECG)** is often normal but helps in excluding other differential diagnoses (e.g. acute myocardial infarction and pericarditis). It may show sinus tachycardia, changes of acute pulmonary hypertension and right ventricular strain. Other abnormalities include atrial fibrillation; ECG changes include the **S I Q3T3** sign: an S wave in lead 1, a Q wave in lead III, and an inverted T wave in lead III.
- **Arterial blood gases:** Show a hypoxemia (reduced PaO<sub>2</sub>) and a normal or hypocapnia (low PaCO<sub>2</sub>) i.e. type I respiratory failure pattern and an increased alveolar–arterial oxygen gradient.
- **Noninvasive Imaging Modalities**
  - **Ultrasound scanning:** For the detection of clots in deep veins, pelvic or iliofemoral veins.
  - **Venous ultrasonography:** Color Doppler ultrasound of the leg veins examines the venous flow dynamics and is the investigation of choice in suspected DVT. Normally, manual compression of calf increases the Doppler flow pattern. Loss of normal respiratory variation is seen when there is occluding DVT or any obstruction within the pelvis.

– Chest X-ray

- ◆ Pulmonary embolism

- ◇ Normal or nearly normal
- ◇ Increased radiolucency in lung zones (due to decreased or absent blood flow).
- ◇ Small infiltrative shadows (due to linear atelectasis)
- ◇ Elevated hemidiaphragm
- ◇ Difference in the diameter of pulmonary arteries and their main branches on either side.
- ◇ Abrupt “cut-off” of a blood vessel
- ◇ Enlarged right descending pulmonary artery (Palla’s sign).

- ◆ Pulmonary infarction

- ◇ May be normal during early stages
- ◇ Parenchymal, peripheral, wedge-shaped (pulmonary infarct) density above the diaphragm (Hampton’s hump). Previous infarcts may appear as opaque linear scars.
- ◇ Translucent under perfused distal zone, infiltrative shadow abutting against the pleura (usually appears 12–36 hours later) (Westmark’s sign).
- ◇ Abrupt cutoff of a pulmonary artery

◇ Blunting of a costophrenic angle (due to a small pleural effusion).

- **Chest CT:** CT of the chest with intravenous contrast is the main imaging test for the diagnosis of PE.
- **Lung scanning:** It is the second line diagnostic test for PE and performed in patients who cannot tolerate intravenous contrast. The perfusion scan defect favors absent or decreased blood flow possibly due to PE whereas a normal perfusion scan excludes significant pulmonary embolism. However, an abnormal perfusion scan may be due to lung pathology (e.g. asthma and chronic obstructive pulmonary disease). In such patients, a ventilation-perfusion scan is needed though it may still give ambiguous results.
- **Magnetic resonance (MR) (contrast-enhanced) imaging:** It is useful mainly in detecting large proximal PE but is not reliable for smaller segmental and subsegmental PE.
- **Echocardiography** is not useful for diagnosis of acute PE, but is very useful for detecting conditions that mimic PE (e.g. acute myocardial infarction, pericardial tamponade, and aortic dissection).
- **Radionuclide ventilation/perfusion scanning (V/Q scan):** It uses less radiation and contrast and is a good diagnostic tool. Pulmonary Tc scintigraphy shows under perfused regions indicative of pulmonary infarcts. However, this test should be interpreted in consideration of history, examination and other investigations.
- **Invasive diagnostic modalities**
  - **Pulmonary angiography:** Chest CT with contrast has replaced invasive pulmonary angiography as a diagnostic test. It is performed in patients planned for interventional procedure (e.g. catheter-directed thrombolysis). Features of PE includes visualization of a filling defect in the lumen, abrupt blockage (“cutoff”) of vessels, segmental oligemia or avascularity, a prolonged arterial phase with slow filling, and tortuous, tapering peripheral vessels.

**Q. Write short essay/note on management of pulmonary embolism.**

#### **Management**

##### ***Supportive measures***

- Prompt recognition and treatment.
- Bed rest in acute stage.

- Oxygen should be given to hypoxemic patients to maintain arterial oxygen saturation above 90%.
- Intravenous saline and/or noradrenaline may be necessary to maintain venous pressure in massive embolism.
- Avoid diuretics and vasodilators because they will reduce cardiac output.
- Analgesics: Opiates may be needed to relieve pain and distress.
- External cardiac massage in the moribund patient may dislodge and breaking up a large central embolus.

### **Anticoagulation**

- **Unfractionated heparin:** Initial dose is 5000–10,000 units IV, followed by maintenance.
- Maintenance: By any one of the three regimens namely (1) continuous intravenous, (2) intermittent intravenous and (3) intermittent subcutaneous.
- Dosage and monitoring of anticoagulant therapy.
  - After initiating heparin therapy, repeat APTT every 6 hour for first 24 hours and then every 24 hours when therapeutic APTT is achieved.
  - Warfarin 5 mg/d can be started on day 1 of therapy; there is no benefit from higher starting doses.
  - Platelet count should be monitored at least every 3 day during initial heparin therapy.
  - Therapeutic APTT should correspond to plasma heparin level of 0.2–0.4 IU/mL.
  - Heparin is usually continued for 5–7 days. Heparin can be stopped after 4–5 d of **warfarin** therapy when INR is in 2.0–3.0 range.
- Novel oral anticoagulants.
  - **Rivaroxaban** is an oral factor Xa inhibitor approved by the FDA in November 2012 for the treatment of DVT or PE. Apixaban was approved for treatment of PE in August 2014.
  - Direct thrombin inhibitors: **Argatroban, ximelagatran.**
- Anticoagulation is maintained for at least 6 months.

### **Thrombolytic therapy**

- Indications: Hemodynamic instability, hypoxia on 100% oxygen, and right ventricular dysfunction by echocardiography.
- Approved thrombolytics for pulmonary embolism
  - Streptokinase: 250,000 IU as loading dose over 30 minutes, followed by 100,000 U/h for 24 hours.
  - Urokinase: 4400 IU/kg as a loading dose over 10 minutes, followed by 4400 IU/kg/h for 12–24 hours.
  - Recombinant tissue-plasminogen activator: 100 mg as a continuous peripheral intravenous infusion administered over 2 hour
- **Contraindications**
  - Absolute: Active internal bleeding
  - **Relative:** Recent surgery, bleeding disorder (thrombocytopenia, renal failure, liver failure), hypertension >200 mm Hg systolic or 110 mm Hg diastolic, hypertensive retinopathy with hemorrhages or exudates.

**Surgical therapy:** Include surgical pulmonary embolectomy, inferior vena caval filters (to prevent recurrent emboli) and venous interruption.

**Prophylaxis:** To prevent pulmonary embolism (refer prophylaxis for venous thrombosis in page 542).

## Venous Thrombosis

**Q. Discuss the risk factors, clinical features, investigations, diagnosis, and treatment of venous thrombosis (deep venous thrombosis–DVT).**

Venous thrombosis is the formation of thrombus in the venous circulation namely veins or right side of the heart.

### *Sites of Venous Thrombosis*

Most commonly deep or superficial veins of the leg are involved.

- **Deep venous thrombosis (DVT):**
  - Usually develops in the lower extremity, starting at the larger calf vein level and progressing proximally to involve popliteal, femoral, or iliac veins. In about 80–90% pulmonary embolism, the source is deep vein thrombus. Lower extremity DVTs are associated with venous stasis and hypercoagulable states. More prone to embolization into the lungs and produce pulmonary infarction. About 50% of DVTs are asymptomatic and are detected after embolization.
  - **Other systemic veins**, e.g. pelvic veins
  - **Right side of the heart:** Atrium (e.g. in patients with atrial fibrillation and cardiac failure) and right ventricle.
- **Superficial venous thrombi:** They develop in the varicosities involving saphenous veins. It can cause local congestion, swelling (edema), pain, and tenderness. Embolization is very rare.

### *Risk Factors of Venous Thrombosis (refer Table 7.106)*

### *Clinical Features of Deep Venous Thrombosis (DVT)*

- Often DVT is asymptomatic with minimal symptoms and signs in about 50% of patients. It may present with clinical features of pulmonary embolism.
- Usually unilateral (only one leg) but may be bilateral (both legs), and thrombus may extend proximally into the inferior vena cava. Bilateral DVT develops more commonly associated with underlying malignancy.
- Major presenting features are: Pain in the calf or tenderness, or both, swelling (ankle edema), redness, an increase in temperature (affected calf is warmer) and dilatation or engorgement of the superficial veins.

- **Homan's sign:** Pain in the posterior calf on forced dorsiflexion of the foot while the knee is fully extended. It can be usually demonstrated, but is not diagnostic and may be observed with all lesions of the calf. This test should not be done, because it has the possibility to dislodge the deep vein thrombosis (DVT) and development of pulmonary embolism.
- **Moses test** is tenderness over calf muscles on squeezing the muscles from side to side. It is also not done because of possibility of pulmonary embolism.
- **Thrombosis in the iliofemoral region:** Severe pain, swelling of the thigh and/or ankle edema.
- **Complete occlusion of a large vein:** Cyanosis of the limb, severe edema, and very rarely lead to venous gangrene.

**Table 7.107:** Wells probability score.

<i>Clinical parameter</i>	<i>Score</i>
Active cancer (ongoing treatment or within 6 months of palliative)	+1
Paralysis or recent plaster immobilization of the lower extremities	+1
Recently bedridden for >3 days or major surgery <4 weeks	+1
Localized tenderness along the distribution of the deep veins	+1
Swelling of entire leg	+1
Calf swelling >3 cm compared to the asymptomatic leg	+1
Pitting edema (greater in the symptomatic leg)	+1
Previously documented DVT	+1
Collateral superficial veins (non-varicose)	+1
Alternative diagnosis (at least as likely as DVT)	-2

## ***Diagnosis of DVT***

**Q.** Write short essay/note on Wells probability score.

Wells clinical prediction guide for diagnosis of DVT is presented in Table 7.107. It incorporates risk factors, clinical signs, and the presence or absence of alternative diagnoses. *It helps in quantifying the pretest probability of DVT namely high score is 3 or more, a moderate score 1–2 and a low score 0. It groups the patients into high, moderate, or low-risk categories.*

## ***Complications***

- Pulmonary embolism
- **Post-thrombotic syndrome:** Consists of edema, skin pigmentation, venous eczema/dermatitis, ulceration around the medial malleolus, venous claudication, nocturnal cramping, and lifelong pain in the involved limb.
- **Venous gangrene:** Due to complete obstruction of large veins.

## *Investigations*

- **D-Dimer:** Raised (>500 ng/mL) but is not specific. May be raised in trauma, recent surgery, hemorrhage, cancer, etc. In DVT, it remains raised for 7 days.
  - **Negative D-dimer assay:** Rules out DVT in patients with low-to-moderate risk and a Wells score  $\leq 1$ . No further investigations needed.
  - **Positive D-dimer assay:** With a moderate-to-high risk of DVT (Wells score  $\geq 2$ ) need diagnostic investigation, e.g. Doppler ultrasonography.
- **B mode venous compression, ultrasonography or Doppler (duplex) ultrasonography:** Compression ultrasound is the imaging investigation of choice and has sensitivity for proximal DVT (of the popliteal vein or above) of 99.5%. Venous thrombosis is associated with failure to compress the vascular lumen.
- **Contrast venography** (phlebography) can reliably detect below knee thromboses, but is now rarely by **venography** with noninvasive.
- **Impedance plethysmography (IPG)** also detects above knee thrombi.
- **Radiofibrinogen scanning** is very accurate in calf vein and lower thigh thrombi.

**Box 7.62:** High risk factors for deep vein thrombosis and pulmonary thromboembolism.

- **Patients undergoing major surgery**, e.g. abdominal, thoracic or gynecological
- **Fractures:** Involving pelvis or extremities
- **Significant medical comorbidities**, e.g. heart disease, metabolic, endocrine or respiratory diseases pathologies, acute infectious diseases, inflammatory conditions
- **Patients admitted with major medical diseases:**
  - Acute coronary syndrome, Acute congestive failure (NYHA classes III, IV)
  - Acute respiratory diseases (respiratory failure with or without mechanical ventilation), chronic respiratory disease (e.g. chronic obstructive pulmonary disease)
  - Active cancer or cancer treatment
  - Inflammatory bowel disease
  - Acute arthritis of lower extremities

- Sepsis, stroke, paraplegia, obesity
- Varicose veins with phlebitis

### **Treatment of Deep Venous Thrombosis (DVT)**

- Bed rest till the patient is fully anticoagulated.
- **Legs:** Elevation by 15° and physiotherapy.

### **Prophylaxis**

#### **Q. Write short essay/note on prophylaxis of venous thrombosis (deep venous thrombosis-DVT).**

- Prophylaxis for DVT and pulmonary embolism is indicated in at high-risk patients (Box 7.62).

### **Prophylaxis of DVT**

- Nonpharmacological measures:
  - Mechanical VTE (antiembolism stockings) thigh or knee length.
  - Foot impulse devices.
  - Physiotherapy
  - Intermittent pneumatic compression devices (thigh or knee length): Compress the calf intermittently (usually once a minute).
- Pharmacological prophylaxis
  - Fondaparinux or low-molecular weight heparin or unfractionated heparin are given before operation or on admission to hospital, continued until the patient is ambulatory.
  - When risk factors are present treatment with warfarin to be given for a prolonged time.

## **DISORDERS OF BLOOD LIPIDS AND LIPOPROTEINS**

### **Q. Write short essay/note on structure of lipoproteins and their transport in body.**

- **Classes of lipid:** Most important are:
  - **Cholesterol:** It is composed of hydrocarbon rings.
  - **Triglycerides (TG):** These are esters composed of glycerol linked to three long-chain fatty acids.
  - **Phospholipids:** Composed of a hydrophobic ‘tail’ consisting of two long-chain fatty acids connected to a hydrophilic head containing a phosphate group by glycerol. Phospholipids are present in cell membranes and constitute important signaling molecules.

Both plasma cholesterol and TG are clinically important because they are major treatable risk factors for atherosclerosis.

## Lipoproteins

Lipids are poorly water soluble, but are absorbed from the gastrointestinal tract and transported throughout the body. This is achieved by lipids by forming complexes known as lipoproteins. Lipoproteins are spherical or disc-shaped and composed of:

- **Hydrophobic core:** Consisting of TG and cholesterol ester which is enveloped by a less hydrophobic surface coat (mentioned below).
- **Less hydrophobic surface coat:** Consisting of phospholipids, unesterified cholesterol and special proteins called apolipoproteins. Some apolipoproteins make these lipoproteins to act as enzyme co-factors or cell receptor ligands.

### *Types of Lipoprotein*

- Chylomicrons
- Very low density lipoprotein (VLDL)
- Intermediate density lipoprotein (IDL)
- Low-density lipoprotein (LDL): Lipoprotein [Lp(a)] is a type of lipoprotein similar to LDL with the addition of apolipoprotein (a)/ Lp(a) links lipid metabolism with blood coagulation.
- High-density lipoprotein (HDL).

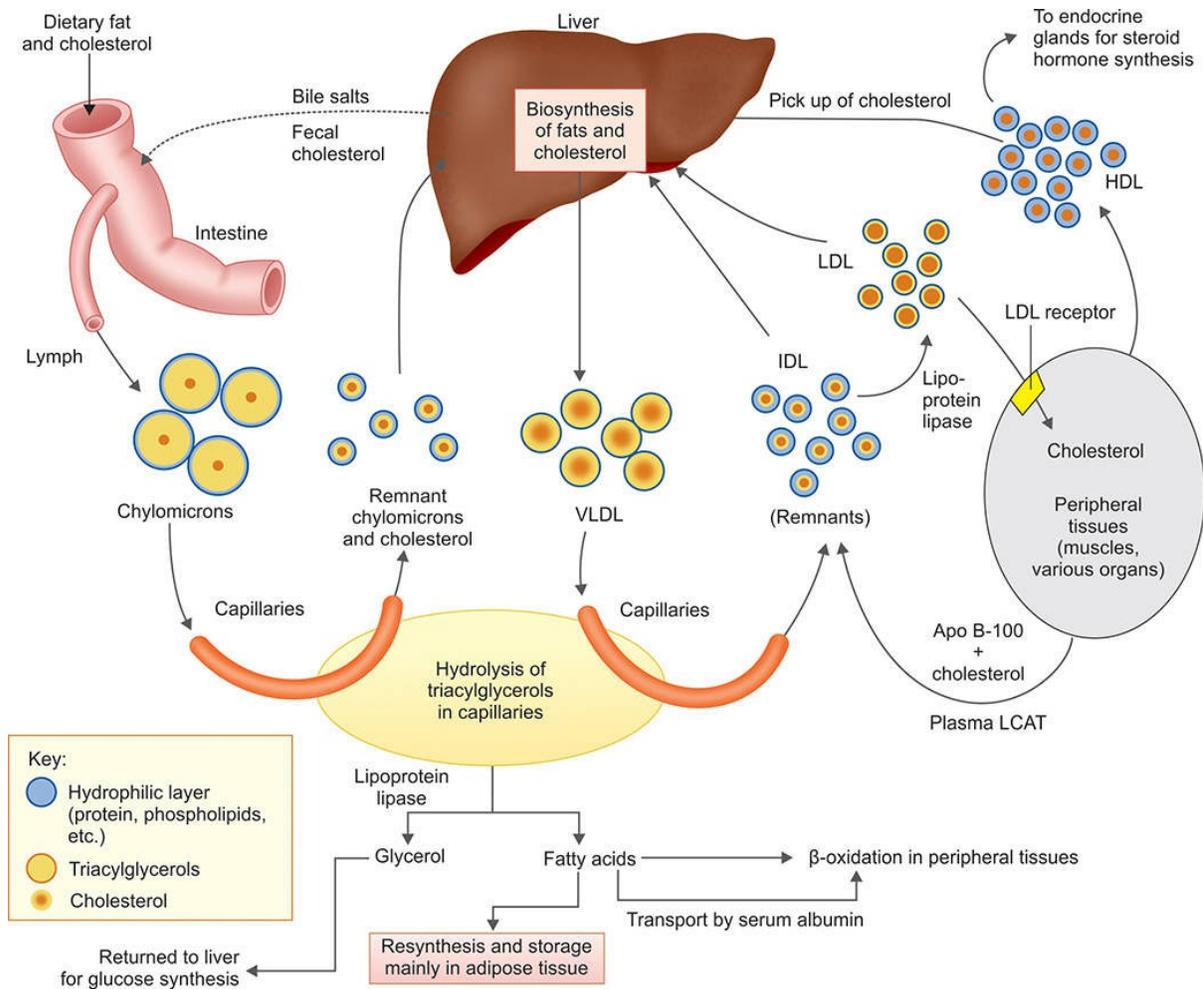

VLDL particles containing more cholesterol ester are more atherogenic than LDL particles.

### *Transport and Storage of Lipids (Fig. 7.56)*

Three main pathways involved in metabolism of lipid are:

#### 1. **Exogenous (dietary) Lipid Pathway**

- Dietary lipids are digested and absorbed in the small intestine and form chylomicrons in the epithelial cells of the intestines. Chylomicrons are the largest lipoprotein particle containing TG and cholesterol ester.
- Chylomicrons enter the blood circulation and are hydrolyzed by lipoprotein lipase (LPL) located on the endothelium of tissue capillary beds and release fatty acids. These fatty acids are utilized locally for energy production or stored as TG in muscle or fat.

**Fig. 7.56:** Absorption, transport and storage of lipids in body.

## 2. Endogenous Pathway

- During fasting, the liver is the main source of plasma lipids and constitute endogenous pathway.
- TGs and cholesterol ester are produced by the liver and these lipids are secreted by the liver into the circulation as very low-density lipoproteins (VLDL). VLDL is also rich in TG but differ from chylomicrons in that they contain full-length Apo B100.
- VLDL secreted into the circulation undergoes metabolic processing similar to that of chylomicrons. Hydrolysis of VLDL TG by capillary LPL releases fatty acids to tissues (utilized by fat and muscle) and remaining lipid portion of VLDL is converted into ‘remnant’ particles termed as intermediate-density lipoproteins (IDL).
- Major part of IDL is taken up and quickly cleared by LDL receptors in

the liver. Some of IDL is processed by hepatic lipase, which converts the IDL to LDL by removing TG.

- LDL is an atherogenic lipoprotein. LDL particles carry the majority of the cholesterol in the blood and are a source of cholesterol for cells and tissues.
- **Regulation of plasma LDL concentration:** LDL cholesterol is taken up by receptor-mediated endocytosis through the LDL receptor in the peripheral cells or liver.
  - **Controls the rate of cholesterol synthesis:** The supply of cholesterol through this pathway down-regulates further expression of the LDL receptor gene. This in turn decreases the synthesis and activity of the rate-limiting enzyme for cholesterol synthesis, HMGCoA reductase. This negative feedback loop, along with the modulation of cholesterol esterification, controls the intracellular free cholesterol level.

### 3. Reverse Cholesterol Transport

- It is the process in which cholesterol is removed from the peripheral tissues and is returned to the liver. This protects against excessive cholesterol accumulation in peripheral tissues.
- High-density lipoproteins (HDL) are the main lipoprotein along with lipid-poor Apo A1 (derived from the liver, intestine and the outer layer of chylomicrons and VLDL) involved in his reverse cholesterol transport process. HDL is produced and catabolized in the liver and intestines.
- HDL is able to accept more free cholesterol from atherogenic lipoproteins and peripheral tissues to the liver. A circulating enzyme called lecithin cholesterol acyltransferase (LCAT) esterifies these HDL.

## Hyperlipidemia

**Q. Write short essay/note on hyperlipidemias, their causes and management.**

Hyperlipidemia is characterized by an abnormality in the lipid profile, consisting of a variety of disorders with raised total cholesterol, LDL or TG, or conversely, lower levels of HDL.

### *Classification and Causes*

- **Primary hyperlipidemia:** It is a genetic disorder of lipid metabolism (e.g. familial hypercholesterolemia). It is characterized by a genetic mutation, which causes impaired clearance of LDL from the circulation due to absence of LDL receptors.
- **Secondary hyperlipidemia:** These are characterized by hyperlipidemia secondary to a disease/disorder other than the genetic defect (Table 7.108).

### **Management Strategies**

- Lipid profile of an individual should be interpreted along with the risk factors for coronary artery disease (CAD).
- Coronary heart disease risk based on risk factors other than the LDL level is listed in Box 7.63.
- **Major modifiable risk factors:** (1) hypercholesterolemia (2) smoking, (3) diabetes mellitus and (4) hypertension as per Framingham Risk Score (FRS). It provides the risk of an individual and developing a cardiac event in the next 10 years.
- Emerging risk factors: That may contribute to the risk of CAD include:
  - Apoliopoprotein B
  - Lipoprotein (a)
  - C-reactive protein
  - Hyperhomocysteinemia
  - Small, dense LDL particles
- Coronary artery diseases (CAD) equivalents: These include:
  - Diabetes mellitus
  - Patients with Framingham Risk Score (FRS)  $\geq 20\%$
  - In these patients, the goals of treatment are same as those for patients with established CAD.
- LDL cholesterol goals in different categories (Table 7.109).

**Table 7.108: Causes of secondary hyperlipidemia.**

<i>Increased LDL cholesterol level</i>	<i>Increased triglyceride level</i>	<i>Decreased HDL cholesterol level</i>
Diabetes mellitus	Alcoholism	Cigarette smoking
Hypothyroidism	Diabetes mellitus	Diabetes mellitus
Nephrotic syndrome	Hypothyroidism	Hypertriglyceridemia
Obstructive liver disease	Obesity	Menopause
		Obesity
		Uremia
		Anabolic steroids
		Beta-adrenergic

<b>Drugs</b> <ul style="list-style-type: none"> <li>• Anabolic steroids</li> <li>• Progestins</li> <li>• Beta-adrenergic blockers (without intrinsic sympathomimetic action)</li> <li>• Thiazides</li> </ul>	<b>Renal insufficiency</b> <b>Drugs</b> <ul style="list-style-type: none"> <li>• Beta-adrenergic blockers (without intrinsic sympathomimetic action)</li> <li>• Bile acid binding resins</li> <li>• Estrogens</li> <li>• Ticlopidine</li> </ul>	<b>blockers (without intrinsic sympathomimetic action)</b> <b>Progestins</b>
--	--	---

(LDL: low-density lipoprotein; HDL: high-density lipoprotein)

### Box 7.63: Coronary heart disease risk based on risk factors other than the LDL level.

#### Positive risk factors

- **Sex:** Male  $\geq 45$  years and female  $\geq 55$  years or postmenopausal without estrogen replacement therapy
- **Family history of premature coronary heart disease:** Myocardial infarction or sudden death before age 55 in father or other male first-degree relative or before age 65 in mother or other female first-degree relative)
- **Current cigarette smoking**
- **Hypertension:** Blood pressure  $\geq 140/90$  mm Hg or patient is receiving antihypertensive drug therapy
- **HDL cholesterol level**  $< 35$  mg per dL ( $< 0.90$  mmol per L)
- **Diabetes mellitus**
- **Negative risk factor#:** High HDL cholesterol level ( $\geq 60$  mg per dL [ $\geq 1.60$  mmol per L])

#Subtract one positive risk factor if negative risk factor is present. (LDL: low-density lipoprotein; HDL: High-density lipoprotein).

#### Management

- **Therapeutic lifestyle changes.**
  - **Patients with normal-weight, dyslipidemia (BMI 18.5–24.9 kg/m<sup>2</sup>):** Focus on healthy eating and regular exercise.
  - **Overweight and obese patients (BMI  $\geq 25$  kg/m<sup>2</sup>):** Reduce caloric intake from fats, simple carbohydrate and  $\geq 30$  mins physical activity most days.
  - Intake of soluble fiber to be increased (10–25 g/day).
  - Diet (rich fruits, veg, nuts, whole grains, monounsaturated oils; low red meat, animal fat) reduces LDL 5–15% (ATP III TLC diet).
  - **Aerobic exercise:** Running, walking, cycling, swimming enhance weight reduction facilitates achieving optimum lipid levels.
- Therapeutic drug classes, their effect on lipid profile and side effects are presented in Table 7.110.

- Table 7.111 shows drugs to be considered depending on cholesterol level.
- Ezetimibe** inhibits the absorption of cholesterol from the diet.
- Omega-3 fatty acid:** Useful to reduce TG levels. Dose is 1–2 g/day.
- Newer agents: Torcetrapib** is a cholesteryl ester transfer protein (CETP) inhibitors.

**Table 7.109: LDL cholesterol goals in different categories.**

<i>Risk group</i>	<i>LDL cholesterol goals</i>
<b>Very high-risk:</b> Cardiovascular disease plus multiple risk factors (especially diabetes), or severe/poorly controlled risk factors, or metabolic syndrome, or acute coronary syndrome	<100 mg/dL or optional goal <70 mg/dL
<b>High-risk:</b> Coronary heart disease (CHD) or CHD risk equivalents (10-year risk >20%)	<100 mg/dL
<b>Moderately high-risk:</b> 2 or more risk factors (10 year risk 10–20%)	<130 mg/dL or optional goal <100 mg/dL
<b>Moderate-risk:</b> 2 or more risk factors (10-year risk 5–10%)	<130 mg/dL
<b>Low-risk:</b> 0-1 risk factors	<160 mg/dL

(LDL: low density lipoprotein)

**Table 7.110: Drug classes, their effect on lipid profile and side effects.**

<i>Drug class</i>	<i>Total cholesterol levels</i>	<i>LDL levels</i>	<i>HDL levels</i>	<i>Triglycerides</i>	<i>Side effects</i>
Bile acid binding resins	20%	10–20%	3–5%	Neutral	Unpalatability, bloating, constipation, heartburn
Nicotinic acid	25%	10–25%	15–35%	20–50%	Flushing, nausea, glucose intolerance, abnormal liver function test
Fibric acid analogs	15%	5–15%	14–20%	20–50%	Nausea, skin rash
HMG-CoA reductase inhibitors	15–30%	20–60%	5–15%	10–40%	Myositis, myalgia, elevated hepatic transaminases

(LDL: low-density lipoprotein; HDL: high-density lipoprotein)

**Table 7.111: Drugs to be considered depending on cholesterol level.**

<i>LDL cholesterol level</i>	<i>Drugs to be considered</i>
High LDL-C level only	Statins first, resins or intestinal absorption blocker second, niacin third
High LDL-C and low HDL-C levels	Statins first, niacin second
High LDL-C, low HDL-C, and high triglyceride levels	Niacin and statins first, fibrates second
High triglyceride levels, with or without low HDL-C levels	Fibrates first, niacin second
Low HDL-C levels only	Niacin first, fibrates second

(LDL-C: low density lipoprotein cholesterol; HDL-C: high-density-lipoprotein cholesterol)

## LIPODYSTROPHY

### **Q. Write a short note on lipodystrophy.**

Lipodystrophy is changes in the distribution body fat. Lipoatrophy implies partial or complete decrease of fat. However, the terms lipoatrophy and lipodystrophy are used interchangeably in clinical practice.

### Classification of Lipodystrophies

- **Total lipodystrophy:** Two types namely congenital and acquired.
  - **Berardinelli-Seip (congenital):** Autosomal recessive, hypermetabolic state.
  - **Seip-Lawrence (acquired):** Begins <15 years old, often <5 years
- **Partial lipodystrophy**
  - **Kobberling-Dunnigan syndrome:** Inherited form, autosomal dominant
  - **Progressive partial lipodystrophy:** Acquired forms
- **Centrifugal:** One type is seen primarily in infants from Japan. 90% are under 5 years. Centrifugally spreading loss of abdominal fat over 3–8 years with regional lymphadenopathy. Resolves completely after progression stops.
- **Semicircular:** Adult women affected with single or multiple, asymptomatic, symmetric depressions of anterolateral thigh. Often after trauma, resolves in several years.

- **Annular atrophic panniculitis:** 10 cm band of atrophy, bilaterally, around the ankles of children and young adults. Rare.
- **Lipoatrophia annularis:** Bracelet-like constrictions of upper extremities 1–2 cm wide on women following a period of swelling and erythema of extremity. Arthralgias and pain of affected extremity. Persist up to 20 years.
- **Localized lipodystrophy: Secondary** to injection of medications especially insulin.
- **HIV associated lipodystrophy:**
  - Occurs in effectively treated AIDS patients with reverse transcriptase inhibitors and protease inhibitors.
  - Fat redistribution from face, buccal, buttocks and limbs is lost to neck, upper back and inter abdominal areas.
  - Peripheral lipodystrophy, central fat accumulation and lipomatosis.

**Box 7.64:** Indications for low dose aspirin.

- Secondary prevention of cardiovascular disease: CAD (coronary artery disease, stroke, post CABG (coronary artery bypass grafting)
- Primary prevention of ischemic heart disease
- TIA(transient ischemic attacks)
- APLA(anti-phospholipid antibody) syndrome
- Preeclampsia
- Essential thrombocytosis, polycythemia vera
- Venous thromboembolism- prophylaxis

**Q. Write short note on indications for low dose aspirin.**

Indications for low dose aspirin (Box 7.64).

## STRAIGHT BACK SYNDROME

**Q. Write short essay/note on straight back syndrome (SBS).**

- In straight back syndrome, there is loss of normal curvature upper thoracic spinal which reduces the anteroposterior diameter of the chest. This deformity compresses or ‘pancakes’ the heart (cardiomegaly) and great vessels so as to appear enlarged. There is displacement of the heart towards left, resulting in cardiac murmurs.

- **Clinical features:** Chest pain, tracheal compression and mitral valve prolapse (MVP).
- **Chest X-ray:** Lateral chest X-ray reveals significant reduction of distance from the middle of the anterior border T8 to a vertical line connecting T4 and T12. A value less 1.2 cm is diagnostic.
- ECG often shows right bundle branch block.

## CARDIAC TUMORS

### Myxoma

- Most common type of primary cardiac tumor in adults seen in third to sixth decade of life.
- Most common in females.
- Most are sporadic, but some are familial (autosomal dominant)–10%.
- Most are solitary and located in left atrium arising from inter atrial septum near fossa ovalis.
- Its presentation most commonly mimics that of mitral valve disease.
- ‘Tumor plop’ is a characteristic low-pitched sound which may be audible during early or mid-diastole and is thought to result from the tumor abruptly stopping as it strikes the ventricular wall.
- **Symptoms and signs:** Fever, weight loss, cachexia, malaise arthralgia, rash, clubbing, Raynaud’s phenomenon. Peripheral or pulmonary embolization can develop.
- **Investigations:**
  - Anemia, polycythemia, elevated ESR, thrombocytopenia or thrombocytosis.
  - 2-D echocardiography: Useful screening tool
  - CT and MRI are investigations of choice
- Treatment is surgical excision using cardiopulmonary bypass.

**Rhabdomyomas** are the commonest cardiac tumor in children.

## DIGOXIN

**Q. Write short essay/note on digoxin, manifestations of digoxin/digitalis**

## **toxicity and its management.**

Digoxin is a purified glycoside derived from *Digitalis lanata* having cardiac inotropic property.

### **Pharmacological Actions**

- Force of myocardial contraction is increased by a direct action of digitalis.
- **Heart rate:** Decreased and bradycardia is more marked in CHF.
- **Electrophysiological properties:**
  - Prolongs the refractory period of V node → slows the ventricular rate.
  - Reflex vasodilation in CHF.

### **Pharmacokinetics**

- Has a good oral absorption.
- Digoxin concentration in the heart is 30 times more than in the plasma.
- The elimination half-life for digoxin is **36 to 48 hours** in patients with normal or near-normal renal function. This permits once-a-day dosing; near steady-state blood levels are achieved one week after initiation of maintenance therapy.
- About 85% of digoxin is excreted through the kidneys and the remaining 15% through the stool.

### **Indications**

- **Cardiac arrhythmias:** Supraventricular tachycardia, tachyarrhythmias and atrial fibrillation with a fast ventricular rate.
- Heart failure with reduced ejection fraction (HFrEF)
- Heart failure accompanied by atrial fibrillation or flutter with a rapid ventricular rate.

### **Dosage and Route of Administration**

The dosage and route is determined based on the desired action.

- **Rapid digitalizing (loading dose) regimen**
  - **Intravenously:** Initial loading dose of 0.25–0.5 mg followed by 0.25 mg every 6 hour. Careful monitoring of clinical response and toxicity should be performed before each dose.
  - **Orally:** Initial loading dose is 0.5–1 mg followed by 0.25 mg 6 hourly. Careful monitoring of clinical response and toxicity before each dose.

- **Slow digitalization:** Maintenance dose (0.125–0.25 mg/day) given from the beginning. Dose may be increased every 2 weeks depending on clinical response, serum levels of the drug, and toxicity.
- As per ACCF/AHA guidelines, a loading dose to initiate digoxin therapy in patients with heart failure is not required.

## Digoxin Toxicity and its Management

- Digitalis has high toxicity low margin of safety. Definite toxicity defined as nausea/vomiting, with cardiac effects and resolution of side effects on discontinuation. Serum digoxin concentration (SDC) is not a necessary criterion but SDC > 2.0 ng/mL helpful.

### *Manifestations of Digoxin Toxicity*

- Extracardiac manifestations
  - Nonspecific but more common
  - **Gastrointestinal (60–80%):** Nausea/vomiting, anorexia, abdominal pain, diarrhea
  - Malaise (30–40%), lethargy, fatigue
  - **Neurological (20–30%):** Dizziness, confusion, headache, visual changes (flashing lights, halos, color disturbances in green-yellow spectrum, blurred vision)
- Cardiac side effects
  - More specific but less common
  - Almost any permutations and combinations of heart block (partial to complete), brady and tachydysrhythmias can be produced.
  - **Classical:** Paroxysmal atrial tachycardia, ventricular bigeminy, bidirectional ventricular tachycardia, nodal and ventricular extra systoles.
- **ECG changes of digoxin toxicity:** Inverse check mark with proximal ST segment depressed, in leads other than those with tall R waves, with T wave not rising above baseline (Inverted T), with shortened QTc.

### Management of digoxin toxicity

- Stop digoxin.
- **Blood test:** Urea, electrolytes and plasma digoxin concentration.
- **Correction of hypokalemia:** Intravenous supplementation of no more than 20 mmol/h of potassium. More rapid infusion may cause asystole.

- **Heart blocks:** Atropine and temporary cardiac pacing.
- Malignant ventricular arrhythmias
  - Phenytoin (100 mg intravenously, repeated after 5 minutes if required) opposes digitalis binding and may improve atrioventricular conduction by its anticholinergic properties.
  - Ultrashort acting beta blockers, e.g. esmolol.
  - Avoid cardioversion wherever possible, due to the risk of precipitating asystole.
  - **Digoxin-specific antibody fragments:** Digoxin-specific fab antibody fragments (Digibind) are the most effective but expensive. Hence, reserved for treatment of serious toxicity, especially in the presence of malignant cardiac dysrhythmias.

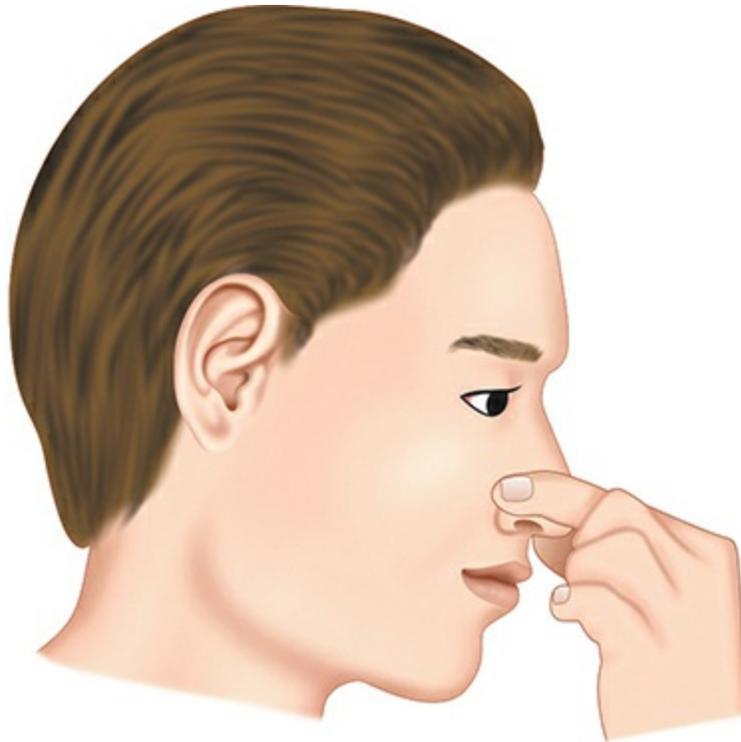

## VALSALVA MANEUVER

### **Q. What is the Valsalva maneuver?**

The Valsalva maneuver is a forceful attempted exhalation against a closed glottis.

### **Method (Fig. 7.57)**

- **Instruction:** Take a deep breath, close your mouth and pinch your nose with the thumb and index finger and attempt to breathe out gently, keeping your cheek muscles tight, not allowing the air to escape by keeping the lips pursed.
- **“Standard” or “quantitative:”** Blowing out with an open glottis into a tube of a sphygmomanometer against the pressure of 40 mm Hg.

**Fig. 7.57:** The Valsalva maneuver.

## Phases of Valsalva Maneuver

Physiological effects on blood pressure heart rate and phases of Valsalva maneuver are presented in Figure 7.58 and Table 7.112.

**Phase 1:** The onset of blowing. The pressure within the chest and abdomen increases and presses upon the arteries in the chest, which results in an increase in mean arterial blood pressure. This activates the baroreceptor reflex, which results in an increase in parasympathetic (vagal) activity and hence in a drop in heart rate. The increased intrathoracic pressure also reduces the amount of blood that comes into the right atrium (decreased venous return or preload).

**Table 7.112:** Various phases of Valsalva maneuver and its associated changes.

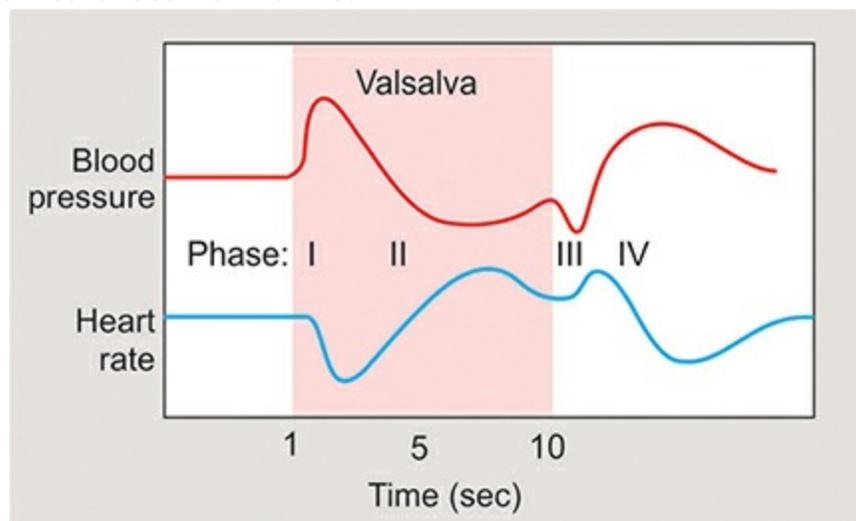

<i>Phase</i>	<i>1</i>	<i>2a</i>	<i>2b</i>	<i>3</i>	<i>4</i>
Intrathoracic pressure	Increased	Increased	Increased	Normal	Normal
Mean arterial blood pressure	Increased	Decreased	Increased	Decreased	Increased

Heart rate	Decreased	Increased	Decreased	Increased	Decreased
Sympathetic activity	Decreased	Decreased	Increased	Increased	Increased
Parasympathetic (vagal) activity	Increased	Increased	Decreased	Decreased	Increase

**Phase 2:** A decrease of venous return results in a lower amount of blood that is ejected from the heart, which results in a decrease of central venous pressure and consequently in a decrease of mean arterial blood pressure. This activates the baroreflex, which results in a decrease of the parasympathetic (vagal) activity and consequent increase of the heart rate, and in an increase in sympathetic activity, which constrict the arteries (an increase of peripheral resistance), which results in a slight rise of the blood pressure at the end of phase 2 (2b).

**Phase 3:** Relaxation – the end of the maneuver. The intrathoracic pressure decreases, so the intrathoracic arteries widen, which results in a brief drop in blood pressure. At the same time, the venous blood fills the heart.

**Phase 4:** The heart ejects the blood into the arterial system against increased peripheral resistance (which has developed in phase 2), so the blood pressure rises again (blood pressure overshoot). This activates the baroreflex, which results in a drop in heart rate (bradycardia). Eventually, both the blood pressure and heart rate normalize.

**Fig. 7.58:** Mean arterial blood pressure and heart rate changes during the Valsalva maneuver.

## Uses

- Eustachian tube dysfunction
- Heart murmurs: Valsalva increases murmurs in hypertrophic cardiomyopathy and mitral valve prolapse and decreases them in atrial septal defects and aortic stenosis.
- Congestive heart failure: Valsalva responses lost
- Function of the autonomous nervous system: An abnormal blood pressure response (for example, an absence of the blood pressure rise in phase 4) suggests an abnormality of the sympathetic system.
- An abnormal heart rate response suggests an abnormality of the parasympathetic Valsalva maneuver can be used as a provocative test to check for:
  - Neurogenic orthostatic hypotension
  - Chiari malformation, the Valsalva maneuver (coughing) triggers a headache at the back of the head.
- Diagnosis of inguinal hernia, prolapse of the uterus, bladder or vagina, varicocele and intrinsic sphincter deficiency in stress urinary incontinence system.
- Valsalva maneuver can help: Equalize the pressure between the middle ear and the ambient pressure during scuba diving, driving from a steep hill, elevator descending, parachuting or plane landing or in individuals with Eustachian tube dysfunction.

**Modified valsalva maneuver:** Modified Valsalva maneuver is used to terminate an attack of supraventricular tachycardia (SVT); it includes blowing against a closed glottis followed by lying down face up and raising legs with the help of an assistant, may be effective in 19–54% of cases.

**Reversed valsalva—Müller’s maneuver:** Müller’s maneuver is the opposite of the Valsalva maneuver and includes forced exhalation followed by an attempted forceful inhalation with a closed mouth and nose or just with a closed glottis. The test can be used to evaluate weakness of the soft palate and throat walls in individuals with obstructive sleep apnea.

# Hematology

# CHAPTER

# 8

## DISORDERS OF RED BLOOD CELL

### INTRODUCTION

**Q.** Write short note on the structure of normal hemoglobin.

#### Hemoglobin Structure

A hemoglobin molecule is a conjugated protein composed of iron containing pigment called **heme** and protein **globin**. About 65–70% of hemoglobin is synthesized in normoblasts and 30–35% is synthesized at the reticulocyte stage.

- Each molecule of **heme** consists of protoporphyrin with an iron in ferrous state ( $\text{Fe}^{++}$ ). Heme synthesis occurs mainly in the mitochondria of normoblasts.
- Each **globin** chain is made up of **two pairs of distinct polypeptide** chains (composed of a number of amino acids) bound to a heme molecule.
  - **Hemoglobin A (HbA)**, is composed of two  $\alpha$  and two  $\beta$  globin chains ( $\alpha_2 \beta_2$ ) and normally represents more than 95% of the hemoglobin in adult red blood cell (RBCs). Fetal hemoglobin is replaced by adult hemoglobin during the first year of life (hemoglobin switching).
  - **Fetal hemoglobin (HbF)** contains two  $\alpha$  and two  $\gamma$ -globin chains ( $\alpha_2 \gamma_2$ ). It is the major hemoglobin (70–90%) during fetal development and is normally found in low levels in adults.
  - **Hemoglobin A<sub>2</sub> ( $\alpha_2 \delta_2$ )** is normally found at low levels in adults (2%).
  - Normal hemoglobin in the adult are Hb-A ( $\alpha_2 \beta_2$ ) and Hb-A<sub>2</sub> ( $\alpha_2 \delta_2$ )
  - Normal hemoglobin in the fetus are Hb-F ( $\alpha_2 \gamma_2$ ) and Hb-Bart's ( $\gamma_4$ ).

## Red Cell Indices

**Q. Describe various blood indices used in patients with anemia.**

- 1. Mean corpuscular volume (MCV):** It is used for classification and differential diagnosis of anemias.
  - **Normal range: 82–98 fL;** (fL stands for femtoliters)Microcytic anemia have MCV <80 fL and macrocytic anemia have MCV >100 fL.
- 2. Mean corpuscular hemoglobin (MCH):**
  - **Normal range: 27–32 pg**MCH <26 pg is seen in microcytic anemia and MCH >33 pg is seen in macrocytic anemia.
- 3. Mean corpuscular hemoglobin concentration (MCHC):** It is a better indicator of hypochromasia than MCH.
  - **Normal range: 31–35 g/dL.**MCHC <31 g/dL is seen in hypochromic RBC such as IDA and thalassemia. MCHC is increased in hereditary spherocytosis.
- 4. Red Cell Distribution Width (RDW)**
  - RDW is a quantitative measure of anisocytosis.
  - **Normal RDW is 11.5 to 14.5%.**
$$\text{RDW} = (\text{Standard deviation} + \text{mean cell volume}) \times 100$$
  - **Significance:** RDW is used for differentiating anemia due to iron deficiency and thalassemia. Increased in iron deficiency anemia (along with low MCV) and megaloblastic anemia (with high MCV) while in thalassemia trait, RDW is normal with low MCV.

**RBC count:** Normal range in males 4.5–5.5 millions/cumm; females 4–4.5 millions/cumm

## Reticulocyte

**Q. Write short essay/note on laboratory technique of reticulocyte count and causes of reticulocytosis.**

Reticulocytes are immature, non-nucleated RBCs released from bone marrow. They are demonstrated by using visual method brilliant cresyl blue/new methylene blue stain or by automated method.

**Reticulocyte count** is expressed as percentage of RBC count (normal <2.5%). Reticulocyte count reflects the erythropoietic activity of the bone marrow and provides an estimate of red cell production. Increased erythropoiesis results in increased reticulocyte release. The reference range of the corrected reticulocyte percentage in adults is 0.5–1.5%. Causes of increased and reduced reticulocyte count are listed in Table 8.1.

**Table 8.1: Causes of increased and reduced reticulocyte count.**

<i>Causes of increased reticulocyte count (reticulocytosis)</i>	<i>Causes of reduced reticulocyte count</i>
<ul style="list-style-type: none"> <li>• Hemolytic anemias</li> <li>• Hemolytic crisis</li> <li>• Hemorrhage</li> <li>• Following treatment in iron/folic acid/vitamin B<sub>12</sub> deficiency anemias. Highest counts are found on 6th/7th day of treatment and indicate marrow response to iron and 3rd day in response to vitamin B<sub>12</sub></li> </ul>	<ul style="list-style-type: none"> <li>• Due to decreased erythropoietic activity</li> <li>• Aplastic anemia</li> <li>• Aplastic crisis due to parvovirus (in hereditary spherocytosis and sickle cell disease)</li> <li>• Pure red cell aplasia</li> <li>• Fanconi anemia</li> <li>• Myelofibrosis</li> </ul>

- **Reticulocyte production index (RPI)** is expressed as % and it accounts for premature release of reticulocytes from bone marrow in anemia. It is important in determining if a patient’s bone marrow is responding appropriately to the level of anemia.

$$\text{Reticulocyte index} = \text{Reticulocyte count} \times \frac{\text{Hematocrit}}{\text{Normal hematocrit for the age}}$$

$$\text{Reticulocyte production index (RPI)} = \text{Reticulocyte count} \times \frac{\text{Hemoglobin}}{\text{Normal hemoglobin for the age}} \times 0.5$$

- **Significance:** Normal RPI is 1.0 to 2.0. However, RPI <2 with anemia indicates decreased RBC production (hypoproliferative anemia) and RPI >2 with anemia indicates hemolysis or loss of RBCs leading to compensatory production of reticulocytes and is observed in hyperproliferative anemia.

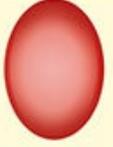

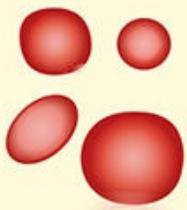

## RBC Abnormalities

Various RBC abnormalities are presented in Figures 8.1 to 8.4.

**Q. Discuss the RBC abnormalities seen on a peripheral blood smear examination.**

**Q. Write short note on value of peripheral smear in the diagnosis of**

## anemia.

Term	Description	Appearance	Condition
Normocyte	<ul style="list-style-type: none"><li>• Normal RBC is biconcave, 7.2 <math>\mu\text{m}</math> in diameter</li></ul>		<ul style="list-style-type: none"><li>• Normal RBC normochromic</li><li>• Normocytic anemia</li></ul>
Microcyte	<ul style="list-style-type: none"><li>• RBCs smaller than normal and less than 6 <math>\mu\text{m}</math> in diameter</li></ul>		<ul style="list-style-type: none"><li>• Iron deficiency anemia</li><li>• Thalassemia</li><li>• Sideroblastic anemia</li></ul>

**Fig. 8.2A:** Variation in shape of red blood cells and associated conditions.

Term	Description	Appearance	Condition
Acanthocytes/ spur cells	<ul style="list-style-type: none"> <li>RBCs with few spicules of uneven (irregular) length and shape</li> </ul>		<ul style="list-style-type: none"> <li>Abetalipoproteinemia</li> <li>Liver disease</li> </ul>
Echinocyte/ Burr cells	<ul style="list-style-type: none"> <li>Very small irregular shrunken cells with pointed projections. Resemblance to the small thorny 'burrs'</li> </ul>		<ul style="list-style-type: none"> <li>Uremia</li> <li>Post-transfusion</li> </ul>
Elliptocyte or Ovalocyte	<ul style="list-style-type: none"> <li>Oval in shape</li> </ul>		<ul style="list-style-type: none"> <li>Hereditary ovalocytosis</li> <li>Hemolytic anemia</li> </ul>
Pencil shaped cells	<ul style="list-style-type: none"> <li>Elongated thin cells (exaggerated ovalocytes)</li> </ul>		<ul style="list-style-type: none"> <li>Iron deficiency anemia</li> </ul>
Tear drop and pear-shaped cells	<ul style="list-style-type: none"> <li>These abnormal RBCs have a teardrop or pear-like shape</li> </ul>		<ul style="list-style-type: none"> <li>Myelofibrosis</li> <li>Marrow infiltration</li> </ul>
Stomatocytes	<ul style="list-style-type: none"> <li>Red cells with a slit-like area of central pallor</li> </ul>		<ul style="list-style-type: none"> <li>Hereditary stomatocytosis</li> <li>Liver disease</li> </ul>

**Fig. 8.2B:** Variation in shape of red blood cells and associated conditions.

Term	Description	Appearance	Condition
Normochromic	Cell with 1/3 central pallor		• Normal RBC
Hypochromic	Central pallor more than 1/3		• Iron deficiency anemia • Thalassemia • Sideroblastic anemia
Polychromasia	Cells stained purple and are larger than normal		• Hemolytic anemias • Response to therapy in deficiency anemias

**Fig. 8.3:** Variation in color of red blood cells.

Term	Description	Appearance	Condition
Basophilic stippling (punctate basophilia)	• Red cells contain small, blue black inclusions and represent precipitated ribosomal RNA		• Lead poisoning • Megaloblastic anemias • Hemolytic anemias like thalassemias • Sideroblastic anemias • Alcoholism • Pyrimidine-5 nucleotidase deficiency
Howell-Jolly bodies	• Small, round, densely staining dark blue particles and represent nuclear remnants		• Megaloblastic anemias • Acute hemolytic anemias • Postsplenectomy state
Cabot rings	• Rings or figure of eight shaped and are probably remnants of the nuclear membrane		• Hemolytic anemia • Megaloblastic anemia • Leukemia • Rarely after splenectomy
Pappenheimer bodies/ siderotic granules (RBCs with Pappenheimer bodies are called siderocytes)	• Aggregates of ferritin and appear pale blue, but are easily demonstrable with Perl's stain (Prussian blue reaction)		• Sideroblastic anemias • Megaloblastic anemias • Hemolytic anemias • Postsplenectomy
Hemoglobin H inclusions	• Free $\beta$ chains in red cells. Small, regular, multiple and diffusely distributed (golf ball like appearance). Stained by supravital stains.		• $\alpha$ -thalassemias
Heinz bodies	• Refractive, single or multiple rounded inclusions of denatured globin detected by supravital stains		• Intake/exposure to oxidizing drugs or chemicals. • G-6-PD deficiency • Unstable hemoglobin disease
Hemoglobin C crystals	• Crystallization of hemoglobin C		• Splenectomy in homozygous hemoglobin C

**Fig. 8.4:** Inclusions in red blood cells and associated conditions.

## ANEMIA

**Q. Define and classify anemia.**

### Definition

Anemia is defined as **decrease** in circulating red blood cell mass. It is characterized by decrease of **hemoglobin concentration (Hb)/RBC count/hematocrit (PCV)** below normal for the patient's age, sex and altitude

of residence.

Normal adult hemoglobin level is in the range of 13 to 17 g/dL in males and 12 to 15 g/dL in females.

## Classification of Anemia

Anemia may be classified (1) based on the morphology of red cells (morphological classification) and (2) based on the etiology/cause of anemia.

### *Morphological Classification*

- Normocytic normochromic (with a normal MCV)
- Microcytic hypochromic (with a low MCV)
- Macrocytic (with a high MCV).

### *Etiological Classification (Table 8.2)*

**Q. Write short essay/answer on etiology of anemia.**

**Table 8.2:** Etiological classification of anemia.

#### **1. BLOOD LOSS**

- **Acute:** Loss of large volume over short period: **Trauma**, postpartum bleeding
- **Chronic:** Small volume over long period lesions of gastrointestinal tract (e.g. peptic ulcer, hemorrhoids, carcinoma colon, hook worms), gynecological disturbances (excessive menstrual loss), urinary blood loss

#### **2. IMPAIRED RED CELL PRODUCTION (HYPOPROLIFERATIVE ANEMIAS)**

- **Disturbed Proliferation and Maturation of Erythroblasts**
  - **Defective DNA synthesis**
    - ◆ Megaloblastic anemias due to deficiency or impaired utilization of vitamin B<sub>12</sub> and folic acid
    - ◆ Anemia of renal failure due to deficiency of erythropoietin
    - ◆ Anemia of chronic disease due to iron sequestration and relative erythropoietin deficiency
    - ◆ Anemias of endocrine disorders
  - **Defective hemoglobin synthesis**
    - ◆ Defective heme synthesis: Iron deficiency, sideroblastic anemia
    - ◆ Defective globin synthesis: Thalassemias
- **Marrow Replacement**
  - *Primary hematopoietic neoplasms:* Acute leukemia, myelodysplastic syndromes
- **Marrow Infiltration (myelophthisic anemia)**
  - *Metastatic neoplasms*
- **Disturbed Proliferation and Differentiation of Stem Cells**

– *Aplastic anemia, pure red cell aplasia*

### 3. INCREASED RED CELL DESTRUCTION (HEMOLYTIC ANEMIAS)

- **Intrinsic (Intracorpuseular) Abnormalities**

- **Hereditary**

- ◆ Membrane abnormalities: Spherocytosis, elliptocytosis
- ◆ Enzyme deficiencies: Glucose-6-phosphate dehydrogenase, pyruvate kinase
- ◆ Disorders of hemoglobin synthesis
  - ◇ Deficient globin synthesis: Thalassemia syndromes
  - ◇ Structurally abnormal globin synthesis (hemoglobinopathies): Sickle cell anemia

- **Acquired**

- ◆ Membrane defects: Paroxysmal nocturnal hemoglobinuria

- **Extrinsic (Extracorpuseular) Abnormalities**

- **Antibody-mediated**

- ◆ Isohemagglutinins: Transfusion reactions, Rh disease of the newborn
- ◆ Autoantibodies: Idiopathic (primary), drug-associated, systemic lupus erythematosus

- **Mechanical trauma to RBCs**

- ◆ Microangiopathic hemolytic anemia: Disseminated intravascular coagulation, prosthetic valves

- **Infections:** Malaria, infective endocarditis, mycoplasma

## Clinical Features

**Q. Discuss the clinical features of anemia. How to approach a case of anemia?**

### Symptoms

They depend on (1) speed of onset of anemia, (2) severity of anemia, (3) age of the patient and (4) underlying illness. General clinical features are either due to tissue hypoxia or compensatory mechanisms.

- **Due to tissue hypoxia:**

- Nonspecific symptoms: Weakness, malaise, lassitude, and easy fatigability
- Dyspnea on mild exertion, angina, intermittent claudication, transient cerebral ischemia
- Central nervous system (CNS): Headache, vertigo, tinnitus, dizziness, syncope, irritability, sleep disturbances and lack of concentration.
- Gastrointestinal tract (GIT): Anorexia, indigestion, nausea, bowel disturbances
- Female genital tract: Amenorrhea, polymenorrhea

- **Due to compensatory mechanisms:**

- Cardiac features: Dyspnea on mild exertion, palpitation, tachycardia and congestive cardiac failure.

**Figs. 8.5A and B:** (A) Pallor of palpebral conjunctiva; (B) Pale palms with pale creases.

### **Signs**

- Pallor (Figs. 8.5A and B) is observed on skin, palms, mucous membranes (oral, vaginal, rectal) nail beds and palpebral conjunctiva.
- Pulse: Tachycardia, wide pulse pressure.
- Cardiovascular system (CVS): Cervical venous hum, hyperdynamic precordium, ejection systolic murmur (best heard over the pulmonary area), cardiac dilatation and later, signs of cardiac failure.
- Ankle edema.

*Signs suggesting etiology of anemia (Table 8.3)*

**Table 8.3:** Various signs of anemia suggesting the probable etiology.

<b>Sign</b>	<b>Probable etiology</b>
Angular cheilitis, blue sclera, koilonychia	Iron deficiency anemia
Glossitis	Iron, vitamin B <sub>12</sub> and folate deficiency anemia
Neurological changes (neuropathy, dementia, ataxia), Knuckle pigmentation	Vitamin B <sub>12</sub> deficiency
Jaundice	Hemolytic anemia, megaloblastic anemia
Splenomegaly	Malaria, chronic hemolytic anemia, acute infection, leukemia, lymphoma, portal hypertension, megaloblastic anemia, iron deficiency anemia (rare)
Frontal bossing, dental malocclusion, skin ulcers	Chronic hemolytic anemia (e.g. beta-thalassemia, sickle cell anemia)
Leg ulcers	Sickle cell disease

### *History in diagnosis of anemias (Table 8.4)*

**Table 8.4:** History suggesting the possible etiology of anemia.

<b>History: Signs and symptoms</b>	<b>Possible etiology of anemia</b>
Known normal complete blood cell count in the past	Probably not a hereditary/congenital disorder
Anemia known since childhood	Inherited/congenital hemolytic anemia
Splenectomy, gallstones and/or jaundice	Chronic hemolytic anemia, liver disease
Family history of splenectomy, gallstones and/or jaundice	Hereditary hemolytic anemia (RBC enzyme or membrane disorder, thalassemia, or hemoglobinopathy)
Poor or unconventional diet, malnutrition or severe alcoholism	Bone marrow hypoplasia, folate deficiency
Paresthesias, foot numbness, loss of balance, altered mental status	Cobalamin (vitamin B <sub>12</sub> ) deficiency
Gastrectomy, surgical removal of the ileum, chronic malabsorption disorder	Cobalamin (vitamin B <sub>12</sub> ) deficiency
Chronic gastritis, peptic ulcer disease, chronic use of ASA or NSAIDs, recurrent epistaxis or rectal bleeding, melena, menorrhagia, metrorrhagia, multiple pregnancies, duodenal surgery, gastrectomy	Iron deficiency
Chronic rheumatologic, immunologic, infectious or neoplastic disease	Anemia of inflammation, autoimmune hemolytic anemia
Decreased urine output	Anemia secondary to renal insufficiency
Dark urine	Hemolytic anemia (intravascular hemolysis)
Recent onset of infections, mucosal and skin bleeding, easy bruising, oral ulcerations	Bone marrow aplasia/hypoplasia, acute leukemia, myelodysplasia, myelophthisis
Occupational/environmental toxin exposure	Bone marrow aplasia/hypoplasia, acute leukemia,

(benzene, ionizing radiation, lead)	myelodysplasia, lead poisoning
Drug/medication exposure:	
<ul style="list-style-type: none"> <li>• Penicillin, cephalosporin, procainamide, quinidine, quinine, sulfonamide</li> </ul>	Drug-induced immune hemolytic anemia
<ul style="list-style-type: none"> <li>• Fava beans, dapson, naphthalene</li> </ul>	Oxidant-induced hemolysis (G6PD deficient)
<ul style="list-style-type: none"> <li>• Cancer chemotherapeutic drugs (recent use)</li> </ul>	Bone marrow aplasia/hypoplasia, oxidant damage, fluid retention/dilutional anemia, megaloblastic anemia
<ul style="list-style-type: none"> <li>• Cancer chemotherapeutic drugs (past use)</li> </ul>	Bone marrow hypoplasia, myelodysplasia, acute myeloid leukemia
<ul style="list-style-type: none"> <li>• Chloramphenicol, gold salts, sulfonamides, anti-inflammatory drugs</li> </ul>	Bone marrow aplasia/hypoplasia
<ul style="list-style-type: none"> <li>• Ethanol, chloramphenicol</li> </ul>	Acute reversible bone marrow toxicity
<ul style="list-style-type: none"> <li>• Methotrexate, azathioprine, pyrimethamine, trimethoprim, zidovudine, sulfa drugs, hydroxyurea, antimetabolites</li> </ul>	Bone marrow aplasia/hypoplasia, megaloblastic anemia

## IRON METABOLISM (FIG. 8.6)

Iron is required for synthesis of normal heme of hemoglobin. Its deficiency leads to decreased erythropoiesis and anemia.

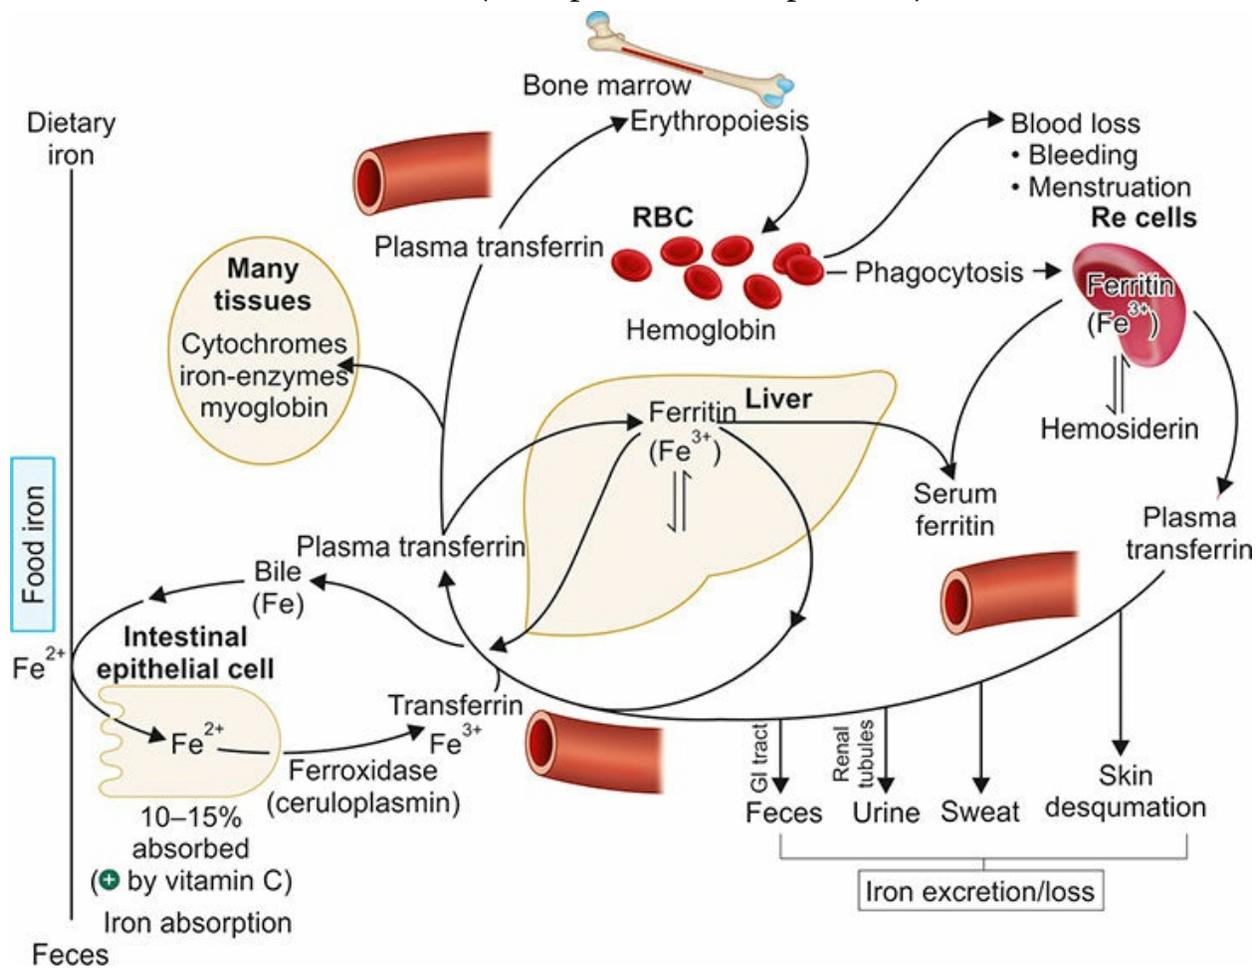

### Distribution of Iron

Iron is an essential metal present in the human body. The total body iron content (3–4 g) is divided into functional and storage compartments (Table 8.5). Iron in the body is extensively recycled between the functional and storage pools.

1. **Functional:** Approximately 80% (2.5 g) of the functional iron is present in hemoglobin. The remaining functional iron is found in myoglobin and iron-containing enzymes (catalase, cytochromes and peroxidases).
2. **Storage:** The storage pool contains 15–20% (0.5–1.5 g) of total body iron. Free iron is highly toxic because it can result in tissue damage due to its capacity to form free radicals. Therefore, iron is bound to protein and stored in the body in two forms namely; ‘**ferritin**’ and ‘**hemosiderin**’. The storage iron can be readily mobilized whenever there is increase in the requirements of iron, as may occur after blood loss. Two-third of the iron is stored as ferritin and one-third as hemosiderin.
  - **Ferritin** ( $\text{Fe}^{3+}$ ) is a protein-iron complex (apoferritin + iron) found in

all tissues but particularly in liver, spleen, bone marrow and skeletal muscles. Very small amounts of ferritin circulate in the serum, the value normally being 15–300 µg/L. **Serum ferritin levels reflect the iron stores** and is a sensitive indicator of the amount of iron in the body. Serum ferritin level is usually below 12 µg/L in iron deficiency and it is very high (as high as 5000 µg/L may be observed) in conditions associated with iron overload. Ferritin is water-soluble and not visible by light microscopy.

- **Hemosiderin** is an aggregate of iron and protein which is found in the reticuloendothelial cells of bone marrow, spleen and liver. It is formed when iron is in excess (amorphous iron deposition).

**Fig. 8.6:** Iron metabolism.

**Table 8.5:** Iron distribution in healthy young adults.

Pool	Grams	%
------	-------	---

<b>Functional</b>		
Hemoglobin	2.5	68
Myoglobin	0.15	4
Transferrin (iron-binding blood plasma glycoprotein)	0.003	0.1
Iron-containing enzymes	0.02	0.6
<b>Storage</b>		
Ferritin and hemosiderin in tissue	1.0	27
Ferritin, serum	0.0001	0.004

**Daily requirements:** Recommended dietary allowance 10–15 mg. The daily requirement in adult males is 5–10 mg/day and in females 20 mg/day.

**Dietary sources:** The diet contains iron either in the form of heme contained in animal products and/or non heme iron in vegetables. Of 10–50 mg in the diet, only 10–15% is normally absorbed.

## Iron Absorption

- *Site of absorption:* Iron is absorbed from the **duodenum** and **proximal jejunum**. Iron balance is maintained mainly by regulating the dietary absorption of iron (by the synthesis of apoferritin within mucosal cells).

## Transport of Iron

- **Transferrin:** Iron is transported in plasma by the iron transport protein **transferrin**, which is synthesized in the liver. The major function of plasma transferrin is to deliver iron to erythroid precursors for the synthesis of hemoglobin. In normal individuals, transferrin is about 33% saturated with iron, with an average serum iron levels of 120 µg/dL in men and 100 µg/dL in women. Thus, the total iron-binding capacity of serum is in the range of 310 to 340 µg/dL. Unsaturated transferrin protects against infections (iron overload and infection).
- **Lactoferrin:** It binds iron in milk. It has antimicrobial effect (protects newborns from gastrointestinal infections).
- **Haptoglobin:** It binds hemoglobin in the plasma.

## Iron Excretion/Loss

Iron metabolism is unique as it is very efficiently utilized and reutilized by the body. There is no physiological regulated mechanism for iron excretion and 1 to 2 mg per day is lost by shedding of epithelial cells of GI tract, skin

epithelial cells (by sweat) and renal tubules; and by menstruation, pregnancy, multiple births, lactation and bleeding.

## Regulation of Iron Balance

Iron is essential for cellular metabolism; at the same time, excess of it is highly toxic. Therefore, the total body iron stores must be properly regulated. Iron balance is mainly achieved by regulating the absorption of iron in the diet. As body stores decrease, the absorption of iron rises and vice versa.

### *Hepcidin*

#### **Q. Write short note on role of hepcidin.**

It is synthesized in the liver and is the **central** (key) **regulator of iron homeostasis** and it **controls** intestinal iron **absorption** plasma iron concentrations, tissue iron distribution and **storage**.

- Ferroportin is the cellular iron exporter which exports iron into plasma
  1. from absorptive enterocytes,
  2. from macrophages that recycle the iron of senescent erythrocytes, and
  3. from hepatocytes that store iron.
- The major mechanism of hepcidin is the regulation of transmembrane iron transport. Hepcidin binds to ferroportin and forms hepcidin-ferroportin complex. This complex is degraded in the lysosomes and thus degrades its receptor ferroportin. By this mechanism hepcidin reduces resorption of iron in the intestine and inhibits iron transfer from the enterocyte to plasma (thereby reduces concentration of iron in plasma).
- When hepcidin levels rise, it lowers iron absorption in the intestine, iron gets stored (locked) within enterocytes forming mucosal ferritin and is shed with the cells. It also lowers iron release from hepatocytes and macrophages (through degradation of ferroportin) leading to decreased serum iron. Actions of hepcidin are presented in Figure 8.7.

#### *Significance of hepcidin*

- Increased hepcidin concentration is seen in inflammation (chronic disease anemia).
- Reduced hepcidin production → hereditary hemochromatosis.

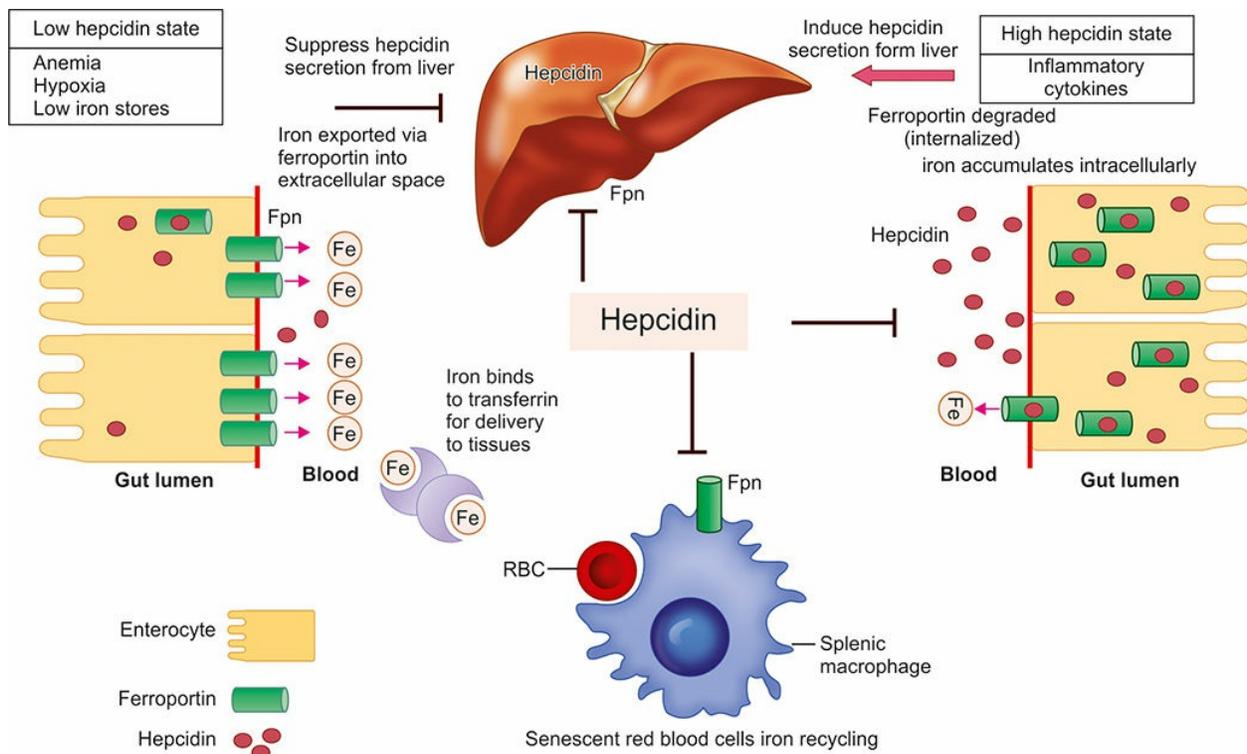

## Functions of Iron

1. **Heme iron:** Hemoglobin, myoglobin, cytochrome c oxidase, catalase
2. **Non-heme iron:** Fe-S complexes (xanthine oxidase), DNA synthesis (ribonucleotide reductase)

## IRON DEFICIENCY ANEMIA (IDA)

**Q. Discuss the etiology, clinical features, investigations, and management of iron deficiency anemia.**

**Q. Write short note on causes of iron deficiency anemia. What is the commonest cause in tropical countries?**

**Fig. 8.7:** Actions of hepcidin.

## Etiology (Table 8.6)

**Table 8.6:** Causes of iron deficiency anemia.

### 1. Decreased iron intake

- Milk fed infants
- Elderly with improper diet and poor dentition
- Low socioeconomical sections

- Vegetarians (contains poorly absorbable inorganic iron)

## 2. Decreased absorption of iron

- Total/partial gastrectomy
- Intestinal absorption is impaired in sprue, other causes of intestinal steatorrhea and chronic diarrhea
- Specific items in the diet, like phytates of cereals, tannates, carbonates, oxalates, phosphates and drugs can impair iron absorption

## 3. Increased demand/requirement for iron

- Rapid growth in infancy or adolescents
- Pregnancy and lactation

## 4. Increased iron loss: Chronic blood loss due to bleeding from the:

- Gastrointestinal tract (e.g. peptic ulcers, gastric carcinoma, colonic carcinoma, hemorrhoids, hookworm infestation or nonsteroidal anti-inflammatory drugs)
- Urinary tract (e.g. renal or bladder tumors, schistosomiasis)
- Genital tract (e.g. menorrhagia, uterine cancer)

- IDA is due to deficiency of iron causing defective **heme synthesis**. Iron deficiency anemia is the most common cause of anemia.
- Daily requirement of iron is 10–15 mg. Children consuming large amounts of cow milk develop iron deficiency anemia because iron from cow milk poorly absorbed and calcium in the milk inhibits iron absorption.

**Q. Discuss the clinical manifestations and complications of iron deficiency anemia.**

**Q. Write short note on Plummer-Vinson syndrome.**

## Clinical Features

- Clinical features of iron deficiency anemia include the usual symptoms and signs of anemia (refer pages 554-5).
- Characteristic signs of advanced iron deficiency include:
  - Cheilosis (fissures at the corners of the mouth)/angular stomatitis
  - **Atrophic glossitis** (Fig. 8.8)
  - Brittle finger nails, platonychia and **koilonychia** (spooning of the fingernails)(Figs. 8.9A and B), brittle hair
  - **Blue-tinged sclerae**, alopecia
  - **Pica** is the unusual craving for substances which has a ‘crunching’ sound with no nutritional value like clay or chalk. Craving for ice

(pagophagia) specific to iron deficiency or less commonly for clay (geophagia) or starch (amylophagia); pagophagia is believed to be the most specific to iron deficiency.

◆ Restless leg syndrome is seen in around 25% of patients with IDA.

- **Plummer-Vinson syndrome or Patterson-Brown-Kelly** or sideropenic dysphagia develops in long-standing iron deficiency.
  - Iron deficiency (microcytic hypochromic) anemia
  - Atrophic glossitis
  - Esophageal/post-cricoid webs resulting in dysphagia for solids than liquids. The web can be demonstrated either by endoscopy or by barium swallow
  - These patients have increased risk of squamous cell carcinoma of pharynx and esophagus.

**Treatment of Plummer-Vinson syndrome:** Administration of iron. Severe obstruction by the web may require dilatation. Regular upper GI endoscopy may be required for the early detection of cancers.

**Beeturia** is a phenomenon in which the urine turns red following ingestion of beets. Beeturia is increased in individuals with iron deficiency (49–80% of individuals with iron deficiency).

## Diagnosis of Iron Deficiency Anemia

**Q. Discuss the investigations/diagnosis of iron deficiency anemia.**

### Laboratory Investigations

These investigations may be divided into two major categories namely:

#### 1. To confirm iron deficiency

- **Hemoglobin and hematocrit (PCV):** Decreased
- **Red cell indices: MCV:** <80 fL **MCH:** <25 pg and **MCHC:** <27 g/dL. **RDW:** Increased and >15%. It is **earliest sign of iron deficiency.**
- **Peripheral smear (Fig. 8.10):** RBCs are **microcytic (small)** and **hypochromic (pale)**. Severe anemia shows ring/pessary, pencil/cigar-shaped cells with **moderate anisocytosis and poikilocytosis.**
- **Reticulocyte count** is low for the degree of anemia.
- Bone marrow
  - Moderate **erythroid hyperplasia** and **micronormoblastic maturation**
  - **Absence of bone marrow iron: ‘Gold standard’ test,**

demonstrated by **negative Prussian blue reaction**

- **Serum iron profile** (Table 8.7)
  - **Hepcidin:** Decreased. Hepcidin regulates iron concentrations and tissue iron distribution.
2. **To determine the cause of iron deficiency:** These depend on the age, sex of the patient, and also history and clinical findings. In the absence of any significant features, the following investigations are performed to identify the chronic blood loss, especially from the GI tract.
- **Stool:** Examine for occult blood and hook worm infestation.
  - **Endoscopy:** Includes upper gastrointestinal endoscopy, sigmoidoscopy and colonoscopy.
  - **Radiological investigations:** Barium meal and barium enema.
  - **Urine:** Examine for parasites such as schistosomiasis.
  - **Investigations for malabsorption:** If there are features of malabsorption such as steatorrhea relevant investigations has to done to find out the cause.

**Table 8.7:** Serum iron profile in IDA.

	<i>Normal range</i>	<i>Value in IDA</i>	<i>Observation</i>
Serum ferritin	15–300 µg/L	<15 µg/L	↓
Serum iron	50–150 µg/dL	10–15 µg/dL	↓
Serum transferrin saturation	30–40%	<15%	↓
Total plasma iron-binding capacity (TIBC)	310–340 µg/dL	350–450 µg/dL	↑
Serum transferrin receptor (TFR)	0.57–2.8 µg/L	3.5–7.1 µg/L	↑
Red cell protoporphyrin	30–50 µg/dL	>200 µg/dL	↑

**Fig. 8.8:** Atrophic glossitis producing bald tongue in iron deficiency anemia. There is also mild cheilosis.

**Figs. 8.9A and B:** Koilonychia (spooning of the fingernails) in iron deficiency anemia.

**Fig. 8.10:** Peripheral blood smear showing microcytic hypochromic red blood cells.

### **Box 8.1:** Differential diagnosis of microcytic hypochromic blood picture.

- Iron deficiency
- Thalassemia: It is an inherited defect in globin chain synthesis. It can be differentiated from iron deficiency by serum iron values; normal or increased serum iron levels and transferrin saturation. The red blood cell distribution width (RDW) index is generally normal or reduced in thalassemia and elevated in iron deficiency.
- Anemia of chronic disease
- Sideroblastic anemia
- Lead poisoning

### **Box 8.2:** Complications of severe iron deficiency anemia.

- During pregnancy: Poor pregnancy outcomes such as premature births and low birth weight babies
- Heart failure
- Delayed growth and development in infants and children
- Increased susceptibility to infections
- Exacerbates cardiorespiratory problems especially in the elderly

## ***Differential diagnosis***

**Q. Mention the causes/differential diagnosis of microcytic hypochromic blood picture/anemia.**

The microcytic hypochromic anemia does not necessarily mean only iron deficiency. The various causes of microcytic hypochromic anemia are listed in Box 8.1.

Complications of severe iron deficiency anemia are listed in Box 8.2.

**Q. Discuss the management/treatment of iron deficiency anemia.**

**Q. Write short note on (1) iron therapy and (2) parenteral iron therapy.**

**Management**

Treatment can be divided into:

- Treatment of underlying cause for iron deficiency. The correct management of iron deficiency is to identify and treat the underlying cause for deficiency.
- Treatment of iron deficiency: Next step is to give iron to correct the anemia and replace iron stores. There are three major therapeutic approaches: (1) oral iron therapy (2) parenteral iron therapy and (3) red cell transfusion.

**1. Oral iron therapy**

Most patients can be treated with oral iron preparations.

- **Iron preparations and dose:** Oral iron dose is 6 mg/kg/day. Commonly used and best are ferrous sulfate (200 mg three times daily, a total of 180 mg ferrous iron), ferrous gluconate (300 mg twice daily, only 70 mg ferrous iron), ferrous fumarate (325 mg two or three times daily), and others.
- **Side effects:** Few patients may develop metallic taste, nausea, dyspepsia, constipation, black tarry stools or diarrhea. These can be reduced by taking iron tablets with food or reducing the dose or by using preparation with less iron (e.g. ferrous gluconate) or a controlled-release preparation or a liquid preparation.
- **Response to oral iron therapy:** The response appears within 7–10 days of treatment with iron in the form of an increased reticulocyte count (usually not exceeding 10%, normal <2.5%).
- **Duration of oral iron therapy:**
  - Iron should be given to correct the Hb level to normal range and usually occurs within 4–6 weeks. If it does not occur, it may be due to failure of response to therapy.
  - Once the hemoglobin returns to normal, oral iron therapy should be continued to replace the iron stores. This may take 6 months to 1 year.
  - Patients having iron deficiency due to malabsorption, deficient intake, continuing blood loss, etc. may require long-term iron supplements at a minimum dose.
- **Causes of failure to respond to oral iron therapy:** It may be due to one or more of the following reasons:
  - **Failure to take the iron tables:** Patients taking iron preparations have gray or black colored stools.
  - Continuing hemorrhage/blood loss.
  - **Incorrect/wrong diagnosis:** For example, thalassemia trait.
  - Ingestion of drugs which reduces iron absorption: Certain drugs if taken along with oral iron

- (e.g. H<sub>2</sub>-receptor blockers, proton-pump inhibitors, antacids, tetracyclines) may interfere with iron absorption.
- Severe malabsorption.

## 2. Parenteral iron therapy

Parenteral iron therapy should be given only after the definite diagnosis of iron deficiency; otherwise it may lead to iron overload and its consequences. Iron stores are replaced much faster with parenteral iron than with oral iron, but the hematological response is not quick.

**Indications of parenteral iron therapy:** The indications are:

- Intolerant to oral iron preparation.
- Severe malabsorption.
- Primary blood loss is uncontrollable: When rate of iron (blood) loss exceeds the rate of its absorption.
- Chronic GI tract disease (e.g. inflammatory bowel disease) which may worsen with oral iron.

### Calculation of total iron dose required.

Iron dose in mg = Body weight (kg) × 2.3 × (normal Hb-patient's hemoglobin, g/dL) + 500 or 1000 mg (to provide body iron stores).

**Route of administration:** Parenteral iron can be given by slow intravenous infusion or by intramuscular injection.

**Types of parenteral iron preparations:** These include iron-sorbitol, iron-dextran (imferon) and preparations with much lower rates of adverse effects such as iron sucrose or sodium ferric gluconate, ferric carboxymaltose, iron isomaltoside.

#### *Iron-sorbitol*

- Administered only intramuscularly and never by intravenous route.
- Dose is 1.5 mg of iron/kg body weight daily, to a dose not exceeding 2.5 g.

#### *Iron-dextran (Imferon)*

Low-molecular-weight iron dextran is most commonly used. It may be given either intramuscularly or intravenously (more ideal). Test dose is required before administration to prevent anaphylaxis.

- **Intramuscular:** Dose is 100 mg daily till the total required dose is administered or to a maximum of 2 kg. It should be given deep intramuscularly into the buttocks using a 'Z-tract technique'.
- **Slow Intravenous infusion:** Total dose intravenous infusion is rarely required. If a large dose is to be given (>100 mg), it should be diluted in 5% dextrose in water or 0.9% NaCl solution and infused slowly.

#### *Iron sucrose*

- It has lesser adverse effects and is considered to be the safe intravenous iron preparation.
- Single dose of 100–200 mg as an intravenous injection or up to 500 mg infused over a period of 3 hours.

#### *Sodium ferric gluconate*

- It is the preferred form of parenteral iron owing to the low incidence of adverse reactions.
- Administered intravenously at a dose of 125 mg over 10 minute.

**Ferric carboxymaltose:** A novel iron complex that consists of a ferric hydroxide core stabilized by a carbohydrate shell, allows for controlled delivery of iron to target tissues. Administered intravenously, it is effective in the treatment of iron-deficiency anemia, delivering a replenishment

dose of up to 1000 mg of iron during a minimum administration time of  $\leq 15$  minutes with least reactions.

*Ferumoxytol*: Superparamagnetic iron oxide nanoparticles coated with a LMW semisynthetic carbohydrate. It can be given in doses of 17 mL (equivalent to 510 mg of elemental iron).

*Iron isomaltoside* can be administered in a single infusion, at a dose of 20 mg/kg, over 15 minutes.

#### **Side effects/toxicity of parenteral iron preparations**

- Pain and swelling at the site of injection/infusion.
- Anaphylactic reactions: Fever, generalized urticarial rash, lymphadenopathy, splenomegaly, and arthralgias.
- Hemochromatosis.

#### **c. Red cell transfusion**

- **Indication:** It is reserved for patients who have symptoms of anemia, cardiovascular instability, continued and excessive loss of blood loss from any site, and require immediate intervention.
- Transfusions correct the anemia acutely as well as transfused red cells provide a source of iron for reutilization.

## MACROCYTIC ANEMIA

### **Q. Write a short note on vitamin B<sub>12</sub>.**

Vitamin B<sub>12</sub> and folic acid are closely related and both are essential for normal DNA synthesis and nuclear maturation.

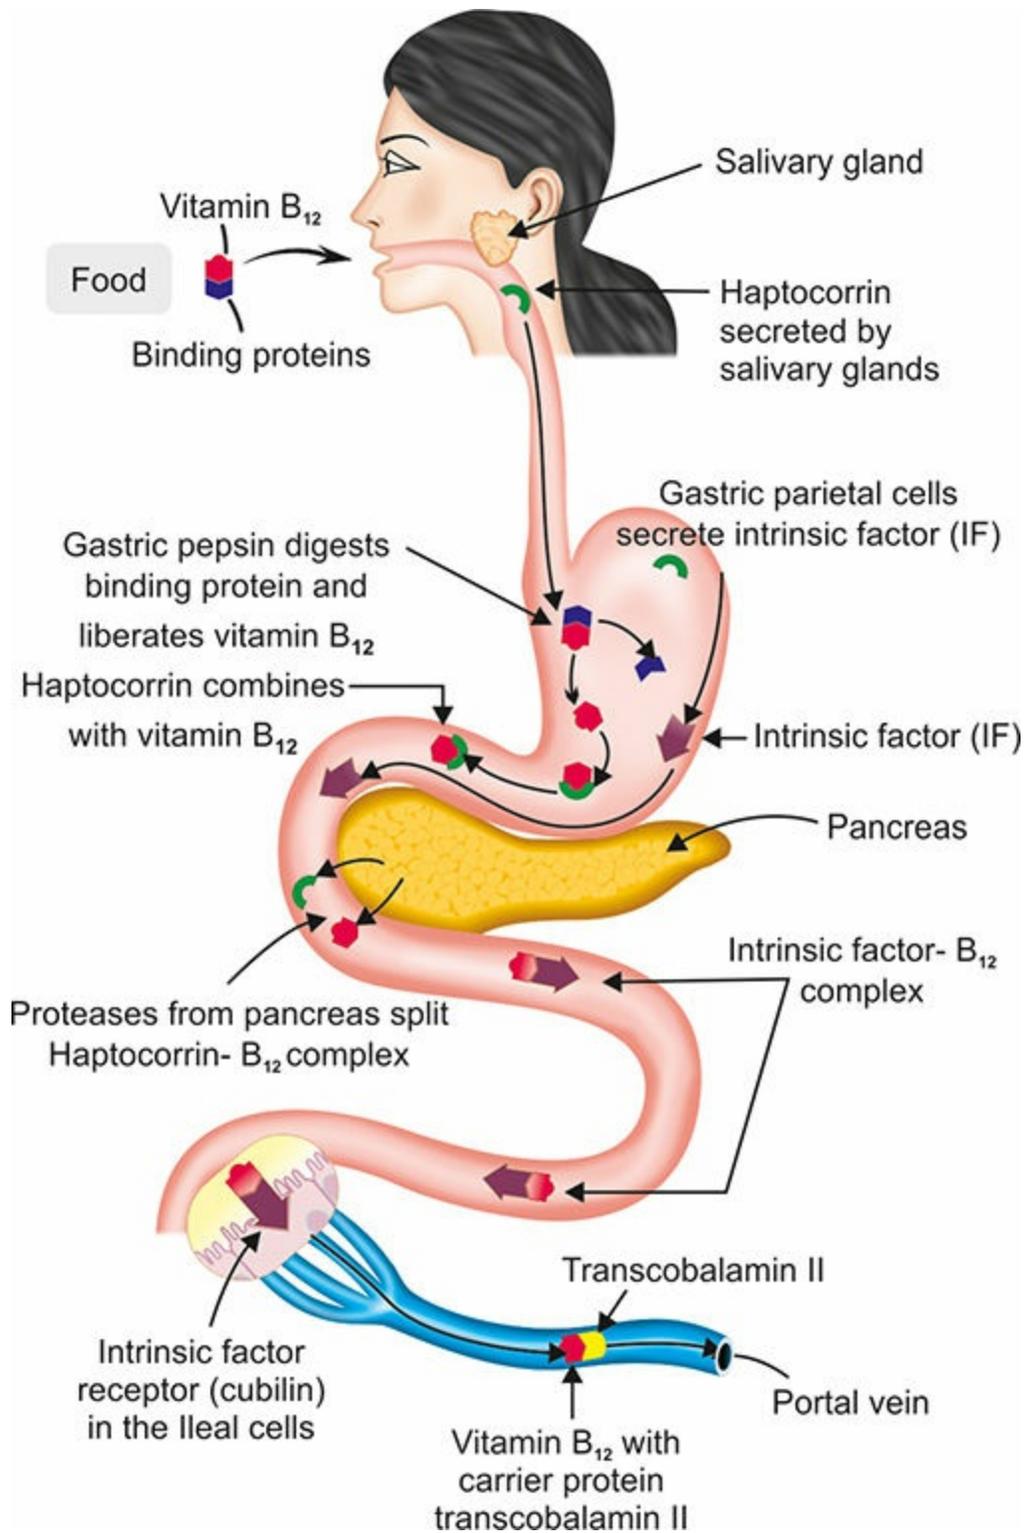

### **Vitamin B<sub>12</sub> Metabolism**

- Vitamin B<sub>12</sub> is present only in animal proteins and dairy products and not present in vegetables. Therefore, strict vegetarians do not get an adequate quantity of vitamin B<sub>12</sub>.
- A balanced diet (not rigid vegetarian!) contains significantly large amounts of vitamin B<sub>12</sub> which accumulates in the body (liver) and is enough for several (about 3) years. Hence, if there is any dietary deficiency or malabsorption of vitamin B<sub>12</sub>, its clinical manifestations appear only after about 2 to 4 years.
- Normal daily requirement is about 2 to 3  $\mu\text{g}$ .

### **Absorption, Transport and Storage (Fig. 8.11)**

- Vitamin B<sub>12</sub> in food is usually in coenzyme form (as deoxyadenosylcobalamin and methylcobalamin) and bound to binding proteins in the diet.

- In the stomach, peptic digestion at low pH is required for release of vitamin B<sub>12</sub> from binding protein in the food. The released vitamin B<sub>12</sub> binds with salivary protein called **haptocorrin**, which is secreted in salivary juice.
- These haptocorrin-B<sub>12</sub> complexes leave stomach along with unbound special protein called **intrinsic factor** (IF), which is produced by gastric (fundus and cardia) parietal (oxyntic) cells.
- As haptocorrin-B<sub>12</sub> complexes pass into the second part of the duodenum, pancreatic proteases release vitamin B<sub>12</sub> from haptocorrin. Vitamin B<sub>12</sub> then associates with the intrinsic factor and forms IF-B<sub>12</sub> complex.
- This stable IF-vitamin B<sub>12</sub> complex is transported to the ileum, where it is endocytosed by ileal enterocytes. These ileal enterocytes express a receptor on their surfaces for the intrinsic factor. These receptors are called **cubilin**.
- In the ileal epithelium, vitamin B<sub>12</sub> combines with a major carrier protein, transcobalamin II, and is actively transported into the mucosal cells and then into the blood.
- Transcobalamin II-vitamin B<sub>12</sub> complex delivers vitamin B<sub>12</sub> to the liver and other cells of the body, particularly rapidly proliferating cells in the bone marrow and mucosal lining of the gastrointestinal tract.

**Fig. 8.11:** Mechanism of vitamin B<sub>12</sub> absorption.

## ***Role of Vitamin B<sub>12</sub>***

Vitamin B<sub>12</sub> is essential for:

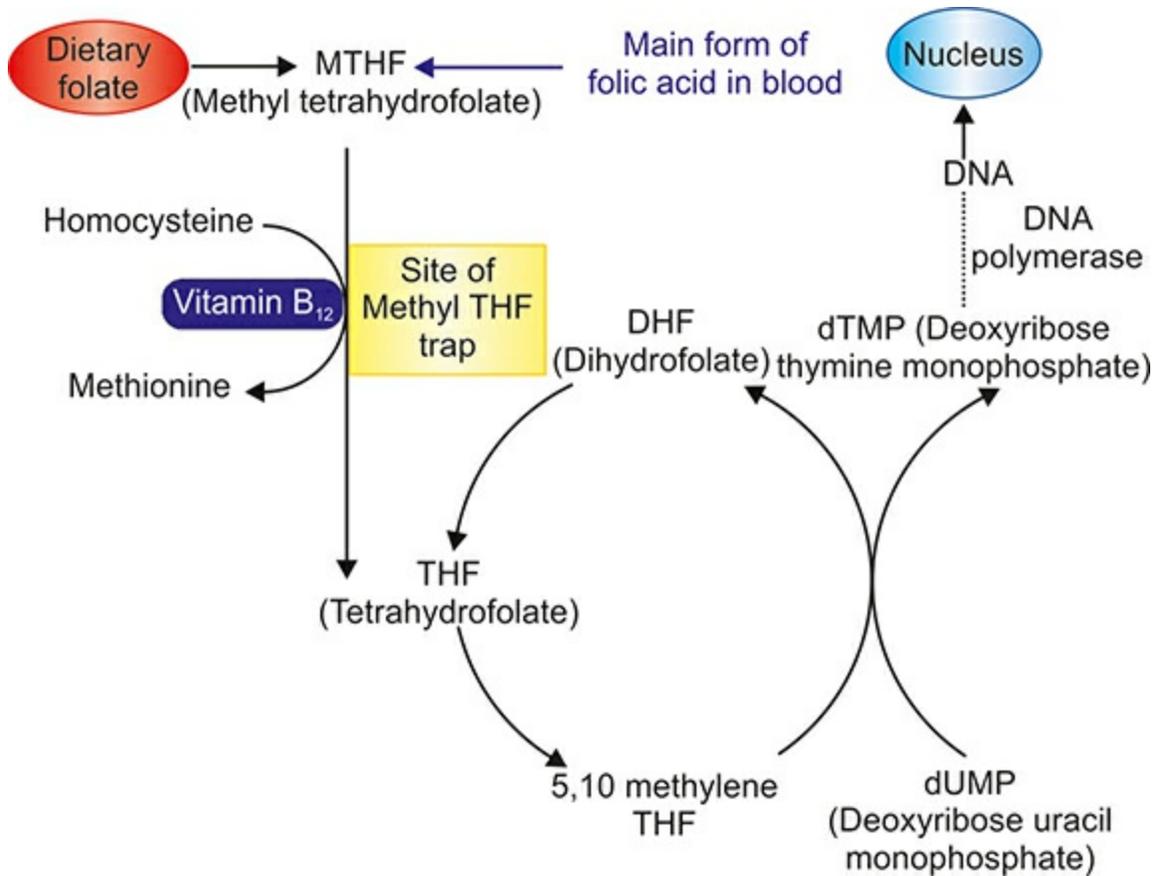

- Normal hemopoiesis
- Maintenance of normal integrity of the nervous system.

Vitamin B<sub>12</sub> is indirectly required for DNA synthesis in various metabolic steps and its deficiency impairs DNA synthesis. There are two biologically active forms of cobalamin in the body, both act as coenzymes namely: (1) methylcobalamin and (2) adenosylcobalamin.

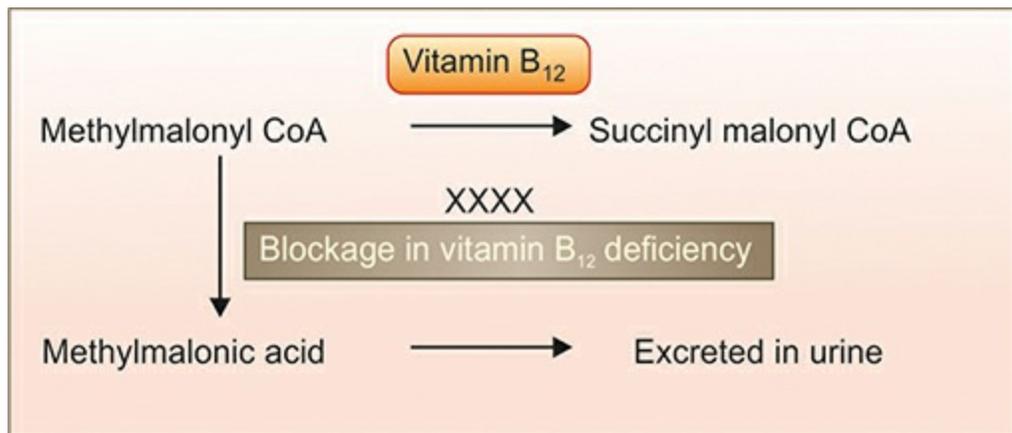

1. Methylcobalamin is the main form of vitamin B<sub>12</sub> in plasma, and is an essential coenzyme for conversion of homocysteine to methionine and formation of tetrahydrofolate (THF) from methyl THF (Fig. 8.12). During the former reaction, vitamin B<sub>12</sub> loses its methyl group and this is replaced from methyl THF, the principal form of folic acid in plasma. Tetrahydrofolate is essential for the generation of a precursor of DNA known as deoxythymidine monophosphate (dTMP).

In vitamin B<sub>12</sub> deficiency, main cause of impaired DNA synthesis is that methyl THF is not converted into THF. Methyl THF accumulates in the cell and is known as '**Methyl THF trap**'. Lack of folic acid is the next cause of anemia in vitamin B<sub>12</sub> deficiency, as the anemia invariably improves with folic acid administration.

2. Deoxyadenosylcobalamin form of vitamin B<sub>12</sub> is a coenzyme required for conversion of methylmalonyl CoA to succinyl malonyl CoA (Fig. 8.13). Deficiency of vitamin B<sub>12</sub> causes increased levels of methylmalonic acid in plasma and urine. This results in the formation of abnormal fatty acids which get incorporated into neuronal lipids. Consequently, this predisposes to myelin breakdown and is probably responsible for neurologic complications of vitamin B<sub>12</sub> deficiency.

**Fig. 8.12:** Inter-relation and role of vitamin B<sub>12</sub> and folate in DNA synthesis.

**Fig. 8.13:** Role of vitamin B<sub>12</sub> in methylmalonyl CoA metabolism.

## Folic Acid Metabolism

**Q. Write short essay/note on folic acid.**

- **Daily requirement:** 50–200 mg.

- **Source:** Green vegetables, yeast, legumes, fruits and animal proteins are the richest sources. The folic acid in these foods is largely in the form of polyglutamates. Polyglutamates are sensitive to heat (thermolabile); boiling, steaming or frying, and which destroys most of the folic acid (destroyed by cooking). Intestinal conjugates split the polyglutamates into monoglutamates.
- **Site of absorption:** Proximal jejunum. During intestinal absorption, they are modified to 5-methyltetrahydrofolate, the normal transport form of folic acid (FA).
- **Storage:** Folate is mainly stored in the liver and is enough for about 3 months and hence the manifestations of folate deficiency appear after about 3 months.

### ***Role of Folic Acid***

Active form of folic acid is tetrahydrofolate (THF) which is the biologic 'middleman' involved in metabolic processes which synthesize DNA. The various reactions in which folic acid plays a main role are:

- Purine (required for DNA and RNA) synthesis.
- Conversion of homocysteine to methionine, a reaction also requiring vitamin B<sub>12</sub>.
- Deoxythymidylate monophosphate synthesis: 5,10-methylene THF polyglutamate is required for conversion of dUMP to dTMP and DNA, a rate limiting step in pyrimidine synthesis.

Folic acid is associated with metabolism of histidine: Histidine is metabolized to form iminoglutamic acid (FIGLU) which combines with THF to form glutamic acid (Fig. 8.14). In FA deficiency, this reaction cannot take place and therefore FIGLU accumulates and is excreted as such in urine. This is used as a test to measure folic acid deficiency.

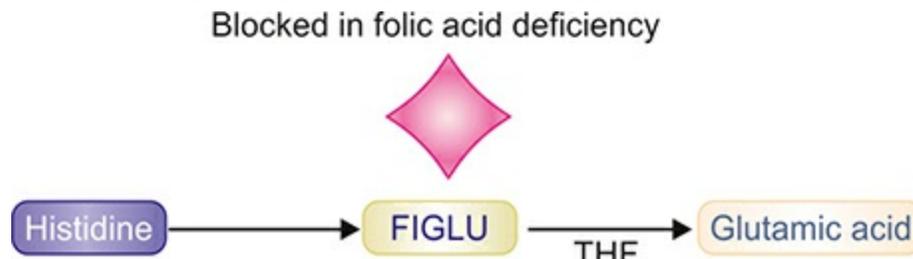

### **Manifestations of Megaloblastic Anemia**

**Q. Write short essay/note on the etiology/causes of megaloblastic/macrocytic anemias.**

**Q. Discuss the causes, clinical features/manifestations and management of vitamin B<sub>12</sub> deficiency/megaloblastic anemia.**

**Q. Discuss the causes, clinical features/manifestations and management of folate deficiency.**

Megaloblastic anemias are a group of disorders characterized by **defective/impaired DNA synthesis** and **distinct megaloblasts in the bone marrow** and **macrocytes in the peripheral blood**. Megaloblastic anemias are common among anemias due to impaired red cell production. They are usually caused **due to deficiency of either cobalamin (vitamin B<sub>12</sub>) or folate (folic acid)**, but may occur because of genetic or acquired abnormalities that affect the metabolism of these vitamins.

**Fig. 8.14:** Role of folic acid in metabolism of histidine

## Etiology of Megaloblastic Anemia (Table 8.8)

**Q. Write short note on causes of macrocytic anemia.**

### Table 8.8: Causes of megaloblastic anemia.

#### *Vitamin B<sub>12</sub> deficiency*

- 1. Decreased intake:** Inadequate diet, 'pure vegetarians'
- 2. Impaired absorption**
  - Gastric: Deficiency of gastric acid or pepsin or intrinsic factor
    - Pernicious anemia
    - Postgastrectomy
    - Drugs: Prolonged use of H<sub>2</sub>-receptor blockers and proton-pump inhibitors
  - Intestinal:
    - Loss of absorptive surface
      - ◆ Malabsorption syndromes
      - ◆ Diffuse intestinal disease, e.g. lymphoma, systemic sclerosis
      - ◆ Ileal resection and Crohn's disease
    - Bacterial or parasitic competition for vitamin B<sub>12</sub>
      - ◆ Bacterial overgrowth in blind loops and diverticula of bowel
      - ◆ Fish tapeworm (*Diphyllobothrium latum*) infestation
- 3. Increased demand:** Pregnancy, hyperthyroidism, disseminated cancer

#### 4. **Abnormal cobalamin transport:** Transcobalamin II deficiency

#### **Folic acid (vitamin B9) deficiency**

1. **Decreased intake:** Inadequate diet—alcoholism, malnutrition
2. **Impaired absorption**
  - Malabsorption states: Nontropical and tropical sprue, celiac disease
  - Diffuse infiltrative diseases of the small intestine (e.g. lymphoma)
  - Drugs: Anticonvulsant phenytoin, oral contraceptives, metformin, cholestyramine
3. **Increased loss:** Hemodialysis
4. **Increased demand:** Pregnancy, lactation, infancy, disseminated cancer, markedly increased hematopoiesis (hemolytic anemias), chronic exfoliative skin disease, chronic inflammatory and infective diseases
5. **Impaired utilization:** Folic acid antagonists (antifolate drugs) such as methotrexate, trimethoprim, pyrimethamine, pentamidine, 5-fluorouracil, hydroxyurea

#### **Others**

1. Therapy with antifolate drugs: For example, methotrexate
2. Independent of either cobalamin or folate deficiency

## **Pathogenesis (Mechanism) of Megaloblastic Anemia**

- Megaloblastic anemias are commonly due to deficiency of **vitamin B<sub>12</sub> (cobalamin) or folic acid**, which are coenzymes required for the synthesis of one of the four bases found in DNA namely thymidine.
- Deficiency of cobalamin or folate results in failure of DNA synthesis and delayed/arrested nuclear maturation. Synthesis of RNA and protein is normal resulting in normal cytoplasmic maturation. Thus, the **nuclear maturation lags behind the cytoplasmic maturation** producing nucleocytoplasmic asynchrony. This results in abnormal cell proliferation that affects rapidly dividing cells in the bone marrow (erythroid, myeloid and megakaryocyte series).
- Impaired DNA synthesis causes delay in cell division, increased time between divisions, more cell growth and size of the cells become large and are called as 'megaloblasts'. The **megaloblasts** have an open, stippled and lacy chromatin. The megaloblastic changes are most prominent in the early nucleated red cell precursors.
- Erythroid precursor cells show reduced number of mitoses and synthesis of hemoglobin is unimpaired. The mature RBCs derived from these megaloblasts are large (**macrocytes**) and **oval** but well hemoglobinized.
- In the bone marrow, large number of megaloblastic precursors does not mature enough to be released into the blood and are destroyed in the bone

marrow (ineffective erythropoiesis). There is also mild hemolysis of red cells in the peripheral blood. This releases large amounts of **lactate dehydrogenase (LDH)** resulting in **raised** levels in the blood.

- In the bone marrow, abnormal proliferation affects myeloid series producing giant metamyelocytes and the megakaryocyte series resulting in dysplastic megakaryocytes.
- All rapidly dividing cells of the body (including skin, GI tract, bone marrow) exhibit megaloblastic changes and anemia is only a manifestation of a more generalized defect in DNA synthesis.

### ***Pathogenesis of Neurological Changes in Vitamin B<sub>12</sub> Deficiency***

Two mechanisms are responsible for neurologic changes seen of vitamin B<sub>12</sub> deficiency. Deficiency of vitamin B<sub>12</sub> causes

- **Impairment in the conversion of homocysteine to methionine:** Methionine is required for the production of choline and choline containing phospholipids. These are needed by the neuronal cells.
- **Lack of adenosylcobalamin:** It is a vitamin B<sub>12</sub>-containing cofactor required for the conversion of methylmalonyl CoA to succinyl CoA. Lack of this cofactor results in increased levels of methylmalonyl CoA and its precursor, propionyl CoA. This causes production of non-physiologic fatty acids and incorporated into neuronal lipids.

## **PERNICIOUS ANEMIA**

**Q. Discuss the etiology of Addisonian pernicious anemia.**

Pernicious anemia (PA) is a chronic autoimmune disorder characterized by atrophic gastritis with loss of parietal cells in the gastric mucosa which causes failure of production of intrinsic factor. Absence of intrinsic factor results in failure of absorption of dietary vitamin B<sub>12</sub> and deficiency which eventually produces megaloblastic macrocytic anemia.

- **Age and gender:** PA is a disease of older age and generally presents in the fifth to eighth decades of life. Females are more involved than males (F : M is 1.5 : 1).

### **Etiology**

Pernicious anemia is an autoimmune disease causing destruction and permanent atrophy of gastric mucous membrane. The evidences for autoimmune etiology are:

- It is associated with other autoimmune diseases like Graves' disease, Hashimoto's thyroiditis, vitiligo and Addison's disease.
- Microscopically, stomach shows **chronic atrophic gastritis** with damage to gastric parietal cells.
- Response to steroids.
- Presence of autoantibodies in most of the patients. **Two major types** of autoantibodies are found.

1. **Anti-intrinsic factor (IF) antibody:**

- ◆ Type I (blocking) antibody: This blocks the binding of vitamin B<sub>12</sub> to IF and are present in 50–75% of the cases and can be detected in both plasma and gastric juice.
- ◆ Type II (binding) antibody: It attaches to the IF–vitamin B<sub>12</sub> complex and prevent their binding to receptors in the ileal mucosa. They are present in about 40% of patients.

2. **Parietal cell (type III) antibody:** It is directed against  $\alpha$  and  $\beta$  subunits of the gastric proton pump (H<sup>+</sup>, K<sup>+</sup>-ATPase) in parietal cells but is neither specific for PA nor other autoimmune disorders. They are found in 90% of patients with PA as well as in older patients with chronic nonspecific gastritis.

**Role of *Helicobacter pylori*:** *H. pylori* gastritis may play role in PA.

There is a **higher incidence of gastric carcinoma** in patients with PA.

Incidence is higher in patients with blood group A.

## Clinical Features of Macrocytic Anemias (Fig. 8.15)

**Q. Discuss clinical manifestations of vitamin B<sub>12</sub> deficiency/folate deficiency/pernicious anemia.**

### **Onset**

Insidious and progress slowly unless halted by therapy.

*Clinical features related to vitamin B<sub>12</sub> deficiency:*

- Classic triad: Weakness, sore throat and paresthesias.

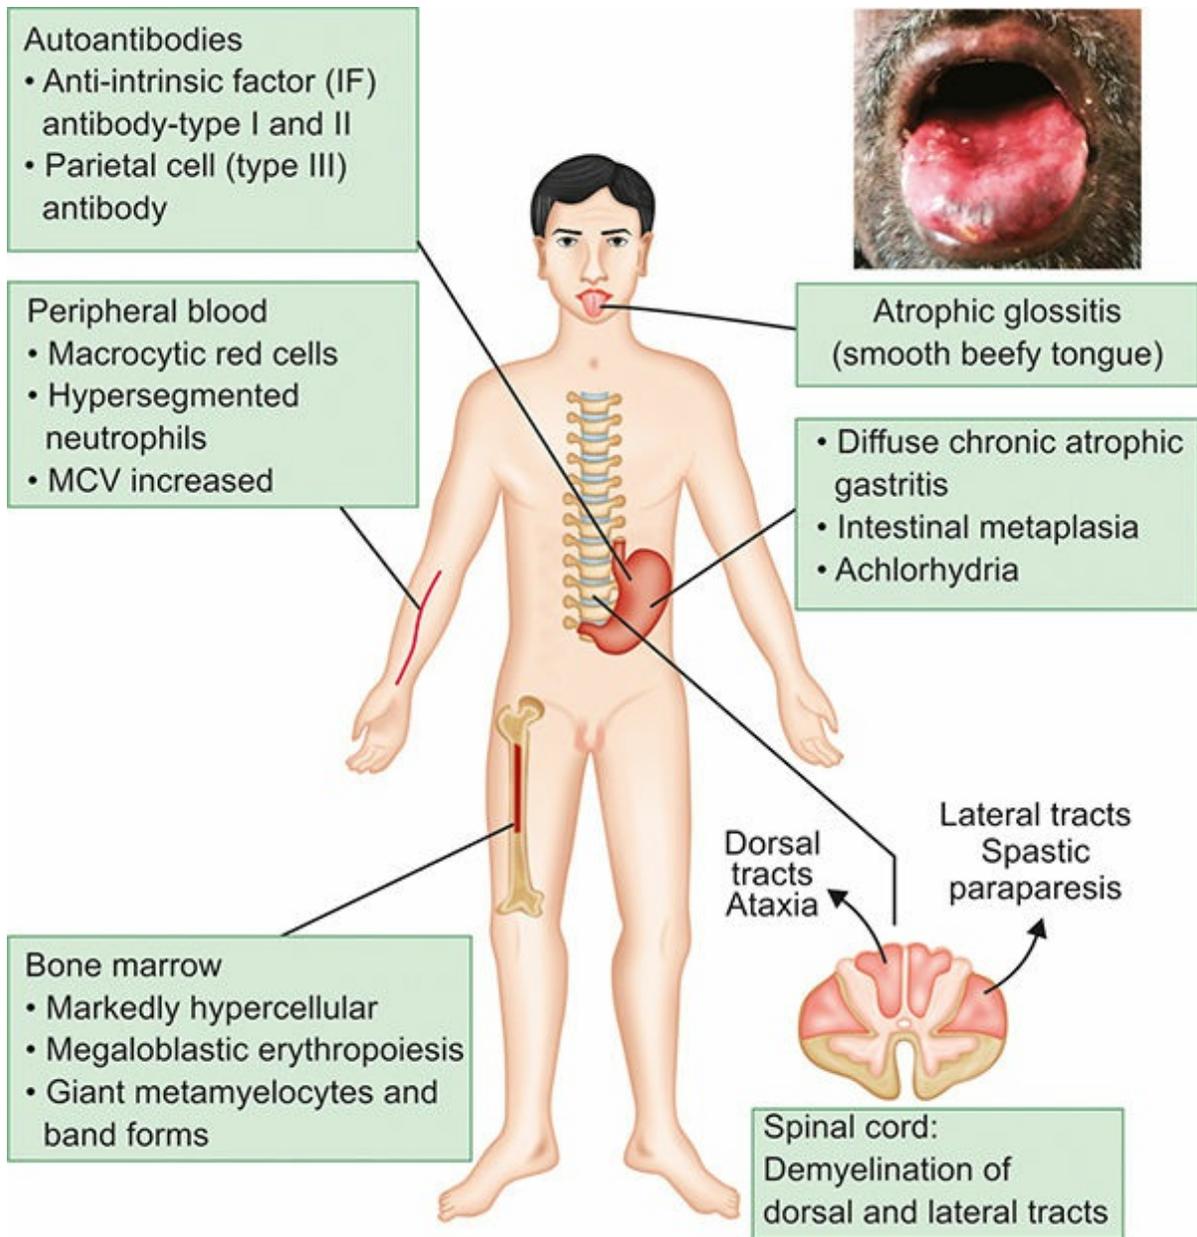

- Tongue: Painful **red 'beefy'** tongue due to glossitis and atrophy of papillae (Fig. 8.15). The patient complains of loss of taste and appetite.
- Patients may have a lemon-yellow color due to combination of pallor and mild jaundice caused by excess breakdown of hemoglobin.

**Pigmentation:** Pigmentation of knuckles and creases are common (Figs. 8.16A and B). The generally accepted mechanism of pigmentation is an increase in the melanin synthesis. The other hypothesis proposed are (1) Deficiency of vitamin B<sub>12</sub> decreases the level of reduced glutathione, which activate tyrosinase and thus leads to transfer to melanosomes. (2) Defect in the melanin transfer between melanocytes and keratinocytes, resulting in pigmentary incontinence.

### ***Neurological Features***

**Q. Write short essay/note on neurological complications of pernicious anemia/megaloblastic anemia.**

- **Peripheral nerves-peripheral neuropathy:** Glove and stocking distribution of numbness or paresthesia. This tingling begins in tips of toes and progresses proximally and is bilateral and symmetric. Loss of ankle reflexes.

**Fig. 8.15:** Clinical features and laboratory findings in pernicious anemia.

**Figs. 8.16A and B:** (A) Pigmentation of knuckles; (B) Pigmentation of creases.

- **Spinal cord:** Subacute combined degeneration of the cord.
  - Posterior columns: Impaired/diminished vibration and position sensation.
  - Corticospinal tracts: Upper motor neuron signs—ataxic, uncoordinated gait. Bilateral extensor plantar with absent ankle jerks.
- **Cerebrum:** Depression and loss of memory (dementia), optic atrophy.
- A positive Romberg sign and Lhermitte sign may be elicited.
- Folate deficiency in adults does not give rise to significant neurologic findings.
- Prematurely gray-haired.
- Atherosclerosis: Serum homocysteine level is raised and is a risk factor for atherosclerosis and thrombosis (myocardial infarction, stroke).

**Pernicious anemia:** Symptoms are same as those of vitamin B<sub>12</sub> deficiency. In addition:

- **Hypochlorhydria:** Atrophic gastritis causes decreased secretion of hydrochloric acid and IF. The symptoms include dyspepsia, postprandial fullness and early satiety.

### ***Clinical Features Related to Folate Deficiency***

They are similar to those of vitamin B<sub>12</sub> deficiency except for neurological features.

### **Diagnosis/Laboratory Findings of Megaloblastic Anemia**

- Q** Discuss the diagnosis of megaloblastic anemias.
- Q** Discuss the diagnosis of anemias due to vitamin B<sub>12</sub> deficiency.
- Q** Discuss the causes, clinical features/manifestations, diagnosis and management of anemias due to folic acid/folate deficiency.
- Q** Write short essay on the diagnosis of Addisonian pernicious anemia.

Blood findings in vitamin B<sub>12</sub> (including pernicious anemia) and/or folic acid deficiency are similar.

## ***Common Findings***

### *Peripheral blood*

**Q. Describe the peripheral blood and bone marrow picture in megaloblastic anemia.**

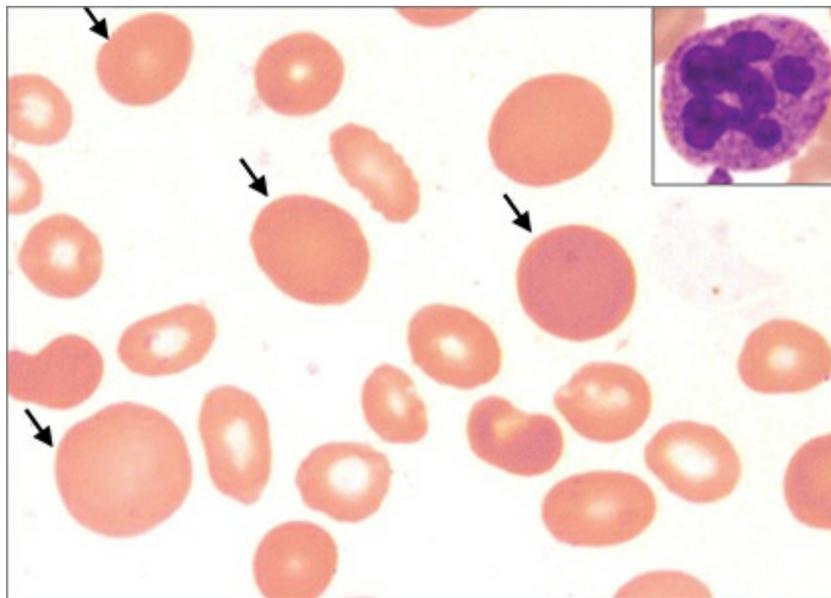

- **Hemoglobin and hematocrit (PCV):** Reduced
- **Red cell indices: MCV raised** above 100 fL (normal 82–98 fL)
- RBC, WBC and platelet count: All are reduced.
- **Peripheral smear (Fig. 8.17): Pancytopenia** (decreased RBCs, WBCs and platelets)
  - **RBCs:**
    - ◆ Macrocytic and oval (egg-shaped macro-ovalocytes) and are diagnostic.
    - ◆ Marked variation in the size and shape of red cells (anisopoikilocytosis).
    - ◆ Evidence of dyserythropoiesis: Basophilic stippling, Cabot ring and Howell-Jolly bodies.
  - **WBCs:**
    - ◆ Decreased WBC count (leukopenia)
    - ◆ **Hypersegmented neutrophils** (more than five nuclear lobes): First and specific morphological sign of megaloblastic anemia. These neutrophils are also larger than normal.
  - **Platelets: Decreased**
- **Reticulocyte count:** Normal or low. Reticulocytosis occurs in response to very small doses of parenteral vitamin B<sub>12</sub>.

### *Bone marrow*

- **Markedly hypercellular.**
- **Megaloblastic type of erythropoiesis.**
- Granulocytic precursors display nuclear-cytoplasmic asynchrony in the form of **giant metamyelocytes and band forms.**
- **Megakaryopoiesis:** Normal or increased in number.
- **Bone marrow iron:** Moderately increased.

*Biochemical tests (Common for both vitamin B<sub>12</sub> and folic acid deficiency)*

- **Deoxyuridine suppression test:** It is a sensitive measure of deficiency of 5, 10-methylene THF, which occurs in both folic acid and vitamin B<sub>12</sub> deficiency.
- Serum homocysteine levels are raised.
- Serum bilirubin: Indirect bilirubin is mildly increased due to increased breakdown of red cells in bone marrow and produces mild jaundice.
- Serum iron and ferritin raised and iron binding capacity is reduced.
- Plasma lactate dehydrogenase (LDH) is markedly increased.
- Serum vitamin B<sub>12</sub>/folate decreased.

**Fig. 8.17:** Peripheral blood smear showing macro-ovalocytes (short arrows) and hypersegmented neutrophil (inset).

### **Diagnostic/Specific Tests for Vitamin B<sub>12</sub> Deficiency**

- Serum vitamin B<sub>12</sub> levels: Reduced **and levels are very low** (<200 pg/ $\mu$ L).
- Serum methylmalonic acid (MMA) and homocysteine levels (Table 8.9): Raised
- Urinary excretion of methylmalonic acid: Raised.

**Table 8.9:** Test results on metabolites: Serum methylmalonic acid and total

## homocysteine in megaloblastic anemia.

<i>Methylmalonic acid</i> (Normal: 70–270 nM)	<i>Total homocysteine</i> (Normal: 5–14 μM)	<i>Diagnosis</i>
Increased	Increased	Vitamin B <sub>12</sub> deficiency confirmed; folate deficiency still possible (i.e. combined Vitamin B <sub>12</sub> plus folate deficiency possible)
Normal	Increased	Folate deficiency is likely; <5% may have vitamin B <sub>12</sub> deficiency
Normal	Normal	Vitamin B <sub>12</sub> and folate deficiencies are excluded

- **Schilling test** (refer below) for vitamin B<sub>12</sub> absorption which was discontinued in 2003, once provided invaluable information on the locus and mechanism of cobalamin malabsorption.

### Diagnostic/Specific Tests for Folic Acid Deficiency

- **RBC folic acid levels: Reduced**
- **FIGLU in urine: Excessively excreted**

### *Determining the Cause of the Vitamin (Folate/Vitamin B<sub>12</sub>) Deficiency*

- The cause of folate deficiency is usually determined from the history, physical examination, and clinical features.
- In adults, the cause of vitamin B<sub>12</sub> deficiency is either due to vitamin B<sub>12</sub> malabsorption or dietary deficiency of vitamin B<sub>12</sub>. To determine the basis for malabsorption needs additional diagnostic tests (e.g. intestinal biopsy, examination of stool for malabsorption or *D. latum* infestation) and requires specific therapy (e.g. gluten-free diet, folate, antibiotics, antihelminthics). A detailed dietary history or past medical history (e.g. gastroduodenal disease, pancreatic insufficiency, impaired bowel motility, or other autoimmune diseases) and physical examination can provide additional clues for other causes.

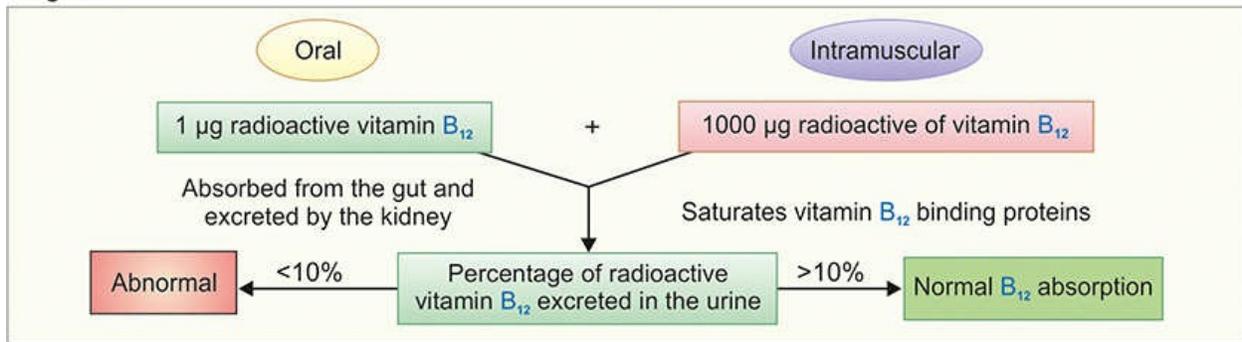

*Schilling test for vitamin B<sub>12</sub> absorption (Fig. 8.18)*

**Q. Write short essay on Schilling test/vitamin B<sub>12</sub> absorption test.**

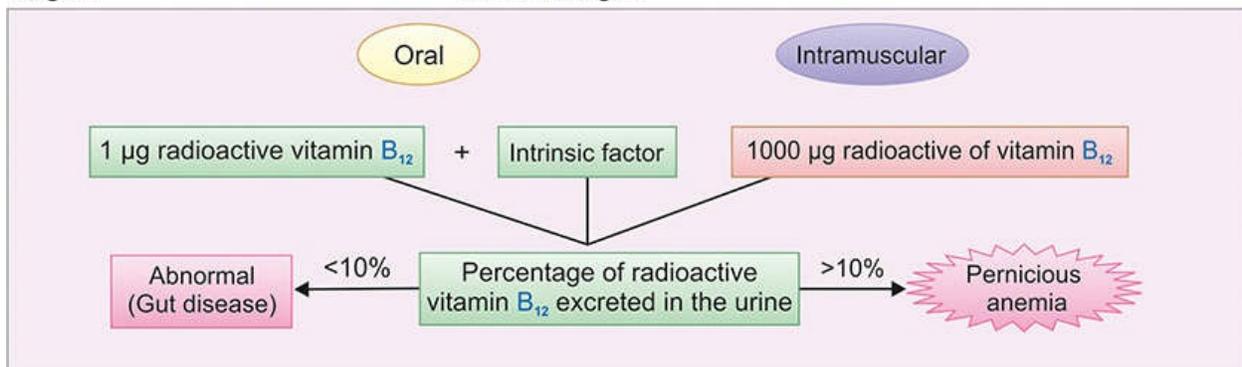

**Use:** Schilling test helps in distinguishing megaloblastic anemia due to IF

deficiency (pernicious anemia) from other causes of vitamin B<sub>12</sub> deficiency. It is diagnostic of PA but now very infrequently performed.

### Stage 1

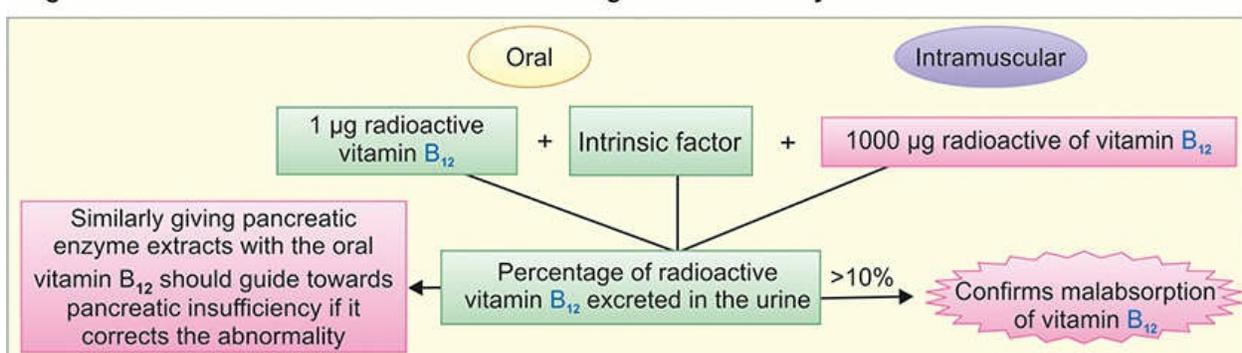

### Stage 2

### Stage 3

### Stage 4

**Fig. 8.18:** Stages of Schilling test.

### Method and interpretation

Radioactive vitamin B<sub>12</sub> (1 µg) is given orally to a fasting patient. This is

followed by non-radioactive 1000 µg of vitamin B<sub>12</sub> intramuscularly. The injected vitamin B<sub>12</sub> saturates vitamin B<sub>12</sub> binding proteins and flush out the ingested radioactive vitamin B<sub>12</sub> which will be excreted in urine. The urine is collected for 24 hours.

- **Stage 1:**
  - Normal persons excrete more than 10% of oral radioactive dose in 24 hour urine.
  - Patients with pernicious anemia excrete less than 5% of the oral dose.
- **Stage 2:** If the test is abnormal
  - The test is repeated with addition of oral intrinsic factor to radioactive vitamin B<sub>12</sub>.
  - If the urinary excretion is now normal, the diagnosis is intrinsic factor deficiency either due to pernicious anemia or gastrectomy.
- **Stage 3:** Giving pancreatic enzyme extracts with the oral vitamin B<sub>12</sub> should guide towards pancreatic insufficiency if it corrects the abnormality.
- **Stage 4:**
  - If the excretion is still abnormal, the lesion must be in the terminal ileum or there may be bacterial overgrowth. The bacterial overgrowth may be corrected by a 7 day course of oral tetracycline/antibiotics. The test is repeated after a course of oral tetracycline.
  - If the excretion returns to normal, it confirms that malabsorption of vitamin B<sub>12</sub> due to bacterial overgrowth in the intestine.

#### *Specific diagnostic tests for pernicious anemia*

- Serological tests
  - Anti-intrinsic factor antibodies in serum (in 70% of patients; highly specific for pernicious anemia)
  - Antiparietal cell antibodies (in 85–90%; less specific compared to anti-intrinsic antibodies).
- Achlorhydria with histamine stimulation.
- Severe deficiency of intrinsic factor.

#### ***Other Nonspecific Tests***

- Serum gastrin raised
- Pepsinogen I decreased
- Gastric biopsy shows mucosal atrophy and inflammatory infiltrate of lymphocytes and plasma cells.

**Q. Discuss the management of megaloblastic macrocytic anemias.**

**Q. Discuss the management of Addisonian pernicious anemia.**

### Management of Megaloblastic Macrocytic Anemia

Treatment consists of treating the underlying cause, whenever possible.

#### *Specific therapy*

Treatment of underlying cause of vitamin B<sub>12</sub> or folate deficiency.

#### *Vitamin B<sub>12</sub>/Cobalamin deficiency*

Vitamin B<sub>12</sub> therapy (cyanocobalamin, hydroxocobalamin or methylcobalamin may be used).

- **Dosage:**
  - **Initial dose:** It is treated with six intramuscular injections of hydroxocobalamin 1000 µg given at 3- to 7-day intervals.
  - **Maintenance dose:** Maintenance dose of 1000 µg to be given intramuscularly every 3 months for rest of the patient's life. Methylcobalamin, metabolically active form of vitamin B<sub>12</sub> can also be used.
- An aggressive scheme to replace vitamin B<sub>12</sub> rapidly is 1 mg of intramuscular cyanocobalamin per day (week 1), 1 mg twice weekly (week 2), 1 mg/week for 4 weeks, and then 1 mg/month for life.
- **Response:** Clinical improvement may occur within 48 hours (LDH and bilirubin will normalize) and a reticulocytosis peak by the 3–4th day after therapy and may be as high as 50%. Anemia will correct by 4–6 weeks. Improvement of the sensory polyneuropathy may take 6–12 months to correct but longstanding spinal cord damage is irreversible. Hypokalemia during the initial week of treatment as there is marked potassium uptake during production of new blood cells.
- **Dimorphic anemia:** If there is associated iron deficiency, ferrous sulfate 200 mg thrice daily orally should be started soon after the commencement of vitamin B<sub>12</sub> therapy.

#### *Folate deficiency*

- **Dosage:** Oral dose of 5 mg folate (folic acid) daily for 3 weeks will treat acute deficiency and 5 mg once weekly is adequate maintenance therapy.
- Folinic acid is of value to bypass the block of dihydrofolate reductase by methotrexate and trimethoprim-sulfamethoxazole.
- Congenital folate malabsorption arising from inadequate folate transport across the gastrointestinal tract and blood-brain barrier responds to parenteral leucovorin in high doses.
- **Response** is same as seen after treatment of vitamin B<sub>12</sub> deficiency.
- **Precaution:** Large doses of folic acid alone should not be given to treat megaloblastic anemia (such as pernicious anemia or other vitamin B<sub>12</sub> deficiency anemias) unless the serum vitamin B<sub>12</sub> level is known to be normal. If vitamin B<sub>12</sub> deficiency is present, it should be corrected first;

otherwise cobalamin neuropathy may be aggravated or precipitated despite a response of the anemia of cobalamin deficiency to folate therapy.

- **Prophylactic folic acid in pregnancy:** Prophylactic folic acid in the dose of 400 µg daily is recommended for all women planning a pregnancy to reduce the risk of fetal neural tube defects.

#### *Supportive therapy*

- Blood transfusions: Transfusion is usually not necessary and not advisable. It should be given in significantly symptomatic and severely anemic patients with angina or heart failure.
- Other measures: Treatment of infection and physiotherapy in nervous system involvement.

#### *Follow-up*

- Clinical and hematological examination should be carried out every 6 months.
- Pernicious anemia: Carcinoma stomach, gastric carcinoids are more common in patients with pernicious anemia and early detection is important.

## Causes of Macrocytosis

**Q. Enumerate the causes of macrocytosis/macrocytic anemia. Write short note on macrocytic.**

Macrocytes are large red blood cells with a diameter of more than 9 µ and mean corpuscular volume of more than 95 fl. The macrocytic anemias can be divided into megaloblastic and non-megaloblastic types, depending on the appearance of developing red cell precursors in the bone marrow.

### ***Megaloblastic Macrocytic Anemia***

It is characterized by raised MCV with macrocytosis on the peripheral blood and the presence of abnormal red precursors the bone marrow known as megaloblasts. Causes of megaloblastic anemia include deficiency of vitamin B<sub>12</sub>, folate or copper and drugs that interfere with purine or pyrimidine metabolism (Box 8.3). The peripheral blood smear shows macro-ovalocytes and hypersegmented neutrophils.

### ***Non-megaloblastic Macrocytic Anemia***

It is characterized by a raised MCV with macrocytosis on the peripheral blood film with a normoblastic rather than a megaloblastic bone marrow. Common causes are listed in Table 8.9. These conditions are associated with normal levels of vitamin B<sub>12</sub> and folate.

## HEMOLYTIC ANEMIAS

**Q. Define and classify hemolytic anemia. Discuss the clinical features, diagnosis and management of hemolytic anemias.**

## Definition

Hemolytic anemias are defined as anemias that result due to increase in the rate of red cell destruction. The life span of red cells (normal life span is 90–120 days) is shortened.

## *Compensated Hemolytic Disease*

Shortening of red cell survival may not always cause anemia as bone marrow can compensate by increased production of red cells by six to eight times.

## Classification of Hemolytic Anemias (Table 8.10)

**Q. Write short essay/note on classification/causes of hemolytic anemia.**

The hemolytic anemias are classified in a variety of ways.

1. **Location of hemolysis:** Depending upon the site of red cell destruction it can be classified as **intravascular and extravascular** hemolytic disorders.
2. **Source of defect causing hemolysis:** Those due to a defect intrinsic to the red cell itself (**intracorpuseular defect**) or those due to an abnormality outside the red cell (**extracorpuseular mechanism**).
3. **Mode of onset: Hereditary and acquired** disorders.
4. **Clinical point of view: Acute or chronic.**

**Box 8.3:** Causes of non-megaloblastic macrocytic anemia.

### Physiological causes:

- Pregnancy
- Newborn

### Pathological causes:

- Alcohol excess
- Chronic liver disease
- Reticulocytosis
- Hypothyroidism
- Postsplenectomy
- Myeloproliferative disorders
- Hematological disorders
  - Aplastic anemia
  - Sideroblastic anemia
  - Pure red cell aplasia

- Drugs
  - Azathioprine
  - Hydroxycarbamide, metformin, zidovudine, leflunomide

**Table 8.10:** Classification and causes of hemolytic anemia.

<i>Hereditary hemolytic anemias</i>	<i>Acquired hemolytic anemias</i>
<p>A. Defects in red cell membrane:</p> <ul style="list-style-type: none"> <li>• Hereditary spherocytosis</li> <li>• Hereditary elliptocytosis</li> <li>• Stomatocytosis</li> <li>• Abetalipoproteinemia (acanthocytosis)</li> </ul> <p>B. Red cell enzyme deficiencies:</p> <ul style="list-style-type: none"> <li>• Pyruvate kinase deficiency</li> <li>• Hexokinase deficiency</li> <li>• Glucose-6-Phosphate dehydrogenase deficiency (G-6-PD)</li> </ul> <p>C. Defects in globin synthesis: Hemoglobinopathies (abnormal hemoglobins)</p> <ul style="list-style-type: none"> <li>• Thalassemia—quantitative hemoglobinopathies</li> <li>• Sickle cell syndromes—qualitative hemoglobinopathies</li> <li>• Alpha thalassemia</li> <li>• Unstable hemoglobin disease</li> </ul>	<p>A. Immuno-hemolytic anemias</p> <ul style="list-style-type: none"> <li>• Autoimmune hemolytic anemias           <ul style="list-style-type: none"> <li>– Due to warm antibodies: Idiopathic or secondary</li> <li>– Due to cold antibodies: Cold agglutinin disease, paroxysmal cold hemoglobinuria</li> </ul> </li> <li>• Hemolytic disease of the newborn</li> </ul> <p>B. Fragmentation syndromes</p> <ul style="list-style-type: none"> <li>• Hemolytic uremic syndrome</li> <li>• Thrombotic thrombocytopenic purpura</li> <li>• Disseminated intravascular coagulation</li> <li>• Prosthetic cardiac valves</li> </ul> <p>C. Paroxysmal nocturnal hemoglobinuria</p> <p>D. Drugs and chemicals</p> <ul style="list-style-type: none"> <li>• Drugs: For example, oxidant drugs, primaquine and dapsone</li> <li>• Chemicals: For example, naphthalene, nitrites and nitrates, oxidizing chemicals</li> </ul> <p>E. Thermal injury: Burns</p>

## Clinical Features of Hemolytic Anemia

### *Symptoms/history*

- Mild jaundice
- Symptoms due to anemia
- Urine color
  - Urine passed appears normal in color (acholuric), but turns dark on standing due to oxidation of urobilinogen to urobilin.
  - Black urine with hemoglobinuria seen in intravascular hemolysis (e.g. malaria, mismatched blood transfusion, G6PD deficiency).
- Infections

- Splenic pain due to enlargement or infarction of spleen
- Acute crisis due to sudden fall in hemoglobin and sometimes, fever, joint pains and abdominal pain.
- Symptoms due to pigment gallstones which develops as a complication of chronic hemolysis.
- Leg ulcers manifest in adult males especially in patients with hereditary spherocytosis and sickle cell anemia.
- Family history in congenital hemolytic anemias.

### ***Physical Findings/Signs***

- Anemia
- Mild jaundice
- Splenomegaly in some cases of hemolytic anemia (e.g. thalassemia, hereditary spherocytosis).
- Chronic leg ulcers in some cases (e.g. sickle cell anemia).
- Skeletal abnormalities: Expansion of bone marrow may develop in some congenital hemolytic anemias (sickle cell anemia) due to increased erythropoiesis. These manifests are enlargement of maxillary bones and frontal bossing and malocclusion of the teeth due to overgrowth of upper jaw (thalassemic facies).
- Signs of systemic diseases: Predisposing to hemolysis.
- Signs of cholelithiasis: Cholecystitis.

### **Diagnosis of Hemolytic Anemias**

**Q. Write short essay on laboratory investigations/features of hemolysis/hemolytic anemia.**

### ***Recognition of Hemolysis (Table 8.11 and Fig. 8.19)***

**Table 8.11:** Summary of laboratory features of hemolytic anemia.

#### ***1. Features/consequences of increased RBC destruction/ breakdown***

- Anemia
- Unconjugated hyperbilirubinemia (jaundice)
- Increased urobilinogen in urine (resulting from bilirubin breakdown in the intestine) leading to high-colored urine

- Shortened red cell life span (demonstrated by  $^{51}\text{Cr}$ -labeled red blood cells)
- Other features
  - In extravascular hemolysis: Splenomegaly usual
  - In intravascular hemolysis
    - ◆ Decreased plasma haptoglobin and hemopexin
    - ◆ Increased plasma lactic dehydrogenase (LDH)
    - ◆ Hemoglobinemia, hemoglobinuria, hemosiderinuria and methemoglobinemia (in some)

### ***2. Consequences of increased RBC production***

- **Peripheral smear:** Reticulocytosis
- **Bone marrow:** Erythroid hyperplasia

### ***3. Morphological features of damaged red cells***

- **Peripheral smear:** For example, microspherocytes, elliptocytes, red cell fragments

**Features of increased RBC production:** As a compensatory mechanism to hemolysis, there is increased production of red cells.

- **Bone marrow** shows **compensatory erythroid hyperplasia**
- **Peripheral smear** shows **increased reticulocytes** (reticulocytosis) nucleated red cells and polychromasia. Other findings vary depending on the cause are mentioned below.
- **Radiological changes:** Hair on end appearance in skull radiograph (thalassemia, sickle cell anemia).

## ***Recognition of Cause of Hemolysis***

- Common tests:
  - **Peripheral smear examination:** Red cell morphology provides a clue to the underlying hemolytic disorder like (1) spherocyte (hereditary spherocytosis, autoimmune hemolytic anemia), (2) sickle cell (sickle cell anemia), (3) target cell (thalassemia), (4) acanthocyte, (5) schistocyte (Intravascular hemolysis-fragmented red cells, helmet cells, triangular cells), (6) malarial parasite.
  - Coomb's test
  - Osmotic fragility, sucrose lysis and Ham's test
  - Heinz body preparation
  - Hemoglobin electrophoresis
  - High performance liquid chromatography (HPLC)
  - Measurement of enzyme activity.

- Specific tests: Identification of specific cause of hemolysis is dealt under individual diseases.

## DEFECTS IN HEMOGLOBIN PRODUCTION

**Q. Write short note on classification of disorders of hemoglobin (hemoglobinopathies/hereditary disorders of hemoglobin).**

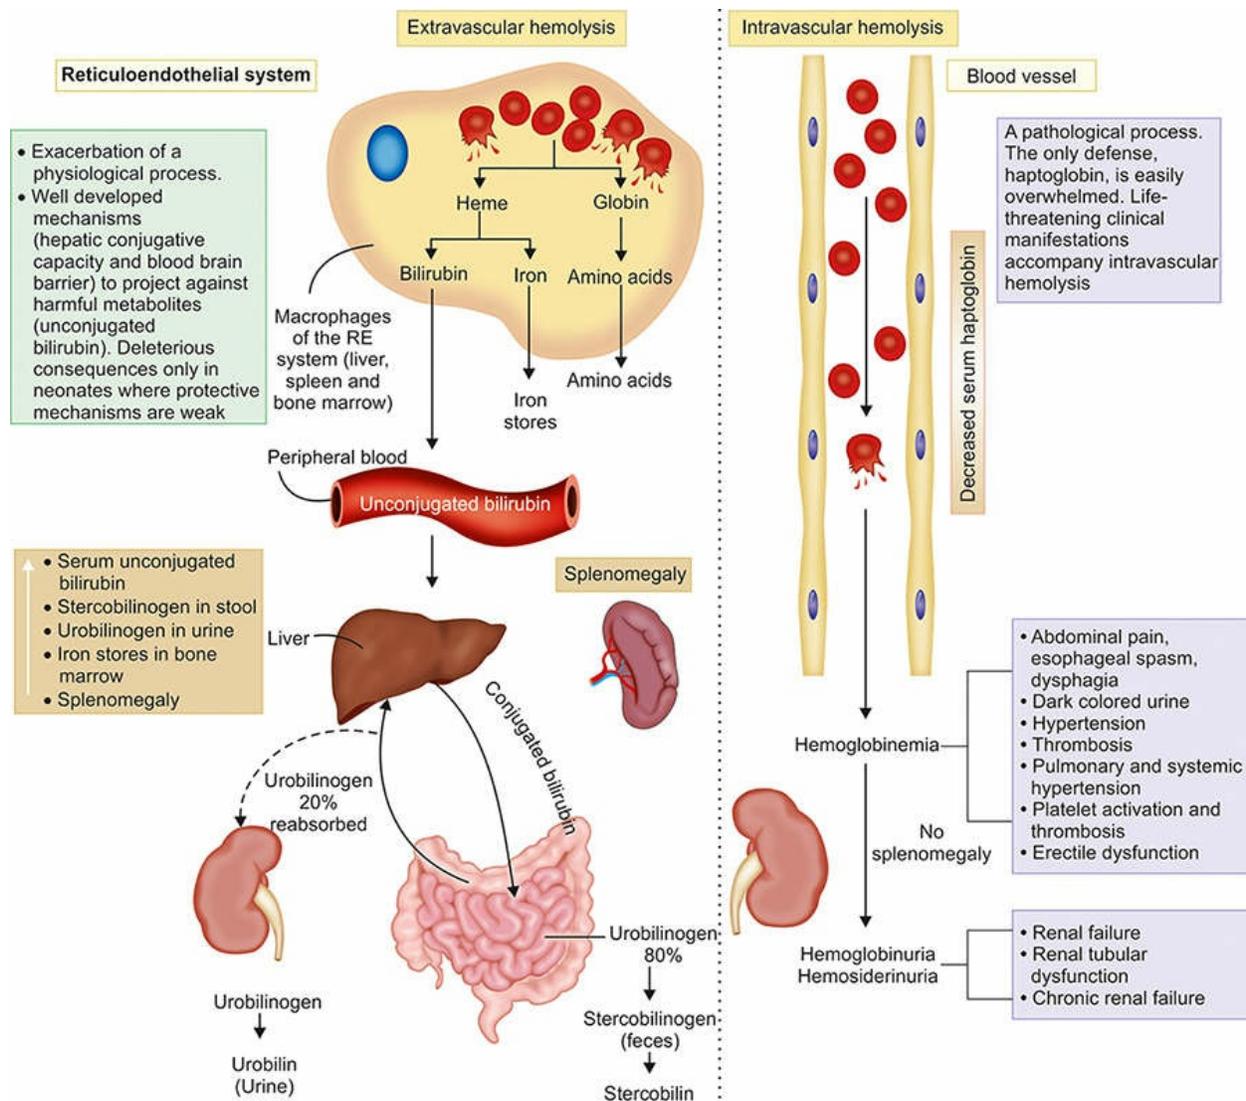

Hemoglobin defects may be in the form of production of abnormal (qualitative) or reduced production (quantitative) of normal hemoglobin (Table 8.12). The term hemoglobinopathy unless specified usually indicates a qualitative hereditary disorder.

## SICKLE CELL DISEASE

**Q. Discuss the etiopathogenesis, clinical features, investigations and management of sickle cell anemia.**

Sickle cell disease (SCD) is an important group of autosomal recessive hereditary disorder of hemoglobin characterized by production of defective hemoglobin synthesis called sickle hemoglobin (HbS). HbS imparts sickle shape to red cells on low oxygen tension or deoxygenation. The term sickle cell disease includes all entities associated with sickling of hemoglobin within the red blood cells. The major entities included are:

- **Sickle cell anemia (SS)** is a homozygous state in which both the  $\beta$  globin chains are abnormal.
- **Sickle cell trait (AS)** is a heterozygous state in which one gene is defective for HbS (abnormal) while the other gene is for HbA (normal).
- **Compound heterozygous** is characterized by both the  $\beta$ -globin chains having different abnormalities, (e.g. Hb SC, HbS- $\beta$ -thalassemia).

**Fig. 8.19:** Mechanism and consequences of extravascular and intravascular hemolysis.

In India, it is seen in certain tribes of South India, Assam, Bihar and Odisha.

### Table 8.12: Classification of hemoglobin defects.

- 1. Qualitative defect in (structurally abnormal) hemoglobins**
  - Hemoglobin S
  - Hemoglobin C
  - Hemoglobin D Punjab
- 2. Quantitative defect in hemoglobins**
  - Thalassemias ( $\alpha$ ,  $\beta$ -thalassemia)
- 3. Combined qualitative and quantitative defects in hemoglobins**

- Hemoglobin E
- Sickle-cell  $\beta$ -thalassemia

#### 4. Acquired hemoglobinopathies

- Methemoglobinemia due to toxic exposures
- Carboxyhemoglobinemia

## Etiology and Pathogenesis

Sickle cell anemia is caused by production of abnormal hemoglobin called sickle hemoglobin (HbS). In HbS, there is an adenine (A) to thymidine (T) substitution (GAG  $\rightarrow$  GTG) in codon 6 of the  $\beta$ -globin gene. This point mutation results in **replacement of the normal glutamic acid residue by a valine** and alters the solubility or stability of the hemoglobin.

### Pathogenesis

The change in the shape due to dehydration, partly caused by potassium leaving the red cells via calcium activated potassium channels called the Gárdos channel.

Deoxygenated HbS molecules are insoluble and polymerize to form pseudocrystalline structures known as ‘tactoids’. RBCs become rigid, deformed and assume a characteristic sickle/crescent shape (sickle-shaped cells). Initially, on reoxygenation this process is reversible. But with repeated episodes of sickling, the RBCs eventually lose their membrane flexibility and become irreversibly **sickled cells (ISC)**. Factors that favor and hinder sickling are listed in Table 8.13.

**Table 8.13:** Factors affecting sickling.

<i>Factors</i>	<i>Favors sickling</i>	<i>Hinders sickling</i>
Other hemoglobins	-	HbA
	-	HbF
	HbC	-
Transit time in microvasculature	Slowing of blood stream	-
MCHC	Increased MCHC	Decreased MCHC
Intracellular pH	Decreased pH	-
Other factors	Temperature above 37 °C	-
	Infections	-
Oxygen tension	Low	High

## ***Consequences of Sickling***

Irreversibly sickled cells are dehydrated and dense and will not return to normal when oxygenated. Sickling can produce:

- **Microvascular occlusions:** Impaired passage of ISCs through the microcirculation, produces obstruction of small vessels and leads to tissue ischemia and infarction.
- **Hemolytic anemia:** Due to shortened survival of the sickle cells which are destroyed by the reticuloendothelial system.

## **Clinical Features**

**Q. Write short essay/note on the complications of sickle cell anemia.**

The clinical features change as life advances.

### ***In Children***

- Infant till 3 months may be asymptomatic, because of the protective role of HbF. Since, HbF disappears after 3rd month majority of cases present after 3 months and before 1st year of life.
- **Prone to infections:** Children are susceptible to acute infections with encapsulated organisms. Common infections are pneumococcal pneumonia, meningitis due to *S. pneumonia* and osteomyelitis due to *Salmonella*. Increased susceptibility to infections is because of hypofunction of spleen and defects in the alternative complement pathway which impair opsonization of encapsulated bacteria such as *pneumococci* and *Haemophilus influenzae*. Septicemia and meningitis are the most common causes of death in children. Increased frequency of **osteomyelitis** is because of repeated bone infarcts which act as nidus for infection.
- In children, **bone involvement** may resemble acute osteomyelitis. They manifest as the **hand-foot syndrome, dactylitis** of the bones of the hands or feet or both. It is due to microinfarcts in the carpal and tarsal bones.
- **Sequestration crisis:** Usually occurs in children with chronically enlarged but normal functioning spleen. Sudden trapping of blood in spleen or liver causes rapid enlargement of the organ with resultant drop in hematocrit and hypovolemic shock. This may require blood transfusions.
- **Changes in spleen:** Splenomegaly is observed during early childhood. Repeated episodes of splenic infarct results in atrophy of the spleen

(autosplenectomy).

- **Acute chest syndrome** can develop in both children and adults. It is due to infection or infarction in the lung and presents with pain in the chest, fever, respiratory distress and hypoxemia.
- **Others** include acute coronary syndrome and stroke. Chronic hypoxia in children is responsible for generalized impairment of growth and development.

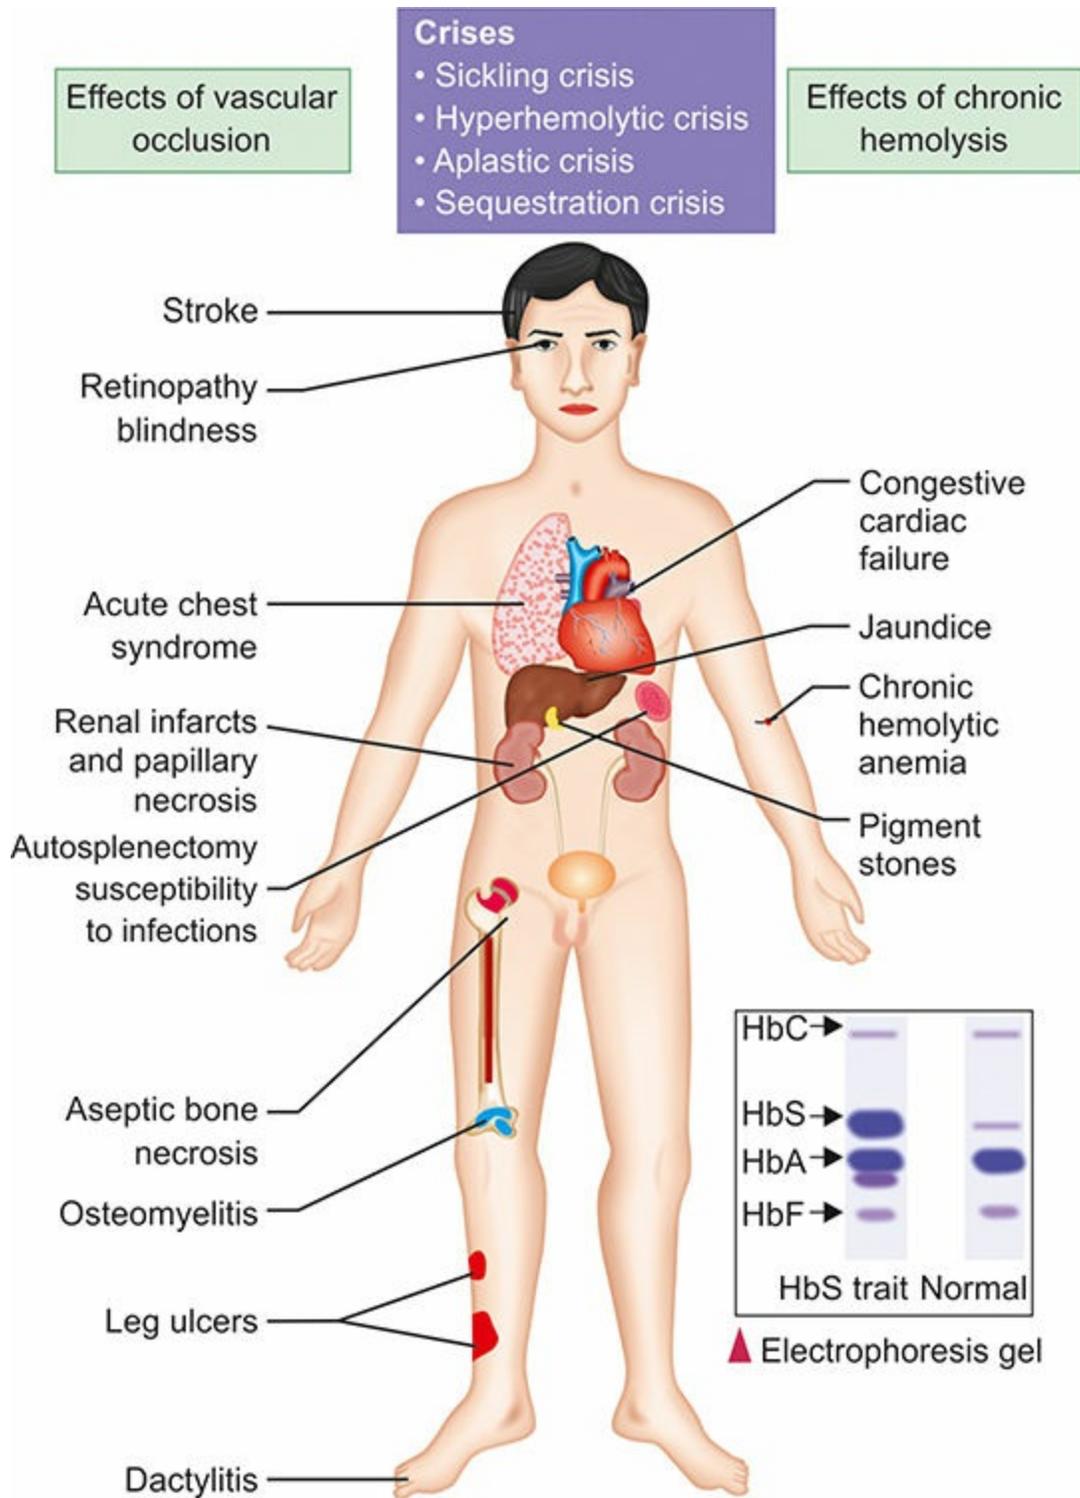

### ***In Adults (Fig. 8.20)***

- **Anemia:** Patients develop severe hemolytic anemia which is exacerbated by secondary folate deficiency. Chronic anemia presents with fatigue, frequent infections, cardiomegaly and systolic murmurs. Chronic hemolytic anemia causes increased levels of unconjugated (indirect) bilirubin, which predisposes to development of pigmented bilirubin gallstones. Cholelithiasis may lead to cholecystitis.

### **Q. Write short essay/note on sickle cell crises.**

- **Crises:** Irreversibly sickled cells have a shortened survival and plug vessels in the microcirculation. Any new syndrome or episode that develops rapidly in sickle cell anemia is termed crises. The protracted course of sickle cell anemia is frequently exacerbated by a variety of crises. Four types of crises are encountered. These are:
  - **Infarction (sickling) crisis (vaso-occlusive crisis):** Due to blockage of microcirculation by sickled red cells causes hypoxic injury and infarction.
    - ◆ Most common and the hallmark of sickle cell disease.
    - ◆ Clinically presents with acute, severe pain in the affected region. It commonly involves bones, lungs, liver and spleen.
    - ◆ Bone: Sudden attacks of bone pain are due to ischemia and infarction. Avascular necrosis of the head of femur is also common.
    - ◆ Lung: involvement presents with fever, cough, chest pain and pulmonary infarcts and known as *acute chest syndrome (dangerous)*. These are sometimes initiated by a simple lung infection.
    - ◆ Spleen: Acute abdominal pain caused by infarcts of spleen and leads to autosplenectomy.

- ◆ Other sites of infarction: Mesenteric infarction results in acute abdominal pain, cerebral infarctions result in hemiplegia, infarction of renal papillae results in hematuria. And retinal microinfarcts result in loss of vision.
- **Aplastic crisis:** Temporary suppression of bone marrow erythropoiesis may develop due to an acute infection of erythroid progenitor cells by parvovirus B19.
- **Hemolytic crisis** is characterized by episodes of increased sequestration and destruction of red cells. It presents with marked increase in hemolysis with a sudden lowering of hemoglobin, rapid enlargement of liver and spleen and reticulocytosis.
- **Sequestration crisis** (described above).

**Fig. 8.20:** Various effects of vascular occlusion and hemolysis in sickle cell anemia.

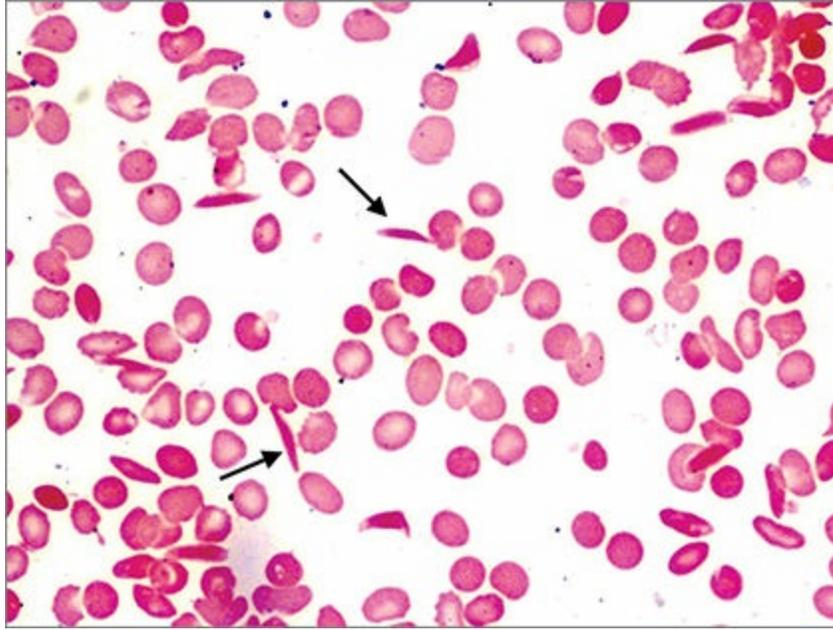

Other crisis encountered rarely is hypoplastic crisis and megaloblastic crisis (due to inadequate folate).

**Q. Write short essay/note on long-term complications of sickle cell anemia.**

Described in Table 8.14.

## Investigations

- **Evidences of hemolysis (refer page 572)**
- **Blood count:** Hb is in the range 6–8 g/dL with a high reticulocyte count (10–20%).
- **Peripheral smear:** The characteristic red cell which appears in smear is the **sickle cell (Fig. 8.21)**. These appear as long, curved cells with pointed ends. Features of hyposplenism include: Howell-Jolly bodies (small nuclear remnants), **target cells** (due to red cell dehydration) **and ovalocytes**.
- **ESR is low** because sickle cells do not form rouleaux.
- **Sickling test** is induced by adding a reducing (oxygen-consuming) agent like 2% sodium metabisulfite or sodium dithionite to blood sample.
- **Sickle solubility test:** A mixture of HbS in a reducing solution (e.g. sodium dithionite) gives a turbid appearance because of precipitation of HbS, whereas normal Hb gives a clear solution.
- **Hemoglobin electrophoresis:** There is no Hb-A, 80–95% Hb-SS and 2–20% HbF. HbS is slow moving hemoglobin compared to HbA and HbF. In sickle cell trait (heterozygous state) Hb-S is 20–40% and the rest is Hb-A.
- Tests for iron overload: Serum ferritin levels, transferrin saturation, liver iron concentration using liver biopsy specimen, measurement of liver iron using MRI.
- Prenatal diagnosis can be done by analysis of fetal DNA obtained by amniocentesis or chorionic villous biopsy.

**Fig. 8.21:** Peripheral blood smear with sickle cells (arrows).

### Table 8.14: Long-term complications of sickle cell anemia.

- **Impaired growth and development** with low weight and delayed sexual maturation
- **Chronic infarcts** of bones
- **Infections** of bones (*Salmonella osteomyelitis*), lungs, kidneys (*pyelonephritis*, chronic tubulointerstitial nephritis)
- **Leg ulcers**
- **Cardiac:** Cardiomegaly, arrhythmias, myocardial infarctions and iron overload cardiomyopathy
- **Neurological:** Transient ischemic attacks, seizures, cerebral infarction, cerebral hemorrhage and coma
- **Cholelithiasis**
- **Liver:** Chronic hepatomegaly, liver dysfunction.
- **Priapism**
- **Iron overload** due to repeated transfusions
- **Eye:** Background retinopathy, proliferative retinopathy, vitreous hemorrhages and retinal detachments
- **Pregnancy:** Spontaneous abortion, intrauterine growth retardation, preeclampsia and fetal death

### Management

#### General Measures

Sickle cell disease is a chronic disorder which requires following general measures:

- **Good nutrition** and folic acid supplementation (5 mg daily) to be given to all patients with hemolysis.
- **Timely immunizations** against *Streptococcus pneumoniae*, seasonal influenza, *Neisseria*

*meningitidis*, *Haemophilus influenzae type B*, and hepatitis B virus.

- **Antibiotic prophylaxis** with phenoxymethyl penicillin 500 mg daily starting at the age of 2 months. Older children do not routinely need continued antibiotic prophylaxis.
- Precipitating factors should be avoided or treated quickly. These include avoidance of cold, dehydration and hypoxia.
- Prevention, prompt identification and treatment of infections with antibiotics.

### **Anemia**

- Transfusions should only be given for clear indications. Transfusion should not be given to patient with chronic stable anemia, those having minor surgery or having painful episodes without complications.
- **Indications for blood transfusion:** Transfusion is required to increase the oxygen carrying capacity, replace the rigid, sickle-shaped RBCs with normal cells and to restore blood flow. Acute transfusions with packed RBCs can be life-saving and chronic transfusions reduce the incidence and severity of most complications.
  - Heart failure, TIAs, strokes, acute chest syndrome and severe anemia due to aplastic crises and acute splenic sequestration.
  - **Repeated transfusions** may be used to reduce the proportion of circulating HbS to less than 20% to prevent sickling, before elective operations and during pregnancy. Chronic RBC transfusion reduces the chance of recurrent ischemic stroke.
  - **Exchange transfusions** may be necessary in patients with severe or recurrent crises or before emergency surgery. Whether exchange transfusion is preferable to simple transfusion in the acute chest syndrome, stroke or other acute complications has not been established by clinical trials.
  - Infarction crises are managed with hydration, oxygen, analgesics and transfusion with RBC concentrate in selected cases.
- **Iron overload:** With repeated transfusion, iron overload inevitably develops and can result in heart and liver failure and other complications. Iron overload is treated by using iron chelators (deferoxamine or deferasirox).

**Hydroxycarbamide (hydroxyurea):** May be used as therapy for patients with severe symptoms. Hydroxyurea (10–30 mg/kg per day) increases fetal hemoglobin and suppress the neutrophil and reticulocyte counts (which may play a major role in the pathogenesis of sickle cell crisis). Hydroxycarbamide reduces the episodes of pain, the acute chest syndrome, and the need for blood transfusions.

**Senicapoc**, a Gardos channel inhibitor, prevented erythrocyte dehydration in clinical trials of patients with sickle cell disease. This drug has antiplasmodium activity.

### **Acute Painful Crisis**

Require supportive therapy with intravenous fluids, oxygen, antimicrobial agents and adequate analgesia. Acute severe pain is treated with narcotic, analgesia (morphine) and milder pain can be relieved by codeine, paracetamol and NSAIDs. Inhaled nitric oxide inhibits platelet function, reduces vascular adhesion of red cells and is also a vasodilator. It can provide short-term pain relief and shown to reduce opiate requirements in acute painful episodes. But, should be restricted to experts to avoid hypoxia and respiratory depression. Nasal oxygen should be employed as appropriate to protect arterial saturation.

Acute chest syndrome is treated with antibiotics, maintenance of arterial oxygenation, pain relief, bronchodilators, and if required, exchange transfusion.

**Chronic leg ulcers:** Elevation of limb, daily dressings with zinc sulfate and exchange transfusion in

extreme cases.

*Curative*

- **Bone marrow/stem cell transplantation:** in children and adolescents younger than 16 years of age who have severe complications (strokes, recurrent chest syndrome, or refractory pain) can provide definitive cure.
- **Gene therapy** is intensively pursued, but no safe measures are currently available.

## HEREDITARY SPHEROCYTOSIS

### **Q. Write short note on hereditary spherocytosis (HS).**

- Most common inherited hemolytic anemia in adults.
- **Autosomal dominant** inheritance in more than 75% cases.
- Defect in the RBC membrane is due to cytoskeleton protein (e.g. **ankyrin, band 3, spectrin or band protein 4.2**) deficiency.
- This results in red cells losing part of the cell membrane as they pass through the spleen and assume spheroidal shape (spherocytes) that are less deformable (rigid) and more susceptible to osmotic lysis.
- Red cells have decreased life span of as low as 10 to 20 days.

### **Clinical Features**

- Disease may present during anytime from the neonatal period to adulthood.
- **Family history:** Most (75%) HS are inherited as autosomal dominant trait and there is strong family history of anemia, jaundice, splenomegaly and cholelithiasis.
- **Anemia** is usually mild to moderate
- **Jaundice:** Intermittent attacks of jaundice
- **Splenomegaly:** Moderate splenic enlargement is characteristic and constant feature.
- **Children:** Growth retardation due to hemolysis and bone changes due to marrow hyperplasia.
- **Adults:** Anemia, intermittent jaundice and moderate splenomegaly.
- Complications of hereditary spherocytosis are listed in Box 8.4.

### **Box 8.4:** Complications of hereditary spherocytosis.

- Cholelithiasis (pigment gallstones)

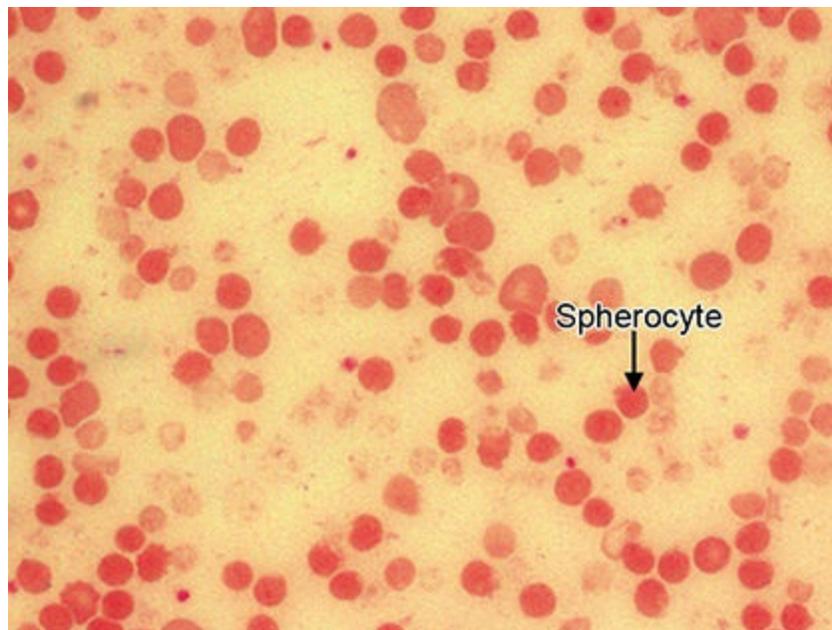

- Chronic leg ulcers
- Aplastic crises due to parvovirus B19 infection
- Hemolytic crises (rare)

## Investigations

- **Anemia:** Usually mild, but occasionally can be severe.
- **Peripheral blood film** shows **spherocytes** (Fig. 8.22) and reticulocytes. **MCHC is increased.**
- **Demonstration of a hemolytic state:** Raised serum bilirubin and urinary urobilinogen.
- Specific diagnostic tests are listed in Box 8.5. Increased osmotic fragility may be absent in mild cases and may be positive in autoimmune hemolytic anemia.
- **Negative Coombs test.**
- **Strong family history will be present.**

### Box 8.5: Specific diagnostic tests for hereditary spherocytosis.

- Osmotic fragility testing
- Ektacytometry
- Acidified glycerol lysis test
- Cryohemolysis test
- Eosin-5-maleimide binding test

**Fig. 8.22:** Peripheral blood smear with numerous spherocytes (arrow) in hereditary spherocytosis.

### Treatment

- Splenectomy is the treatment of choice and should not be done before the age of 6 years. Splenectomy corrects the anemia and its complications, but increases the risk of infections. Hence, it should be preceded by *pneumococcal* and *Haemophilus influenzae* immunization, and followed by lifelong penicillin prophylaxis).
- Folic acid supplementation in patients without splenectomy.
- Regular blood transfusions are required in few patients with severe disease.
- Cholecystectomy is indicated only for symptomatic gallstones.

## THALASSEMIA SYNDROME

**Q. Write short essay/note on definition, common forms and genetics of thalassemias.**

Thalassemia syndrome is a heterogeneous group of inherited disorders which result from reduced or absence of synthesis of one of the globin chains (either  $\alpha$  or  $\beta$  globin chain).

### Classification

Thalassemic syndromes are mainly classified into two main types depending on the defective globin chain  $\alpha$  or  $\beta$  thalassemia (Box 8.6). Mode of inheritance is autosomal recessive. Rarely, HBB gene mutation is inherited as autosomal dominant.

### Genetics

**$\beta$ -thalassemia syndromes** are classified into 3 types depending on the genetic defect ( $\beta^+$  or  $\beta^0$ ):

1.  **$\beta$ -Thalassemia major** also called Cooley's anemia, Mediterranean anemia, transfusion-dependent thalassemia is the homozygous disorder and is the most severe form of  $\beta$ -Thalassemia. There is either no production of  $\beta$ -chains ( $\beta^0$ ) or  $\beta$ -chain production is markedly reduced ( $\beta^+$ ). The anemia is of severe degree and is transfusion dependent. There is high level of HbF in the blood.
2.  **$\beta$ -Thalassemia intermedia** is the double heterozygous state and anemia is moderately severe and not transfusion dependent.
3.  **$\beta$ -Thalassemia minor or  $\beta$ -thalassemia trait** is the heterozygous state and is asymptomatic with mild anemia.

**Box 8.6: Classification of thalassemic syndromes.**

---

***α-thalassemia (synthesis of α chains is affected)***

- Silent carrier state
- α-Thalassemia trait
- Hemoglobin H disease
- Hydrops fetalis (Hb Barts)

***β-thalassemia (synthesis of β chains is affected)***

- β-thalassemia minor (heterozygous state)
- β-thalassemia intermedia
- β-thalassemia major (Cooley’s anemia homozygous state)

## ***α-Thalassemia Syndromes***

Each cell has four genes coding for α-globin, two on each chromosome. Each of the four α-globin genes normally contributes 25% of the total α-globin chains. Severity of α-thalassemia depends on the number of α-globin genes deleted or affected. Deleted genes may vary from 1 to 4.

- Silent carrier state develops with deletion of one α-chain gene
- α-thalassemia trait: Due to deletion of two α-genes
- HbH disease: With deletion of three α-genes
- Hb Barts (hydrops fetalis): Develops if all four genes are absent. It is incompatible with life and the infants are either stillborn or die shortly after birth. They are pale, edematous, and have large liver and spleen.

Classical thalassemia syndromes (genotypes and laboratory findings) are presented in Table 8.15.

**Table 8.15: Classical thalassemia syndromes (genotypes and laboratory findings).**

<b><i>Syndrome</i></b>	<b><i>Genotype</i></b>	<b><i>Typical findings on CBC</i></b>	<b><i>Hemoglobin analysis (HPLC or electrophoresis)</i></b>
<b>Alpha thalassemias (reduction in alpha globin chains)</b>			
Hydrops fetalis with Hb Barts	(-ε-ε/ -ε-ε)	Severe microcytic anemia with hydrops fetalis; usually fatal in utero	Hb Barts (γ globin tetramers); Hb Portland (embryonic hemoglobin); no HbF, HbA or HbA <sub>2</sub>
HbH disease	(αε- / - -) or (α <sup>t</sup> -ε/ -ε-)*	Moderate microcytic anemia	HbH (up to 30%); HbA <sub>2</sub> (up to 4%)
Minor	(αε-ε/αε-ε) or	Mild microcytic anemia	Hb Barts (3 to 8%)

	( $\alpha\alpha / -\epsilon-$ )		
Silent carrier	( $\alpha\alpha / \alpha-$ )	Normal hemoglobin, normal MCV	Normal
<b>Beta thalassemias (reduction in beta globin chains)</b>			
Major (transfusion-dependent)	$\beta^0 / \beta^0$ or $\beta^0 / \beta^+$	Severe microcytic anemia with target cells (typical Hb 3 to 4 g/dL)	HbA <sub>2</sub> (5% or more); HbF (up to 95%); no HbA
Intermedia (non-transfusion-dependent)	$\beta^+ / \beta^+$	Moderate microcytic anemia	HbA <sub>2</sub> (4% or more); HbF (up to 50%)
Minor (also called trait or carrier)	$\beta / \beta^0$ or $\beta / \beta^+$	Mild microcytic anemia	HbA <sub>2</sub> (4% or more); HbF (up to 50%)

## $\beta$ -THALASSEMIA MAJOR

**Q. Discuss the clinical features, salient investigations, diagnosis and management of  $\beta$ -thalassemia major (Cooley's anemia).**

- $\beta$ -thalassemia major (Mediterranean or Cooley's anemia) is the homozygous form of  $\beta$ -thalassemia characterized by absent or reduced synthesis of  $\beta$ -chain.
- It is most common in Mediterranean countries, parts of Africa and Southeast Asia. In India, it is common among certain communities (e.g. Sindhi, Punjabi, Gujarati, Parsee) in North India and less common in South India.
- **Anemia** is produced due to diminished synthesis of HbA, ineffective erythropoiesis and extravascular hemolysis.
- **Consequences of ineffective erythropoiesis**
  - Marked erythroid hyperplasia: Severe hemolytic anemia stimulates erythropoietin (EPO) production by kidney leading to marrow erythroid hyperplasia.
  - Changes in the bone: Thalassemic facies and hair on end appearance of skull X-ray.
  - Extramedullary hematopoiesis.

### Clinical Features

- **Severe anemia:** Infants with thalassemia major are well at birth but develop moderate to severe anemia 6 to 9 months after birth, when hemoglobin synthesis switches from HbF to HbA.
- **Retardation of growth and development:** Untreated/untransfused children **fail to thrive** (growth retardation) and die early within 4–5 years of age from the effects of anemia. They are **susceptible to recurrent bacterial infections**.
- **Changes in bone:** Those who survive longer, bone marrow hyperplasia cause expansion and widening of marrow and give the **classical X-ray changes**.
  - **Thalassemic (Chipmunk) facies (Fig. 8.23):** Due to enlargement and distortion of craniofacial bones (frontal bossing of the skull, prominent malar eminence, depression of bridge of nose, and hypertrophy of the maxillae, which tends to expose the upper teeth).
  - **Hair on end (‘crew-cut’) appearance (Fig. 8.24):** In the skull X-ray due to new bone formation.
- **Splenomegaly** may be massive and enlarges up to 1,500 g due to hyperplasia and extramedullary hematopoiesis.
- Liver (hepatomegaly) and lymph nodes also may show extramedullary hematopoiesis.
- **Hemosiderosis:** Although blood transfusions improve the anemia but iron overload will lead to hemosiderosis and secondary hemochromatosis. This may be due to increased gastrointestinal absorption of iron. It damages organs like heart, liver and pancreas.
  - Cardiac hemosiderosis results in arrhythmias, heart blocks and congestive heart failure.
  - Hepatic hemosiderosis results in cirrhosis
  - Pancreatic hemosiderosis results in diabetes.
  - Pituitary: Leads to hypogonadotropic hypogonadism.
- Treated patients can survive beyond 40 years of age.

**Fig. 8.23:** Chipmunk facies in thalassemia.

## Investigations

- **Peripheral smear (Fig. 8.25):** Marked **microcytic hypochromic anemia** with moderate to marked anisocytosis and poikilocytosis. Many **target cells** (hemoglobin collects in the center of RBCs) and nucleated red cells.
- **HbF level is increased** (30–92%) on hemoglobin electrophoresis.
- **Markedly reduced or absent hemoglobin A** (HbA).
- Osmotic fragility test shows increased resistance to hemolysis.
- Skull radiograph shows a **‘hair on end’/crew cut appearance**.
- Evidence of thalassemia minor in both parents.
- **Red cell distribution width (RDW)** within normal limits (in contrast to iron deficiency anemia).

## Management

- **Aims of treatment:** To suppress ineffective erythropoiesis, prevent deformities of bone and allow normal activity and development. Blood transfusions may be required every 4–6 weeks. **Hyper transfusion** to maintain Hb level between 10–12 g/dL is probably adequate. It decreases the effect of chronic anemia and prevents abnormal growth and development. **Super-transfusion** wherein Hb level is maintained at 12 g/dL is designed to completely suppress hematopoiesis.
- **Maintenance of Hb level:** Long-term folic acid supplement and regular blood transfusions to

keep the Hb >10 g/dL.

- **Treatment of iron overload:** The iron-chelating agent, **desferrioxamine** (administered parenterally) is indicated if serum ferritin >1500 µg/L. Ascorbic acid 200 mg daily along with desferrioxamine increases the urinary excretion of iron in response to desferrioxamine. Deferiprone and deferasirox are oral iron chelators.
- **Splenectomy** is indicated in children with massive symptomatic splenomegaly and those with progressively increasing requirement of blood transfusion or hypersplenism.
- **Bone marrow transplantation** in young patients.
- **Management of associated complications:** For example, congestive heart failure and endocrinopathies.

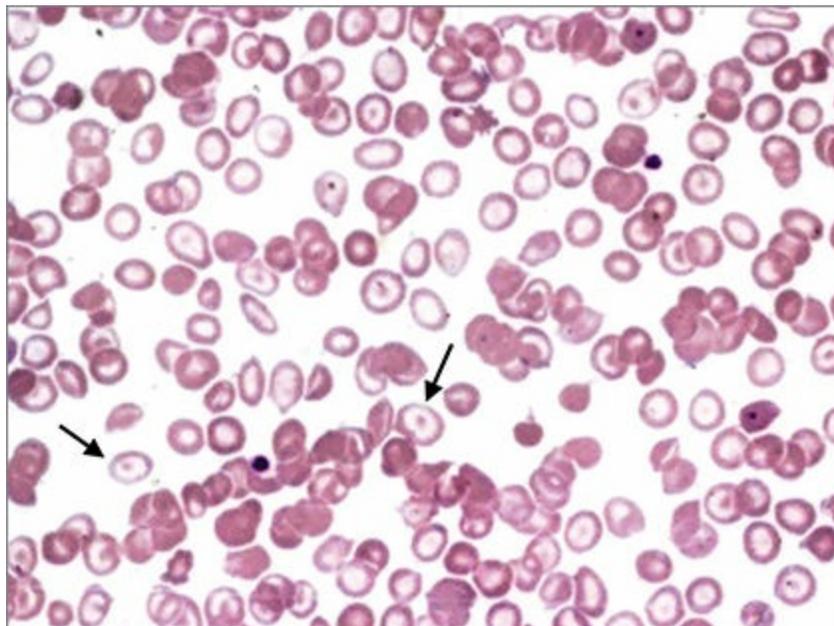

## β-Thalassemia Minor (Trait)

**Q. Write short essay/note on thalassemia minor (trait) and thalassemia intermedia.**

- β-thalassemia minor is more common than β-thalassemia major.
- It is a common carrier (heterozygous) state and is usually **asymptomatic**.
- Anemia is mild or absent.
- **Peripheral blood smear** shows severe microcytic and hypochromic red cells with target cells. It may be confused with iron deficiency.
- Serum ferritin and the iron stores are normal.
- **Hb electrophoresis** usually shows a raised HbA<sub>2</sub> (3.5–7.5%) and often a raised HbF.
- Iron should not be given to these patients unless there is associated iron deficiency.
- **Genetic counseling** to prevent transmission of carrier state from both parents.
- **Prenatal diagnosis** by chorionic villi biopsy at 11 weeks.
- It may be associated with other hemoglobin abnormalities. Examples, HbS/β-thalassemia, HbC/β-thalassemia, HbE/β-thalassemia.

**Fig. 8.24:** Skull X-ray showing crew-cut appearance due to new bone formation.

**Fig. 8.25:** Peripheral blood smear in  $\beta$ -thalassemia showing target cell (arrows).

## **$\beta$ -Thalassemia Intermedia**

- Clinical entity in which patients have a clinical spectrum intermediate between thalassemia trait and thalassemia major.

- Patients are anemic and generally have mild to moderate anemia (Hb 7–9 g/dL).
- Not transfusion dependent.
- Mild splenomegaly, bone deformities, gallstones and chronic leg ulcers may be seen.
- Folic acid supplementation should be given.

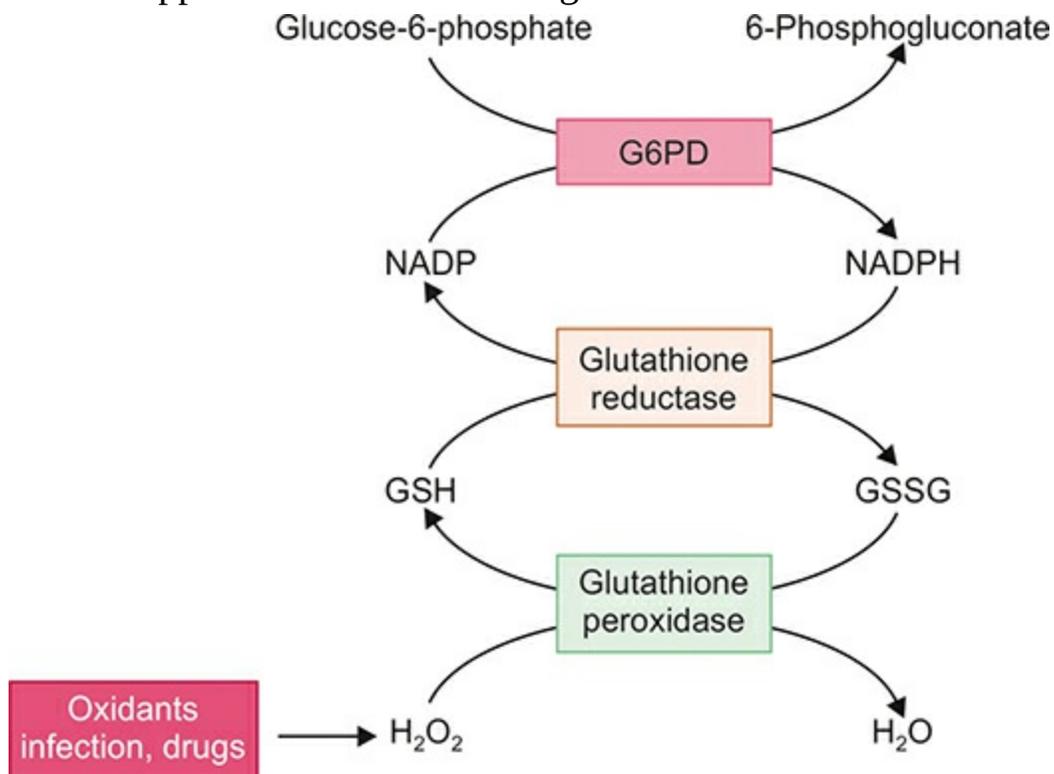

Fig. 8.26: Role of G6PD against injury by oxidants.

## GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY

**Q. Discuss the etiology, precipitating causes, clinical features, investigations and management of glucose-6-phosphate dehydrogenase (G6PD) deficiency.**

- Glucose-6-phosphate dehydrogenase (G6PD) is the initial and rate-limiting step in the hexose monophosphate (HMP) shunt of the Embden-Meyerhof pathway.
- G6PD is the only source of NADPH and NADPH is required for the

generation of glutathione (GSH), which protect red cells from oxidative stress (Fig. 8.26).

- G6PD-deficient patients may develop acute hemolytic anemia after exposure to any oxidative stress.
- G6PD deficiency is an X-linked disorder and is the most common enzyme deficiency.
- RBCs deficient in G6PD are unable to keep glutathione in reduced state. These RBCs are susceptible to injury by oxidants of both exogenous and endogenous origin.
- More than four hundred G6PD genetic variants are known, but most are harmless. The three common variants are:
  - **G6PD A:** The minus sign indicates absence of enzyme activity. Hemolysis develops when exposed to oxidant drugs (primaquine) or infections. The hemolysis is mild to moderate and is limited to the older RBCs.
  - **G6PD (B-) or G6PD Mediterranean/Wild type:** It is prevalent in the Middle East and is the severe form of deficiency. This is the most common variant seen in India. Other variants in India include G6PD Kerala-Kalyan, and G6PD Odisha.
  - **G6PD Canton** seen in Chinese.

## Clinical Features

- Most patients with G6PD deficiency remain clinically asymptomatic; however, all of them have an increased risk of developing clinically significant syndromes: (1) acute hemolytic anemia (AHA), (2) neonatal jaundice (NNJ), and rarely, (3) Chronic non-spherocytic hemolytic anemia (CNSHA).
- **Acute hemolytic anemia:** Due to intravascular hemolysis is the most dramatic clinical presentation of G6PD deficiency. It develops after exposure to an oxidative stress and the triggers include:
  1. **Drugs:** Antimalarials (primaquine, quinine, chloroquine), sulfonamides (sulfamethoxazole), antibacterial/antibiotics (cotrimoxazole, nitrofurantoin), antipyretics/analgesics (acetanilide phenazopyridine) dapsone, quinidine, methylene blue, nitrofurantoin, etc.
  2. **Fava beans.**
  3. **Infections:** Viral and bacterial.

The exposure to triggering agents produces hemolytic attack with rapid development of anemia and hemoglobinuria (cola colored urine). Rarely acute renal failure may develop. The onset can be extremely abrupt, especially following ingestion of the broad beans (**favism**) in children.

- **Neonatal jaundice** is a feature of Mediterranean type. Hemolytic anemia is very rarely severe. Jaundice may be due to decreased hepatic elimination of bilirubin. Severe neonatal jaundice if not adequately treated with phototherapy may result in kernicterus or even death.
- **Chronic nonspherocytic hemolytic anemia (CNSHA):** Develops in very small minority of patients. Such patient is always a male and usually has a history of severe neonatal jaundice, chronic anemia. The degree of chronic anemia is variable and some patients have may require intermittent transfusions. They have reticulocytosis, gallstones and splenomegaly. Hemolysis is mainly extravascular.

G6PD deficiency (African variety) has a protective effect against *Plasmodium falciparum*.

### Laboratory Findings (Investigations)

- **Evidence of intravascular hemolysis:** Raised unconjugated bilirubin, hemoglobinemia, hemoglobinuria, high LDH, and low or absent plasma haptoglobin.
- **Anemia:** Usually range from moderate to extremely severe. It is due to both intravascular and extravascular hemolysis.
- **Peripheral blood film:**
  - Normocytic and normochromic with anisocytosis, polychromasia (reticulocytosis), poikilocytes and spherocytes.
  - Bite (blister) cells are red cells in which parts of them appear bitten away.
  - Heinz bodies consist of membrane-bound precipitates of denatured hemoglobin (methemoglobin) and represents oxidative damage. They are seen as dark inclusions within red cells and can be demonstrated by supravital staining with methyl violet.
- **Confirmation of diagnosis:** By estimating G6PD activity of the red cell. This should be estimated several days after the acute hemolytic episode. This is because if done during or immediately after acute hemolysis may give a falsely normal value as the young red cells and reticulocytes have

near normal G6PD levels.

#### Treatment (management) of G6PD deficiency

- **Removal of the triggering agent** and avoiding its further exposure to triggering factors in previously screened patients. Once cause is recognized, in most cases no specific treatment is required. Management of neonatal jaundice is similar to any other cause of neonatal hyperbilirubinemia.
- Supportive therapy for anemia:
  - Blood transfusion
  - Regular folic acid supplements in CNSHA
- Treatment of infection and genetic counseling.

## MISCELLANEOUS ANEMIAS

**Q. Write short essay/note on the causes and management of normocytic anemia.**

### Normocytic Normochromic Anemia

Normocytic, normochromic anemia is characterized by normal size of the RBCs and normal MCV (Table 8.16).

**Table 8.16:** Various causes of normocytic, normochromic anemia.

<i>Decreased red cell production</i>	<i>Increased red cell loss or destruction</i>

**Management:** Treatment of the underlying disease.

## Differential Diagnosis of Hypochromic Microcytic Anemias (Table 8.17)

**Q. Write short note on causes of microcytic hypochromic anemia. How will you differentiate various causes of hypochromic microcytic anemias?**

**Table 8.17:** Various differentiating features of hypochromic microcytic anemias.

	<i>Iron deficiency anemia</i>	<i>Thalassemia trait</i>	<i>Anemia of chronic disease</i>	<i>Sideroblastic anemia</i>
MCV	Reduced	Very low for degree of anemia	Low normal or normal	Low in inherited type but often raised in acquired type
Serum iron (normal 60–170 µg/dL)	Reduced (<30 µg/dL)	Normal to high	Reduced (<50 µg/dL)	Raised
Serum TIBC (total iron binding capacity) (normal 300–350 µg/dL)	Raised (>350 µg/dL)	Normal	Reduced (<300 µg/dL)	Normal
Serum ferritin (normal 15–300 µg/dL)	Reduced (<15 µg/dL)	Normal (50–30 µg/dL)	Normal or raised (30–200 µg/L)	Raised
Serum soluble transferrin receptors	Increased	Normal or raised	Normal	Normal or raised
Iron in marrow	Absent	Present	Present	Present
Iron in erythroblasts	Absent	Present	Absent or reduced	Ring forms
Hemoglobin A <sub>2</sub> (normal <3%)	Reduced	Increased	Normal	Reduced
Red cell distribution width (RDW)	High	Normal	Normal	High

## Sideroblastic Anemias

**Q. Write short essay/note on sideroblastic anemias.**

## ***Definition***

Sideroblastic anemias are rare inherited or acquired disorders of refractory anemia, characterized by:

- A dimorphic peripheral blood picture. Microcytic hypochromic red cells in hereditary form and macrocytic in the acquired forms of the disease mixed with normochromic cells.
- Presence of **ring sideroblasts**, excess storage iron in the bone marrow and increased serum iron concentration. The diagnostic feature is the presence of ring sideroblasts in the bone marrow. The iron-laden mitochondria surround the nucleus of erythroblasts and appear as the pathognomonic ‘rings’ of iron granules with Prussian blue staining (Perls’ reaction).
- Tiny iron-containing inclusions called as Pappenheimer bodies in the red blood cells (stain positively by Prussian blue staining).
- Ineffective erythroid hyperplasia due to non-viable sideroblasts.

## ***Classification of Sideroblastic Anemia (Box 8.7)***

### **Treatment**

- Withdrawal of causative agent: Some patients respond when the drugs, toxins or alcohol are withdrawn.
- Occasional cases may respond to pyridoxine or folic acid.
- Supportive treatment with transfusions.
- Erythropoietin.

Microcytosis is often seen in hereditary forms, but normochromic, normocytic or even macrocytic RBCs may be seen, especially in the setting of myelodysplasia or in a rare X-linked hereditary form known as Pearson’s syndrome.

### **Box 8.7:** Classification of sideroblastic anemia.

#### **Inherited sideroblastic anemia**

- X-linked disease—transmitted by females

#### **Acquired sideroblastic anemia**

- Primary: Myelodysplasia
- Secondary
  - Drugs, e.g. isoniazid, cycloserine, chloramphenicol, busulfan, D-penicillamine
  - Alcohol abuse
  - Lead toxicity
  - Myeloproliferative neoplasms

- Myeloid leukemia
  - Primary pyridoxine deficiency
  - Others (e.g. rheumatoid arthritis, carcinoma)
-

## ***Hereditary Sideroblastic Anemias***

Hereditary sideroblastic anemias comprise a clinically, genetically and hematologically heterogeneous group of rare disorders. It may be inherited as X-linked or an autosomal (dominant or recessive) disorder. These patients generally have low levels of  $\delta$ -aminolevulinic acid synthase (ALAS) enzyme in the normoblasts leading to defective synthesis of hemoglobin.

## **Paroxysmal Nocturnal Hemoglobinuria**

**Q. Write short essay/note on paroxysmal nocturnal hemoglobinuria (PNH).**

Paroxysmal nocturnal hemoglobinuria (PNH) is a rare **acquired non-malignant, genetic defect due to mutation in the hematopoietic stem cell**. These **clone of red cells are particularly sensitive to destruction by activated complement**. Platelets and granulocytes are also affected and there may be thrombocytopenia and neutropenia.

### ***Etiology and Pathogenesis***

The stem cells and their progeny have **deficient synthesis of glycosylphosphatidylinositol (GPI) linked proteins** namely (1) decay-accelerating factor or CD55, (2) membrane inhibitor of reactive lysis or CD59. This is most important and a potent inhibitor of C3 and prevents activation of the alternative complement pathway on their membrane. In PNH, the red cells are abnormally sensitive to complement-mediated intravascular hemolysis. Severity of hemolysis is proportional to the number of these abnormal red cells. The molecular basis of PNH is the mutations in the *pig-A* (phosphatidylinositol glycan protein A) gene responsible for synthesis of the GPI anchor.

### ***Clinical Features***

- Mainly seen in adults, usually in middle age.
- Both sexes equally affected.
- **Intravascular hemolysis:** Characteristically, only the urine voided at night (nocturnal) and in the morning on waking is dark in color. The hemolysis is due to reduced pH of blood during sleep which enhances the activity of complement. Hemoglobin in acidic urine is converted into acid

hematin which colors the urine dark brown. Urinary iron loss may be sufficient to cause iron deficiency. Other features include: abdominal pain/dysphagia, erectile dysfunction, pulmonary hypertension and renal insufficiency.

- Mild jaundice and mild hepatosplenomegaly often present.
- **Thrombosis:** Very common involving the hepatic (Budd-Chiari syndrome), portal or cerebral veins is often the leading cause of death.
- May begin or progress to aplastic anemia.

## **Diagnosis**

- **Peripheral smear:** Anemia, reticulocytosis, varying degrees of thrombocytopenia and leukopenia (pancytopenia).
- Features of **intravascular hemolysis** like raised bilirubin, hemoglobinemia, hemoglobinuria and hemosiderinuria are present.
- **Bone marrow** is sometimes hypoplastic (or even aplastic) despite hemolysis.
- Diagnosis is confirmed by Ham's test and sucrose lysis test. These tests cannot reliably detect small populations of affected red cells.
  - **Ham's acidified serum test:** Checks whether red blood cells become more fragile when they are placed in mild acid. Ham test can also be positive in congenital dyserythropoietic anemia.
  - **Sucrose hemolysis test:** PNH patient's red cell undergoes lysis when incubated low-tonic-strength solution of sugar sucrose. It can be positive in megaloblastic anemia and autoimmune hemolytic anemia.
- **Flow cytometry:** Detects red cells that are deficient in **GPI-linked proteins (CD55 and CD59)**. It is a rapid and sensitive test for diagnosis.
- **NAP score:** Neutrophil alkaline phosphatase (NAP) score is reduced (normal 40 to 100), because NAP is a GPI linked protein.

## **Treatment**

- Supportive measures: Blood transfusions (for patients with severe anemia) and control of infections.
- Iron therapy often necessary due to loss in urine.
- **Anti-complement therapy: Eculizumab** is a humanized monoclonal antibody that prevents the cleavage of C5 (thereby the formation of the membrane attack complex) and reduces intravascular hemolysis, hemoglobinuria and the need for transfusion.
- Long-term anticoagulants may be necessary for patients with recurrent thrombotic episodes.

- Steroids may be useful in some cases.
- Bone marrow (stem cell) transplantation is curative.

- **Progress:** PNH patients are also at increased risk for developing aplastic anemia or acute myelogenous leukemia or a myelodysplastic syndrome.

## Methemoglobinemia

### **Q. Write short essay/note on methemoglobinemia.**

- Normal oxygen transport depends on the maintenance of iron in hemoglobin in ferrous (reduced) form ( $\text{Fe}^{++}$ ).
- **Methemoglobin (Hi)** is a hemoglobin in which the iron is in oxidized ferric form and unable to combine with oxygen. Normal RBCs contain less than 1% methemoglobin. Increased amount of methemoglobin in the RBCs is called methemoglobinemia.
- Clinically, when methemoglobin level is more than 1.5 g/dL, the patient develops cyanosis. At higher levels, it produces headache, weakness and breathlessness. At higher methemoglobin levels, respiratory depression, altered sensorium, coma, shock, seizures, and death may occur.

### ***Causes of Methemoglobinemia***

- Hereditary: Deficiency of methemoglobin reductase, cytochrome B5 reductase deficiency.
- Acquired: Exposure to certain drugs and toxins (e.g. nitrites and nitrates, nitofurantoin, chloroquine, naphthalene, local aneshthetics (procaine, lidocaine), primaquine, dapson, sulfa drugs phenacetin, phenazopyridine, metoclopramide, nitroglycerine), copper sulfate.

#### **Treatment**

- Methemoglobin reductase deficiency: Oral methylene blue or ascorbic acid.
- Severe methemoglobinemia: Intravenous methylene blue. Ensure adequate tissue oxygenation.

## Autoimmune Hemolytic Anemia (AIHA)

Autoimmune hemolytic anemias are a group of acquired disorders resulting from increased red cell destruction due to red cell autoantibodies.

### **Q. Write short essay/note on autoimmune hemolytic anemias.**

## ***Classification of Autoimmune Hemolytic Anemia***

It may be classified based on:

1. Type of antibody: Interaction of the autoantibody with the red cell antigen is dependent on the temperature, i.e. warm or cold type (Box 8.8).
2. Etiology (Box 8.9).

**Box 8.8:** Classification of autoimmune hemolytic anemia according to type of antibody.

Based on antibody type

- **Warm antibody type (IgG antibodies active at 37 °C)**
  - Primary (Idiopathic)
  - Secondary
    - ◆ Autoimmune disorders (systemic lupus erythematosus others)
    - ◆ Drugs (e.g. methyl dopa, penicillins, quinidine)
    - ◆ Lymphomas, Hodgkin's lymphoma, Chronic lymphatic leukemia
- **Cold agglutinin type (IgM antibodies active at 4–18 °C)**
  - Acute
    - ◆ Mycoplasmal infection
    - ◆ Infectious mononucleosis
  - Chronic
    - ◆ Idiopathic
    - ◆ Lymphomas
- **Cold hemolysin type (Donath-Landsteiner antibodies)** Rare; seen mainly in children; usually postviral

**Box 8.9:** Classification of autoimmune hemolytic anemia based on etiology.

- Idiopathic acquired hemolytic anemia (50%)
- Secondary acquired hemolytic anemia (50%)
  - Drugs: For example, methyl dopa, penicillins, quinidine
  - Mycoplasmal infection
  - Infectious mononucleosis
  - Autoimmune disorders (systemic lupus erythematosus others)
  - Lymphomas

## ***Warm Antibody Immuno-hemolytic Anemia***

- Warm antibody type is the most common type (50–70%).
- The antibodies are mainly of **IgG** type. The antibodies combine with red cell antigen at 37°C and hence known as **warm antibody**.

### *Clinical features*

- They may occur at all ages and in both sexes, although most frequent in middle-aged females.
- They may present with anemia, jaundice, hepatosplenomegaly and manifestations and underlying disease.
- Exclude underlying systemic lupus erythematosus, lymphoma and leukemia.

### *Investigations*

- Evidence of hemolytic anemia
- Spherocytosis (due to red cell damage) and macrocytes in peripheral blood.
- Direct antiglobulin (Coombs) test is positive.
- Autoantibodies may have specificity for the Rh blood group system (e.g. for the e antigen).
- In some cases, **autoimmune thrombocytopenia** and/or neutropenia may also be present (Evans' syndrome).

*Antiglobulin (Coombs) test (Fig. 8.27)*

**Q. Write short essay/note on significance of Coombs test.**

There are two types namely direct and indirect.

**Q. Write short note on Coombs test.**

1. **Direct (Coombs) antiglobulin test (DAT)** detects the immunoglobulin (IgG) antibody and/or C3 complement (usually C3d) on patient's RBCs. **Patient's red cells** are washed and suspended in saline. Antiglobulin serum is added. Agglutination of red cells indicates the presence of antibody on the surface of RBCs and interpreted as positive DAT.
2. **Indirect (Coombs) antiglobulin test (IAT)** detects the immunoglobulin (IgG) antibody or C3 complement (usually C3d) in the patient's serum. **0 Rh +ve normal red cells and antiglobulin serum is added to the patient's serum.** Agglutination of RBCs indicates the presence of antibodies in the patient's serum and test is reported as positive for indirect antiglobulin test.

### **Treatment**

- **Corticosteroids** (e.g. prednisolone in doses of 1 mg/kg daily) are effective in about 80% of patients. Initially for first 2–4 weeks, prednisolone 60 mg daily, followed by gradual tapering of the dose. When a dose of 20 to 30 mg daily achieves a persistent remission (indicated by the stable Hb level and decreasing reticulocyte count), it is recommended to give prednisone on alternate day. Patients with rapid hemolysis may require intravenous methylprednisolone at a dose of 250–1000 mg/day for 1 to 3 days.
- **Avoid blood transfusion** as far as possible, because autoantibodies may cause difficulty in cross-matching the blood.

- Danazol can be used in along with prednisone as first line therapy allowing for a shorter duration of prednisone therapy.
- **Splenectomy** may be necessary.
  - If there is no response to corticosteroids
  - If the remission is not maintained when the dose of prednisolone is reduced
  - Require the equivalent of more than 10–15 mg prednisone per day to maintain an acceptable hemoglobin level.
- **Intravenous immunoglobulin** may also be used as a temporary measure before performing splenectomy for patients refractory to conventional therapy with corticosteroids.
- **Rituximab** is a monoclonal antibody directed against the CD20 antigen expressed on B lymphocytes.
  - **Use:** Useful in refractory cases and also in secondary type of warm AIHA.
  - **Adverse effects:** Hypotension, fever, chills, rigors, hypertension, bronchospasm, pulmonary infiltrates, acute respiratory distress syndrome, myocardial infarction, cardiogenic shock.
  - **Contraindication:** Untreated hepatitis B infection.
- **Other immunosuppressive drugs** (e.g. azathioprine, cyclophosphamide and cyclosporine) may be effective when there is no response to steroids, rituximab and splenectomy.

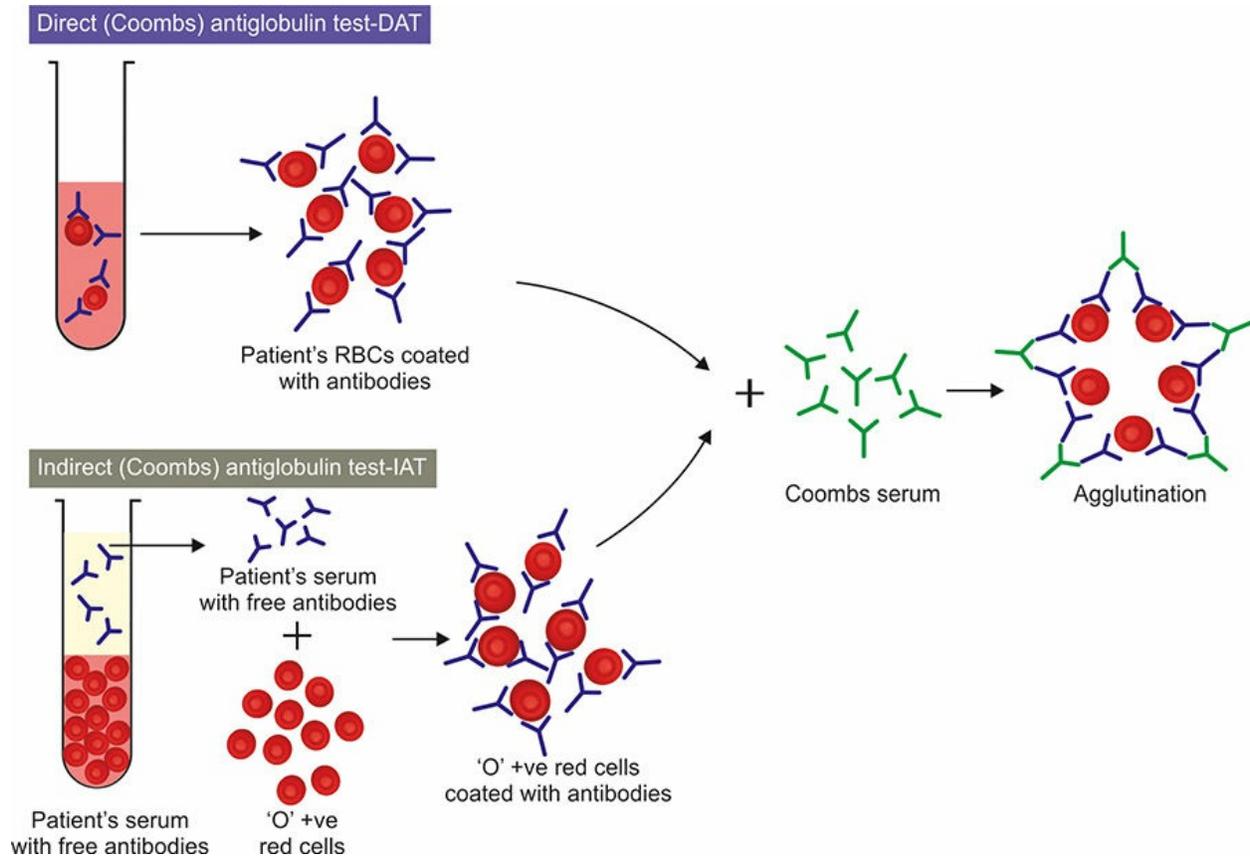

## ***Cold Agglutinin Autoimmune Hemolytic Anemia***

### **Q. Discuss cold hemagglutinin disease (CHAD) in brief.**

- It is less common than the warm antibody type is caused by so-called **cold agglutinins**.
- These antibodies bind to red cell antigens at low temperatures (4–18 °C), i.e. avidity of red cell to antibody increases as the temperature falls.
- The antibodies are of IgM type.
- Clinically, it presents acrocyanosis (i.e. blue color of the fingertips, toes, nose and ear lobes) after exposure to cold. Patients are advised to avoid exposure to cold.

### *Investigations*

- **Red cells** agglutinate in the cold or at room temperature.
- **Direct antiglobulin test** is positive with complement alone.
- **Monoclonal IgM antibodies.**

**Fig. 8.27:** Method of direct and indirect methods of antiglobulin test (Coombs test).

**Treatment:** Rituximab (anti-CD20) is successful in some cases. It does not respond to steroids alkylating agents and splenectomy.

## ***Paroxysmal Cold Hemoglobinuria***

### **Q. Write short essay/note on paroxysmal cold hemoglobinuria (PCH).**

- Paroxysmal cold hemoglobinuria (PCH) is a rare condition often follows common childhood viral infections (e.g. measles, mumps and chickenpox).
- The autoantibodies are IgG type and bind to red cells at low temperatures and fix the complement. These are autoantibodies directed against the P antigen system on red cells.
- Since complement cascade functions more efficiently at 37°C, upon warming, complement gets activated resulting in intravascular hemolysis and hemoglobinuria.
- **Donath-Landsteiner test:** Hemolysis is demonstrated in vitro by

incubating the patient's red cells and serum at 4°C and then warming it to 37°C.

- Hemolysis is usually transient and found mostly in children. Supportive transfusions of warmed blood may be required.
- DAT is usually negative.

## Anemias Due to Blood Loss

**Q. Write short essay/note on anemias due to blood loss.**

Anemias due to blood loss can be acute or chronic. Blood loss causes anemia by two main mechanisms:

1. By the direct loss of RBCs.
2. Continuous blood loss gradually depletes the iron stores resulting in iron deficiency.

### *Anemias Due to Acute Blood Loss*

A healthy adult can lose about 500 mL of whole blood without any untoward effect (e.g. blood donation). Acute blood loss (hemorrhage) causes loss of intravascular volume over a short period and if massive can lead to hypovolemic shock and death. The clinical features of acute blood loss anemia depend on:

- Rate of hemorrhage
- Nature of the bleeding (external or internal).

#### *Clinical features*

After the sudden loss of a large volume of blood over short period—three clinical/pathophysiologic stages can be identified.

- Stage 1: The dominant feature is hypovolemia during which the patient appears pale, cold and sweating. The pulse rate is raised and blood pressure is maintained. Earliest signs especially with internal bleeding are postural hypotension and tachycardia. An ordinary blood count will not show anemia because the hemoglobin concentration is not affected.
- Stage 2: During this stage, the body will shift fluid from the extravascular to the intravascular compartment, producing hemodilution. Thus, the hypovolemia gradually converts to anemia. Anemia appears in 24–36 hours.

- Stage 3:
  - If bleeding stops, anemia gets corrected in a few weeks, provided body iron supply is normal.
  - If bleeding continues, compensatory mechanisms fail and hypovolemic shock develops and results in death.

### *Investigations*

- Hemoglobin and hematocrit:
  - Normal in early stages (before hemodilution)
  - Reduced in 24–36 hours due to hemodilution
- Peripheral smear shows normocytic normochromic anemia and polychromasia (due to increased reticulocytes). A transient leukoerythroblastic blood picture may be seen in very early stages.

**Treatment:** Replacement of blood loss by transfusion of whole blood or packed red cells.

## ***Anemia of Chronic Blood Loss***

In chronic blood loss, compensatory mechanisms replenish the plasma volume and red cell loss. It produces anemia when the rate of blood loss exceeds the regenerative capacity of the bone marrow or when iron reserves are depleted and results in iron deficiency anemia.

## **Anemia of Chronic Disease**

**Q. Write short essay/note on anemia of chronic disease.**

One of the most common types of anemia in developing countries, occurring in patients with chronic infections (also known as anemia of inflammation).

### ***Causes***

It occurs in a wide variety of chronic diseases.

- **Chronic infections:** Infective endocarditis, tuberculosis, osteomyelitis
- **Chronic immune disorders:** Crohn's disease, rheumatoid arthritis, systemic lupus erythematosus (SLE)
- **Associated with malignant tumors** (e.g. carcinoma of lung and breast).

Term anemia of chronic disease is not usually applied to anemias associated with renal, hepatic or endocrine disorders.

## ***Pathogenesis***

- **Impaired iron utilization:** Chronic inflammatory diseases activate macrophages to secrete cytokines like interleukin-6 (IL-6) and tumor necrosis factor (TNF). There is decreased transfer of iron from the storage pool to bone erythroid precursors.
- **Decreased erythropoietin (EPO) production and response:** Resulting in inadequate proliferation of progenitors.
- **Decreased RBC survival** is due to extracorporeal defect.

## ***Investigations***

- Peripheral smear mainly shows normocytic normochromic red cells.
- **Increased storage iron** in the marrow and revealed by Prussian blue staining.
- **Raised serum ferritin** because of the inflammatory process.
- **Reduced total iron-binding capacity (TIBC).**
- **Reduced serum iron.**
- Reduced transferrin levels.
- Normal serum soluble transferrin receptor level.

### **Management**

- Treat the underlying disorder.
- Recombinant erythropoietin therapy may be tried if the anemia is not corrected after treatment of the underlying disorder.

## **Aplastic Anemia**

**Q. Define aplastic anemia. Discuss the etiology/causes, clinical features, investigations and management of aplastic anemia.**

### ***Definition***

Aplastic anemia is characterized by pancytopenia (anemia, neutropenia and thrombocytopenia) with hypocellular (aplasia) bone marrow (less than 30% cellularity), and there are no leukemic or other abnormal cells in the peripheral blood or bone marrow.

### ***Causes (Table 8.18)***

## ***Clinical Features***

Insidious in onset and initial presenting feature depends on which cell line is predominantly affected.

- **Anemia:** Causes progressive weakness, lassitude, fatigability, pallor and dyspnea.
- **Neutropenia:** Presents as frequent infections (mucocutaneous bacterial) or fatal infections. These include sore throat, oral and pharyngeal ulcers, fever with chills and sweating, chronic skin infections, recurrent respiratory infections, pneumonia and septicemia.
- **Thrombocytopenia:** Results in bleeding manifestations in the form of petechiae, bruises and ecchymoses. These include: bleeding into skin (ecchymoses, petechiae), epistaxis, menorrhagia, bleeding from gums and GI tract, retinal hemorrhage and cerebral hemorrhage. Bleeding is often the predominant initial presentation with bruising, with minimal trauma or blood blisters in the mouth.

**Physical findings:** Include ecchymoses, bleeding gums and epistaxis. Mouth infections are common. Lymphadenopathy and **hepatosplenomegaly** are **rare**. In the presence of splenomegaly, the diagnosis of aplastic anemia should not be made.

- Aplastic anemia may coexist or progress to clonal disorders, such as paroxysmal nocturnal hemoglobinuria (PNH), myelodysplastic syndrome (MDS) or acute myeloid leukemia.

## ***Fanconi's Anemia***

- Fanconi's anemia is inherited as an autosomal recessive disorder
- It is associated with skeletal (short stature), renal (ectopic kidney, horseshoe kidney) and central nervous system (hydrocephalus) abnormalities. It usually presents between 5 to 10 years of age. Progressive pancytopenia. Predisposition to hematologic malignancies (MDS < acute myeloid leukemia) and solid tumors (squamous cell carcinomas of head and neck and anogenital region).

## ***Investigations***

Diagnosis is made with: (1) pancytopenia, (2) absence of reticulocytes and (3) hypocellular or aplastic bone marrow with increased fat spaces.

- **Hemoglobin is decreased.**
- **PCV decreased.**
- **Reticulocytopenia** (varies from 0.5 to 1%) is a characteristic feature.
- **Peripheral blood** shows pancytopenia
- **Bone marrow study:** Marked hypocellularity with replacement of more than 70% of the marrow cells by fat. Hematopoiesis: Paucity of all erythroid, myeloid and megakaryocytic precursors. Initial stages may show focal areas of hematopoiesis. Lymphocytes and plasma cells are prominent. Bone marrow iron stores are usually increased.
- Serum iron and transferrin saturation: Increased
- Ferrokinetic studies: Delayed clearance of radioactive iron from the blood and increased uptake by the liver.

**Table 8.18:** Common causes of aplastic anemia.

<b><i>Inherited</i></b>	
Fanconi anemia	
Diamond-Blackfan anemia	
Telomerase defects	
<b><i>Acquired</i></b>	
<b>Idiopathic</b>	<b>6“I”s of aplastic anemia</b>
<ul style="list-style-type: none"> <li>• Acquired defects in stem cell</li> <li>• Immune mediated</li> </ul>	<ul style="list-style-type: none"> <li>• Idiopathic</li> <li>• Ingestion of drugs and chemicals</li> <li>• Idiosyncratic</li> <li>• Irradiation</li> <li>• Infections</li> <li>• Inherited</li> </ul>
<b>Secondary</b>	
<ul style="list-style-type: none"> <li>• <b>Chemical agents</b> <ul style="list-style-type: none"> <li>– Dose related <ul style="list-style-type: none"> <li>◆ Cytotoxic drugs (alkylating agents, antimetabolites)</li> <li>◆ Benzene</li> <li>◆ Inorganic arsenicals</li> <li>◆ Chloramphenicol</li> </ul> </li> </ul> </li> </ul>	
<ul style="list-style-type: none"> <li>• <b>Idiosyncratic</b> <ul style="list-style-type: none"> <li>– Chloramphenicol</li> <li>– Phenylbutazone</li> <li>– Penicillamine</li> <li>– Carbamazepine</li> <li>– Gold salts</li> <li>– Organic arsenicals</li> <li>– Methylphenylethylhydantoin</li> </ul> </li> </ul>	

- **Physical agents: Whole-body irradiation**
- **Viral infections**
  - Hepatitis (unknown type)
  - Epstein-Barr virus infections
  - Cytomegalovirus infections
  - Herpes zoster (Varicella zoster)
  - HIV

### *Severe aplastic anemia*

Presence of two of the following four features is needed to diagnose severe aplasia (1) neutrophil count of  $<0.5 \times 10^9/L$ , (2) platelet count of  $< 20 \times 10^9/L$ , (3) reticulocyte count of  $< 40 \times 10^9/L$ , 4) marrow cellularity  $<25\%$ .

#### **Treatment/Management**

**Removal of the causative factor/agent** wherever possible (refer causes of aplastic anemia in Table 8.18).

**Providing supportive care** while awaiting bone marrow recovery:

- Prevention and treatment of infections
- Treatment of hemorrhage
- Treatment of anemia by red cell transfusion
- **Growth factors:** Granulocyte colony-stimulating factor (G-CSF), Thrombopoietin (TPO) receptor agonists

#### **Severe aplastic anemia**

- **Bone marrow (stem cell) transplantation** is the treatment of choice for patients under 40 years of age who have an HLA-identical sibling donor. Patients over the age of 40 have high risk of graft-versus-host disease.
- **Immunosuppressive therapy** is used for patients without HLA-matched siblings and those above 40 years of age.
  - Eltrombopag, horse ATG, cyclosporine, and prednisone in combination produces hematological response rate of 60–80%. These agents destroy activated suppressor cells.
  - Androgens (e.g. oxymetholone) are sometimes useful in patients not responding to immunosuppression and those with moderately severe aplastic anemia.
  - Steroids have little role in severe aplastic anemia but are useful for serum sickness induced by ALG. However, steroids used in children with congenital pure red cell aplasia (Diamond-Blackfan syndrome) and in some adults with pure red cell aplasia associated with a thymoma.
  - Anti-IL-2 receptor antibody (daclizumab) and arsenic trioxide (ATO) plus cyclosporine have been tried.

**Acquired PRCA** may develop for unknown reasons, but more commonly it develops in association with specific types of malignancy, infection or drugs. Most commonly, acquired PRCA develops as a complication of a neoplastic process such as a thymoma B- or T-cell chronic lymphocytic leukemia, non-

Hodgkin's lymphoma or an autoimmune disorder such as rheumatoid arthritis or SLE.

Investigation of a case of anemia is presented in **Flowchart 8.1**.

## Pancytopenia

**Q. Write short essay/note on the causes of pancytopenia.**

Definition: Combination of anemia, leukopenia and thrombocytopenia.

**Causes of Pancytopenia (Table 8.19).**

**Table 8.19:** Causes of pancytopenia.

## DISORDERS OF WHITE BLOOD CELL

### NON-NEOPLASTIC DISORDERS OF WBC

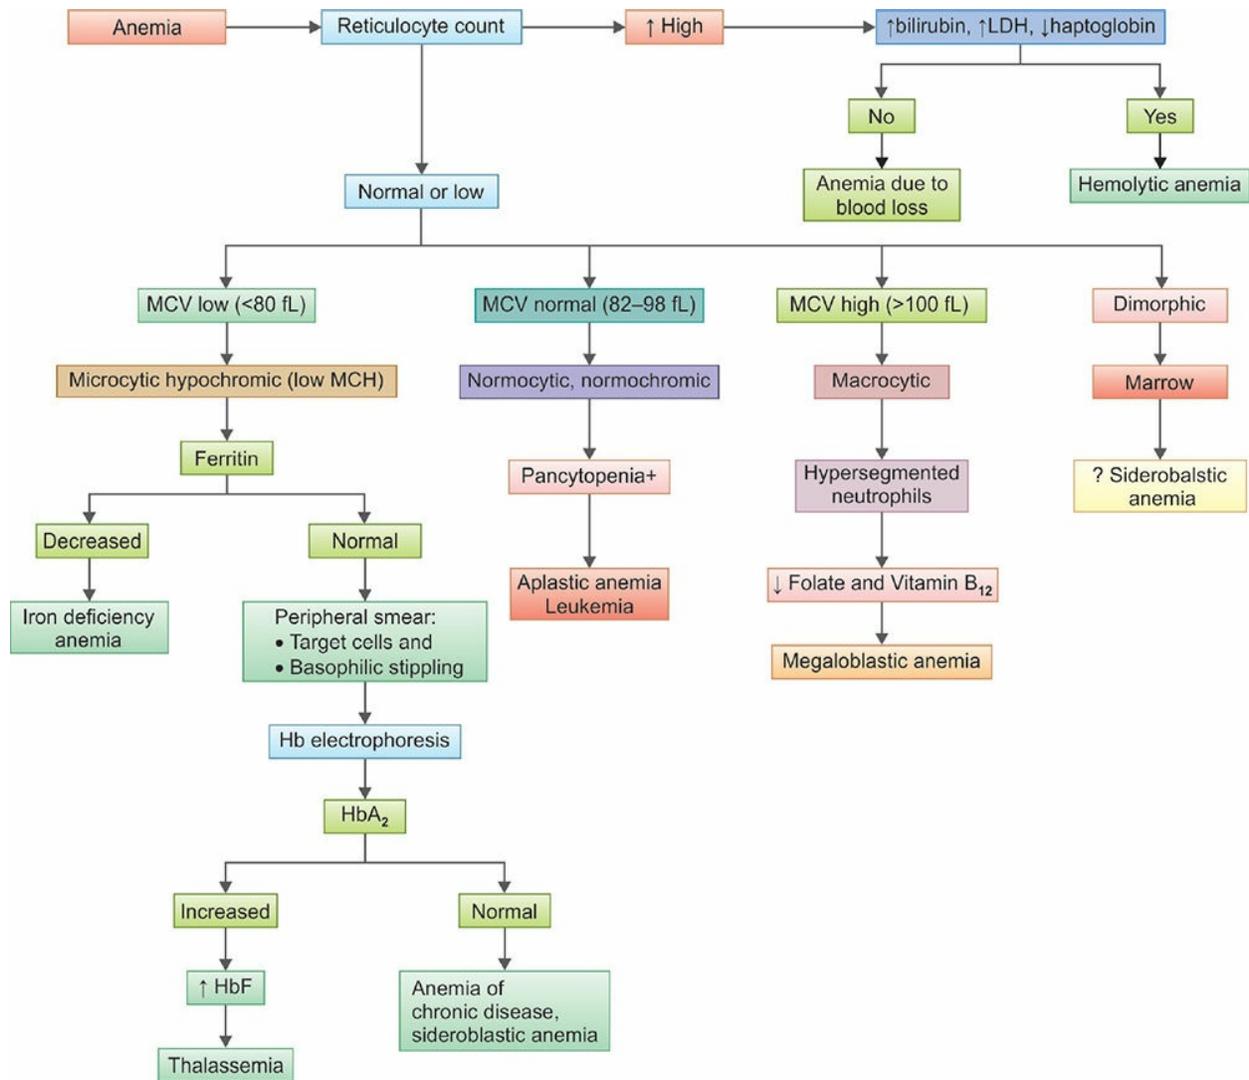

#### Leukocytosis

**Q. Write short note on leukocytosis.**

An increase in the **total** number of **leukocytes** in the blood **more than 11,000/cu mm** ( $11 \times 10^9/L$ ). Usually due to increase in the neutrophils, but may also be due to increased lymphocytes (or rarely monocytes and eosinophils).

**Causes:** Common causes of leukocytosis are shown in Box 8.10.

**Flowchart 8.1:** Investigation of a case of anemia.

## Leukopenia

**Total leukocyte count is less than 4,000/cu mm ( $4 \times 10^9/L$ ).**

**Causes:** Common causes of leukopenia are shown in Box 8.11.

## Neutrophilia

**An absolute neutrophil count of more than 8000/cu mm ( $8 \times 10^9/L$ ).** Differential count shows more than 70% neutrophils and is usually accompanied by leukocytosis ( $15$  to  $30 \times 10^9/L$ ).

**Causes of neutrophilia:** Major causes of neutrophilia are shown in Box 8.12.

**Box 8.10:** Common causes of leukocytosis.

- Infections
  - Bacterial

- Viral infections (e.g. infectious mononucleosis)
- Leukemia
  - Acute
  - Chronic: Chronic lymphocytic leukemia and chronic myeloid leukemia
- Leukemoid reactions
- Physiological
  - Pregnancy
  - Exercise

### Box 8.11: Common causes of leukopenia.

- Typhoid and paratyphoid
- Anemia
  - Aplastic anemia
  - Megaloblastic anemia
- Hypersplenism
- Drugs including cytotoxic drugs
- Radiation
- Rarely leukemia

### Box 8.12: Major causes of neutrophilia.

#### Pathological:

- Acute bacterial and fungal infections:
  - Localized: Pyogenic microorganisms causing infections, e.g. pneumonias, pyogenic meningitis, cellulitis, diphtheria, abscess, tonsillitis, etc.
  - Generalized: Septicemia, acute rheumatic fever
- Acute inflammatory processes: Inflammatory conditions (acute appendicitis), vasculitis
- Tissue necrosis: Burns, myocardial infarction, gangrene, neoplasms (tumor necrosis)
- Acute stress or hypoxic states: Following hemorrhage, hemolysis and surgery
- Myeloproliferative neoplasms: Chronic myeloid leukemia, polycythemia vera
- Metabolic: Uremia, acidosis, gout
- Miscellaneous: Eclampsia, steroid therapy

#### Physiological:

- Exercise (shift from marginating pool to circulating pool), newborns, extremes of temperature, pain, emotional stress and during obstetric labor

## Neutropenia and Agranulocytosis

**Q. Write short note on neutropenia/agranulocytosis and its causes. Mention the drugs that causes agranulocytosis.**

**Reduction in the absolute neutrophil count (total WBC × % segmented**

neutrophils and band forms) below  $1.5 \times 10^9/L$  (1500/cu mm). **Agranulocytosis** is the term used when neutrophil count decreases below  $0.5 \times 10^9/L$ . These patients are highly susceptible to bacterial and fungal infections.

## Etiology

The causes of neutropenia are presented in Table 8.20.

**Table 8.20: Causes of neutropenia.**

<p><b>1. Inadequate production:</b></p> <ul style="list-style-type: none"> <li>• <b>Suppression of stem cells:</b> In these disorders granulocytopenia represents a component of pancytopenia           <ul style="list-style-type: none"> <li>– Aplastic anemia</li> <li>– Marrow infiltration</li> <li>– Metastatic tumors</li> <li>– Granulomatous disorders</li> </ul> </li> </ul>	<p><b>2. Increased destruction of neutrophils:</b></p> <ul style="list-style-type: none"> <li>• <b>Immunologically mediated destruction</b> <ul style="list-style-type: none"> <li>– Idiopathic</li> <li>– Secondary               <ul style="list-style-type: none"> <li>◆ Drugs (Chemotherapeutic drugs, carbimazole, propylthiouracil, phenothiazines, antibiotics, naproxen)</li> <li>◆ Autoimmune disorders: For example, systemic lupus erythematosus</li> </ul> </li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>• <b>Suppression of committed granulocytic precursors</b> <ul style="list-style-type: none"> <li>– Drugs and chemicals (e.g. sulfonamides, analgesics, arsenicals)</li> <li>– Ionizing radiation</li> </ul> </li> <li>• <b>Diseases associated with ineffective hematopoiesis</b> <ul style="list-style-type: none"> <li>– Megaloblastic anemias: Vitamin B<sub>12</sub> or folate deficiency</li> <li>– Myelodysplastic syndromes</li> </ul> </li> <li>• <b>Congenital:</b> Kostmann syndrome (rare)</li> <li>• <b>Severe infections</b> <ul style="list-style-type: none"> <li>– Bacterial (e.g. typhoid, paratyphoid, septicemia)</li> <li>– Viral (e.g. influenza, infectious mononucleosis, hepatitis, measles)</li> <li>– Rickettsial (e.g. scrub typhus)</li> <li>– Protozoal (e.g. malaria, kala-azar)</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>Splenic sequestration</b> may be associated with pancytopenia.</li> </ul> <p><b>3. Shift from the circulating pool to marginating pool:</b> Hemodialysis and cardiopulmonary bypass</p> <p><b>4. Idiopathic:</b></p> <ul style="list-style-type: none"> <li>• Hodgkin and non-Hodgkin lymphoma</li> <li>• Chronic lymphocytic leukemia</li> <li>• Viral infections (HIV, hepatitis)</li> <li>• Cyclic neutropenia</li> </ul>

Treatment of neutropenia/agranulocytosis (refer page 1065).

## Eosinophilia

**Q. Define eosinophilia and mention the causes of eosinophilia.**

Eosinophilia is an absolute **eosinophil count of more than 450/cu mm** ( $0.45 \times 10^9/L$ ).

Causes of eosinophilia are presented in Table 8.21.

**Table 8.21: Causes of eosinophilia.**

<ul style="list-style-type: none"><li>• <b>Allergic/atopic conditions</b><ul style="list-style-type: none"><li>– Asthma</li><li>– Urticaria</li><li>– Hay fever</li><li>– Drug reactions</li><li>– Allergic rhinitis</li></ul></li></ul>	<ul style="list-style-type: none"><li>• <b>Hematological diseases</b><ul style="list-style-type: none"><li>– Chronic myeloid leukemia</li><li>– Polycythemia</li><li>– Hodgkin lymphoma</li><li>– Acute myelomonocytic leukemia</li><li>– Eosinophilic leukemia</li></ul></li></ul>
<ul style="list-style-type: none"><li>• <b>Parasitic/helminthic infestations (with tissue invasion)</b><ul style="list-style-type: none"><li>– Roundworm infestation</li><li>– Hookworm infestation</li><li>– Filariasis</li></ul></li><li>• <b>Fungal infections</b> (e.g. coccidioidomycosis)</li><li>• <b>Skin diseases</b><ul style="list-style-type: none"><li>– Dermatitis (eczema)</li><li>– Pemphigus</li><li>– Scabies</li><li>– Dermatitis herpetiformis</li></ul></li></ul>	<ul style="list-style-type: none"><li>• <b>Miscellaneous</b><ul style="list-style-type: none"><li>– Tropical eosinophilia</li><li>– Pulmonary eosinophilia</li><li>– <i>Löffler's syndrome</i></li><li>– Hypereosinophilic syndrome</li><li>– Eosinophilic granuloma</li><li>– Drugs: Sulfonamides, aspirin, penicillins, cephalosporins, allopurinol, carbamazepine</li></ul></li></ul>

## Lymphocytosis

**Q. Write short note on lymphocytosis and its causes.**

Lymphocyte count more than 4,000/cu mm ( $4 \times 10^9/L$ ) in adults and more than 8,000/cumm ( $8 \times 10^9/L$ ) in child.

Common causes of lymphocytosis are given in the Table 8.22.

**Table 8.22: Causes of lymphocytosis.**

<ol style="list-style-type: none"><li>1. <b>Acute infections</b><ul style="list-style-type: none"><li>• Viral infections</li><li>• Infectious mononucleosis, mumps, measles, chickenpox, infectious hepatitis</li></ul></li></ol>	<ol style="list-style-type: none"><li>3. <b>Hematologic malignancies</b><ul style="list-style-type: none"><li>• Acute lymphoblastic leukemia</li><li>• Chronic lymphocytic leukemia</li></ul></li></ol>
---	---

<ul style="list-style-type: none"> <li>• Toxoplasmosis</li> </ul>	<ul style="list-style-type: none"> <li>• Non-Hodgkin lymphoma with spill over</li> <li>• Adult T-cell leukemia/lymphoma</li> <li>• Hairy cell leukemia</li> </ul>
<p><b>2. Chronic infections/inflammatory diseases</b></p> <ul style="list-style-type: none"> <li>• Tuberculosis</li> <li>• Syphilis</li> <li>• Brucellosis</li> <li>• Inflammatory bowel disease: Crohn's disease and ulcerative colitis</li> </ul>	

## Basophils

Conditions associated with alterations in numbers of blood basophils are presented in Table 8.23.

**Table 8.23:** Conditions associated with alterations in numbers of blood basophils.

<p><b>1. Decreased Numbers (Basopenia)</b></p> <ul style="list-style-type: none"> <li>• Hereditary absence of basophils (very rare)</li> <li>• Elevated levels of glucocorticoids</li> <li>• Hyperthyroidism or treatment with thyroid hormones</li> </ul>	<ul style="list-style-type: none"> <li>• Ovulation</li> <li>• Hypersensitivity reactions</li> <li>• Leukocytosis (in association with diverse disorders)</li> </ul>
<p><b>2. Increased Numbers (Basophilia)</b></p> <ul style="list-style-type: none"> <li>• Allergy or inflammation <ul style="list-style-type: none"> <li>– Ulcerative colitis</li> <li>– Drug, food, inhalant hypersensitivity</li> <li>– Erythroderma, urticaria</li> <li>– Juvenile rheumatoid arthritis</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Endocrinopathy <ul style="list-style-type: none"> <li>– Diabetes mellitus</li> <li>– Estrogen administration</li> <li>– Hypothyroidism (myxedema)</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>• Infection <ul style="list-style-type: none"> <li>– Chicken pox</li> <li>– Influenza</li> <li>– Smallpox</li> <li>– Tuberculosis</li> </ul> </li> <li>• Iron deficiency</li> </ul>	<ul style="list-style-type: none"> <li>• Exposure to ionizing radiation</li> <li>• Neoplasia <ul style="list-style-type: none"> <li>– Basophilic leukemia</li> <li>– Myeloproliferative neoplasms (especially chronic myelogenous leukemia; also polycythemia vera, primary myelofibrosis, essential thrombocythemia)</li> <li>– Carcinoma</li> </ul> </li> </ul>

## ACUTE LEUKEMIAS

**Q. Define leukemia.**

## Definition

Leukemia is defined as a group of malignant stem cell neoplasms characterized by:

- Failure of cell maturation and proliferating of leukocyte precursors (blast/immature cells) which fill the bone marrow.
- Abnormal numbers and forms of immature white blood cells ultimately spill over into the peripheral blood.

## Classification of Leukemias

**Q. Write short essay/note on classification of leukemias.**

1. **General/traditional classification:** According to the light microscopic appearance of the cell and the speed of evolution (Table 8.24).
2. **Revised FAB classification of acute leukemias (Table 8.25).**
  - According to FAB, the marrow should show a blast count of 30% or more.
  - It includes parameters which affect namely morphology, cytochemistry, immunophenotyping, cytogenetics and molecular genetics.
3. **WHO classification (2016) of acute myeloid (Table 8.26) and lymphoid leukemia (Table 8.27).**
  - WHO classification of acute leukemia incorporates parameters namely morphology, cytochemistry, cytogenetic, molecular genetics (which are related to prognosis) and clinical features.
  - The number of blasts necessary for the diagnosis is more than 20% in bone marrow when compared to 30% in FAB classification.

**Table 8.24:** Traditional classification of leukemia.

<i>Acute</i>	<i>Chronic</i>
Acute myeloblastic/myelocytic leukemia (AML)	Chronic myeloid leukemia (CML)
Acute lymphoblastic/lymphocytic leukemia (ALL)	Chronic lymphocytic leukemia (CLL)

**Table 8.25:** Revised FAB classification of acute leukemias.

### *Type of AML*

M0: Minimally differentiated AML

M1: AML without differentiation

M2: AML with maturation

M3: Acute promyelocytic leukemia

M4: Acute myelomonocytic leukemia

M5: Acute monocytic leukemia

M6: Acute erythroleukemia (DiGugliemo's disease)

M7: Acute megakaryocytic leukemia

#### ***Type of ALL***

L1: Small cells with homogeneous nuclear chromatin and scanty cytoplasm

L2: Large, heterogeneous cells with variable amount of cytoplasm

L3: Large, homogeneous cells with prominent nucleoli, abundant, and deeply basophilic vacuolated cytoplasm

## **Etiology of Leukemias**

**Q. Discuss the etiology of leukemias.**

### ***Risk Factors***

In the majority of acute leukemias, the cause is not known. Numerous risk factors may cause mutations in the genes involved in regulating cell proliferation and differentiation. These genes include oncogenes and tumor suppressor genes. Sophisticated molecular techniques like fluorescent in situ hybridization (FISH) and gene array technology have led to the understanding of leukemia at molecular level.

#### ***Environmental factors***

- **Ionizing radiation:** Ionizing radiation and X-rays are associated with increased risk of leukemias. The evidence for this association are:
  - **Atomic bombing:** Survivors of atomic bomb explosions in Hiroshima and Nagasaki, who had high incidence of AML and CML (chronic myeloid leukemia).
  - **Therapeutic radiation:** Increased risk of AML (secondary leukemia) in patients with malignancies/neoplasms treated by radiation.
  - **X-ray exposure to fetus during pregnancy.**
- **Drugs:** Drugs can cause secondary hematopoietic neoplasms.
  - Secondary AML can develop after exposure to chemotherapy drugs.
  - Alkylating agents such as cyclophosphamide can lead to AML that

develops after a median duration of 5 to 7 years, is usually preceded by myelodysplastic syndrome and is associated with chromosome 5 or 7 abnormalities.

- Topoisomerase inhibitors such as anthracyclines lead to AML after a median duration of 1 to 3 years and is associated with MLL gene abnormalities.

- **Chemicals:**

- Benzene used in paint industry, plastic glues, etc. It causes chromosomal abnormalities resulting in higher incidence of acute leukemia, myelodysplastic syndrome and aplastic anemia.

- **Retroviruses:** HTLV-1 is associated with adult T-cell leukemia/lymphoma.

- **Immunological:** Immune deficiency states (e.g. hypogammaglobulinemia).

**Table 8.26:** WHO classification (2016) of acute myeloid leukemia and related precursor neoplasms.

<i>Class</i>	<i>FAB category</i>	<i>Prognosis</i>
<b>1. AML with recurrent genetic abnormalities</b>	M2	Favorable
AML with t(8;21)(q22;q22); <i>RUNX1-RUNX1T1</i>	M4eo	Favorable
AML with inv(16)(p13;q22) or t(16;16)(p13.1;q22); <i>CBFB-MYH11</i>	M3, M3v	Intermediate
APL with t(15;17)(q22;q12); <i>PML-RARA</i>	M4, M5	Intermediate
AML with t(9;11)(p22;q23); <i>MLLT3-MLL</i>	–	Poor
AML with t(6;9)(p23;q34); <i>DEK-NUP214</i>	–	Poor
AML with inv(3)(q21q26.2) or t(3;3)(q21.3;q26.2); <i>GATA2, MECOM</i>	–	Variable
AML(megakaryoblastic) with t(1;22) (p13;q13); <i>RBM15-MKL1</i>	Variable	Favorable
AML with mutated <i>NPM1</i>		Favorable
AML with mutated <i>CEBPA</i>		
<b>II. AML not otherwise specified</b>	M0	Intermediate
AML minimally differentiated	M1	Intermediate
AML without maturation	M2	Intermediate
AML with maturation	M4	Intermediate
Acute myelomonocytic leukemia	M5a, M5b	Intermediate
Acute monoblastic and monocytic leukemia	M6a, M6b	Intermediate
Acute erythroid leukemia	M7	Intermediate
Acute megakaryoblastic leukemia	–	Poor

Acute basophilic leukemia	–	Poor
Acute panmyelosis with myelofibrosis		
<b>III. Myeloid sarcoma</b>	–	–
<b>IV. Myeloid proliferation related to Down syndrome</b>	–	–
Transient abnormal myelopoiesis	–	Variable
Myeloid leukemia associated with Down syndrome		

(AML: acute myeloid leukemia; APL: acute promyelocytic leukemia; MDS: myelodysplastic syndrome)

**Table 8.27: WHO classification (2016) of acute lymphoblastic leukemia.**

**B-cell lymphoblastic leukemia/lymphoma, not otherwise specified**

**B-cell lymphoblastic leukemia/lymphoma, with recurrent genetic abnormalities**

- B-cell lymphoblastic leukemia/lymphoma with hypodiploidy
- B-cell lymphoblastic leukemia/lymphoma with hyperdiploidy
- B-cell lymphoblastic leukemia/lymphoma with t(9;22)(q34;q11.2)[*BCR-ABL1*]
- B-cell lymphoblastic leukemia/lymphoma with t(v;11q23)[*MLL* rearranged]
- B-cell lymphoblastic leukemia/lymphoma with t(12;21)(p13;q22)[*ETV6-RUNX1*]
- B-cell lymphoblastic leukemia/lymphoma with t(1;19)(q23;p13.3)[*TCF3-PBX1*]
- B-cell lymphoblastic leukemia/lymphoma with t(5;14)(q31;q32)[*IL3-IGH*]
- B-cell lymphoblastic leukemia/lymphoma with intrachromosomal amplification of chromosome 21 (iAMP21)
- B-cell lymphoblastic leukemia/lymphoma with translocations involving tyrosine kinases or cytokine receptors ('*BCR-ABL1*-like ALL')

**T-cell lymphoblastic leukemia/lymphomas**

- Early T-cell precursor lymphoblastic leukemia

(ALL: acute lymphoblastic leukemia; WHO: World Health Organization).

*Genetic disorders*

A few genetic disorders may be associated with acute leukemias, e.g. Down's syndrome (ALL or AML), Fanconi's anemia (AML), ataxia telangiectasia (ALL, NHL) and Klinefelter syndrome.

*Acquired disorders*

- Acquired stem cell disorders like PNH and aplastic anemia may transform into acute leukemia.
- Myelodysplastic syndrome (MDS): AML may develop de novo or secondary to MDS.

## Clinical Features

### Q. Discuss the clinical features, investigations, diagnosis and management of acute leukemias.

- Though ALL and AML are distinct (immunophenotypically and genotypically), they usually have similar clinical features. Patient usually presents with nonspecific 'flu-like' symptoms.
- Majority of patients with acute leukemia, regardless of subtype present with symptoms arising from:
  - **Bone marrow failure:** Due to replacement of normal marrow hematopoietic cells by leukemic blast cells.
    - ◆ **Anemia**
      - ◇ Causes shortness of breath on effort, excessive tiredness/fatigue and weakness.
    - ◆ **Neutropenia**
      - ◇ Results in life-threatening infections by bacteria or opportunistic fungi, *Pseudomonas* and commensals. Fever due to septicemia.
      - ◇ The infection may develop in the oral cavity, skin, lungs, kidneys, urinary bladder and colon. The common presentations include respiratory infections (pneumonia), cellulitis or sepsis.
    - ◆ **Thrombocytopenia**
      - ◇ Presents as bleeding manifestations in the form of petechiae, atraumatic ecchymosis, gum bleeding, epistaxis, urinary tract and fundal hemorrhages.
      - ◇ Intracranial bleeding is a serious and fatal complication, usually associated with headache, fundal hemorrhages and focal neurological deficits.
    - ◆ Marrow expansion and infiltration of the subperiosteum causes
      - ◇ Bone pain (more common in ALL) and sternal tenderness.
  - **Leukostasis:** Stasis of blood flow may develop when the blast count is above 50,000/cumm.
    - ◆ Cerebral leukostasis may cause headache, confusion and visual disturbances.
    - ◆ Pulmonary leukostasis can cause dyspnea at rest, tachypnea, chest

- pain, pulmonary infarction, and acute respiratory distress syndrome.
- **Coagulopathy:** Both disseminated intravascular coagulation (DIC) and primary fibrinolysis may lead to hemorrhagic diathesis. DIC is observed in AML-M<sub>3</sub> (promyelocytic leukemia).
  - **Extramedullary leukemic infiltration:**
    - Gingival hypertrophy and infiltration of skin (leukemia cutis)
  - Hepatosplenomegaly.
  - Generalized lymphadenopathy.
  - Leukemic meningitis is rare. It presents as headache and nausea. As the disease progresses, papilledema, cranial nerve palsies, seizures and altered consciousness develop. CSF characteristically shows leukemic blast cells, elevated proteins and reduced glucose levels.
  - Chloromas are localized, solid, soft-tissue tumor masses known as myeloblastomas, granulocytic sarcomas or chloromas.
    - **Metabolic abnormalities:** Hyperuricemia, elevated serum liver transaminases, serum LDH are found in patients with acute leukemia.

## Investigations

**Q. Write short essay on laboratory diagnosis of acute myeloid leukemia. What are Auer rods?**

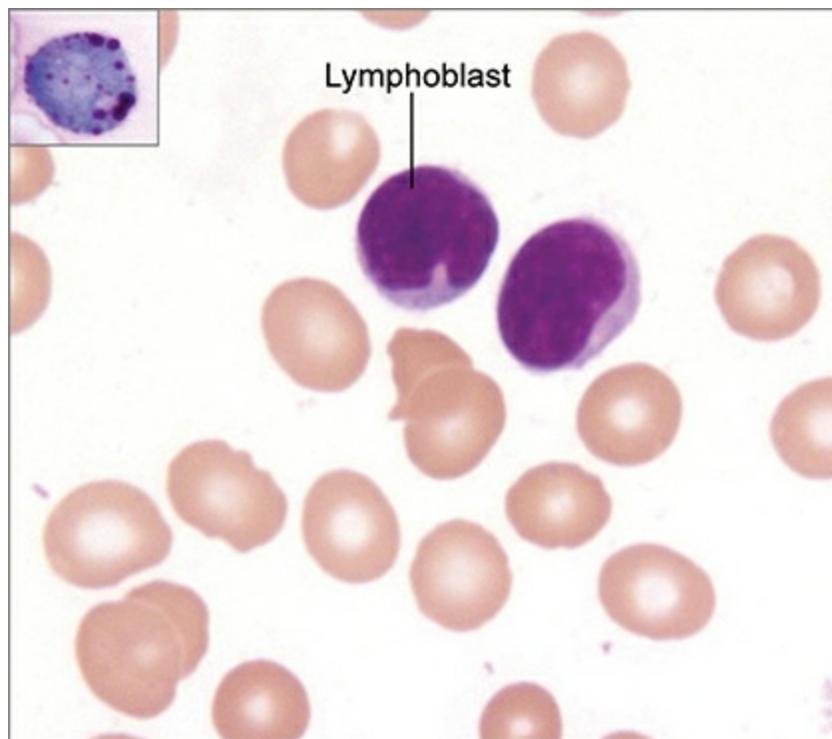

### *Confirmation of Diagnosis*

- **Blood count**
  - Hemoglobin is low.
  - Total leukocyte count: Markedly raised, but usually less than  $100 \times 10^9/L$  (range  $1 \times 10^9/L$  to  $500 \times 10^9/L$ ). Leukopenia is common in AML.
  - Platelet count: Markedly decreased.
- **Peripheral blood smear**
  - Shows numerous **blast cells** (Figs. 8.28 and 8.29) and types of blasts can be identified morphologically, and confirmed with immunophenotyping.
  - **Auer rods** are seen as rod-shaped red inclusion in the cytoplasm of myeloblast.

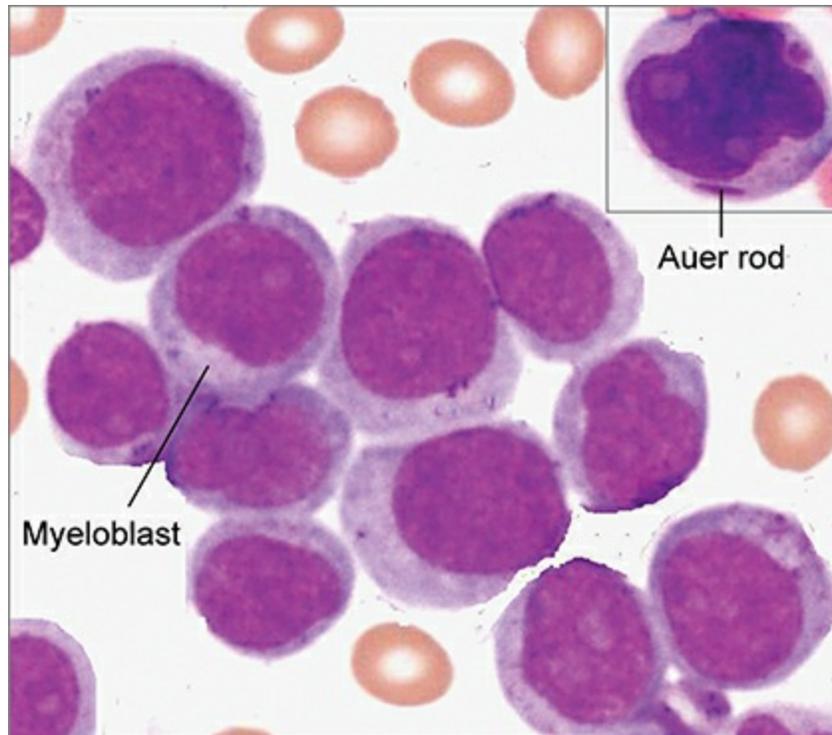

- Severe normochromic anemia.
- **Bone marrow aspirate:** Hypercellular with reduced erythropoiesis, and reduced megakaryocytes. **Blast cells >20%** (often approaching 100%) and type of blast is confirmed by flow cytometry, immunophenotyping (FISH), cytogenetic and molecular genetics.
- **Chest X-ray:** Mediastinal widening is often seen in T lymphoblastic leukemia.
- **CSF examination:** To rule out occult CNS involvement.

### *For Planning Therapy*

- Biochemical parameters: Serum urate, liver function tests, renal function tests, coagulation studies, serum LDH, etc.
- Cardiac function: ECG and direct tests of left ventricular function (e.g. echocardiogram or MUGA scan).

**Fig. 8.28:** Peripheral blood smear in acute lymphoblastic leukemia showing lymphoblasts. Inset shows lymphoblast with block positivity with PAS stain.

**Fig. 8.29:** Peripheral smear in AML with myeloblasts. Inset shows myeloblast with Auer rod.

## **Q. Discuss the management of acute leukemias.**

### **Management**

#### ***Principles of Management***

At initial presentation, acute leukemia may be:

- Probably curable (childhood acute lymphoblastic leukemia).
- Possibly curable (de nov low-risk AML).
- Probably incurable (AML with adverse cytogenetic features in the elderly, secondary AML, recurrent acute leukemia).

#### ***Type of therapy***

- **Palliative therapy:** It is directed towards symptomatic benefit by means for medications, transfusions with or without chemotherapy.
- **Curative intent:** The goal is to cure the patient, involves chemotherapy +/- stem cell transplant.

#### ***Active therapy***

The first and major decision to be taken is whether to give specific therapy or supportive therapy.

#### ***Supportive care/therapy***

Forms the basis of treatment for both curative and palliative therapy.

- Treatment of anemia with repeated transfusion of packed red cells to avoid symptoms of anemia (hemoglobin >10 g/dL).
- Prevention or control of bleeding due to thrombocytopenia with platelet transfusions.
- Treatment of infection:
  - a. *Prophylactically:* Education about handwashing and isolation facilities. Use of selected

antibiotics and antifungal agents barrier nursing.

b. *Therapeutically*: Management of fever by identifying the microorganism and giving appropriate antimicrobial treatment in bacterial, fungal, protozoal and viral infections.

- Continuous monitoring of liver, kidney and hemostatic functions.
- Maintenance of fluid and electrolyte balance: In patients receiving chemotherapy, rapid lysis of leukemic cells may produce tumor lysis syndrome characterized by hyperuricemia, hyperkalemia, hypocalcemia and hyperphosphatemia leading to renal injury, arrhythmias, seizures and is potentially life-threatening. It can be prevented by close attention to hydration, urine alkalization and prophylactic allopurinol before starting chemotherapy.
- Treatment of hyperleukocytosis: Reduction in leukocyte counts can be achieved by using chemotherapy or hydroxyurea, and leukapheresis (removal of circulating cells and re-infusion of leukocyte-poor plasma).
- Psychological support.

**Bone marrow transplantation** has to be considered in following condition:

1. Acute myeloblastic leukemia (Intermediate and poor risk) in first remission in patients below 60 years of age.
2. Acute lymphoblastic leukemia (ALL) (high risk) in first, second or subsequent remission.

#### *Specific therapy*

The specific therapy is intended to return the peripheral blood and bone marrow to normal (complete remission; CR).

The survival outcomes of acute leukemia are variable, they could be in excess of 90% in situations like- APML, childhood ALL to as low as 10% in recurrent acute leukemia and high risk AML.

**Q. Discuss the management of acute lymphocytic leukemias. Enumerate the drugs used in acute lymphocytic leukemia.**

#### ***Acute lymphocytic leukemia***

Specific therapy (Table 8.28) involves:

1. **Remission induction** with combination chemotherapy
  - Goal of induction therapy: To induce morphologic remission and to restore normal hematopoiesis in the bone marrow with less than 5% blasts.
  - Remission induction consists of combination chemotherapy including vincristine, prednisolone (dexamethasone), asparaginase (crisantaspase) and usually an anthracycline antibiotic, e.g. doxorubicin. It induces complete morphologic response within 4–6 weeks.
2. **CNS preventive therapy** that includes administration of high-dose systemic therapy and CNS-directed treatment.
  - **Aim:** To eliminate disease in the CNS and to reduce systemic minimal residual leukemic burden.
  - **CNS-directed therapy:** Triple intrathecal chemotherapy (cytarabine/methotrexate/hydrocortisone) or 1800 cGy cranial radiation.
3. **Post-remission therapy** (similar to induction phase) reduces chances of relapse.
4. **Remission maintenance** to prevent relapse and affect cure. It involves administering drugs for 2 years or more and consists of daily 6-mercaptopurine and weekly methotrexate.

**Table 8.28: Treatment for ALL (acute lymphoblastic leukemia).**

### ***Induction therapy***

t(9;22)/BCR-ABL1 negative ALL

- Weekly administration of vincristine for three to four weeks, daily corticosteroids (prednisone, prednisolone, or dexamethasone) and asparaginase

t(9;22)/BCR-ABL1 positive ALL

- Tyrosine kinase inhibitors (TKI) such as imatinib or dasatinib

Patients with trisomy 21

- High-dose methotrexate

### ***CNS preventive therapy***

- Triple intrathecal chemotherapy (cytarabine/methotrexate/hydrocortisone) or 1800 cGy cranial radiation

### ***Post-remission therapy***

- Consolidation
- Cytarabine, methotrexate
- Anthracyclines (daunorubicin, doxorubicin)
- Alkylating agents (cyclophosphamide, ifosfamide)
- Epipodophyllotoxins (etoposide, etopophosphamide)

### **Allogeneic hematopoietic cell transplantation**

#### ***Maintenance therapy***

- Daily oral 6-mercaptopurine, weekly methotrexate with periodic vincristine, prednisone and intrathecal therapy

**Table 8.29:** Treatment for AML (acute myeloid leukemia).

#### ***Initial treatment for AML***

Intensive remission induction (7+3 therapy)

- Continuous infusion of cytarabine (100 or 200 mg/m<sup>2</sup> daily for seven days) together with daunorubicin (by short infusion or bolus for the first three days)

Alternative remission induction approaches

Gemtuzumab ozogamicin (GO)

- 6 mg/m<sup>2</sup> on day 1, and 3 mg/m<sup>2</sup> on day 8, and continue treatment with GO for up to eight monthly cycles

Other regimens

- FLAG (fludarabine, cytarabine, G-CSF) FLAG-IDA (idarubicin), MITO-FLAG (mitoxantrone) and FLAMSA (amsacrine)
- CLAG (cladribine, cytarabine, G-CSF)
- Vorinostat (histone deacetylase inhibitor) plus idarubicin and cytarabine
- Bortezomib, daunorubicin, and cytarabine
- Lenalidomide

### **Post-remission management**

- Consolidation chemotherapy—cytarabine + daunorubicin or with gemtuzumab ozogamicin
- Hematopoietic cell transplantation (HCT)
- Maintenance therapy—with gemtuzumab ozogamicin Or Midostaurin

### **Relapsed or resistant AML**

Gemtuzumab ozogamicin midostaurin, enasidenib, lower intensity treatments (e.g. azacitidine, decitabine) or palliative management

## **Q. Discuss the management of acute myeloid leukemias.**

### **Acute myeloid leukemia (Table 8.29)**

Initial therapeutic goal is to quickly induce complete remission (CR) and further therapy to prolong survival and achieve cure. Curative therapy is given to the majority of adults below the age of 60 years (without any significant comorbidity).

**Specific therapy** (Table 8.29) of the newly diagnosed patient with AML usually divided into two phases (1) induction and (2) consolidation phase (postremission) therapy.

#### **1. Induction chemotherapy:**

- Moderately intensive combination chemotherapy that includes an anthracycline (e.g. daunorubicin or idarubicin) and cytosine arabinoside (cytarabine) ± etoposide.
- ‘High risk’ patients (include patients <70 years with high-risk karyotype) may only be treated with curative intent if an HLA-identified sibling is available for stem cell transplantation.

#### **2. Consolidation or post-remission therapy:** For patients achieving remission with induction therapy in young patients (<60 years) consists of 3 to 4 cycles of high-dose cytosine arabinoside.

- Low risk patients in AML, patients with t(8;21) or inv(16) ( i.e. low risk karyotype) do not benefit from allogeneic stem cell transplantation during their first complete remission.
- Patients with high-risk karyotypes should have stem cell transplantation because they respond poorly to conventional chemotherapy.

### **Acute promyelocytic leukemia (M3)**

- Uncommon variant of AML associated with severe coagulation complications.
- It has favorable prognosis.
- Induction therapy is with all-trans-retinoic acid and anthracyclines or a combination of ATA with arsenic trioxide.
- Allogeneic transplantation: Necessary if the leukemia is not eliminated at the molecular level, only in relapsed/refractory cases.
- In relapsed cases, arsenic trioxide (induces apoptosis via activation of the caspase cascade) has been also found to be effective.

### **Alternative chemotherapy**

- Used to curb excessive leukocyte proliferation and not for achieving remission.
- Hydroxyurea up to 4 g daily and L asparaginase 10,000 units are used to reduce leukocyte count without inducing bone marrow failure.

## **Poor Prognostic Factors in AML and ALL (Table 8.30)**

**Table 8.30: Poor prognostic factors in AML and ALL.**

<b>Features</b>	<b>Acute myeloblastic leukemia (AML)</b>	<b>Acute lymphoblastic leukemia (ALL)</b>
Age	>60 years	<1 year or > 9 years
TLC	>1,00,000/mm <sup>3</sup>	> 30,000 in B ALL and >100,000 in T ALL
French-American-British (FAB) type	M <sub>0</sub> , M <sub>5</sub> , M <sub>6</sub> , M <sub>7</sub>	L <sub>3</sub> type
Chromosomal abnormality	High-risk karyotype [t(6;9), inv(3)]	Hypodiploidy (<45 chromosomes), pH positive ALL t (1:19) MLL rearranged

*Differences between acute lymphoblastic leukemia from acute myeloblastic leukemia (Table 8.31)*

**Q. How do you differentiate acute lymphoblastic leukemia from acute myeloblastic leukemia?**

**Table 8.31: Differences between acute lymphoblastic leukemia from acute myeloblastic leukemia.**

<b>Clinical features</b>	<b>Acute lymphoblastic leukemia</b>	<b>Acute myelogenous leukemia</b>
Age	Predominantly children	Predominantly adults
Coagulopathy (DIC)	Absent	Seen in M3
Gingival hypertrophy and dermal infiltrate (chloromas)	Absent	Seen in M4 and M5
Hepatosplenomegaly	In majority (50–75%)	Frequent
Lymphadenopathy	More common	Less common
Leukemic meningitis	More common	Less common
Testicular involvement	In 10–20%	-
Eye involvement	More common	Less common
<b>Investigations</b>		
Type of leukemic blasts	Lymphoblasts (10–15 μm) are smaller than	Myeloblasts (12–20 μm) are larger than lymphoblasts,

	myeloblasts, with a thin rim of agranular cytoplasm and round or convoluted nucleus	with discrete nuclear chromatin and multiple nucleoli
Auer rods (in the cytoplasm)	Absent	Present in 10–20% (diagnostic)
Terminal deoxynucleotidyl transferase (Tdt) in leukemic blasts	In more than 90%	Rare
<b>Cytochemistry</b>		
• Myeloperoxidase	-ve	+ve
• Sudan Black B	-ve	+ve
• Nonspecific esterase	-ve	+ve in M4 and M5
• Periodic acid Schiff (PAS)	+ve in >50% of cells (Block positivity)	Negative

## Subleukemic Leukemia/Aleukemic Leukemia

### Q. Write short note on subleukemic leukemia.

- In acute leukemia, the immature neoplastic leukemic ‘blast’ cells proliferate and accumulate, but fail to mature. The blasts diffusely replace the normal bone marrow and a variable number of these accumulate in the peripheral blood.
- Acute leukemia should be diagnosed when the blast cells constitute more than 20% of the nucleated cells in the marrow (normally blast cells <5%) with an increase in total leukocyte count.
- **Subleukemic/aleukemic leukemia** is characterized by a total leukocyte count is normal or lower than  $4 \times 10^9/L$  and peripheral blood shows very few abnormal blasts. It is observed in a small percentage of patients with acute leukemia.
- Diagnosis is confirmed from the bone marrow examination which shows replacement by leukemic cells.

## Leukemoid Reaction

### Q. Write short note on leukemoid reaction (including its definition).

- Extreme neutrophilia sometimes is associated with the presence of immature white cells and is called as leukemoid reaction.
- A **leukemoid reaction** is a benign leukocytic proliferation characterized by a total leukocyte count of more than  $50 \times 10^9/L$  with many immature

white cells (like metamyelocytes, myelocytes and promyelocytes and even a few myeloblasts) in the peripheral smear.

- Leukemoid reaction is the response of the normal healthy bone marrow to various stresses.
- Causes: Include infections (including tuberculosis), acute hemorrhage, hematological and non-hematological malignancies and various toxic states.
- Bone marrow is normal with accelerated leukopoiesis.
- LAP source is increased.
- Philadelphia chromosome negative.
- No absolute eosinophilia or basophilia (versus CML).
- Treatment of underlying disorder corrects the blood picture.
- Type of leukemoid reactions are listed in Box 8.13.
- It should be differentiated from chronic myelocytic leukemia (Table 8.32).

**Box 8.13:** Types of leukemoid reactions.

1. Myeloid
2. Lymphoid

**Table 8.32:** Differences between leukemoid reaction and chronic myeloid leukemia.

<i>Clinical features</i>	<i>Leukemoid reaction</i>	<i>Chronic myeloid leukemia</i>
<b>Peripheral blood findings</b>	Features of causative disease	Splenomegaly, lymphadenopathy and bone pain are common
<b>WBC series</b>		
Total WBC count	Moderately increased, rarely exceeds $50 \times 10^9/L$	Markedly increased and usually exceeds $50 \times 10^9/L$
Differential leukocyte count	<ul style="list-style-type: none"> <li>• Shift to the left with few immature forms</li> <li>• Toxic granulation seen</li> </ul>	<ul style="list-style-type: none"> <li>• Shift to the left with numerous immature forms</li> <li>• Myelocyte and neutrophil peak</li> </ul>
Eosinophilia and basophilia	Variable	Present
Leukocyte alkaline phosphatase (LAP)	Increased	Decreased
<b>RBC series</b>		
Anemia	Usually minimal or absent	Severe and progressive
<b>Platelets</b>		

Number	Variable	Normal or increased
<b>Extramedullary myeloid tumors</b>	Absent	Present
<b>Philadelphia chromosome</b>	Absent	Present

## Hairy Cell Leukemia

**Q. Discuss the clinical features, investigations and management of hairy cell leukemia.**

### *Clinical Features*

- Hairy cell leukemia (**HCL**) is an uncommon chronic malignant disorder of mature B-cells with characteristic fine cytoplasmic projections.
- The term **hairy cell leukemia** is derived from the appearance of fine hairlike cell membrane projections on the leukemic cells, under the phase-contrast microscope.
- Hairy cell leukemia affects middle-aged to elderly men, with a male-to-female ratio of 5:1.
- Clinical features are mainly due to leukemic infiltration of bone marrow, liver and spleen
  - **Massive splenomegaly** is the most common finding, hepatomegaly is less common and lymphadenopathy is distinctly rare.
  - **Pancytopenia** is due to marrow failure and splenic sequestration, and is found in more than 50% of cases.
  - **Infections:** About one-third of patients present with infections especially with atypical mycobacteria, which may be due to monocytopenia. Infections are the most common cause of death.
  - Risk of secondary malignancies: Such as Hodgkin's lymphoma, non-Hodgkin's lymphoma and thyroid cancer.

### *Investigations*

- Total leucocyte count: Normal or low. Majority of patients have pancytopenia.
- Peripheral smear: Shows the characteristic hairy cells. These are the medium-sized malignant B lymphocytes with filamentous hairy structures on the surface of the cell. They have a reniform nucleus and abundant pale

blue cytoplasm. Cytochemically, these hairy cells stain positively for **tartrate-resistant acid phosphatase (TRAP)**.

- Bone marrow: Aspirate yields a dry tap and biopsy shows fibrosis with infiltration by mononuclear cells and hairy cells (fired-egg or honeycomb appearance).
- LAP score is very high. Flow cytometry reveals CD 11c, 25, 103, 123 positivity.

#### Treatment

- Indications for treatment: If patient develops
  1. Cytopenia
  2. Symptomatic splenomegaly
  3. Constitutional symptoms (e.g. fever, night sweats and fatigue)
- Treatment of infections with antibiotics.
- Chemotherapy: The purine analogues 2-chloroadenosine acetate (2-CDA) (cladribine) and pentostatin are highly effective with just one cycle of treatment. Rituximab is used in patients who do not respond to the above drugs. Pentostatin, interferon alfa and splenectomy are other treatment options available.
- Contraindicated drugs: Corticosteroids and myelotoxic drugs.

**Prognosis:** Follows an indolent course and prognosis is excellent.

## CHRONIC MYELOID LEUKEMIA

**Q. Define chronic myeloid leukemia (CML). Write a short note on Philadelphia chromosome and its significance.**

**Definition:** Chronic myeloid leukemia is one of the **myeloproliferative neoplasms (MPN)** of **pluripotent hematopoietic stem cell** characterized by **overproduction** of cells of the **myeloid series** (results in marked splenomegaly and leukocytosis) and the presence of the Philadelphia chromosome.

### Molecular Pathogenesis

- **Philadelphia (Ph) chromosome**
  - Acquired chromosomal abnormality of **hematopoietic stem cells**
  - **Balanced reciprocal translocation between the long arms of chromosomes 9 and 22 (t 9,22)** increases the length of chromosome 9 and shortening of 22. The **shortened chromosome 22** is known as

Philadelphia chromosome (**Ph**).

- **BCR-ABL1 fusion gene**

- Translocation results in fusion of the breakpoint cluster region (*BCR*) gene on chromosome 22q with the *ABL1* (named after the Abelson murine leukemia virus) gene located on chromosome 9q.
- It produces a new hybrid oncogene namely BCR-ABL1 fusion gene. The products of this gene are oncoproteins which have uncontrolled kinase activity and triggers the excessive proliferation and reduced apoptosis of CML cells.
- **Significance:** Apart from CML, Philadelphia (Ph) chromosome can be found in acute lymphoblastic leukemia (ALL, 25–30% in adult and 2–10% in pediatric cases) and occasionally in acute myeloid leukemia (AML). In patients with Ph positive/negative and BCR-ABL1 positive, the survival rate and therapeutic response is better than those with both Ph and BCR-ABL1 negative patients.

## Natural Course of CML

**Q. Discuss the natural course and clinical features of chronic myeloid leukemia.**

It has three phases:

1. **Chronic stable phase:** Most of the CML are diagnosed in this phase and lasts for about 3–5 years if untreated.
2. **Accelerated phase:** More aggressive and lasts for few months.
3. **Blast crisis phase:** It resembles acute (myeloid or lymphoid) leukemia and has poor prognosis.

## Clinical Features in Chronic Stable Phase of CML

**Q. Discuss the clinical features in chronic stable phase.**

- **Age:** Usually occurs between 40 to 60 years of age.
- **Onset:** Insidious.

### *Symptoms*

Many patients are asymptomatic during early stage of CML and may be diagnosed during routine peripheral blood examination.

- **Nonspecific symptoms:** Fatigue, weakness, weight loss, anorexia.

- **Symptoms due to massive splenomegaly: Fullness of abdomen** (abdominal distension, post-prandial fullness), reflux esophagitis, dyspnea and dragging discomfort in the left hypochondrium due to splenomegaly (caused by leukemic infiltration and extramedullary hematopoiesis). Splenomegaly is moderate to severe and is characteristic feature in majority (80–90%) of patients.
- **Symptoms of hypermetabolic state:** Due to rapid turnover of cells may result in symptoms like fatigue, weakness, fever, sweating, heat intolerance weight loss, anorexia.
- **Priapism:** Painful penile erection due to leukostasis (associated with marked leukocytosis or thrombocytosis).
- Bleeding tendencies occur late in the disease.

### *Signs*

- **Pallor** due to anemia.
- **Splenomegaly:** Moderate to massive, non-tender splenomegaly. It is due to leukemia infiltration and extramedullary hematopoiesis. Presence of tender spleen and splenic friction rub indicate splenic infarction.
- Mild **hepatomegaly** as a result of leukemic infiltration may develop in 60–70% of cases.
- **Sternal tenderness and bone pain:** It is due to hypercellularity of marrow and irritation of periosteum.

### *Investigations*

**Q. Discuss the investigations/laboratory investigations/diagnosis of chronic myeloid leukemia.**

- **Hemoglobin** is usually less than 11 g/dL.
- **Total leucocyte count** is markedly raises, almost always more than 20,000/ $\mu$ L, often exceeding 1,00,000/ $\mu$ L. In untreated patients, the leukocyte count progressively increases.

### *Peripheral Smear (Fig. 8.30)*

- **RBC** shows moderate degree of **normocytic normochromic anemia**.
- **WBC:**
  - **Shift to left (shift to immaturity)** with granulocytes at all stages of

development (neutrophils, metamyelocytes, myelocytes, promyelocytes and occasional myeloblasts). **Predominant cells are neutrophils and myelocytes** in an untreated patient. **Blasts** are usually **less than 10%** of the circulating white blood cells.

– Increase in basophils (<20%) and eosinophils.

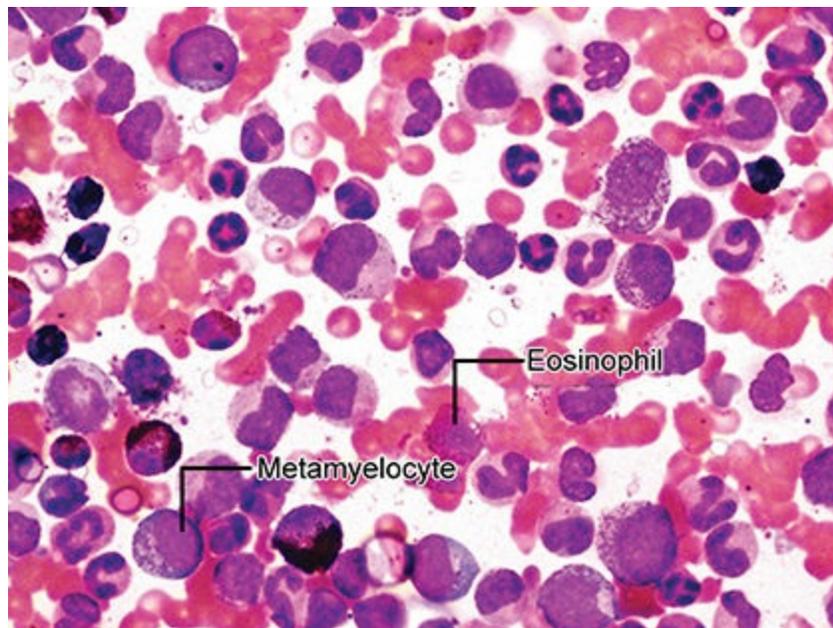

- **Platelets:** Count may be normal, increased or decreased. Automated analyzers may give falsely elevated platelet counts due to disruption of granulocytes.

### ***Bone Marrow Study***

- Markedly hypercellular due to marked hyperplasia of all granulocytic elements.
- About 20–30% of the patients may develop bone marrow fibrosis in late stages.

### ***Philadelphia Chromosome (Ph)***

- It is positive in more than 95% of cases, in all three phases. In Ph negative cases, evidence of translocation can be demonstrated by cytogenetics, reverse transcription-polymerase chain reaction (RT-PCR) and fluorescence *in situ* hybridization (FISH).
- **BCR-ABL1 fusion gene** can be demonstrated in peripheral blood or bone marrow.

**Fig. 8.30:** Peripheral blood picture in chronic stable phase of chronic myeloid leukemia.

## ***Decreased NAP/LAP Score***

It is usually below 20 (normal score range from 40 to 100) in majority of patients. This is helpful in differentiating CML from leukemoid reaction.

## ***Biochemical Findings***

- Serum LDH and uric acid is increased.
- Serum alkaline phosphatase is increased.
- Serum vitamin B<sub>12</sub> is markedly elevated due to production of binding protein (transcobalamin) by the granulocyte series.
- Marked thrombocytosis may raise serum potassium spuriously as platelets release potassium during clotting.
- Blood sugar may be falsely decreased due to glucose uptake and metabolism by leukocytes.

**Q. Write short essay/note on the treatment and complications of chronic myeloid leukemia. Enumerate the drugs used in chemotherapy.**

**Q. Write short note on Imatinib.**

### **Treatment of CML**

**Goal of therapy in CML:** Complete molecular remission.

- Achieve prolonged, durable, non-neoplastic, nonclonal hematopoiesis.
- Eradication of any residual cells containing the *BCR-ABL1* transcript.

### **Chemotherapy (Table 8.33)**

- Imatinib mesylate is the first-line treatment for the chronic phase of CML.
- If there is failure of response or progress on imatinib, options include: (1) second-generation tyrosine kinase inhibitors (such as dasatinib or nilotinib), (2) allogeneic bone marrow transplantation or (3) classical cytotoxic drugs such as hydroxycarbamide (hydroxyurea) or interferon- $\alpha$  or melphalan, and busulphan (4) Omacetaxine/homoharringtonine (plant alkaloid).

### **Imatinib mesylate**

- Imatinib mesylate is a tyrosine kinase inhibitor (TKI) provides targeted therapy, i.e. high specificity blocks the enzymatic action of the BCR-ABL fusion, providing a broader therapeutic window with less toxicity.
- In all newly diagnosed CML, imatinib (400 mg/d) is more effective and has replaced IFN- $\alpha$  and cytarabine. It reduces the uncontrolled proliferation of white cells, producing apoptosis of cancer cells.
- In chronic stable disease, it can produce complete hematological response in >95% of cases and complete cytogenetic response (disappearance of the Ph chromosome and BCR-ABL transcripts in the blood) in >76% at 18 months of therapy. Imatinib can be continued indefinitely.

- Over expression of the BCR-ABL chimeric gene or genetic alteration can produce resistance to imatinib mesylate.
- Side effects of imatinib: Nausea, headaches, fluid retention, muscle cramps, diarrhea, skin rash and myelosuppression (causing cytopenias).

### **Recombinant interferon- $\alpha$**

- **Recombinant interferon- $\alpha$**  (rINF- $\alpha$ ) was considered first-line treatment before the invention of imatinib.
- It was given alone or combined with the chemotherapy agent cytosine arabinoside, and induced remission and controlled chronic stable phase of CML in about 70% of cases. But has no role as a single agent in most patients.
- It should be considered in patients not responding to imatinib.
- It is not effective in accelerated phase or blast crisis phase.
- Dosage: 3–9 mega units/day intramuscularly or subcutaneously.
- Actions of rINF- $\alpha$ :
  - Reduces cellularity of the bone marrow.
  - Reduces the number of Philadelphia positive tumor cells in 20% of patients.
  - Total eradication of Philadelphia chromosome in ~5% of patients.
  - Reduces platelet count when it is very high.
- Side effects: Flu-like syndrome, weight loss, fatigue, nausea, vomiting and headache.

**Table 8.33:** Drugs used and their dosage for induction and maintenance in chronic stable phase of CML.

<b>Drug</b>	<b>Induction dose</b>	<b>Maintenance dose</b>
Imatinib mesylate	300–400 mg/day	300–400 mg/day
Hydroxyurea (hydroxycarbamide)	0.5–2.0 g/day	0.5–2.0 g/day
Melphalan	4–12 mg/day	2–4 mg/day
Busulphan	4 mg/day	2–4 mg/day

### **Splenectomy**

- Indicated to relieve the symptoms due to massive splenomegaly and in repeated splenic infarctions.

### **Stem cell transplantation (SCT)**

- Indication:
  - Patients under the age of 60 years who have a suitable donor.
  - Those who do not respond to 2nd line TKI and those who present with accelerated phase or blast crisis.
- Best results are obtained if SCT is done in early chronic stable phase and can cure about 70% of cases.
- It can result in permanent disappearance of the Ph-positive clone.
- Disadvantages: Risk of complications and death due to graft-versus-host disease (GVHD) and

opportunistic infections.

- Factors determining complications:
  - Increasing age
  - In acute phase
  - Degree of histocompatibility between donor and recipient.
- Features of failure of response:
  - Failure to achieve
  - Complete hematological response at 3 months
  - Complete cytogenetic response at 6 months
  - Major molecular response at 12 months

### **Monitoring**

- Bone marrow biopsy: At 6 month intervals to determine the cytogenetic response.
- Quantitative RT-PCR (qPCR): From peripheral blood at 3–6 month intervals should be done once cytogenetic response has been achieved.

## **Prognostic Scores in CML**

- **Sokal score:** Age, spleen size, platelet count, blast cell counts
- **Euro score:** Age, spleen, platelet, blast cell counts, basophil counts, eosinophil counts
- **EUTOS score/Hassford:** Basophils and spleen size.

## **Accelerated Phase of Chronic Myeloid Leukemia**

Chronic myeloid leukemia may transform to a more aggressive blastic phase with or without going through an accelerated phase after 1–5 years of onset. It lasts for a few months.

### ***Features of Accelerated Phase***

- Increasing anemia
- Increasing white blood cell count with an increase in circulating immature cells unresponsive to therapy
- Blasts 10–19% are seen in the blood or bone marrow
- Increase in the size of spleen
- Increase in basophil count (<20%)
- Persistent thrombocytopenia or persistent thrombocytosis unresponsive to therapy
- Hydroxyurea is the most effective drug in accelerated phase.

## **Blast Crisis Phase of Chronic Myeloid Leukemia**

- Blast crisis phase of CML represents the transformation of CML into an acute leukemia.
- This final phase lasts for a few weeks to months and has a poor prognosis.

- Blasts constitute 20% or more and may be:
  - Myeloid blast crisis that occurs in 70% when the disease transforms into acute myeloblastic leukemia.
  - Lymphoid blast crisis occurs in 30% when the disease transform into acute lymphoblastic leukemia.

### ***Features of Blast Crisis***

- Refractory to treatment
- Abrupt increase in the size of spleen
- Bone pain and sternal tenderness
- Anemia and bleeding tendencies
- Generalized lymphadenopathy may appear
- Peripheral smear and bone marrow showing >30% cells simulating acute leukemia
- Basophils may increase to 20%
- Thrombocytopenia may result in bleeding episodes.

Treatment of blast crisis is same as that for acute myeloblastic or lymphoblastic leukemia. Complications of chronic myelogenous leukemia is enlisted in Box 8.14.

### **Box 8.14:** Complications of chronic myelogenous leukemia (CML).

- Fatigue due to anemia.
- Excess bleeding due to thrombocytopenia
- Bone pain or joint pain due to expansion of bone marrow.
- Enlarged spleen
- Vulnerable to infection due to impaired immune system
- Death

## **CHRONIC LYMPHOCYTIC LEUKEMIA**

**Q.** Discuss the types, clinical features, investigation, clinical staging and management of chronic lymphocytic leukemia.

### **Definition**

Chronic lymphocytic leukemia (CLL) is a tumor of immature small round lymphocytes characterized by the accumulation of neoplastic mature looking lymphocytes in the peripheral blood, bone marrow and lymphoid organs (spleen and lymph nodes).

## Types

- B-cell origin: More than 95% of the cases of CLL express the pan B-cell markers CD19 and CD20. And also aberrant expression of T-cell antigen CD5 (found only in a small subset of normal B-cells).
- T-cell origin: Constitute less than 5%.

## Clinical Features

- Most common form of chronic leukemia.
- **Age:** Most of the patients at the time of diagnosis are over 50 years of age.
- **Sex:** More common in males than in females with a ratio of 2:1.
- **Asymptomatic:** In about 25% of patients and are detected either because of nonspecific symptoms or routine blood examination for some other disease.
- **Nonspecific symptoms:** This includes fatigue, loss of weight and anorexia.
- **Painless generalized lymphadenopathy:** Initially, the cervical lymph nodes are enlarged and in later stages there may be generalized lymphadenopathy. Involved nodes are rubbery, discrete, non-tender, small and mobile.
- **Splenomegaly and hepatomegaly:** Mild degree is observed in very few cases.
- **Presenting symptoms** may be:
  - Slowly developing anemia: Due to immune hemolysis and bone marrow infiltration.
  - Recurrent infections: Develops due to hypogammaglobulinemia. *Streptococcus pneumoniae*, *Staphylococcus* and *Haemophilus influenzae* cause most of the infections. Herpes zoster is also common.
  - Bleeding manifestations: Uncommon.

## Transformation

CLL may transform to:

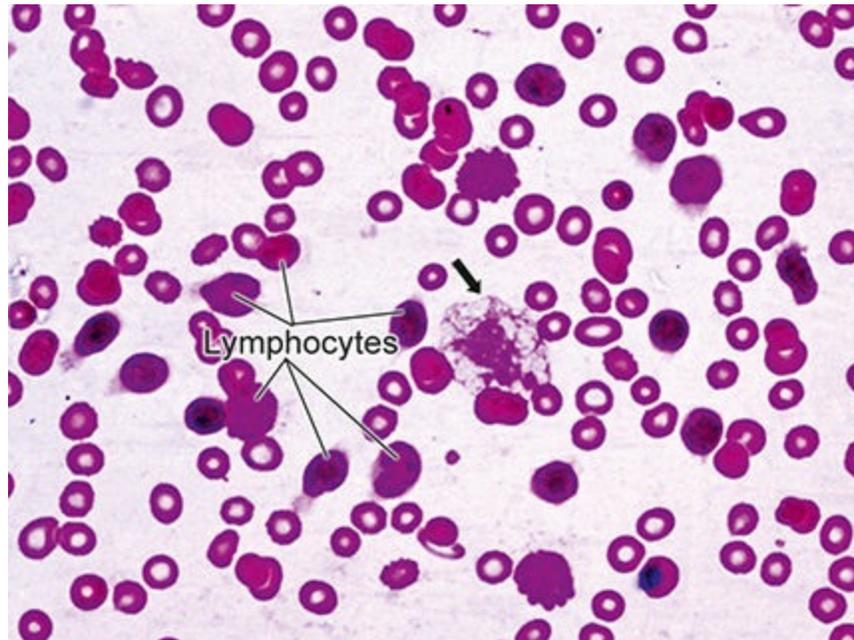

- Prolymphocytic transformation with appearance of 'prolymphocytes' in the peripheral blood (>10%).
- Transformation to diffuse large B-cell lymphoma (Richter syndrome).
- **Monoclonal B-cell lymphocytosis (MBL):** WHO criteria for monoclonal

B-cell lymphocytosis (MBL) is the presence of monoclonal B-cell populations in the peripheral blood (PB) of up to  $5 \times 10^9/L$  either with the phenotype of chronic lymphocytic leukemia (CLL), atypical CLL, or non-CLL (CD52) B cells in the absence of other lymphomatous features. It has been found that MBL precedes almost all cases of CLL/SLL. In 2016 WHO subdivided MBL into “low count” MBL (characterized by PB CLL count of  $<0.5 \times 10^9/L$ ) and “high count” MBL. The distinction is important because low count MBL does not require routine follow-up whereas, high count MBL requires routine/yearly follow-up.

## Investigations

- **Hemoglobin:** Usually below 13 g/dL and as the disease progresses, it may decrease below 10 g/dL. This is due to marrow failure, but associated autoimmune hemolysis may also be contributory, when present.
- **Blood counts:**
  - Total leukocyte count is increased and varies from  $20 \times 10^9/L$  to  $50 \times 10^9/L$ .
  - Platelet count may be normal or low.
- **Peripheral blood smear (Fig. 8.31):**
  - Mild to moderate normocytic normochromic anemia.
  - Lymphocytosis is the characteristic features and constitute more than 50% of the white cells and absolute lymphocyte count should be more than  $5000 \times 10^9/L$ .
  - Lymphocytes are of mature type in majority of the cases.
  - **Smudge cells or basket cells** are disintegrated lymphocytes and is due to the rupture of neoplastic lymphocytes while making the peripheral smear due to its fragile nature.
  - Platelets: Normal or reduced in number (autoimmune thrombocytopenia).
- **Bone marrow:** Involved in all cases of CLL and its infiltration by mature lymphocytes results in hypercellular marrow.
- **Direct Coombs’ test:** About 15–20% of patients manifest autoimmune hemolytic anemia and have positive direct Coombs’ test.
- **Lymph node** biopsy shows well-differentiated, small, non-cleaved lymphocytes.

- **Immunoglobulins:** Low or normal.
- Serum folic acid levels are low.

**Fig. 8.31:** Peripheral blood smear in chronic lymphocytic leukemia showing numerous small lymphocytes and few smudge cells (arrow).

### ***Diagnostic Criteria for Chronic Lymphocytic Leukemia (Table 8.34)***

**Table 8.34:** Diagnostic criteria for chronic lymphocytic leukemia.

Lymphocytosis	Immunophenotype
Absolute lymphocyte count should be more than $5000 \times 10^9/L$	Positive for B-cell surface antigens (CD19, CD20, CD23)
	Aberrant expression of T-cell antigen CD5
Lymphoid cells $\leq 55\%$ prolymphocytes	Evidence of monoclonality in the form of 'light chain restriction'

### **Clinical Staging**

Binet staging and Rai staging of CLL are presented in Tables 8.35 and 8.36 respectively.

**Table 8.35:** Binet staging for CLL.

<b>Stage</b>	<b>Features</b>	<b>Survival</b>
--------------	-----------------	-----------------

A	No anemia or thrombocytopenia Less than 3 lymphoid areas enlarged	>10 years
B	No anemia or thrombocytopenia Three or more lymphoid areas enlarged	7 years
C	Anemia (Hb $\leq$ 10 g/dL) and or thrombocytopenia ( $<10,000/\text{mm}^3$ ) present, regardless of the number of areas of lymphoid enlargement	2 years

Lymphoid enlargement includes cervical, axillary and inguinal lymph nodes.

**Table 8.36: Rai staging of CLL.**

Stage	Features	Survival
0	Peripheral blood lymphocytosis alone	>10 years
I	Lymphocytosis with lymphadenopathy	9 years
II	Lymphocytosis with splenomegaly or lymphadenopathy or both	7 years
III	Lymphocytosis with anemia (hemoglobin $<11$ g/dL) and organomegaly	5 years
IV	Lymphocytosis with anemia, thrombocytopenia and organomegaly	5 years

### Treatment

Absolute indications for treatment: When any of the following features is present:

1. Anemia or thrombocytopenia that can be attributed to CLL.
2. Recurrent fever, extreme fatigue, night sweats and weight loss.
3. Bulky or progressive lymphadenopathy; massive or progressive splenomegaly with discomfort.
4. Autoimmune cytopenias not responsive to corticosteroids.
5. Progressive disease manifest by doubling of the lymphocyte count in 6 months.

### Treatment options based on Binet staging (Table 8.37)

**Chlorambucil (Leukeran):** Two regimes

1. Continuous low dose therapy: 5 mg/day orally.
  2. Intermittent high dose therapy (pulse therapy): 0.4 mg/kg for every 2 weeks.
- Complications: Development of myelodysplasia and acute myeloid leukemia.

### Newer drugs:

1. Anti CD 20 antibodies: Ofatumumab, obinituzumab
2. BTK inhibitors: Ibrutinib
3. PI3K inhibitors: Idelalisib

**Table 8.37:** Treatment options based on Binet staging.

<b><i>Binet staging</i></b>	<b><i>Treatment</i></b>
Stage A	No specific therapy required
Stage B	<ul style="list-style-type: none"><li>• No specific treatment if asymptomatic</li><li>• Medically unfit elderly patients with symptoms: Chlorambucil (oral)</li><li>• Young patients: Fludarabine (IV)</li><li>• Local radiotherapy to troublesome lymph nodes.</li></ul>
Stage C	<ul style="list-style-type: none"><li>• Young patients: Chemoimmunotherapy: Fludarabine, cyclophosphamide, rituximab, bendamustine</li><li>• Refractory cases: Combination chemotherapy with cyclophosphamide, doxorubicin, vincristine and prednisolone (CHOP)</li><li>• Rituximab in combination with fludarabine</li><li>• Packed red cell transfusion (for anemia) with fludarabine</li><li>• Prednisolone for patients with hemolytic anemia and thrombocytopenia</li><li>• Splenectomy for symptomatic splenomegaly</li><li>• Palliative total body irradiation</li></ul>

**Fludarabine:** It is a purine nucleoside analogue that is drug of choice in young patients.

- Dose: 25–30 mg/m<sup>2</sup> IV/day for 5 days every 4 weeks.
- Complications: Autoimmune hemolytic anemia, opportunistic infections (e.g. *Legionella pneumophila*, *Pneumocystis jiroveci*, *Listeria monocytogenes* and *Cytomegalovirus*).

**Cladribine:** It is also a purine nucleoside analogue, an alternative to fludarabine.

Dose:

- 0.2 mg/kg continuous infusion daily for 7 days every 4 weeks or
- 0.14 mg/kg over 2 hours daily for 5 days every 4 weeks.

**Pentostatin:** It is a purine nucleoside analogue that can be used instead of fludarabine or cladribine.

**Rituximab and alemtuzumab:** They are monoclonal antibodies against CD20 and CD52 respectively.

- CD20 is expressed on normal and malignant B-cells.
- CD52 expressed on all CLL cells.
- **Side effects:** Fever, chills, nausea, headache, myalgias.

- **Alkylating agents:** Cyclophosphamide, bendamustine.

## MYELOPROLIFERATIVE NEOPLASMS

**Q. Define and write short essay/note on myeloproliferative diseases (disorders) or myeloproliferative neoplasms and enumerate myeloproliferative neoplasms.**

### Definition

Myeloproliferative neoplasms (old synonym myeloproliferative disorder/diseases) are clonal hematopoietic stem cell disorders which are characterized by proliferation of one or more of the myeloid lineages (erythroid, granulocytic, megakaryocytic and mast cells).

It is seen usually in adults with a peak in the 5th to 7th decade. Splenomegaly and hepatomegaly occurs commonly due to sequestration of excess hematopoietic cells or proliferation of abnormal hematopoietic cells.

**Box 8.15:** WHO classification of myeloproliferative neoplasm (MPN).

- Chronic myelogenous leukemia, *BCR-ABL1* positive
- Chronic neutrophilic leukemia
- Polycythemia vera (PV)
- Essential thrombocythemia (ET)
- Primary myelofibrosis (PMF)
- Chronic eosinophilic leukemia not otherwise specified
- Myeloproliferative neoplasm, unclassifiable

Mastocytosis is no longer listed under the broad heading of MPN in WHO (2016) classification.

### WHO Classification (2016) of Myeloproliferative Neoplasm (MPN): (Box 8.15) Polycythemia

**Q. Write short essay/note on polycythemia and its classification.**

### Definition

Polycythemia, or erythrocytosis, refers to an **increase in the number of RBCs above normal** in the circulating blood, usually with a corresponding increase in hemoglobin and PCV level. PCV is a more reliable indicator of

polycythemia than is hemoglobin.

## Classification and Causes of Polycythemia (Table 8.38)

**Q. Write short note on causes of secondary polycythemia.**

**Table 8.38:** Pathophysiologic classification of polycythemia.

### *Relative*

- Reduced plasma volume with normal red cell mass (hemoconcentration) due to dehydration—low fluid intake, vomiting, diarrhea, sweating, acidosis
- Gaisböck syndrome (spurious polycythemia)

### *Absolute* (increased red cell mass)

- **Primary (Low erythropoietin level)**
  - Polycythemia vera (erythremia)
- **Secondary (High erythropoietin level)**—erythrocytosis
  - ◆ **Compensatory**
    - ◇ Lung disease [e.g. chronic obstructive pulmonary disease (COPD)]
    - ◇ Living in high-altitude
    - ◇ Cyanotic congenital heart disease (Tetralogy of Fallot, Eisenmenger’s complex)
    - ◇ Chronic carbon monoxide poisoning
    - ◇ Sleep apnea syndrome
    - ◇ Smokers
  - ◆ **As a consequence of local hypoxia:** Renal artery stenosis, end-stage renal disease, hydronephrosis, renal cysts (Polycystic kidney disease), postrenal transplant erythrocytosis
  - ◆ **Paraneoplastic:** Erythropoietin-secreting tumors. Examples: Renal cell carcinoma, hepatocellular carcinoma, cerebellar hemangioblastoma, uterine leiomyoma, pheochromocytoma

## Clinical Features of Polycythemia

**Q. Write short essay/note on clinical features of polycythemia.**

- Usually appears insidiously, in late middle age (median age at onset: 60 years).
- Most symptoms are due to the increased red cell mass and hematocrit.
- Plethora and cyanosis due to stagnation and deoxygenation of blood in peripheral vessels are early findings. Headache, dizziness, and visual problems result from vascular disturbances in the brain and retina.
- Increased incidence of thrombotic episodes and bleeding.
- Secondary polycythemia, in addition shows manifestations of the

underlying disease.

## Polycythemia Vera

**Q. Discuss the clinical features, diagnosis and management of polycythemia vera.**

### ***Definition***

- Polycythemia vera (PV) is an **acquired myeloproliferative neoplasm** arising from malignant transformation of **hematopoietic stem cell**.
- It is characterized by **trilineage** (erythroid, granulocytic, and megakaryocytic) **hyperplasia** in the bone marrow.
- It leads to **uncontrolled production of red cells, granulocytes and platelets** (panmyelosis) and leads to **erythrocytosis** (polycythemia) and or granulocytosis and thrombocytosis.

### ***Etiology***

The etiology of PV is not known. PV is partly due to a failure of apoptosis as a result of deregulation of the *Bcl-x* gene (anti-apoptotic gene), in addition a mutation in the tyrosine kinase **JAK 2 V617F** (which causes the substitution of phenylalanine for valine at position 617) has been found; this stimulates low grade erythropoiesis.

### ***Clinical Features***

- Onset is insidious.
- Age and gender: Late middle age (median age at onset is 60 years) and more common in males.
- Features due to increased viscosity and/or decreased cerebral perfusion
  - Plethora (excessive fullness of blood) and deep dusky cyanosis due to stagnation and deoxygenation of blood in peripheral vessels are early findings.
  - Headache, dizziness, vertigo, a sense of fullness in the head, rushing in the ears, visual problems, tinnitus, tiredness, syncope and even chorea result from vascular disturbances in the brain and retina.
- Severe itching (pruritus) after a hot bath or when the patient is warm is frequent and may be disabling.

- Thrombotic episodes: For example, deep venous thrombosis, myocardial infarction, thrombosis of hepatic veins (producing Budd-Chiari syndrome).
- Bleeding manifestations: include epistaxis, bleeding from peptic ulcer, bruising and intramuscular hemorrhages.
- Peptic ulcer is seen in few patients and is five times more frequent than general population.
- Hyperuricemia: May result in urate stones, gout and uric acid nephropathy.

### *Physical findings*

- Injection of the conjunctivae, deep red palate, dusky red hands and retinal venous engorgement.
- Splenomegaly is very common (~70%) and is useful in distinguishing PV from secondary polycythemia.
- Hepatomegaly occurs in ~50%.

### **Diagnosis**

- **Hemoglobin increased ranging from 14 to 28 g/dL.**
- **PCV (hematocrit)** increased to about 60%. However, in many patients, the plasma volume is also increased giving rise to near normal hematocrit. Hence, it is important to determine the red cell mass.
- **Red cell count: Increased and usually about 6 million/cu mm ( $6 \times 10^{12}/L$ )**
- **Increased red cell volume and blood viscosity:** Isotope dilution using the patient's  $^{51}\text{Cr}$ -tagged red cells ( $>36\text{ mL/kg}$  in males and  $32\text{ mL/kg}$  in females).
- Total white cell count (~70% ) and platelet count (~50%) usually increased.
- Absolute basophil count: Increased to  $>100/\mu\text{L}$  in majority of patients.
- **Arterial oxygen saturation ( $\text{PO}_2$ )** is normal and is useful for differentiating it from secondary polycythemia.
- **Erythropoietin (EPO) levels are decreased** in urine and serum, in contrast to secondary polycythemia.
- **Bone marrow:** Shows either erythroid hyperplasia or hyperplasia of all

elements (trilineage hyperplasia) and depletion of iron stores.

- **Leukocyte alkaline phosphatase (LAP):** Increased in majority of patients.
- **Serum vitamin B<sub>12</sub> and vitamin B<sub>12</sub>-binding protein** transcobalamin I (TC I) levels: Increased (not routinely measured)
- **Serum uric acid:** Increased indicating increased cell turnover.
- Abnormal liver function tests.
- Janus kinase 2 (JAK2) mutations (e.g. JAK2V617F mutation)
  - In ~95% patients with polycythemia vera, and in ~50% of essential thrombocytosis and primary myelofibrosis.
  - Janus kinases belong to tyrosine kinase family located on chromosome 9.
  - JAK2 is used by the EPO, thrombopoietin and G-CSF receptors to transmit signals and are involved in hematopoiesis.
  - JAK2 inhibitors are used for managing these patients.

*WHO diagnostic criteria for polycythemia vera (PV) (Table 8.39)*

**Table 8.39: WHO (2016) diagnostic criteria for polycythemia vera (PV).**

<b>Major criteria</b>	<b>Minor criteria</b>
1. Hb >16.5 g/dL (men), >16.0 g/dL (women) <b>OR</b> Hematocrit >49% in men, >48% in women <b>OR</b> Elevated red cell mass >25% above mean normal predicted value 2. Bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) including prominent erythroid, granulocytic and megakaryocytic proliferation with pleomorphic, mature megakaryocytes (differences in size) 3. Presence of JAF2V617 F (a mutation in JAK2) or JAK2 exon 12 mutation	Subnormal serum EPO level
<b>Diagnostic criteria for PV</b> Either all three major criteria, or the first two major criteria and the minor criterion.	

## ***Clinical Course***

The clinical course tends to proceed as a series of phases.

- Proliferative phase: Erythroid proliferation with increased red cell mass.
- Spent phase: Excessive proliferation of erythroid cells ceases, resulting in stable or decreased erythrocyte mass
- Progression to myelofibrosis
- Acute myelogenous leukemia in 2–5% of cases.

## ***Complications of PV (Box 8.16)***

### **Box 8.16:** Complications of PV.

- Thrombotic and bleeding episodes
- Peptic ulcer
- Hyperuricemia (gout)
- Sudden increase in splenic size
- Acute nonlymphocytic leukemia
- Myelofibrosis and myeloid metaplasia
- Erythromelalgia (thrombocytosis, involving the lower extremities with erythema, warmth, and pain and occasionally digital infarction)

#### **Treatment (Fig. 8.32)**

PV generally has a very slow course.

**Aim of treatment:** To maintain a normal blood count, PCV below 0.45 L/L and the platelet count below  $400 \times 10^9/L$  and to prevent the complications (mainly thrombosis and hemorrhage).

- **Venesection:** Repeated venesection (phlebotomy) is the treatment of choice and relieves many of the symptoms of PV.
- **Chemotherapy**
  - Chemotherapy is indicated if the patient is intolerant to venesection, or thrombocytosis occurs, or symptomatic or progressive splenomegaly develops.
  - Continuous or intermittent treatment with **hydroxycarbamide (hydroxyurea)** is the treatment of choice in patients above 40 years. It controls thrombocytosis and generally safer than alkylating agents (e.g. busulfan) and  $^{32}P$  (Phosphorus) which carry an increased risk of acute leukemia.
  - In younger patients, interferon- $\alpha$  is used.
- **Radioactive  $^{32}P$ :** One dose may give control for up to 1½ years, but carries an increased risk to acute leukemia. In elderly patients (>70 years),  $^{32}P$  or low-dose intermittent busulphan may be more convenient.
- **Other measures:**
  - Low dose aspirin: May be used to reduce thrombotic episodes.
  - Anagrelide (inhibits platelet aggregation): May be used if thrombotic features develop despite above treatment.
  - Itching should be treated with antihistamines. If do not relieve, hydroxyurea, interferon- $\alpha$  and psoralens with UV light in ‘A’ range (PUVA) may be helpful.

– Asymptomatic hyperuricemia does not require treatment.

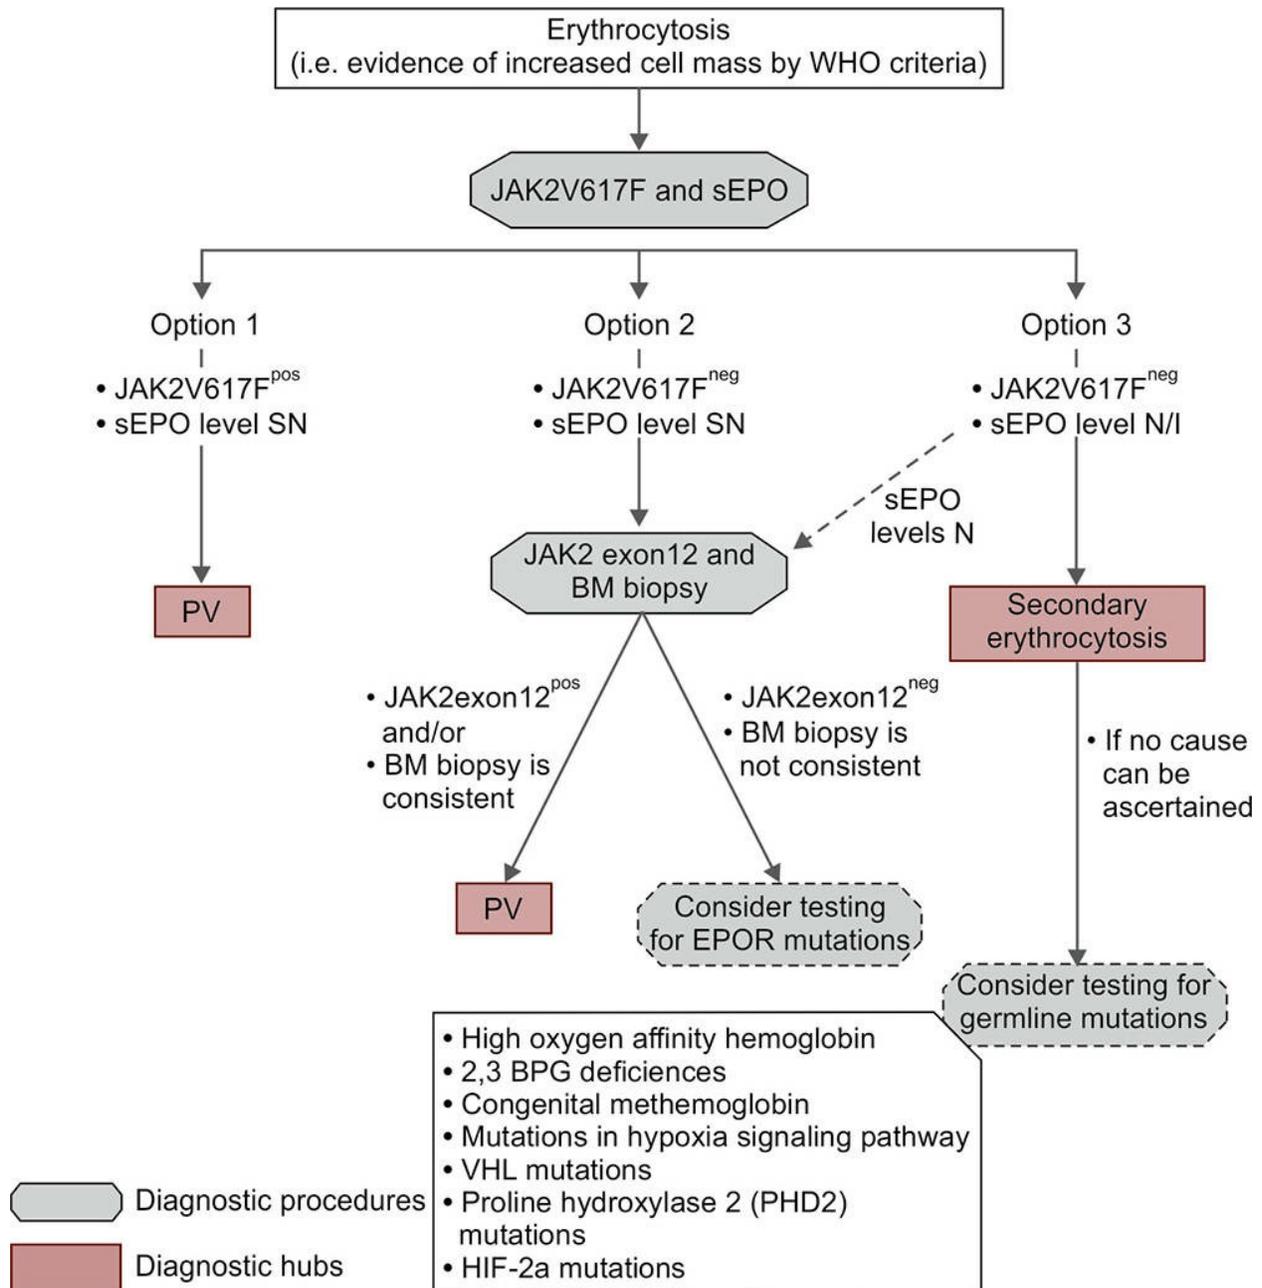

Fig. 8.32: Approach to polycythemia.

**Q.** How will you differentiate primary polycythemia (polycythemia vera) from secondary polycythemia with hypoxia [(e.g. chronic obstructive pulmonary disease (COPD))]?

*Differences between polycythemia vera and secondary polycythemia (Table 8.40)*

**Table 8.40:** Differences between polycythemia vera and secondary polycythemia.

<i>Feature</i>	<i>Polycythemia vera</i>	<i>Secondary polycythemia</i>
1. Oxygen saturation	Normal	Low
2. EPO (erythropoietin) levels	Decreased	Increased
3. Blood counts	Increased	Normal
– Total white cell count	Increased	Normal
– Absolute basophil count	Increased	Normal
– Platelet count		
4. Leukocyte alkaline phosphatase (LAP)	Raised	Normal
5. Vitamin B <sub>12</sub> levels	Increased	Normal
6. Bone marrow	Trilineage (panhyperplasia)	Erythroid hyperplasia
7. Splenomegaly	Present	Absent

## Primary Myelofibrosis

**Q.** Discuss the clinical features, investigations and management of primary myelofibrosis (agnogenic myeloid metaplasia, myelofibrosis with myeloid metaplasia).

**Definition:** Primary myelofibrosis is a clonal MPN characterized by increased fibrosis within the marrow, which replaces hematopoietic cells leading to cytopenias, splenomegaly and extensive extramedullary hematopoiesis. The extramedullary hematopoiesis is seen in the spleen, liver and at times in lymph nodes, kidneys and adrenals.

- It can arise from polycythemia vera (PV) or essential thrombocytosis (ET).

### *Clinical Features*

- Usually found above 60 years of age.
- A significant number of cases develop acute myeloid leukemia.

### *Symptoms*

- Symptoms due to progressive anemia: Fatigue, weakness and anorexia.
- Symptoms due to massive splenomegaly: Abdominal distension, postprandial fullness, reflux esophagitis, dyspnea and dragging discomfort

in the left hypochondrium.

- Symptoms resulting from hypermetabolic state: Fever, fatigue, weight loss, night sweats and heat intolerance.
- Bleeding tendencies due to thrombocytopenia develops at late stages.
- Death usually occurs due to portal hypertension and infections.
- Median survival is about 5 years.

### *Signs*

- Massive splenomegaly and hepatomegaly.
- Anemia, lymphadenopathy, bleeding manifestations, ascites, cardiac failure, and jaundice.
- Hyperuricemia and secondary gout due to a high rate of cell turnover.
- Extramedullary hematopoiesis: May produce paraspinal masses with spinal cord compression, ascites, and effusions (pleural and pericardial).

### *Investigations*

- Hemoglobin level: Normal in the early stages, but markedly reduced in the late stages.
- Total leukocyte count: Normal/increased (early stages)/decreased (late stages).
- Platelet count: Increased in early stages and decreased in the late stages.
- Peripheral smear:
  - **RBC series**
    - ♦ Moderate to severe degree of normochromic normocytic anemia accompanied by **leukoerythroblastic blood picture** (precursors of granulocytes and nucleated RBCs being present simultaneously).
    - ♦ **Many tear drop-shaped red cells** (dacryocytes) probably due to damage in the fibrotic marrow.
    - ♦ Basophilic stippling.
  - **Giant platelets** with vacuoles.
- **Bone marrow:** The peripheral smear findings are not specific and bone marrow biopsy is diagnostic.
  - Cellularity: Early stages (cellular phase), it is often hypercellular and in later stages (hypocellular phase), it becomes hypocellular and

diffusely fibrotic.

– Megakaryocytes are large, dysplastic and abnormally clustered.

- **LAP score:** Raised
- **Philadelphia chromosome:** Negative.
- JAK2 V617F mutation occurs in ~50% patients. CALR mutation is also present.
- **Serum vitamin B<sub>12</sub>:** Moderately increased.
- **Radiological examination shows** increased bone density of vertebrate and proximal ends of long bones.

### Treatment

No specific therapy exists for primary myelofibrosis.

#### 1. Treatment of anemia

- Correct other causes of anemia like gastrointestinal blood loss and folic acid deficiency (Folic acid 5 mg daily).
- Packed red cell transfusions.
- Neither recombinant erythropoietin nor androgens (such as Danazol) is consistently effective in controlling anemia but can be tried in some patients.
- Glucocorticoids (prednisolone) may control constitutional symptoms and autoimmune complications.
- Combination with low-dose thalidomide (50–100 mg/day) with prednisolone can control anemia and splenomegaly in a significant number of patients.

#### 2. Treatment of splenomegaly

- **Patients with cellular bone marrow and marked leukocytosis:** Busulphan 2 mg daily.
- Indications for splenectomy in selected cases
  - With hypersplenism
  - If splenomegaly impairs alimentation and should be performed before cachexia sets in.
- Splenic irradiation: To reduce splenic size is reserved for patients, who cannot undergo splenectomy. Patients often develop severe cytopenias.
- Hydroxyurea is useful to control splenomegaly, but can produce myelosuppression that may exacerbate underlying anemia.

#### 3. Treatment of extramedullary hematopoiesis: By low dose irradiation

#### 4. Curative treatment: Allogeneic bone marrow transplantation is the only curative treatment. It should be performed in younger patients as most patients in IMF are above 60 years of age.

#### 5. Others

- Allopurinol can control hyperuricemia.
- Etanercept (TNF- $\alpha$  antagonist) used in patients with severe constitutional features.
- JAK2 inhibitors ruxolitinib is used in clinical practice.

## Prognosis

Median survival varies from 27 to 135 months and depends on prognostic factors (Table 8.41).

**Table 8.41:** Shows poor prognostic factors.

Age > 65 years	Hemoglobin level <10 g/dL	Total WBC count >25,000/mm <sup>3</sup>
Presence of blasts in peripheral blood	Presence of constitutional symptoms	

**Table 8.42:** Various causes of secondary myelofibrosis.

<i>Malignant conditions</i>	<i>Non-malignant conditions</i>
Hematological <ul style="list-style-type: none"> <li>• Leukemia                             <ul style="list-style-type: none"> <li>– Acute leukemia (lymphoid/myeloid)</li> <li>– Chronic myeloid leukemia</li> <li>– Hairy cell leukemia</li> </ul> </li> <li>• Multiple myeloma</li> <li>• Polycythemia vera</li> <li>• Hodgkin’s lymphoma</li> <li>• Essential thrombocytosis</li> </ul>	Infections <ul style="list-style-type: none"> <li>• HIV infection</li> <li>• Tuberculosis</li> <li>• Exposure to thorium dioxide</li> <li>• Systemic lupus erythematosus</li> <li>• Renal osteodystrophy</li> <li>• Hyperparathyroidism</li> <li>• Radiation therapy or treatment with radiomimetic drugs</li> <li>• Gaucher disease</li> </ul>
Non-hematological <ul style="list-style-type: none"> <li>• Metastasis to marrow                             <ul style="list-style-type: none"> <li>– Carcinoma breast, lung or prostate</li> <li>– Neuroblastoma</li> </ul> </li> </ul>	

## Myelophthisis

**Q. Write short note on myelophthisis and its causes.**

- Fibrosis of the bone marrow can occur as a primary hematologic disease is known as primary myelofibrosis (myeloid metaplasia), and as a secondary reactive process, known as myelophthisis (secondary myelofibrosis).

**Causes of myelophthisis** (other causes of myelofibrosis) are presented in Table 8.42. These causes may also produce splenomegaly.

**Q. How will you differentiate chronic myeloid leukemia from myelofibrosis?**

## Difference between chronic myeloid leukemia from myelofibrosis (Table 8.43).

**Table 8.43:** Difference between chronic myeloid leukemia from myelofibrosis.

<i>Features</i>	<i>Chronic myeloid leukemia</i>	<i>Myelofibrosis</i>
<b>Total leukocyte count</b>	Markedly raised usually more than 20,000/ $\mu$ L.	May be raised, but always less than 20,000/ $\mu$ L
<b>Peripheral blood</b>		
Peripheral smear	Shows full range of granulocyte precursors, predominantly mature forms	Shows leukoerythroblastosis with tear drop cells
Nucleated red cells	Few or absent	Numerous
Thrombocytopenia	Occurs late	Common
Marrow fibrosis	Uncommon and minimal	Common and dense
LAP (leukocyte alkaline phosphatase) score	Very low, usually <5	High, usually >100
Philadelphia chromosome	Positive	Negative
Serum vitamin B <sub>12</sub> levels	Very high	Moderately raised

## Myelodysplastic Syndromes

**Q.** Describe the etiology, classification, clinical features, diagnosis and treatment of myelodysplastic syndrome (MDS).

### **Definition**

Myelodysplastic syndromes (MDS) are a heterogeneous group of acquired clonal stem cell disorders characterized by:

- Progressive cytopenias (low blood cell counts)
- Dysplasia in one or more major cell lines (erythroid, myeloid and megakaryocytic forms)
- Ineffective hematopoiesis
- Increased risk of development of AML
- A subtype of myeloid neoplasms.

### **Etiology**

- In primary MDS the exact cause is not known, however genetic factors

may play a role.

- Causes of secondary/t-MDS: Exposure to radiation, benzene, postchemotherapy (particularly alkylating agents and topoisomerase inhibitors), viruses, cigarette smoking and PNH.
- Median age is 65 years.

### ***WHO (2016) Classification of MDS***

The revised WHO (2016) diagnosis and classification of MDS introduces refinements in morphologic interpretation, cytopenias assessment and genetic information. Cytopenia is necessary for diagnosis of any MDS and in WHO (2008) classifications, MDS nomenclature included references to ‘cytopenia’ or to specific types of cytopenia (e.g. refractory anemia). Present WHO (2016) classification depends mainly on the degree of dysplasia and blast percentages and specific cytopenias have only minor impact. Hence, the terminology for adult MDS has replaced the terms such as ‘refractory anemia’ and ‘refractory cytopenia’ with ‘myelodysplastic syndrome’ followed by the appropriate modifiers: single versus multilineage dysplasia, ring sideroblasts, excess blasts, or the del (5q) cytogenetic abnormality (Table 8.44).

### ***Clinical Features***

- Usually found in patients above 60 years and slightly more common in males.
- Detected incidentally on routine blood examination in about 50% of patients.
- Symptoms are due to cytopenias which may be single-lineage cytopenia, bicytopenia or pancytopenia. Symptoms include:
  - Weakness (anemia)
  - Infections (leukopenia)
  - Hemorrhage (thrombocytopenia).
- Extramedullary hematopoiesis may cause hepatomegaly and splenomegaly but is uncommon.
- About 10–40% progresses to AML because of which MDS was referred to as preleukemic syndrome.

**Table 8.44:** WHO (2016) classification, peripheral smear and bone marrow findings of myelodysplastic syndromes.

<i>Disease</i>	<i>Dysplastic lineages</i>	<i>Cytopenias<sup>1</sup></i>	<i>Ring sideroblasts as % of marrow erythroid elements</i>	<i>Bone marrow (BM) and peripheral blood (PB) blasts</i>
1. MDS with single lineage dysplasia (MDS-SLD)	1	1 or 2	<15%/<5% <sup>2</sup>	BM <5%, PB <1%, no Auer rods
2. MDS with multilineage dysplasia (MDS-MLD)	2 or 3	1–3	<15%/<5% <sup>2</sup>	BM <5%, PB <1%, no Auer rods
3. MDS with ring sideroblasts (MDS-RS)				
– MDS-RS with single lineage dysplasia (MDSRS-SLD)	1	1 or 2	≥15%/≥5% <sup>2</sup>	BM <5%, PB <1%, no Auer rods
– MDS-RS with multilineage dysplasia (MDS-RS-MLD)	2 or 3	1–3	≥15%/≥5% <sup>2</sup>	BM <5%, PB <1%, no Auer rods
4. MDS with isolated del (5q)	1–3	1–2	None or any	BM <5%, PB <1%, no Auer rods
5. MDS with excess blasts (MDSEB)				
– MDS-EB-1	0–3	1–3	None or any	BM 5–9% or PB 2–4%, no Auer rods
– MDS-EB-2	0–3	1–3	None or any	BM 10–19% or PB 5–19% or Auer rods
6. MDS, unclassifiable				

(MDS-U)				
– with 1% blood blasts	1–3	1–3	None or any	BM <5%, PB=1% <sup>3</sup> , no Auer rods
– with single lineage dysplasia and pancytopenia	1	3	None or any	BM <5%, PB <1%, no Auer rods
– based on defining cytogenetic abnormality	0	1–3	<15% <sup>4</sup>	BM <5%, PB <1%, no Auer rods
7. Refractory cytopenia of childhood	1-3	1–3	None	BM <5%, PB <2%

<sup>1</sup>Cytopenias defined as hemoglobin <10 g/dL, platelet count <100 × 10<sup>9</sup>/L, and absolute neutrophil count <1.8 × 10<sup>9</sup>/L; rarely, MDS may present with mild anemia or thrombocytopenia above these levels. PB monocytes must be <1 × 10<sup>9</sup>/L.

<sup>2</sup>If *SF3B1* mutation is present.

<sup>3</sup>1% PB blasts must be recorded on at least two separate occasions.

<sup>4</sup>Cases with ≥15% ring sideroblasts by definition have significant erythroid dysplasia, and are classified as MDS-RS-SL.

## Diagnosis

- Minimal morphologic criterion for the diagnosis of an MDS: Dysplasia in at least 10% of cells of any one of the myeloid lineages.
- Complete blood count: May give clues to this diagnosis.
- **Peripheral smear:**
  - **RBC:** Mild to moderate degree of macrocytic or dimorphic anemia with evidence of dyspoiesis.
  - **WBC** count may be normal or low. Neutropenia with few blasts. Number of blasts determines the type of MDS (see Table 8.44). The cytoplasm of neutrophils is hypogranular or agranular. The nuclei of neutrophils may show hyposegmentation with only two nuclear lobes (Pseudo-Pelger-Huet cells), hypersegmentation or ringed neutrophils.
  - **Platelets:** Variable thrombocytopenia, presence of large hypogranular or giant platelets is seen.

- **NAP score** is moderately or severely decreased.
- **Bone marrow:** The most characteristic features are varying degree of dyspoietic (disordered) differentiation affecting all non-lymphoid lineages (erythroid, granulocytic, monocytic and megakaryocytic) associated with cytopenias.
- Cytogenic study of the marrow: Most important for establishing the diagnosis. Chromosome abnormalities of chromosome 5 or 7 are frequent.

#### Treatment

- Therapy is supportive:
  - Packed red cell transfusion for anemia.
  - Platelet transfusions for bleeding due to thrombocytopenia.
  - Antibiotic therapy for infections.
  - Iron chelators to reduce iron overload from multiple transfusions.
- EPO (erythropoietin) and G-CSF (granulocyte colony stimulating factor) may be useful in some patients, to ameliorate symptoms.
- Others: Use of thalidomide, lenalidomide (a derivative of thalidomide), 5-azacitidine and decitabine. 5-azacytidine and decitabine (hypomethylating agents) may reduce requirements of blood transfusion and to retard the progression of MDS to AML. Lenalidomide is found useful in the 5q-syndrome.
- Allogeneic hematopoietic stem cell transplantation: Curative. However, it may be performed in less than 5–10% of patients because MDS is most common during seventh or eighth decade of life.

## PLASMA CELL NEOPLASMS

**Q. Write short essay/note on plasma cell neoplasms/disorders.**

**Classification of plasma cell proliferative disorders (Table 8.45).**

### Multiple Myeloma

**Q. Discuss the immunopathology, pathology, clinical features, investigations, diagnosis and treatment of multiple myeloma.**

- Multiple myeloma (MM) is a malignant plasma cell neoplasm derived from a single clone plasma cells of the bone marrow and produces multiple, lytic bone lesions.
- Plasma cells are derived from B lymphocytes.
- Normal plasma cells secrete equal quantities of heavy and light chains. But the neoplastic plasma cells frequently synthesize excess of light (L) or

heavy (H) chains along with complete Igs. Rarely, only light chains or heavy chains are produced.

- The excess of free light chains are small with low molecular weight and therefore excreted in the urine. They are known as Bence-Jones proteins.
- **Classification of myeloma:** It is based on the type of paraprotein secreted namely: (1) IgG (55%), (2) IgA (25%), (3) IgD (uncommon), (4) IgE (uncommon), and (5) light chain disease (20%). In non-secretory myeloma, there is no M-protein in the blood or urine but bone marrow shows plasmacytosis.
- The cause of multiple myeloma is unclear. Exposure to radiation, benzene, and other organic solvents, herbicides, and insecticides may play a role. Multiple myeloma has been reported in familial clusters of two or more first-degree relatives and in identical twins.

**Table 8.45: Classification of plasma cell proliferative disorders.**

I. Monoclonal gammopathies of undetermined significance (MGUS)

- Benign (IgG, IgA, IgD, IgM, and rarely, free light chains)
- Associated neoplasms or other diseases not known to produce monoclonal proteins
- Biclonal gammopathies
- Idiopathic Bence-Jones proteinuria

II. Malignant monoclonal gammopathies

- Multiple (plasma cell) myeloma (IgG, IgA, IgD, IgE, and free light chains)
  - Overt multiple myeloma
  - Smoldering multiple myeloma
  - Plasma cell leukemia
  - Nonsecretory myeloma
  - IgD myeloma
  - Osteosclerotic myeloma (POEMS syndrome)
  - Solitary plasmacytoma of bone
  - Extramedullary plasmacytoma
- Waldenström's macroglobulinemia

III. Heavy chain diseases (HCDs)

- A.  $\gamma$ -HCD
- B.  $\alpha$ -HCD
- C.  $\mu$ -HCD

IV. Cryoglobulinemia

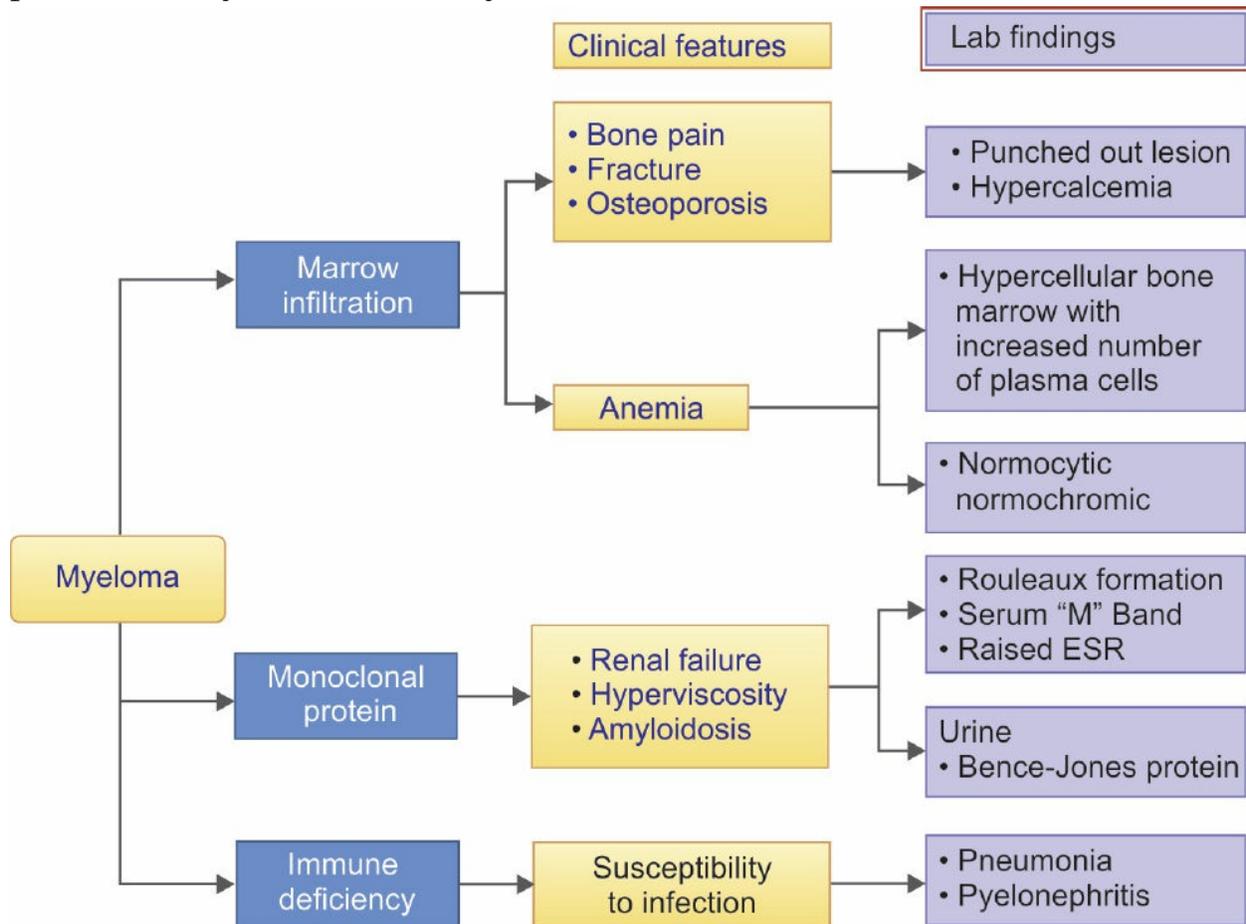

V. Primary amyloidosis (AL)

## Clinical Features

- Insidious in onset.
- Age and gender: Peak incidence is seen during 6th to 7th decade, and males are more affected than females.
- Symptoms (Flowchart 8.2 and Table 8.46).
  - Some patients may be asymptomatic, and is accidentally detected during the preclinical phase.

## Osteosclerotic Myeloma (POEMS Syndrome)

This syndrome is characterized by polyneuropathy, organomegaly, endocrinopathy, M-protein, and skin changes (POEMS). The major clinical features are a chronic inflammatory-demyelinating polyneuropathy with predominantly motor disability and sclerotic skeletal lesions.

**Flowchart 8.2:** Clinical features and laboratory findings in myeloma.

**Table 8.46: Clinical features in multiple myeloma based on involved organ/system.**

<i>Involved organ/system</i>	<i>Features (Box 8.17)</i>
Bone	<ul style="list-style-type: none"> <li>• Localized bony swellings over vertebrae, skull, sternum, ribs and clavicle</li> <li>• Bone pain due to pathological fractures, backache due to involvement of vertebra (60%)</li> <li>• Neurological symptoms of sensory and/or motor loss due to lesion in the vertebra compressing the spinal cord nerve root</li> </ul>
Bone marrow	<ul style="list-style-type: none"> <li>• Anemia, leukopenia and thrombocytopenia</li> </ul>
Immune system	<ul style="list-style-type: none"> <li>• Humoral immune deficiency leading to increased susceptibility to infections (recurrent infections), particularly of the respiratory system and urinary tract</li> </ul>
Renal damage is multifactorial due to Bence-Jones proteinuria, hypercalcemia, humoral immune deficiency	<ul style="list-style-type: none"> <li>• Nephrocalcinosis, amyloidosis, renal insufficiency (renal failure in 20–30%), infections or nephrotic syndrome</li> </ul>
Bleeding tendency due to thrombocytopenia	<ul style="list-style-type: none"> <li>• Purpura, epistaxis, gastrointestinal bleeding</li> </ul>
Cryoglobulinemia and hyperviscosity (uncommon) syndrome	<p>Hyperviscosity may affect the:</p> <ul style="list-style-type: none"> <li>• CNS (leading to confusion, headache, vertigo, nystagmus, postural hypotension and dizziness)</li> <li>• Retina (producing blurred vision, retinal venous congestion, papilledema)</li> <li>• CVS (congestive cardiac failure)</li> </ul>
Neurological manifestations	<p>Amyloid peripheral neuropathy, carpal tunnel syndrome, and compressive myelopathy</p>

## ***Diagnosis of Multiple Myeloma***

**Q. Write short essay/note on diagnosis and management of multiple myeloma.**

Requires at least two of the following:

1. Monoclonal immunoglobulin (M protein) or light chains in the blood (>3 g/dL) and/or urine.
2. Infiltration of bone marrow with (clonal) plasma cells (≥10%) or plasmacytoma.
3. Evidence of myeloma-related organ or tissue impairment (≥1)-CRAB
  - Hypercalcemia: Serum (ionized) >5.5 mEq/L.
  - Renal insufficiency creatinine clearance <40 mL/min, calcium >2.75 mmol/L or >0.25 mmol/L

than the ULN.

- Anemia (hemoglobin or 2 g/dL below the LLN).
- Lytic bone lesions and/or osteoporosis.

4. Other criteria

- Free light chain ratio between involved to uninvolved light chains >100
- Presence of >1 bone lesion on MRI
- Bone marrow plasma cell percentage >60.

**Box 8.17:** Mnemonic to remember common symptoms of multiple myeloma.

**CRAB:** C = Calcium (elevated), R = Renal failure, A = Anemia, B = Bone lesions.

### *Smoldering (asymptomatic) multiple myeloma*

- Smoldering multiple myeloma is defined by the presence of serum M-protein level greater than 3 g/dL and/or 10% or more plasma cells in bone marrow and patients are asymptomatic.
- This entity lies in between multiple myeloma and monoclonal gammopathy of uncertain significance. Patients with smoldering multiple myeloma carry a much higher risk of progression to myeloma or related malignancy compared to MGUS.

### *Investigations in Multiple Myeloma*

- **Peripheral blood**
  - Usually shows anemia, leukopenia, thrombocytopenia and raised ESR.
  - Peripheral blood smear: May show **rouleaux formation** due to increased immunoglobulins.
- **Bone marrow examination** is important. Normal bone marrow contains 2–10% plasma cells. In myeloma, the bone marrow is **hypercellular** as a result of increased number of plasma cells and **myeloma cells** (neoplastic plasma cells). Increased number of **myeloma cells, more than 30%** of the cellularity is diagnostic.
- **Urine: Bence-Jones proteins** may be present
- **Serum findings:**
  - **Serum  $\beta_2$  microglobulin:** It is a useful **prognostic marker** and **high values signify poor prognosis.**
  - **Hypercalcemia** is due to extensive osteolytic lesions and osteoporosis and there are also increased levels of serum phosphate.

- Serum alkaline phosphatase: Usually normal in the absence of complications.
- Blood urea and serum creatinine raised in 20% of cases and along with electrolytes are used to assess renal function.
- Serum proteins: Total serum protein level is increased, albumin is decreased and globulins are markedly increased.
- Serum uric acid: Raised.
- Serum immunoglobulin estimation reveals a reduction of normal immunoglobulins below normal levels.
- **Electrophoretic studies on serum and urine:** Electrophoretic studies reveal raised levels of immunoglobulins in the blood and/or light chains (Bence-Jones proteins) in the urine. The monoclonal immunoglobulin (M-protein) is identified as abnormal protein ‘spikes’ in serum or urine electrophoresis. The type of immunoglobulin can be determined by immunofixation. The most common M-protein is IgG type, followed by IgA.
- **Radiological examination:**
  - Reveals generalized osteoporosis.
  - Radiographs of flat bones: Such as **skull (Fig. 8.33), vertebral bodies, ribs and pelvis** show the characteristic punched-out osteolytic lesions.
  - Collapse of multiple vertebrae is a common finding.
- MRI and PET: May detect bone involvement when skeletal survey is normal.

**Fig. 8.33:** X-ray of skull in myeloma showing punched out lesions.

### ***Staging (Tables 8.47 and 8.48)***

**Table 8.47:** Modified from Durie-Salmon staging.

<b><i>Stage</i></b>	<b><i>Criteria</i></b>
Stage-I	<ul style="list-style-type: none"> <li>• Low M-component: IgG &lt; 5 g/dL, IgA &lt; 3 g/dL, Urine Bence-Jones (BJ) protein &lt; 4 g/24 hours</li> <li>• Normal hemoglobin, serum calcium, Ig levels (non-M protein)</li> </ul>
Stage-II	Overall values between stage I and III
Stage-III	One or more of the following:

- Hemoglobin < 8.5 g/dL, serum calcium >12 mg/dL
- High M-component: IgG > 7 g/dL, IgA > 5 g/dL, urine light chain >12 g/24 hours
- Advanced multiple lytic lesions on X-rays

Subclassification based on renal function

- Subclass A = Serum creatinine <2 mg/dL
- Subclass B = Serum creatinine >2 mg/dL

**Table 8.48:** International staging system.

<i>Stage</i>	<i>Characteristic features</i>	<i>Median survival</i>
I	Serum $\beta_2$ -microglobulin < 3.5 mg/dL and serum albumin > 3.5 g/dL	62 months
II	Serum $\beta_2$ -microglobulin < 3.5 mg/dL and serum albumin <3.5 g/dL and or serum $\beta_2$ -microglobulin < 3.5–5.5 mg/dL	44 months
III	$\beta_2$ -microglobulin < 5.5 mg/dL	29 months

## Treatment

### General measures

- High fluid intake of about 3 L/day to treat renal impairment and hypercalcemia.
- Prompt treatment of infections with antibiotics.
- Treatment of anemia may require blood transfusion and erythropoietin often helps.
- Analgesics to be given for relief of bone pain.
- Allopurinol 300 mg daily should be given to reduce/prevent hyperuricemia and urate nephropathy.
- Hyperviscosity syndrome is managed by plasmapheresis.
- Bisphosphonates (e.g. zoledronate, pamidronate, clodronate) which inhibit osteoclast activity. Long-term treatment with this, reduce skeletal events such as pathological fracture, cord compression and bone pain. An important complication of bisphosphonates is osteonecrosis of jaw.
- Orthopedic assistance and physiotherapy can significantly improve the quality of life.
- Renal failure: Treated by rehydration and oral prednisolone.

### Autologous stem cell transplantation

- Young patients (<65 years) without renal failure: Standard treatment is first-line high-dose chemotherapy for myeloablation (melphalan 200 mg/m<sup>2</sup> intravenously) to maximum response and then an autologous stem-cell transplantation.

### Box 8.18: Median survival.

- Patients with advanced myeloma: 7–8 months.
- With good supportive care and chemotherapy: 3 to 5 years. Asymptomatic stage I patients are generally not given chemotherapy.
- Young patients with intensive therapy may live longer.

## Chemotherapy

### Older patients

- Thalidomide combined with the alkylating agent (melphalan or cyclophosphamide or chlorambucil) and prednisolone. Thalidomide is teratogenic. Recent studies have suggested that combination with thalidomide, results in improved response rates and overall survival, albeit with increased toxicity (Box 8.18).
- Bortezomib is a proteasome inhibitor, which is used for upfront and relapsed is combined with doxorubicin and dexamethasone.
- Lenalidomide in combination with steroids has been tried.

### Younger patients (<65–70 years)

- Bortezomib, cyclophosphamide and dexamethasone. OR Newer drugs include carfilzomib, ixazomib, pomalidomide, daratumumab and elotuzumab.
- Orally active cyclophosphamide, thalidomide and dexamethasone-based induction (CTD), followed by a high-dose melphalan autograft.

### Radiotherapy

- Effective for local problems like severe bone pain, pathological fractures and tumorous lesions.
- As an emergency treatment of spinal cord compression complicating extradural plasmacytomas.

## Renal Involvement in Multiple Myeloma

### Q. Write short note on the cause of renal failure of multiple myeloma.

- Renal involvement is observed in 50% of myeloma patients.
- Renal failure develops in ~25% of patients with multiple myeloma.
- Various factors contributing to renal failure in multiple myeloma are:
  - **Tubular damage** from excretion of light chains (Bence-Jones proteinuria).
  - Hypercalcemia resulting in **nephrocalcinosis** and renal damage.
  - **Amyloid deposition** in the glomeruli (renal amyloidosis).
  - Hyperuricemia producing in **urate nephropathy**.
  - **Recurrent urinary tract infections**.
  - **Infiltration** of the kidney by **myeloma cells**.

## Poor prognostic factors in multiple myeloma (Table 8.49)

### Q. Write short note on the indications of poor prognosis in multiple myeloma.

**Table 8.49:** Poor prognostic factors in multiple myeloma.

High levels of $\beta_2$ -microglobulin	Low serum albumin
High serum calcium >12 g/dL at presentation	Low hemoglobin (<8.5 g/dL)
Advanced lytic bone lesions	Thrombocytopenia

Renal failure

Plasma cell leukemia

### Radiographic features in multiple myeloma (Table 8.50)

**Q. Write short note on the role of radiographic examination in the diagnosis of multiple myeloma.**

**Table 8.50:** Radiographic features helpful in the diagnosis of multiple myeloma.

Site of X-ray	Appearance
Skull and pelvis	Multiple punched out osteolytic lesions osteoporosis
Chest	Pathological fractures and punched out lesions of ribs, clavicle and scapulae Osteoporosis
Spine	Collapse of multiple vertebrae Osteoporosis
Kidney Ureter and Bladder (KUB)	Nephrocalcinosis

### Monoclonal gammopathy of uncertain significance (MGUS)

**Q. Write short essay/note on monoclonal gammopathy of uncertain significance (MGUS).**

**Definition:** MGUS is defined as presence of serum M-protein concentration lower than 3 g/dL, bone marrow clonal plasma cells < 10% plasma cells and no end organ damage [CRAB (refer Box 8.17) no hypercalcemia, no renal impairment, no anemia or no osteolytic lesions] or no evidence of other B-cell neoplasms.

- MGUS is one of the most common plasma cell dyscrasias, occurring in about 3–5% of general population above the age of 50 years.
- **Progression:** MGUS should be considered as pre-neoplastic condition. It can progress to multiple myeloma, Waldenstrom's macroglobulinemia, primary AL amyloidosis, or a lymphoproliferative disorder at a rate of 1–1.5% per year. Risk of progression to multiple myeloma and related disorders depends upon:
  - Size of M-component (risk of progression with an M-protein value of 1.5 g/dL almost twice that of a patient with an M-Protein value of 0.5

- g/dL)
- Type of m-component (IgM and IgA increased risk compared to IgG), and
  - Abnormal free light chain ratio (kappa; lambda ratio-normal being 0.26–1.65).
- Follow-up: Patients should be followed with serum protein electrophoresis at 6 months and, if stable, can be followed every 1–2 years.
  - No treatment is indicated.

*Differences between multiple myeloma and monoclonal gammopathy of undetermined significance (Table 8.51)*

**Q. How do you differentiate between multiple myeloma and monoclonal gammopathy of undetermined significance (MGUS)?**

### Solitary Plasmacytoma

**Q. Write short essay/note on solitary plasmacytoma of bone.**

- Solitary plasmacytoma (osseous plasmacytoma) is a solitary tumor occurring in the bone consisting of collection of monoclonal plasma cells.
- Comprises 3–5% of plasma cell neoplasms.
- Sites: Common sites are bones with active hematopoiesis and usually occur in the same sites as in multiple myeloma (vertebrae, ribs, skull, pelvis, femur, clavicle and scapula).
- Clinical features: Localized bone pain or pathological fracture. Vertebral lesions may produce neurologic symptoms secondary to spinal cord or root compression.
- Investigations:
  - M-protein in serum or urine observed 24–72% of patients by immune fixation
  - MRI is useful to rule out occult systemic disease.
- Treatment: Local control is achieved by radiotherapy. Up to two-thirds of patients develop systemic disease.
- Prognosis: Median survival is 7–12 years.

**Table 8.51: Differences between multiple myeloma and monoclonal**

## gammopathy of undetermined significance.

<i>Characteristic features</i>	<i>Multiple myeloma</i>	<i>MGUS</i>
M-protein	Found in serum and /or urine except in patients with non-secretory	Intact immunoglobulin (e.g. IgG, IgM, IgA)
Bone marrow	Clonal plasma cells 10% or more	<ul style="list-style-type: none"> <li>• Clonal plasma cells &lt; 10%</li> <li>• No evidence of other B-cell proliferative disorders</li> </ul>
Organ/tissue involvement	<ul style="list-style-type: none"> <li>• At least one of the following:</li> <li>• Serum calcium (ionized) &gt;5.5 mEq/L</li> <li>• Renal insufficiency (creatinine &gt;2 mg/dL)</li> <li>• Anemic (hemoglobin &lt;10 g/dL)</li> <li>• Bone involvement-osteolytic bone lesions and /or osteopenia</li> </ul>	<ul style="list-style-type: none"> <li>• No hypercalcemia, renal impairment, anemia or bone involvement</li> </ul>

## Solitary Extraosseous Plasmacytoma

### Q. Write short essay/note on solitary extraosseous plasmacytoma.

- Extraosseous (extramedullary) plasmacytoma are localized plasma cell neoplasms that arise in tissues other than bone.
- Comprises 3–5% of all plasma cell neoplasms.
- Sites:
  - Upper respiratory tract (80%): Oropharynx, nasopharynx, sinuses and larynx.
  - Other sites: GI tract, lymph nodes, bladder, CNS, breast, thyroid, testis, parotid and skin.
- Only about 20% of patients have M protein (most commonly IgA).
- Diagnosis: Requires exclusion of occult systemic disease by extensive radiographic imaging.
- Treatment: Eradicated with local radiation therapy.
- Prognosis:
  - About 15% of patients subsequently develop multiple myeloma.
  - About 70% of patients remain disease free at 10 years.

## Plasma Cell Leukemia

**Q. Write short essay/note on plasma cell leukemia.**

- Plasma cell leukemia (PCL) is the term used when the peripheral blood has more than 20% plasma cells with an absolute plasma cell count of 2000/ $\mu$ L or greater.
- Classification: Plasma cell leukemia may be classified as:
  - Primary plasma cell leukemia: It develops without any preceding evidence of multiple myeloma. It is diagnosed in the leukemic phase (60%). It develops in younger individuals and presents with hepatosplenomegaly and lymphadenopathy, a higher platelet count, few bone lesions, mild serum M-protein component and longer survival rate when compared to those with secondary plasma cell leukemia.
  - Secondary: When leukemic transformation develops in a patient with multiple myeloma (40%).
- It is an aggressive disease associated with a high tumor burden and extramedullary dissemination.

## Waldenstrom Macroglobulinemia

**Q. Write short essay/note on Waldenstrom macroglobulinemia.**

- Waldenstrom macroglobulinemia is a syndrome characterized by IgM monoclonal gammopathy sufficient to cause a hyperviscosity of the blood and bone marrow infiltration.
- Most commonly occurs in association with lymphoplasmacytic lymphoma. The tumor cells undergo terminal differentiation to plasma cells and secrete monoclonal IgM.
- It occurs in older adults (median age 60 years).

### *Clinical Features*

May be asymptomatic.

- Usual presenting complaints are nonspecific and include weakness, fatigue, and weight loss. Symptoms develop due to:
  - **Tumor infiltration:** Most patients present with weakness and fatigue due to anemia caused by marrow infiltration. Other features include fever, night sweats, weight loss, lymphadenopathy, hepatomegaly and splenomegaly.

- **Monoclonal protein:** About 10% of patients have autoimmune hemolysis caused by cold agglutinins (monoclonal IgM bind to red cells at temperatures of less than 37°C). IgM may be associated with systemic amyloidosis. IgM-secreted by the tumor, because of its large size, at high concentrations increases the viscosity of the blood, giving rise to hyperviscosity syndrome. Features of hyperviscosity syndrome are:
  - ◆ Visual impairment associated with venous congestion (e.g. blurring or loss of vision)
  - ◆ Neurologic problems (e.g. dizziness, headache, vertigo, nystagmus, hearing loss, ataxia, paresthesias, diplopia)
  - ◆ Bleeding
  - ◆ Cryoglobulinemia produces symptoms such as Raynaud phenomenon and cold urticaria
- Tumor cells can infiltrate organs and result in hepatomegaly, splenomegaly and lymphadenopathy in about 20% patients.

## **Diagnosis**

- Demonstration of monoclonal IgM: By serum electrophoresis, sample may require warming to 37 °C, to avoid interference of cold agglutinins. Immunofixation is required to characterize monoclonal protein.
- Bone marrow aspirate and biopsy: It shows more than 10% lymphoplasmacytic cells (CD20<sup>+</sup>).

## **Treatment**

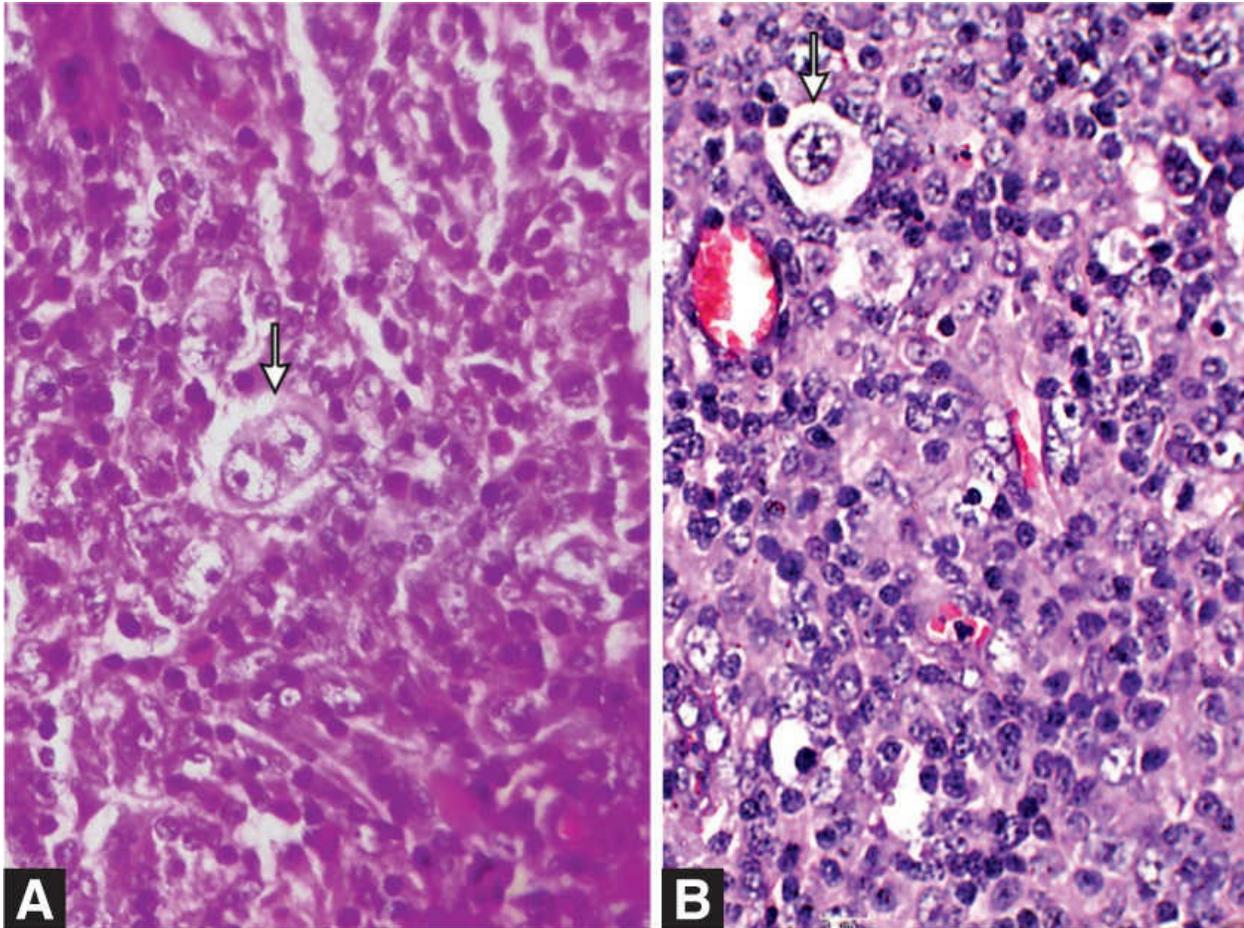

- It is a chemotherapy- and immunotherapy-sensitive disease controllable with currently available therapies.
- No specific treatment needed for patients who do not have systemic symptoms.
- Single agent therapy with rituximab alone is used in symptomatic patients with modest hematologic compromise, IgM-related neuropathy or hemolytic anemia unresponsive to corticosteroids.
- Combination chemotherapy and rituximab (anti CD20): Patients with severe constitutional symptoms, profound hematologic compromise, bulky disease or hyperviscosity syndrome should be treated with the dexamethasone, rituximab and cyclophosphamide Or Bortezomib, dexamethasone and rituximab Or Bendamustine rituximab.
- **Plasmapheresis:** Most of IgM secreted by tumor cells is intravascular. Patient with symptoms due to high IgM levels (such as hyperviscosity and hemolysis) should first undergo plasmapheresis which helps in alleviating these symptoms.

Prognosis: Transformation to large-cell lymphoma occurs but is uncommon. Median survival is 4 years.

## HODGKIN LYMPHOMA

**Q. Discuss the pathological classification, clinical features, clinical staging, investigations, diagnosis and treatment/management of Hodgkin's lymphoma.**

- Hodgkin lymphoma (HL) is a malignant lymphoma characterized by a heterogeneous cellularity comprising of **minority** (1–3%) of specific **neoplastic cells** (Hodgkin cells and Reed-Sternberg cells—Figs. 8.34A and B) in a ‘characteristic background’ of reactive non-neoplastic cells (majority) of various types.
- **Cell of origin:** The neoplastic Reed-Sternberg cells are derived from germinal center or immediate post-germinal center B-cells indicating that most HLs are unusual tumors of B-cell origin.
- **Age:** Bimodal age incidence
  - One peak in young adults (15–35 years)
  - Other peak in older adults (45–75 years)
- The neoplastic cells in Hodgkin lymphoma are **Reed-Sternberg cells** (Figs. 8.34A and B) and its variants.
- Immunophenotype:
  - Reed-Sternberg cells in classical forms of HL are CD15<sup>+</sup> and CD30<sup>+</sup>.
  - Reed-Sternberg cells in lymphocyte predominance HL are CD15-ve and CD30-ve.

**Figs. 8.34A and B:** Microscopic appearance of Hodgkin lymphoma showing RS cells and Hodgkin cells within the background of mixed population of reactive cells.

### ***Etiology***

- **EBV:** Young adults, who have had previous EBV infection (infectious mononucleosis), have an increased risk of developing HL and the EBV genome is frequently identified in the Reed-Sternberg cells.
- **Genetic factors** may play a role because HLA subtypes, particularly HLA-B18, are higher in patients with HL.
- **Immune status:** HL seems to be more frequent in immunocompromised patients or those with autoimmune diseases, such as rheumatoid arthritis.

### ***Classification of Hodgkin Lymphoma***

**Rye classification (Table 8.52):** According to this Hodgkin lymphoma was divided into four types and the prognosis varies depending upon the histological type. The nodular sclerosing type is the most common.

**WHO classification of Hodgkin lymphoma (Box 8.19):** It is the presently followed classification.

**Table 8.52:** Rye classification of Hodgkin lymphoma.

<i>Histological type</i>	<i>Prognosis</i>
Lymphocyte predominant	Very good
Nodular sclerosing	Good
Mixed cellularity	Fair
Lymphocyte depleted	Poor

**Box 8.19:** WHO classification of Hodgkin lymphoma.

- Classical Hodgkin lymphoma (> 95%)
  - Nodular sclerosis (NS) classic Hodgkin lymphoma
  - Mixed cellularity (MC) classic Hodgkin lymphoma (most common type in India)
  - Lymphocyte-rich (LR) classic Hodgkin lymphoma
  - Lymphocyte depletion (LD) classic Hodgkin lymphoma
- Nodular lymphocyte predominance (LP) Hodgkin’s lymphoma (< 5%)

### ***Clinical Manifestations***

- **Most common presentation:** Painless enlargement of one lymph node group (unifocal origin) usually of cervical lymph node, consistency of lymph nodes is described as ‘Indian rubber’ consistency. Then it spreads in a predictable manner to the adjacent lymph node group (contiguous spread).
- **Other presentation**
  - Localized disease of the mediastinum (often young women), with cough due to mediastinal lymphadenopathy or axillary nodes, and rarely in the abdominal, pelvic or inguinal nodes.
  - Generalized disease: With hepatosplenomegaly and constitutional ‘B’ symptoms is uncommon in the beginning, but may become prominent as the disease advances.
  - Rare sites: It include Waldeyer’s ring, mesenteric, epitrochlear and popliteal nodes.
  - Involvement of extralymphatic organs: Not common and may occur in the later stages.

- Classical **Pel-Ebstein fever**: It occurs in a cyclical pattern, characterized by several days or weeks of fever alternating with afebrile periods. It is rarely seen.

**Table 8.53: Clinical staging of Hodgkin lymphomas (Cotswold revision of Ann Arbor staging classification).**

Stage	Definition
I	Involvement of a single lymph node region or lymphoid structure (e.g. spleen, Waldeyer's ring, thymus) or involvement of a single extralymphatic site
II	Involvement of two or more lymph node regions on the same side of the diaphragm (the mediastinum is a single site; hilar nodes, when involved on both sides, constitute stage II disease); localized contiguous involvement of only one extranodal organ or site and lymph-node region(s) on the same side of the diaphragm (IIE). The number of anatomic sites should be indicated by suffix (e.g. II <sub>3</sub> )
III	Involvement of lymph node regions or structures on both sides of the diaphragm, which may also be accompanied by involvement of the spleen (IIIS) or by localized involvement of only one extranodal organ site (IIIE) or both (IIISE)
III <sub>1</sub>	With or without splenic, hilar, celiac or portal nodes
III <sub>2</sub>	With para-aortic, iliac or mesenteric nodes
IV	Diffuse or disseminated involvement of one or more extranodal organs or tissues, with or without associated lymph node involvement E, involvement of a single extranodal site, or contiguous or proximal to known nodal site of disease A: No 'B' symptoms B: Place the patient in the 'B' category when at least one of the following is observed: <ul style="list-style-type: none"> <li>– Unexplained weight loss &gt;10% of bodyweight during 6 month before staging</li> <li>– Recurrent unexplained fever &gt;38 °C during the previous month</li> <li>– Recurrent heavy night sweats during the previous month</li> </ul>

### Common symptoms

- Alcohol-induced pain at the site of lymphadenopathy.
- Pruritus is troublesome at times.
- Nephrotic syndrome: It may develop due to immune complex deposition in the kidneys. It is associated with depressed cell-mediated immunity and increases the risk of infections like herpes zoster, tuberculosis, and infections with *Cryptococci/Cytomegalovirus* and *Candida* species.
- Symptoms due to compression of various organs by lymph node masses or infiltration of various organs may develop with mediastinal involvement.

These include dysphagia, dyspnea, Horner's syndrome, hoarseness of voice, superior vena cava syndrome and inferior vena cava obstruction.

**Clinical staging:** It is currently according to the Cotswolds modification of the Ann Arbor Classification (Table 8.53).

- **Lymphatic structures:** It includes lymph nodes, spleen, thymus, Waldeyer's rings, appendix and Peyer's patches; liver and bone marrow are excluded.
- Each stage is further divided into A or B based on the absence or presence of systemic symptoms (B symptoms), respectively.

### ***Investigations***

- **Peripheral blood:** Normocytic normochromic anemia is common and in advance stage, microcytic anemia develops due to defective utilization of iron. Total leukocyte count is usually normal, but sometimes may show neutrophil leukocytosis. Eosinophilia is observed in ~20% of patients and thrombocytosis in some patients. Lymphopenia (indicates lymphocyte depletion) is associated with bad prognosis. In the terminal stages, there may be leukopenia and thrombocytopenia.
- **Serum alkaline phosphatase:** If raised usually indicate bone marrow or liver involvement.
- **Erythrocyte sedimentation rate (ESR):** It may be raised
- **Biopsy:** Fine needle aspiration of involved lymph node may be helpful in the diagnosis.
  - Lymph node biopsy: Surgically or by percutaneous needle biopsy under radiological guidance will establish the diagnosis.
  - Liver biopsy may be useful for diagnosis in patients with hepatomegaly.
- **Staging of HL (Table 8.53):** It is important not only for predicting the prognosis but also for guiding the choice of therapy. The involves careful physical examination and investigations such as: (1) chest radiographs, (2) liver function tests, (3) renal function tests, (4) abdominal ultrasound, (5) bone marrow trephine and aspirate (indicated in patients with clinically advanced disease, i.e. stage III, IV, those with 'B' symptoms and those who are HIV-positive) and (6) CT scans of neck, chest, abdomen and pelvis.

**Positron emission tomography (PET) scan:** It is utilized for staging as well management of Hodgkin lymphoma.

**Table 8.54:** Popular chemotherapy regimens used in the treatment of Hodgkin lymphoma.

<i>Regimen</i>	<i>Drugs used</i>
ABVD	Doxorubicin (adriamycin), biomycin, vinblastine, dacarbazine
MOPP	Mechlorethamine (mustine hydrochloride), vincristine (oncovin), procarbazine, and prednisone
ABVD/MOPP	Alternating cycles of MOPP and ABVD
BEACOPP escalated	Bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, prednisone in escalated dose

**Table 8.55:** Treatment plan for adults with Hodgkin lymphoma.

<i>Stage of Hodgkin lymphoma</i>	<i>Prognostic category</i>	<i>Choice of treatment</i>
IA or IIA, no bulky disease*		ABVD × 4 if complete remission after 2 cycles or ABVD × 2 + involved-region radiation therapy (IRRT)
IB, IIB, or any stage III or IV or bulky disease, any stage	≤ 3 adverse factors**	ABVD until 2 cycles past complete remission (minimum 6, maximum 8)
	≥ 4 adverse factors**	BEACOPP escalated

\*Bulky = largest diameter of any single mass equal to or greater than 10 cm.

\*\* Adverse factors: Male sex, older than 45 years of age, stage IV, hemoglobin less than 10.5 g/dL, WBC count greater than 15,000/mL, lymphocyte count less than 600/mL or less than 8% of the white cell count, or serum albumin less than 4 g/dL.

### Management

**Aim of treatment:** Curative intent with expectation of success. Patients with localized or good-prognosis disease receive a brief course of chemotherapy followed by radiotherapy to sites of node involvement and cured HD in >90% of cases. Presently, patients with all stages of Hodgkin lymphoma are treated initially with chemotherapy. Patients with more extensive disease or those with B symptoms receive a complete course of chemotherapy.

**Chemotherapy:** Combination chemotherapy has been shown to be highly effective. Popular chemotherapy regimens (Table 8.54) used is as follows:

#### *Treatment plan for adults with Hodgkin lymphoma (Table 8.55)*

**Early stage, ‘low-risk’:** Moderate’ chemotherapy, consisting of 2–4 cycles of ABVD followed by involved field irradiation (20–30 Gy). It has a 90% cure rate.

**Advanced disease** (including locally advanced unfavorable early stage):

- Cyclical chemotherapy with 6–8 cycles of ABVD with involved field irradiation to sites which were initially bulky
- **Stanford V for ABVD:** Consists of weekly chemotherapy regimen of doxorubicin, vinblastine, mechlorethamine, etoposide, vincristine, bleomycin, and prednisone) administered for 12 weeks and includes radiation therapy
- Escalated BEACOPP (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, prednisone, and procarbazine)

**Autologous bone marrow transplantation** is successful in about 40% cases even after the failure of chemotherapy.

**Late complications:** Develop due to high cure rates achieved with modern treatment.

- Development of second malignancies: Such as acute leukemia and solid organ cancers. Acute leukemia usually develops within 10 years of use of alkylating agents in combination with radiotherapy. The risk is higher with MOPP as compared to ABVD. Solid organ cancers usually develop after 10 years of radiotherapy.
- Cardiac failure and accelerated coronary artery disease: Following radiotherapy pulmonary fibrosis and hypothyroidism.

## Non-Hodgkin Lymphoma

**Q. Discuss the pathological classification, clinical staging, clinical features, investigations and management of non-Hodgkin lymphoma.**

- Lymphomas represent solid tumors of the immune system.
- Lymphomas can be divided into two major categories: (1) non-Hodgkin lymphoma (NHL) and (2) Hodgkin lymphoma.
- About 80% of NHL are of B-cell origin and 20% of T-cell origin.

### *Etiology (Table 8.56)*

**Table 8.56:** Various factors associated with the development of non-Hodgkin lymphoma.

#### **Genetic factors/inherited immune disorders**

- Family history of lymphoma: Siblings and first-degree relatives of patients with lymphoma or other hematologic malignancies
- Certain inherited syndromes, e.g. ataxia-telangiectasia and Wiskott-Aldrich syndrome

### Acquired immune disorders

- Immune suppression and immunosuppressant drugs, used for solid organ transplantation
- Acquired immunodeficiency syndrome (AIDS)
- Rheumatoid arthritis and systemic lupus erythematosus, Sjögren syndrome, Hashimoto thyroiditis

### Infectious agents

- Epstein-Barr virus: associated with Burkitt lymphoma and Hodgkin lymphoma
- Human T-lymphotropic virus type 1 with adult T-cell leukemia/lymphoma
- Human herpesvirus 8 (HHV-8, Kaposi's sarcoma-associated herpesvirus) associated with primary effusion lymphoma
- Hepatitis C virus: Lymphoplasmacytic lymphoma and splenic marginal zone lymphoma
- *Helicobacter pylori*: Associated with gastric lymphoma of extranodal marginal zone/mucosa-associated lymphoid tissue (MALT)

### Occupational and environmental exposure

- Ionizing radiation, herbicides, organic solvents, hair dyes, ultraviolet light, high-fat diets and nitrates in drinking water, heavy smoking (associated with follicular lymphoma)

## Pathology and Classification

### Grading of NHL (Box 8.20)

- Size of the lymphoid cells is a guide to prognosis. NHL with small lymphoid cells (mature lymphocytes) is associated with low-grade and those with large lymphoid cells (immature lymphoid cells) are found in high-grade disease.
- Follicular lymphomas are low grade and have good prognosis, and most diffuse lymphomas are high grade and have poor prognosis.

### Box 8.20: Grading of non-Hodgkin lymphoma (NHL).

- Indolent or low grade
- Small lymphocytic
- Follicular, predominantly small cleaved cells
- Follicular, mixed, small cleaved and large cleaved cells
- Aggressive or intermediate grade
- Follicular, predominantly large cell, cleaved and /or non-cleaved
- Diffuse, small cleaved cell
- Diffuse, large cell, cleaved or non-cleaved
- Highly aggressive or high grade
- Large cell, immunoblastic (B- or T-cell type)
- Lymphoblastic
- Small non-cleaved cell (Burkitt and non-Burkitt)

## ***WHO classification of lymphoid neoplasm (Table 8.57)***

It requires immunophenotyping, cytogenetics, fluorescent in situ hybridization (FISH) and antigen receptor gene rearrangement studies.

### ***Clinical Features***

- **Age:** NHL can occur at any age, but the peak incidence is around 60 years.
- **Most common presentation:**
  - Painless firm, lymph node enlargement or symptoms due to lymph node mass.
  - Extranodal involvement is more common in T-cell lymphoma and involves the bone marrow, gut, thyroid, lung, skin, testis, brain and more rarely, bone.
  - Bone marrow involvement is more common in low-grade (50–60%) than high-grade (10%) NHL and can produce cytopenia.
  - Primary extranodal lymphomas present with soft tissue masses and symptoms relevant to the site. Waldeyer's ring and epitrochlear lymph nodes are frequently involved.
  - Pressure effects: Due to NHL includes gut obstruction, ascites, superior vena cava obstruction and spinal cord compression.
  - Involvement of liver and spleen results in hepatosplenomegaly.
  - Patients with lymphoblastic lymphoma often present with an anterior mediastinal mass.
  - Burkitt lymphoma typically disseminates to the bone marrow and meninges and involves extranodal sites.
- It may be associated with 'B' or systemic symptoms. These include weight loss, sweats, fever and itching.
- Immunologic abnormalities: For example, autoimmune hemolytic anemia and immune thrombocytopenia
- Paraneoplastic neurologic complications of non-Hodgkin's lymphoma include demyelinating polyneuropathy, Guillain-Barré syndrome, autonomic dysfunction and peripheral neuropathy. Paraneoplastic syndromes associated with non-Hodgkin's lymphoma can affect the skin (e.g. pemphigus), kidney (e.g. glomerulonephritis) and miscellaneous organ systems (e.g. vasculitis, dermatomyositis, and cholestatic jaundice).

## ***Clinical Staging (Ann Arbor Classification)***

- Same staging system (Table 8.53) is used for both HL and NHL.
- Ann Arbor classification is also used for the clinical staging of non-Hodgkin's lymphoma but is more useful in Hodgkin lymphoma. However, 'B' symptoms are not included as they are not useful in predicting prognosis.

## ***Investigations***

Investigations required for staging the disease are the same as that for Hodgkin lymphoma. Laparotomy is rarely required, only when retroperitoneal nodes are involved.

- **Peripheral blood:** Moderate degrees of anemia may be observed when there is significant bone marrow involvement.
  - Blood counts: Usually normal, but few patients may show lymphocytosis.
  - Splenomegaly with hypersplenism or autoimmune hemolytic anemia may lead to reduced hemoglobin level, reticulocytosis and positive Coombs test.
- **Bone marrow aspiration and trephine biopsy:** It should be performed early, since marrow involvement is common with NHL.
- **Others investigations:**
  - **Immunophenotyping** of surface antigens to distinguish T- and B-cell tumors. This may be done on blood, marrow or lymph node material. It can be performed by flow cytometry and/or immunohistochemistry utilizing a minimal antibody panel (CD45, CD20, and CD3) to identify B, T or NK subtypes.
  - **Immunoglobulin determination:** Some lymphomas are associated with IgG or IgM paraproteins.
  - **Measurement of uric acid levels:** Few very aggressive high-grade NHLs are associated with very high uric acid levels that can precipitate renal failure when treatment is started.
- HIV testing.
- Serum levels of LDH,  $\beta_2$ -macroglobulin, and serum protein electrophoresis are often needed.

- **Diagnostic spinal tap:** Required when a first prophylactic instillation of cytarabine and or methotrexate is indicated in high-risk patients, especially with involvement of CNS, orbit, bone marrow, testis, spine or base of the skull. It is also indicated in HIV-associated lymphoma and highly aggressive lymphoma.

**Table 8.57: WHO classification of the lymphoid neoplasms (2016).**

**I. Precursor lymphoid neoplasms**

- B lymphoblastic leukemia/lymphoma
- T lymphoblastic leukemia/lymphoma

**II. Mature B cell neoplasms**

- Chronic lymphocytic leukemia/small lymphocytic lymphoma
- Monoclonal B-cell lymphocytosis
- B cell prolymphocytic leukemia
- Splenic B cell marginal zone lymphoma
- Hairy cell leukemia
- Lymphoplasmacytic lymphoma
- Heavy chain disease
- Plasma cell neoplasm
- Follicular lymphoma
- Mantle cell lymphoma
- Diffuse large B cell lymphoma
- Burkitt lymphoma

**III. Mature T and Nk cell neoplasms**

- T cell prolymphocytic leukemia
- T cell large granular lymphocytic leukemia
- Mycosis fungoides
- Sézary syndrome
- Peripheral T cell lymphoma, NOS
- Angioimmunoblastic T cell lymphoma
- Anaplastic large cell lymphoma
- Adult T cell leukemia/lymphoma
- Extranodal NK/T cell lymphoma, nasal type

**Management (Box 8.21)**

***Low-grade NHL***

The various options available are:

1. **Radiotherapy:** For localized stage I disease
2. **Chemotherapy:**
  - Oral therapy with chlorambucil (not curative).

– Intensive intravenous chemotherapy in younger patients produces better quality of life without any survival benefit. Bendamustine rituximab is the recommended first line therapy.

3. **Humanized monoclonal antibody therapy:** Three monoclonal antibodies (rituximab, 131I-tositumomab, and 90Y-ibritumomab) are approved. The anti-CD20 antibody rituximab(R) alone or with chemotherapy, i.e. R-CVP (cyclophosphamide, vincristine and prednisolone) is recommended as first-line therapy.

#### 4. **Bone marrow transplantation.**

##### **High-grade NHL**

1. **Chemotherapy:** Majority (>90%) of patients are treated with intravenous combination chemotherapy, with the CHOP regimen (cyclophosphamide, doxorubicin, vincristine and prednisolone).

2. **Radiotherapy:** Indication

- Residual localized site of bulk disease after chemotherapy.
- Spinal cord and other compression syndromes.

3. **Humanized monoclonal antibody therapy:** In combination with CHOP chemotherapy, rituximab (R) improves overall survival. R-CHOP is recommended as first-line therapy for those with stage II or greater diffuse large-cell lymphoma.

4. **Autologous bone marrow transplantation:** In patients with relapsed chemosensitive disease.

**Box 8.21:** Regimen for non-Hodgkin's lymphoma (NHL).

##### *Regimen*

##### **CHOP-R**

- Cyclophosphamide
- Hydroxydaunorubicin (Doxorubicin)
- Oncovin (Vincristine)
- Prednisone, fixed dose
- Rituximab

##### **CVP-R**

- Cyclophosphamide
- Vincristine
- Prednisone, fixed dose
- Rituximab

##### **FCR**

- Fludarabine
- Cyclophosphamide
- Rituximab

## *Diffuse large B-cell lymphoma (DLBCL)*

- Most common lymphoma in the adult population and constitutes about 30–50% of all NHL.
- Present with painless lymphadenopathy at one or several sites. Intra-abdominal disease presents with bowel symptoms due to compression or

infiltration of the GIT.

- Treatment: Refer treatment of high-grade NHL mentioned above.

*Differences between Hodgkin and non-Hodgkin lymphomas (Table 8.58)*

**Q. How do you differentiate Hodgkin’s lymphoma from non-Hodgkin’s lymphoma?**

**Table 8.58: Differences between Hodgkin and non-Hodgkin lymphoma.**

<b>Characteristics</b>	<b>Hodgkin lymphoma</b>	<b>Non-Hodgkin lymphoma</b>
Age	Bimodal peak incidence, 15–35 years and 45–70 years	Peak incidence around 60 years
‘B’ symptoms	More common	Less common
Alcohol induced discomfort in lymph nodal region	Common	Not observed
Disease at the time of diagnosis	Usually well localized	Usually widespread
Site of involvement	Unifocal origin and arises in a single node or chain of nodes (cervical, mediastinal, para-aortic)	Mostly involves multiple peripheral nodes (multicentric origin)
Pattern of spread	Orderly spread by contiguity in a predictable fashion	Noncontiguous spread in an unpredictable fashion
Epitrochlear node	Rarely involved	Commonly involved
Mediastinal involvement	Common	Uncommon
Mesenteric nodes and Waldeyer’s ring	Rarely involved	Commonly involved
Bone marrow involvement	Late	Early
Extranodal involvement	Uncommon	Common
Characteristic of neoplastic cells	Neoplastic cells—Hodgkin or Reed-Sternberg cells form minor tumor cell mass (1 to 5%)	Neoplastic cells form the major tumor cell mass
Number of neoplastic cells	Few neoplastic cells (RS cells)	Majority of the cells are neoplastic

## Burkitt Lymphoma

### Q. Write short note on Burkitt lymphoma/leukemia.

- Burkitt lymphoma (BL) is a highly aggressive, often extranodal B-cell lymphoma.
- Most common childhood malignancy worldwide and majority in children, but can occur in all ages.
- Male: female ratio is 3:1.
- Often presents with extranodal involvement or as leukemia.
- Burkitt lymphoma (about 80% of cases) is associated with a specific chromosomal translocation involving *myc* oncogene from chromosome 8 to the immunoglobulin (Ig) heavy chain region on chromosome 14. [t(8;14)].
- Categories of Burkitt lymphoma is explained in Box 8.22.

### Box 8.22: Three categories of Burkitt lymphoma.

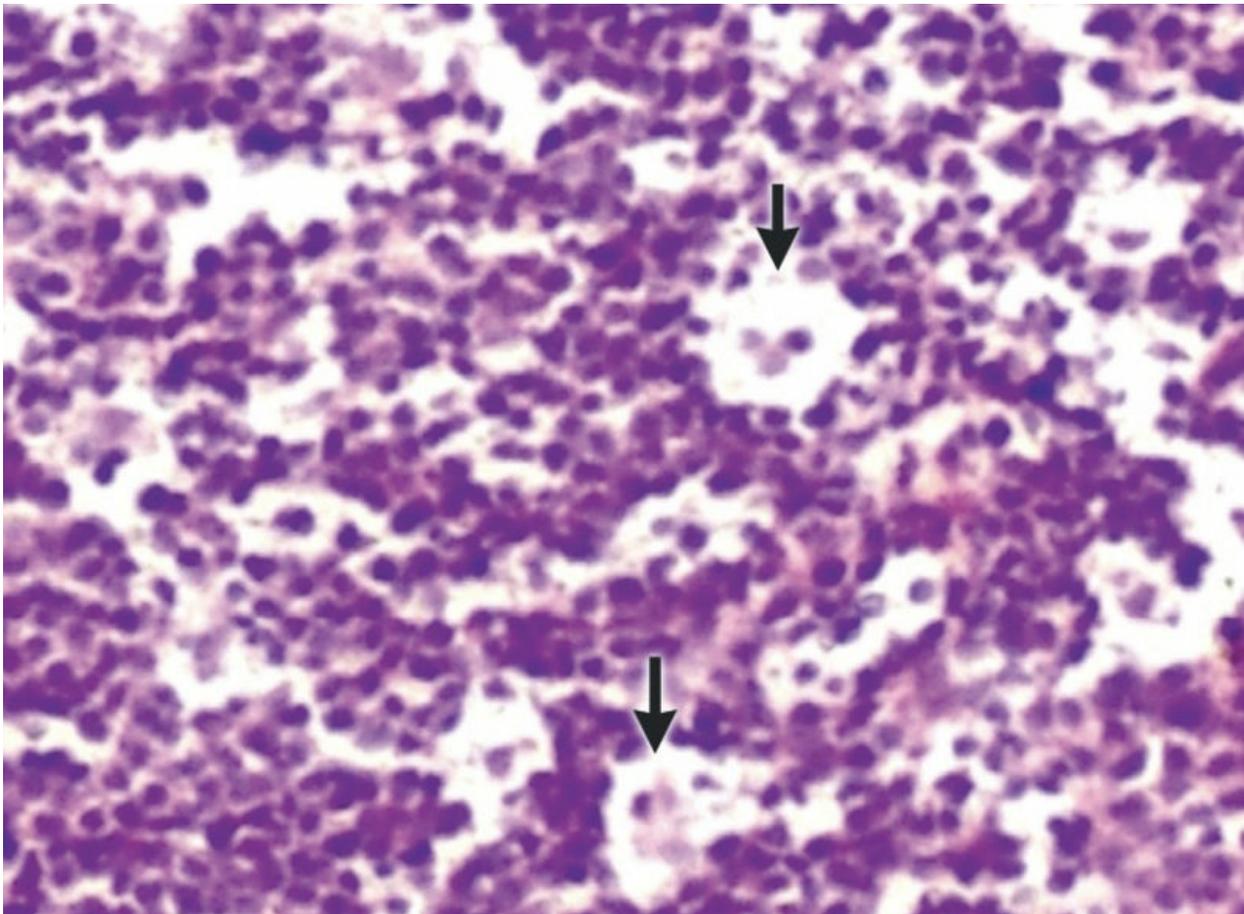

1. Endemic (African)
2. Sporadic (nonendemic) Burkitt lymphoma
3. Immunodeficiency-associated (HIV) lymphomas

### *Clinical Features*

- **Endemic form:** Occurs in Africa. Affects children and adolescents. Associated with Epstein-Barr virus infection and corresponds to the distribution of malaria. Involves extranodal sites, particularly the jaw, gastrointestinal tract and gonads. Commonly presenting as a rapidly growing jaw tumor in a young child (4–7 years). Involvement of mandible and maxillary bone leads to deformity, loosening of teeth and extrusion of the eye with loss of vision.
- **Sporadic form:** It presents as an abdominal mass.
- **Immunodeficiency-associated (HIV) form:** It usually occurs with CD4 counts above 200/mm<sup>3</sup>. It again presents with abdominal involvement.
- **Abdominal involvement:** It presents as mass due to bilateral involvement of kidneys adrenals, ovaries, bowel and lymph nodes.
- **Other sites of involvement:** CNS (common in adults), long bones, salivary glands, thyroid, testes, heart, breast and bone marrow.

## Investigations

- **Histological examination:** Involved tissues show diffuse monotonous infiltrate of medium-sized (intermediate-sized) lymphoid cells, numerous mitoses and plenty of tumor cells undergoing apoptosis. The nuclear remnants of these apoptotic cells are phagocytosed by benign macrophages creating a characteristic ‘**starry sky**’ pattern (resembling stars in the sky)(Fig. 8.35).
- **Chromosome analysis:** The most common form of translocation results in the movement of the *MYC*-containing segment of chromosome 8 to chromosome 14q32, placing it close to the *IGH* gene. The genetic notation for the translocation is t (8:14) (q24; q32). As a result of translocation, *MYC* protein is overexpressed and results in cell proliferation and stimulates apoptosis.
- **Antibodies to EB viral capsid antigen:** It may be detected (in endemic type, and in many with sporadic and HIV-associated tumors).

**Fig. 8.35:** Burkitt lymphoma composed of medium-sized lymphoid cells admixed with benign

macrophages (arrows) giving a “starry sky” appearance.

### Management

- Treatment must be initiated urgently with curative intent whenever feasible.
- Adequate hydration prior to the initiation of specific therapy to prevent the risk of tumor lysis syndrome.
- Standard treatment comprises of high—intensity, brief-duration cyclical combination chemotherapy. Regimens include:
- CHOP (cyclophosphamide, hydroxydoxo-rubicon or doxorubicin, oncovin (vincristine), prednisolone) regimen **OR**
- Rituximab plus EPOCH (etoposide, prednisolone, oncovin (vincristine), cyclophosphamide and doxorubicin) **OR**
- CODOX-M/IVAC regimen (cyclophosphamide, vincristine, doxorubicin, methotrexate/ifosfamide, etoposide or VP-16, cytarabine)
- Prophylactic central nervous system therapy is essential, intrathecal methotrexate or cytosine arabinoside is given in addition to high-dose systemic administration.
- Cure rates: High as 70–80%.

## Adult T-cell Lymphoma/Leukemia

### **Q.** Write short note/essay on adult T-cell lymphoma/leukemia.

- Adult T-cell leukemia/lymphoma is a neoplasm of CD4+ T-cells and develops in adults infected by *human T-cell leukemia virus type 1 (HTLV-1)*.
- Mode of infection of HTLV-1: Transplacental transmission, blood transfusion or sexual contact.
- Latency period between infection and development of lymphoma is long (10–30 years).
- Four major presentations:
  1. Acute aggressive form: It is characterized by peripheral blood lymphocytosis, lymphadenopathy, hepatosplenomegaly, skin infiltration, hypercalcemia, lytic bone lesions and raised LDH levels in blood. Opportunistic infections are common. Peripheral smear usually reveals characteristic, neoplastic cells with multilobulated nuclei and petal-like nuclear lobules connected by thin chromatin strands, known as ‘cloverleaf’ or ‘flower’ cells are found in the involved tissues and peripheral blood. Bone marrow involvement is usually not prominent.
  2. Lymphomatous form: Constitute ~20% of cases and is associated with generalized lymphadenopathy without leukemia

3. Chronic form: Constitute ~15% of cases and may have a low level absolute lymphocytosis in the peripheral blood associated with an exfoliative skin rash.
4. Smoldering form: Constitute ~5% of cases and have a normal peripheral blood lymphocyte count and a small number of circulating tumor cells and skin rashes.

#### Treatment

- Combination chemotherapy prolongs life but does not produce remissions.
- Combination antiretroviral drugs (zidovudine + interferon- $\alpha$ ) may be helpful in some patients.

**Prognosis:** Most cases progress rapidly and are fatal.

## Mucosa-Associated Lymphoid Tissue Lymphoma

**Q. Write short note/essay on mucosa-associated lymphoid tissue lymphoma or primary gastric lymphoma.**

- It is a small-cell NHL of B-cells that is extranodal in origin.
- **Sites:** MALT lymphoma is often localized to the organ from which it arises in ~40% cases and to the organ and surrounding lymph nodes in ~30% cases. Bone marrow involvement is uncommon and occurs in ~15% cases.
  - Gastric type of MALT lymphoma is associated with *H. pylori* infection. Salivary gland MALT is associated with Sjogren's syndrome.
  - Other sites: It may occur in the stomach, orbit, intestine, lung, skin, soft tissue, bladder, kidney, salivary gland and CNS.
- Age: Mainly in elderly patients with median age of 60 years.
- Gastric type of MALT lymphoma
  - It may present as a mass or produce local symptoms such as upper abdominal discomfort and dyspepsia.
  - Endoscopy: Often mimic benign conditions like chronic gastritis or a peptic ulcer. Multiple biopsies are required for establishing diagnosis.
  - Endoscopic ultrasound (EUS) useful for staging of gastric MALT lymphoma.
  - Low-grade gastric MALT lymphoma can achieve remission in 80% of cases with eradication of the infection.

- Prognosis: Good in most cases with 5 year survival of 75%.

#### Treatment

- Localized MALT lymphomas can be treated with surgery or local radiotherapy.
  - Anti *H. Pylori* therapy in gastric MALToma.
- Extensive disease is treated with single chemotherapy agents like chlorambucil, cyclophosphamide, fludarabine or cladribine. Combination regimens that include rituximab are also highly effective.

## Mycosis Fungoides

### Q. Write a short note on mycosis fungoides.

- Mycosis fungoides is a rare type of cutaneous T-cell NHL composed of small to medium-sized lymphoid cells with irregular nuclear outlines.
- Insidious in onset and are derived from CD4+T cells of skin-associated lymphoid tissue.
- Age: They usually present between 55 to 60 years.
- The tumor cells show epidermotropism (predilection for the epidermis) and dermis.
- Clinical features: There are three stages:
  1. *Patch stage* (inflammatory *premycotic phase*), characterized by erythematous macules usually occurring on areas not exposed to sunlight.
  2. *Plaque stage*, with elevated scaly plaques which may be pink or red/brown and are often intensely pruritic.
  - Tumor stage*, with dome-shaped firm tumors which may ulcerate
- **Sézary syndrome:** Patients with mycosis fungoides may develop generalized erythroderma and malignant T-cells with serpentine nuclei are found in the peripheral blood and this condition is known as *Sézary's syndrome*.
- **Immunophenotype:** Tumor cells express pan-T-cell markers CD3, CD5 and CD2.
- **Prognosis:** These are indolent tumors with a median survival rate of 8 to 9 years.

#### Treatment

- Localized early-stage mycosis fungoides: Can be cured with radiotherapy, often total-skin electron beam irradiation.

- More advanced stage: Palliative treatment such as topical glucocorticoids, topical nitrogen mustard, phototherapy, psoralen with ultraviolet A (PUVA), and systemic cytotoxic therapy.

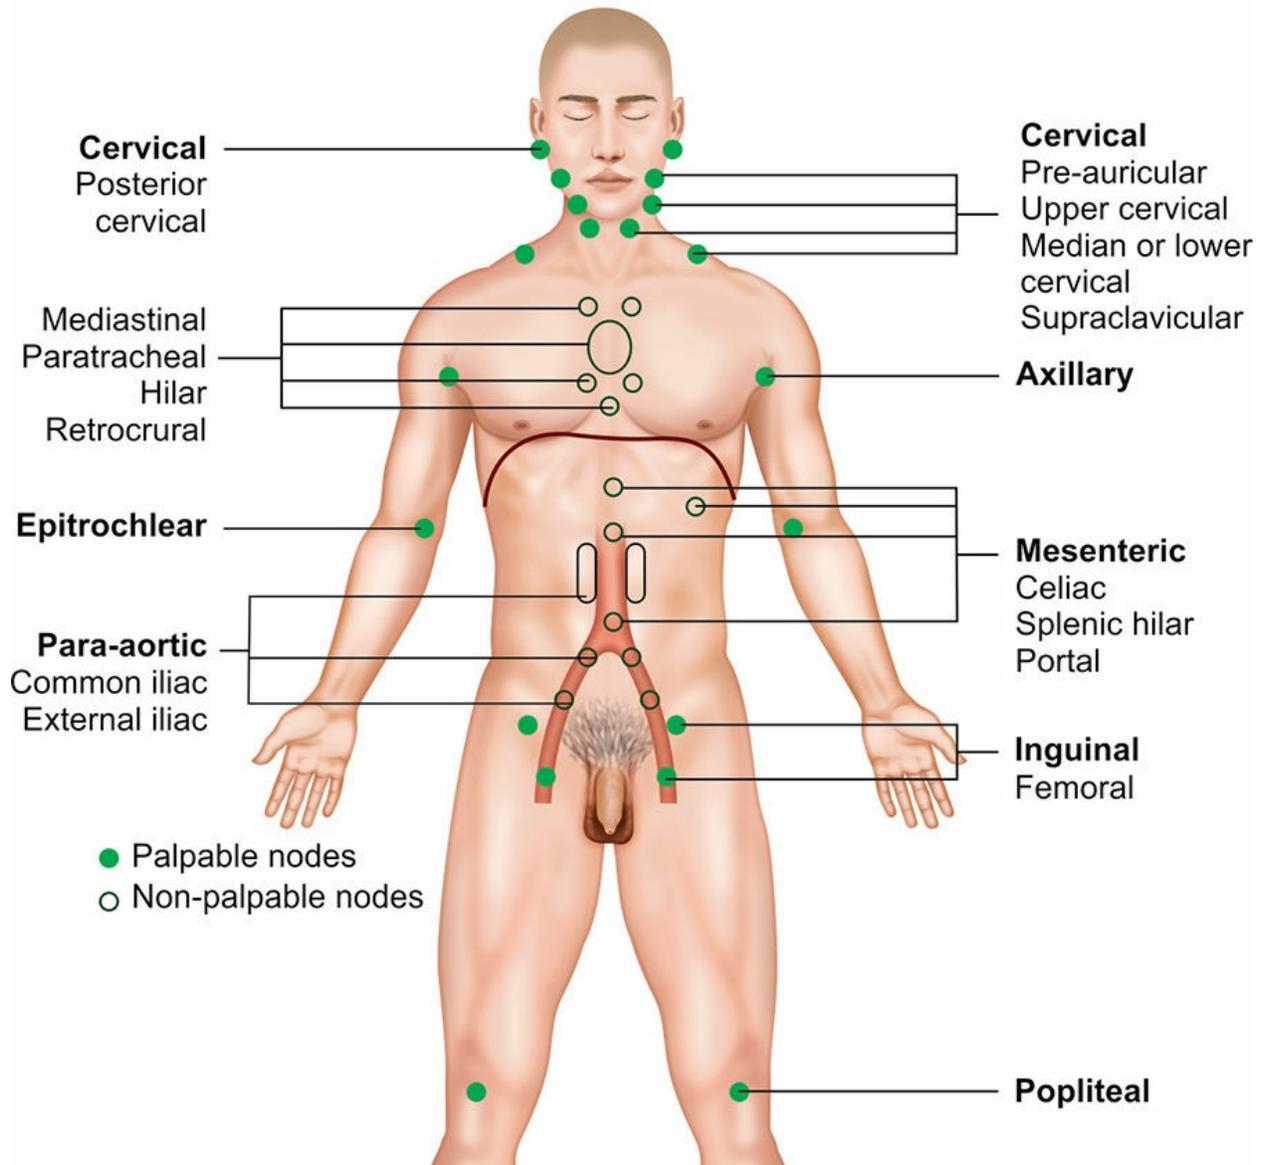

Several rare lymphoproliferative disorders other than lymphoma have distinctive clinical courses.

## Differential Diagnosis of Generalized Lymphadenopathy

**Q. Discuss the differential diagnosis (causes) of generalized lymphadenopathy in an adult.**

**Q. Assessment of the extent of lymph nodal enlargement.**

- Generalized lymphadenopathy is defined as significant enlargement of more than 2 or more noncontiguous lymph node groups. Various lymph node areas are depicted in Figure 8.36.
- Clinical examination of lymph nodes: (1) sites of lymph node enlargement, (2) size, (3) consistency, (4) mobile/fixed, (5) presence or absence of tenderness and (6) draining area.
- Systemic abnormalities if any.
- Investigations:
  - Chest X-ray and CT scan of thorax: To detect lymphadenopathy in the mediastinal, hilar and paratracheal region.
  - Ultrasound scanning and CT scan of abdomen: To detect intra-abdominal lymph nodes.
  - Lymph node groups: Location, lymphatic drainage and differential diagnosis are mentioned in Table 8.59.

**Fig. 8.36:** Lymph node areas.

**Table 8.59:** Lymph node groups: Location, lymphatic drainage and differential diagnosis.

<b>Location</b>	<b>Lymphatic drainage</b>	<b>Causes</b>
Submandibular	Tongue, submaxillary gland, lips and mouth, conjunctivae	Infections of head, neck, sinuses, ears, eyes, scalp, pharynx
Submental	Lower lip, floor of mouth, tip of tongue, skin of cheek	Mononucleosis syndromes, Epstein-Barr virus, cytomegalovirus, toxoplasmosis
Jugular	Tongue, tonsil, pinna, parotid	Pharyngitis organisms, rubella, tuberculosis

Posterior cervical	Scalp and neck, skin of arms and pectorals, thorax, cervical and axillary nodes	Tuberculosis, lymphoma, head and neck malignancy
Suboccipital	Scalp and head	Local infection
Postauricular	External auditory meatus, pinna, scalp	Local infection
Preauricular	Eyelids and conjunctivae, temporal region, pinna	External auditory canal
Right supraclavicular node	Mediastinum, lungs, esophagus	Lung (right lung and left lower lobe), retroperitoneal or gastrointestinal cancer, tuberculosis
Left supraclavicular node	Thorax, abdomen via thoracic duct	Lymphoma, lung (left upper lobe) Carcinoma of bronchus, bowel (gastric), bladder, breast and testes, tuberculosis
Axillary	Arm, thoracic wall, breast, parietal pleura	Infections, cat-scratch disease, lymphoma, breast cancer, brucellosis, melanoma, tuberculosis
Epitrochlear	Ulnar aspect of forearm and hand	Infections, NHL, sarcoidosis, tularemia, cat-scratch disease secondary syphilis, disseminated tuberculosis, HIV
Inguinal	Penis, scrotum, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower anal canal	Infections of the leg or foot, STDs (e.g. herpes simplex virus, gonococcal infection, syphilis, chancroid, granuloma inguinale, lymphogranuloma venereum), lymphoma, pelvic malignancy, bubonic plague

### ***Differential Diagnosis (Table 8.60)***

#### **Castleman's disease, or angiofollicular lymph node hyperplasia**

- Patients often present with a localized lymphoid mass, but some patients have a systemic illness with fevers, night sweats, weight loss and fatigue.
- Frequently, the systemic symptoms of Castleman's disease are related to excessive production of IL-6.
- Castleman's disease in HIV-infected patients is frequently associated with HHV-8.
- Patients with disseminated and plasma cell-rich forms of Castleman's disease may occasionally progress to lymphoma.
- Patients with localized Castleman's disease can be treated with surgical

removal or radiotherapy. Patients with systemic disease may respond to treatment with high-dose corticosteroids.

**Sinus histiocytosis with massive lymphadenopathy, also known as Rosai-Dorfman disease**

- Manifests as bulky lymphadenopathy in children and young adults.
- Extranodal sites such as the skin, upper airways, gastrointestinal tract and CNS can be involved. There is a characteristic pattern of lymphoid proliferation with a thick fibrous capsule, distention of lymphoid sinuses, accumulation of plasma cells, and proliferation of large, often atypical histiocytes.
- The disease is usually self-limited, but it has been associated with autoimmune hemolytic anemia.

**Kikuchi’s disease (histiocytic necrotizing lymphadenitis)**

- Disease of unknown origin that most commonly affects young women.
- Symptoms most commonly consist of painless cervical lymphadenopathy that is often accompanied by fever, flu-like symptoms and rash.
- Sometimes associated with SLE. Treatment is symptomatic, and symptoms usually resolve within weeks or months.
- Lymph node biopsies reveal foci of necrotic histiocytes.

**Table 8.60: Differential diagnosis of generalized lymphadenopathy.**

<i>Cause</i>
<b>A. Malignant neoplasms</b>
1. Lymphomas (Hodgkin and non-Hodgkin)
2. Leukemias <ul style="list-style-type: none"> <li>• Acute lymphoblastic leukemia</li> <li>• Chronic lymphocytic leukemia</li> <li>• Chronic myeloid leukemia in blast crisis</li> </ul>
3. Metastatic disease (head and neck cancers, lung and breast cancers, GIT malignancies)
<b>Infections</b>
1. Disseminated tuberculosis
2. Human immunodeficiency virus (HIV) infection
3. Secondary syphilis
4. Infectious mononucleosis

5. Brucellosis

6. Local infections (cellulitis, pharyngitis)

7. Plague

8. Other infections: Toxoplasmosis, cytomegalovirus infection, hepatitis B, atypical mycobacteria, histoplasmosis, coccidioidomycosis, cryptococcosis

**B. Autoimmune diseases**

1. Systemic lupus erythematosus

2. Rheumatoid arthritis

**C. Drugs induced** (phenytoin, allopurinol, hydralazine, primidone, quinidine)

**D. Systemic disorders:** Amyloidosis, sarcoidosis, serum sickness, hyperthyroidism, Gaucher's disease, Kawasaki disease, Kimura disease, Hemophagocytic lymphohistiocytosis

**E. Rare:** Castleman's disease, Kikuchi Fujimotos disease, Rosai- Dorfman disease

## HEMOSTASIS

**Q. Discuss the mechanism of hemostasis.**

**Q. Write short essay/note on platelets and their functions.**

### Components of Hemostasis

Three major components namely: (1) platelet component, (2) vascular component (endothelium) and (3) coagulation component participate in normal hemostatic mechanism. The first two components are involved in primary hemostasis while the last component is involved in secondary hemostasis.

### Coagulation system

Coagulation factors are listed in Table 8.61. Coagulation can be activated by two pathways namely *extrinsic* and *intrinsic* (Fig. 8.37). Both the pathways converge on the activation of factor X to produce factor Xa (activated X).

- **Extrinsic pathway:**

- It requires an exogenous trigger; hence the name extrinsic. But now it is observed that released tissue factor (a protein-phospholipid complex normally present on vascular cells and activated monocytes) from vascular injury can initiate this pathway. It converts factor VII into activated factor VII (VIIa) in presence of calcium. Activated tissue

factor VII complex activates factors IX and X.

- The coagulation factors utilized in extrinsic pathway are factors VII, X, II, V, and fibrinogen.
- **Prothrombin time (PT)** is the laboratory test which assesses the function of the coagulation factors involved in the extrinsic pathway.

- **Intrinsic pathway:**

- This gets activated with exposure of prekallikrein, high-molecular weight kininogen and factor XII (Hageman factor) to any thrombogenic (negatively charged) surfaces (including glass beads).
- Prekallikrein is converted to kallikrein and factor XII becomes activated factor XII (XIIa).
- Factor XIIa converts factor XI into XIa.
- Factor XIa activates factor IX, and factor IXa with its co-factor FVIIIa activates X to Xa.
- The coagulation factors utilized in intrinsic pathway are, in order of reaction, factors XII, pre-K, HMWK, XI, IX, VIII, X, V, II and fibrinogen.
- The **partial thromboplastin time (PTT)** assesses the function of the coagulation factors utilized in the intrinsic pathway. PTT is initiated by adding negatively charged particles like ground glass.

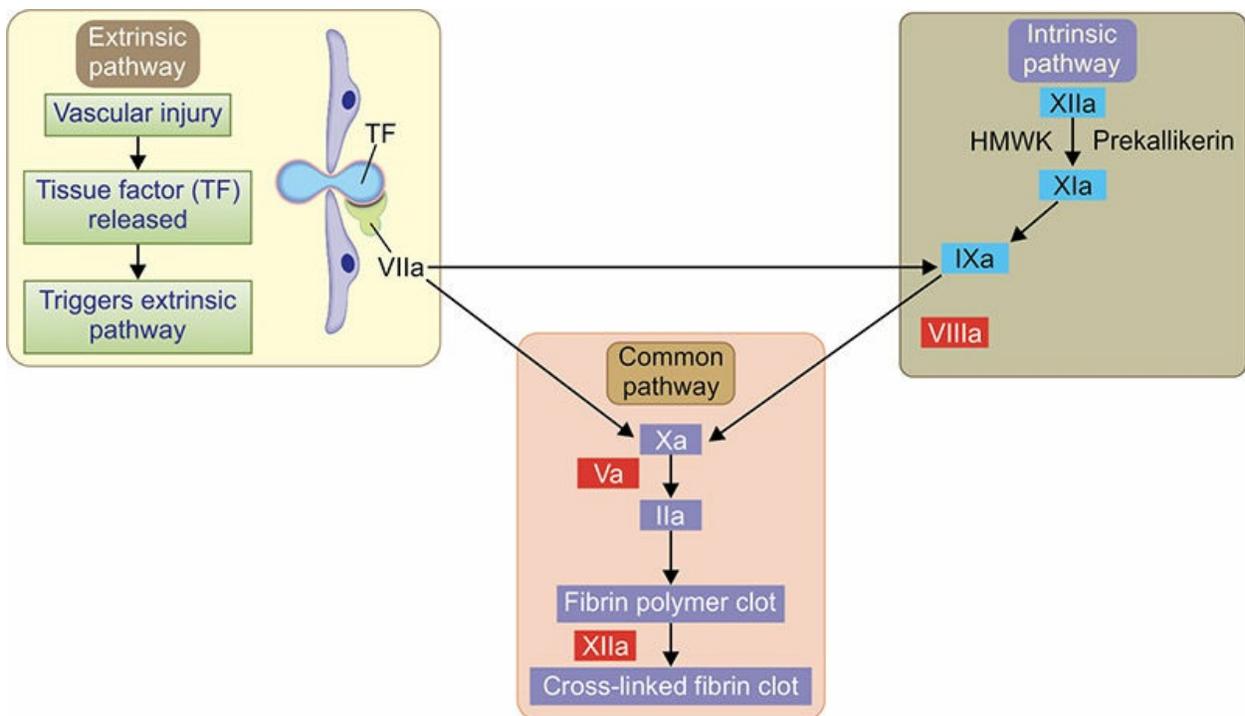

- **Common pathway:**

- Above two pathways have in common factors X, V, prothrombin and fibrinogen; and this part of coagulation pathway is known as the common pathway.
- Common pathway is initiated by factor Xa. Factor Xa converts prothrombin to thrombin (Factor IIa). This is facilitated by Va.
- Factor IIa converts fibrinogen into fibrin and also activates factor XIII to XIIIa that cross links fibrin to fibrin polymers.

**Table 8.61:** Coagulation factors.

<i>Factor</i>	<i>Synonym</i>
I	Fibrinogen
II	Prothrombin
III	Thromboplastin

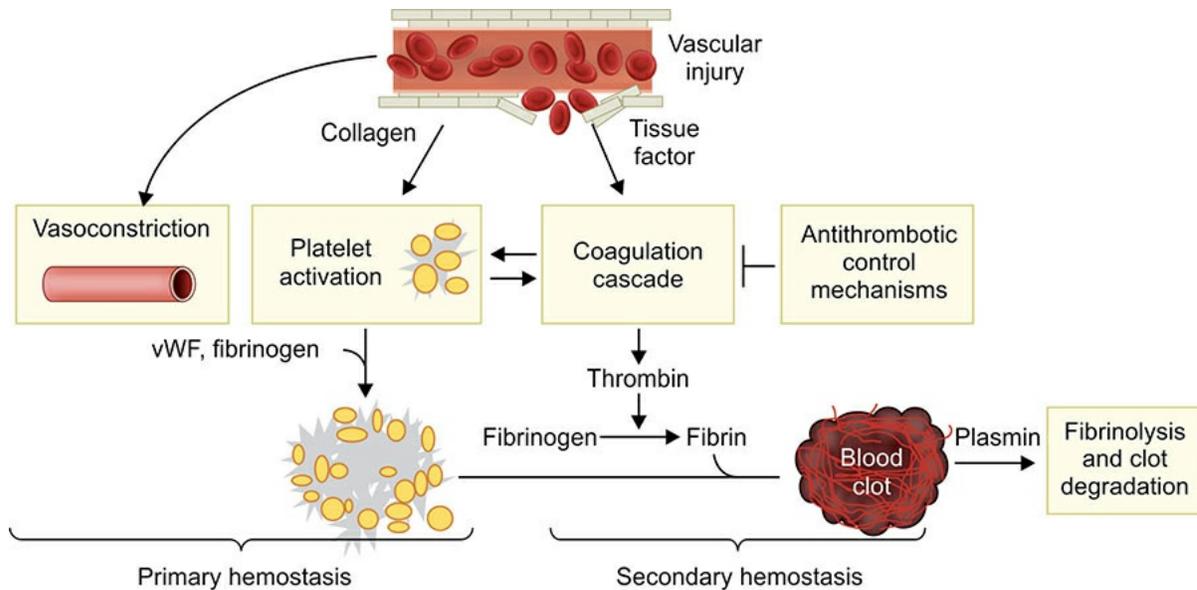

IV	Calcium
V	Proaccelerin
VI	No specific name or function
VII	Proconvertin
VIII	Antihemophilic factor
IX	Christmas factor
X	Stuart-Prower factor
XI	Plasma thromboplastin antecedent
XII	Hagemen factor
XIII	Fibrin stabilizing factor

**Fig. 8.37:** Different pathways of coagulation (extrinsic, intrinsic and common) pathways.

## Mechanism of Hemostasis (Fig. 8.38)

- **Primary hemostatic plug:** The platelet component undergoes three different events-platelet adhesion and shape change, platelet secretion (release of granule contents) and platelet aggregation.

**Fig. 8.38:** Mechanism of hemostasis.

- **Secondary hemostatic plug**

- Exposure of tissue factor at the site of injury activates the extrinsic coagulation system (Box 8.23).
- The process generates thrombin, which cleaves circulating fibrinogen into insoluble *fibrin*, creating a fibrin meshwork at the injured site.
- The platelets contract and form an irreversibly fused mass known as secondary hemostatic plug.
- The sequence of conversion of the initial temporary primary *hemostatic* (platelet) plug into a permanent secondary hemostatic plug is known as *secondary hemostasis*.

**Box 8.23:** Functions of platelets.

- Maintain vascular integrity.
- Spontaneously arrest bleeding through platelet plug formation.
- Participate in the intrinsic coagulation system.
- Promote repair and healing through release of growth factors.

*Coagulation regulatory mechanism (Fig. 8.39)*

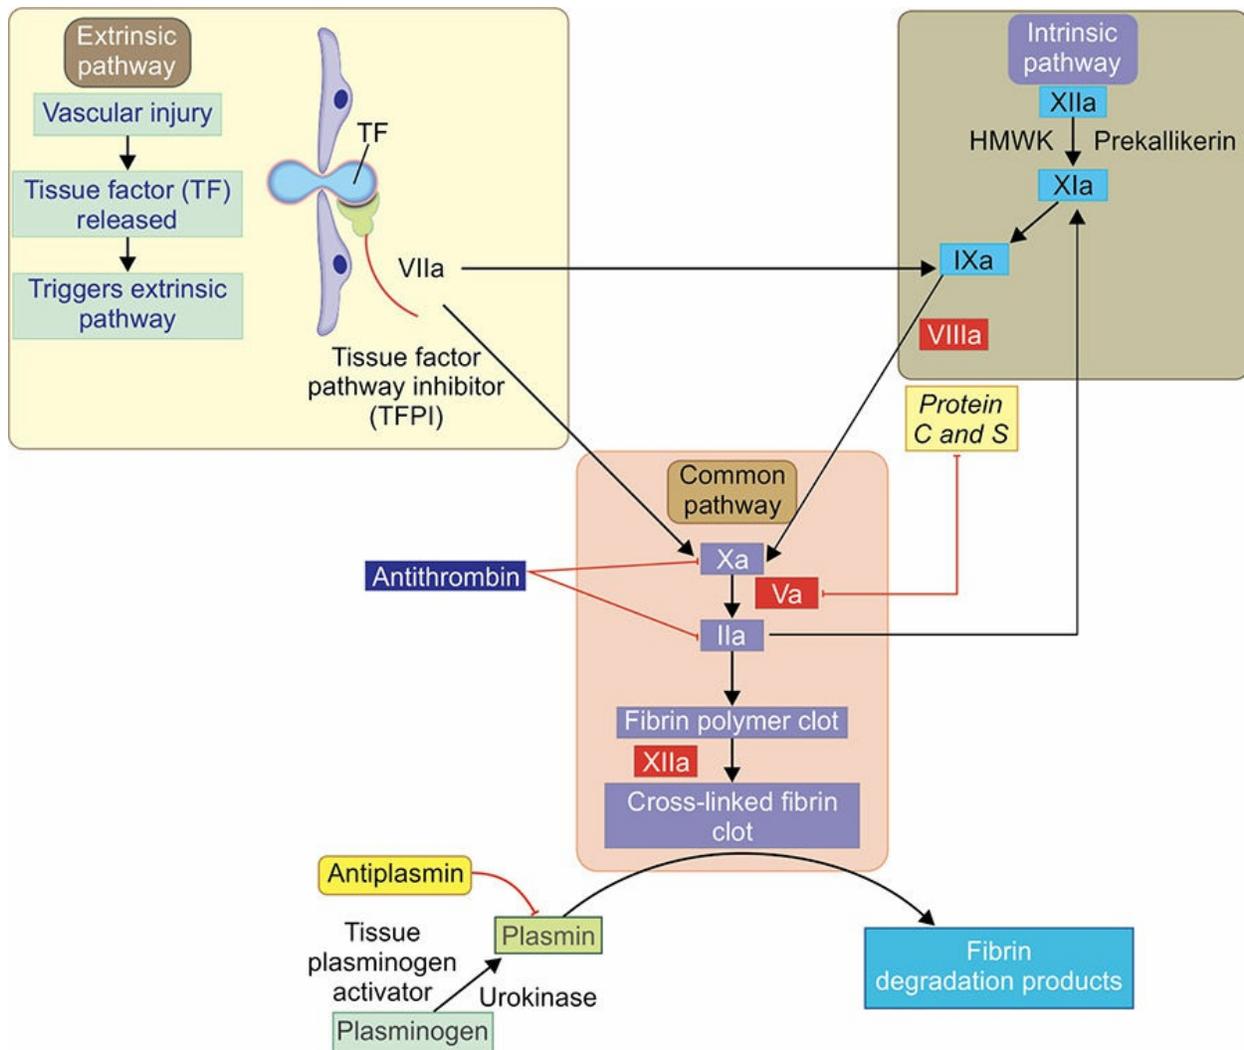

**Q.** Briefly outline the natural inhibitors of coagulation.

The activated coagulation system must be limited to the site of vascular injury so as to prevent coagulation in the entire vascular system. This is

achieved by three endogenous anticoagulants.

### ***Inhibitors of Coagulation***

1. **Antithrombin** is a circulating serine protease inhibitor (serpin) which inhibits the activity of thrombin and factors IXa, Xa, XIa and XIIa. One of these is antithrombin III which gets activated by binding to heparin-like molecules on endothelial cells. The heparin used to minimize thrombosis acts by activating antithrombin III.
2. **Proteins C and S** are vitamin K-dependent proteins that act in a complex. Thrombin generated by activation of coagulation cascade, binds with thrombomodulin present on the endothelial cell membrane and activates the coagulation regulatory system called protein C system. Activated protein C (APC) binds with protein S to form APC-protein S complex. This complex inactivates factors Va and VIIIa. Impaired activity of protein C as occurs in factor V Leiden produces thrombophilia.
3. **Tissue factor pathway inhibitor (TFPI)**: It is a protein which inactivates tissue factor—factor VIIa complexes and inactivates factor VIIa.

**Fig. 8.39:** Coagulation regulatory system consisting of antithrombin, protein C and S and tissue factor pathway inhibitor.

Endothelial cells produce prostacyclin and nitric oxide which inhibit platelet aggregation.

## Fibrinolytic System

### Q. Describe fibrinolytic system.

- Activation of the coagulation also initiates the fibrinolytic system so that the size of the clot is limited. Fibrinolytic system does this by removal of fibrin from the clot. Otherwise, the clot may progress and involve the entire circulation with its consequences.

# BLEEDING DISORDERS (HEMORRHAGIC DIATHESSES)

**Q.** Discuss the evaluation of a patient with bleeding disorder.

## Definition

Increased tendency to hemorrhage (usually with insignificant injury) are collectively called as bleeding disorders (hemorrhagic diatheses). Broad classification of bleeding disorders are listed in Box 8.24.

**Box 8.24:** Broad classification of bleeding disorders.

- Coagulation defects
- Platelet disorders
- Vessel wall abnormalities

## Evaluation/Investigation of Bleeding Disorders

### History

Information to be obtained from the history to determine:

1. Whether there is a generalized hemostatic defect?
  - Evidence includes bleeding from multiple sites, spontaneous bleeding and excessive bleeding after injury.
2. Whether the hemostatic defect is inherited or acquired?
  - Features of inherited defect: (1) A family history of a bleeding (2) Age of onset: Severe inherited defects usually become apparent in infancy, while mild inherited defects are detected later in life (3) Lifelong history.
  - Features of acquired defects: (1) Short duration and (2) Evidence of disease causing the defects. Examples, evidence of liver disease, renal failure, disseminated intravascular coagulation (DIC).
3. Whether the bleeding pattern is suggestive of a vascular/platelet defect or a coagulation defect?

Distinguishing features of bleeding in platelet, vascular and coagulation disorders are shown in Table 8.62.

**Table 8.62:** Distinguishing patterns of bleeding in platelet, vascular and

## coagulation disorders.

<i>Characteristics</i>	<i>Platelet/vascular disorders</i>	<i>Coagulation disorders</i>
Onset	Spontaneous and develops immediately after trauma/surgery	Delayed bleeding after trauma/surgery
Type of lesion	Petechiae (Fig. 8.40A), purpura (Fig. 8.40B), ecchymosis (Fig. 8.40C)	Hematomas
Sites	Skin, mucous membrane	Deep tissues
Mucous membrane	Common from nose, mouth, gastrointestinal and genitourinary tracts	Uncommon except from gastrointestinal or genitourinary tract
Into the joint	Absent	Common in severe factor deficiencies
Into the muscle	Following trauma	Spontaneous
Local pressure	Effective	Ineffective

### ***Physical Examination***

Physical examination consists of search for the following:

- Type of lesions
  - Purpura, bruises, ecchymoses.
  - Examination of joints, particularly knees, ankles and elbows for hemarthrosis.
  - Scars over elbows and knees in factor XIII deficiency.
- Signs of liver cell disease
- Neurological signs
- Hepatosplenomegaly and lymphadenopathy.

### ***Laboratory Investigations***

*Screening tests (Table 8.63)*

**Q. Write short note on screening tests for hemostasis/bleeding disorders.**

#### **1. Bleeding time**

- **Normal range: 4–9 minutes.**
- **Prolonged in platelet disorders.**

**Table 8.63:** Screening tests used in bleeding disorders.

<i>Name of the test</i>	<i>Evaluation</i>
Blood count and film	Show the number and morphology of platelets and any blood disorder such as leukemia or lymphoma
Platelet count (Normal count: 150 to 450 × 10 <sup>9</sup> /L)	Platelets
Bleeding time (Normal: <9 minutes)	Platelet function, von Willebrand factor
Prothrombin time (Normal: 12–14 seconds)	Extrinsic pathway, factors II, V, VII, X
Activated partial thromboplastin time (Normal 33–45 seconds)	Intrinsic pathway, factors II, V, VIII, IX, X, XI, XII
Thrombin time (Normal: 3–5 second > control)	Common pathway, factors I, II
Clot retraction	Platelets
Fibrinogen concentration	Fibrinogen
Fibrin degradation products (FDPs)	Lysis of fibrin

## 2. Prothrombin time (PT)

### **Q. Write short note on prothrombin time.**

- It is measured by adding tissue factor (thromboplastin) and calcium to the patient's plasma.
- Normal is 12–16 seconds
- Measures VII, X, V, prothrombin and fibrinogen (classic 'extrinsic' pathway)
- Prolonged
  - With abnormalities of above factors (II, V, VII and X)
  - In liver disease, DIC, vitamin K deficiency and if the patient is on oral warfarin therapy.

## 3. Activated partial thromboplastin time (APTT)

- Also known as the PTT and is performed by adding a surface activator (such as kaolin, micronized silica or ellagic acid) phospholipid (to mimic platelet membrane) and calcium to the patient's plasma.
- Normal APTT is 26-37 seconds
- APTT measures XII, XI, IX, VIII, X, V, prothrombin and fibrinogen (classic 'intrinsic' pathway).
- **Causes of prolonged APTT**
  - With deficiencies of one or more of above factors (II, V, VIII, IX, X, XI and XII including hemophilia A and B, von Willebrand disease)

- DIC, heparin therapy, and presence of lupus anticoagulant and acquired factor inhibitors.

4. **Correction tests/mixing studies:** It may be used to differentiate various causes of prolonged PT, APTT and TT

- Prolonged PT, APTT or TT due to coagulation factor deficiencies can be corrected by addition of normal plasma to the patient's plasma.
- Failure to correct after addition of normal plasma indicates the presence of an inhibitor of coagulation.

5. **Factor assays:** It confirms coagulation defects.

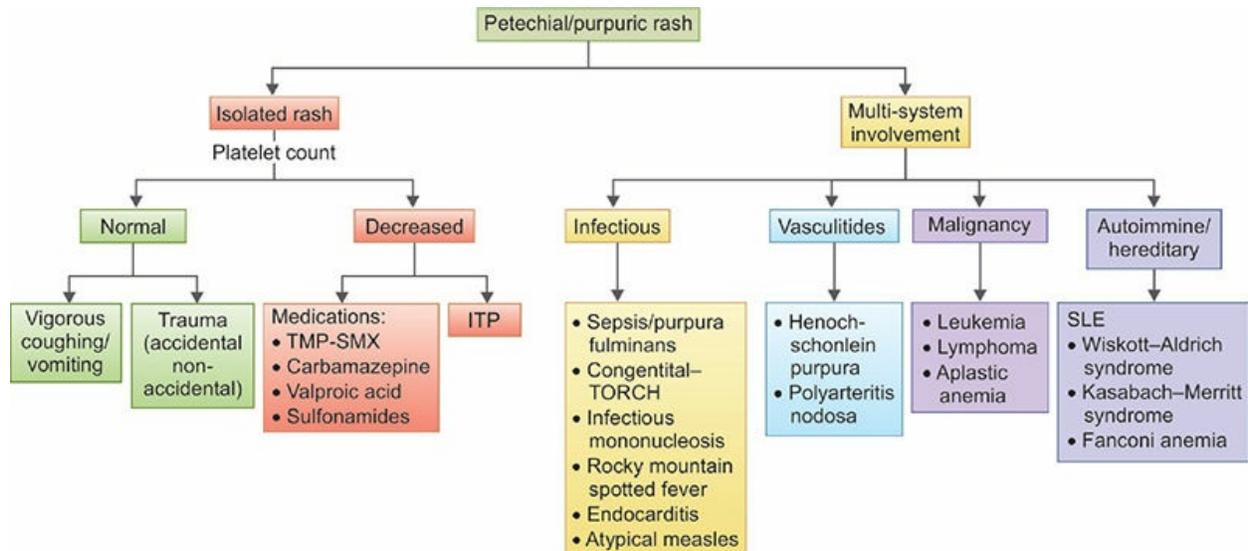

**Figs. 8.40A to C:** (A) Petechiae which appear as small (1 to 2 mm in diameter), red to purple hemorrhagic spots in the skin, mucous membranes or serosal surfaces; (B) Purpura—slightly larger (>3 mm) than petechiae; (C) Ecchymoses are larger (>1–2 cm) and result from blood escaping.

**Table 8.64:** Laboratory tests in various bleeding disorders.

<i>Disorder</i>	<i>PT</i>	<i>A PTT</i>	<i>Platelets</i>	<i>Bleeding time</i>
Vit K deficiency	Prolonged	Prolonged	Normal	Normal
vWF dz	Normal PT	Prolonged	Normal	Prolonged/normal
DIC	Prolonged	Prolonged	Reduced	Prolonged
ITP	Normal	Normal	Reduced	Prolonged
Aplasia and leukemia	Normal	Normal	Reduced	Prolonged
Factor VII deficiency	Prolonged	Normal	Normal	Normal
Factor VIII deficiency (Hemophilia A)	Normal	Prolonged	Normal	Normal
Factor IX deficiency (Hemophilia B)	Normal	Prolonged	Normal	Normal
Factor XI, XII deficiency	Normal	Prolonged	Normal	Normal
Factor XIII deficiency (bleeding esp from umbilicus)	Normal	Normal	Normal	Normal

(PT: prothrombin time; APTT: activated partial thromboplastin time; vWF: von Willebrand factor; DIC: disseminated intravascular coagulation; ITP: immune thrombocytopenic purpura)

**Flowchart 8.3:** Approach to the differential diagnosis for petechiae/purpura.

(ITP: Immune thrombocytopenic purpura; TMP-SMX: trimethoprim-sulfamethoxazole; SLE: systemic lupus erythematosus)

### *Special tests of coagulation*

To confirm the precise hemostatic defect and includes estimation of fibrinogen and FDPs.

Various laboratory tests in bleeding disorders are presented in Table 8.64.

# DISORDERS OF PLATELETS

## THROMBOCYTOPENIA

**Q. Define thrombocytopenia. Enumerate the common causes, clinical manifestations, investigations and management of thrombocytopenia.**

### Definition

Decrease in the platelet count below the lower limit of 150,000/ $\mu$ L is known as thrombocytopenia.

**Causes** (Table 8.65)

**Table 8.65: Causes of thrombocytopenia.**

#### 1. Increased platelet destruction

- Immune mediated
  - Primary: Idiopathic thrombocytopenic purpura—Acute and chronic
  - Secondary:
    - ◆ Autoimmune: Systemic lupus erythematosus
    - ◆ Alloimmune: Post-transfusion or during pregnancy
    - ◆ Drug-induced: Quinidine, heparin, sulfa compounds
    - ◆ Infections: HIV infection, infectious mononucleosis, cytomegalovirus.
- Non-immune mediated
  - ◆ Disseminated intravascular coagulation
  - ◆ Thrombotic thrombocytopenic purpura, hemolytic uremic syndrome
  - ◆ Mechanical destruction
  - ◆ Microangiopathic hemolytic anemias

#### 2. Decreased production of platelets

- Generalized diseases of bone marrow
  - ◆ Aplastic anemia: Congenital and acquired
  - ◆ Marrow infiltration: Leukemia, disseminated cancer
- Selective impairment of platelet production
  - ◆ Drug-induced: Alcohol, thiazides, cytotoxic drugs, alcohol
  - ◆ Infections: Measles, human immunodeficiency virus (HIV)
- Ineffective megakaryopoiesis
  - ◆ Megaloblastic anemia
  - ◆ Myelodysplastic syndromes

### 3. Sequestration

- Hypersplenism: Portal hypertension, lymphomas, myeloproliferative disorders

### 4. Dilutional

## General Clinical Manifestations

- Bleeding into skin: It presents as purpura, petechiae, ecchymoses.
- Bleeding into mucous membranes: It presents as epistaxis, hemorrhagic bullae in oral mucosa, genitourinary bleeding, and gastrointestinal bleeding.
- Severe thrombocytopenia produces fundal hemorrhage and intracranial bleeding (Table 8.66).

Approach to the differential diagnosis for petechiae/purpura is presented in Flowchart 8.3.

## Laboratory Investigations

1. **Platelet count:** Reduced and clinical manifestations roughly correlate with the platelet count.

**Table 8.66:** Clinical features associated with decreased platelet count.

<i>Platelet count /<math>\mu</math>L</i>	<i>Clinical features</i>
30,000 to 50,000	Post-traumatic bleeding
< 30,000	Spontaneous bleeding
< 10,000	Intracranial bleeding

2. **Hess test** (capillary fragility test/tourniquet test) may be positive

- **Principle:** It measures the ability of capillaries to withstand the increased stress.
- **Procedure:**
  - Sphygmomanometer cuff is tied to the upper arm above the elbow and the cuff is inflated to 80 mm Hg for 5 minutes.
  - Release the pressure after 5 minutes.
  - The number of petechiae present in a circle of 5 cm diameter on the flexor aspect of forearm (below the bend of the elbow) is noted.
- **Normal:** 0–5 petechiae.
- **Interpretation:** Positive test is indicated by more than 10 petechiae and is observed in:
  - Vascular purpura
  - Defective platelet function
  - Thrombocytopenia
  - Scurvy.

3. **Bleeding time (BT):** Prolonged, and it bears a close relationship to platelet count.
4. **Bone marrow:**
  - a. Normal or increased number of megakaryocytes indicates increased platelet destruction, hypersplenism or ineffective platelet production.
  - b. Decreased number of megakaryocytes indicates reduced production of platelets.

**Table 8.67:** Classification of platelet function disorders.

#### **A. Hereditary**

- **Disorders of platelet adhesion**
  - Bernard-Soulier syndrome
- **Disorders of platelet secretion**
  - Storage pool deficiency
- **Disorders of platelet aggregation**
  - Glanzmann thrombasthenia

#### **B. Acquired**

- Drugs: Aspirin, non-steroidal anti-inflammatory drugs (NSAID), dipyridamole, sulfipyrazone
- Renal failure (uremia)
- Hematologic malignancies: Myeloproliferative and myelodysplastic disorders

## **QUALITATIVE PLATELETS DEFECTS**

Qualitative defects of platelet function can be hereditary/congenital or acquired (Table 8.67 and Fig. 8.41).

## **IMMUNE THROMBOCYTOPENIC PURPURA**

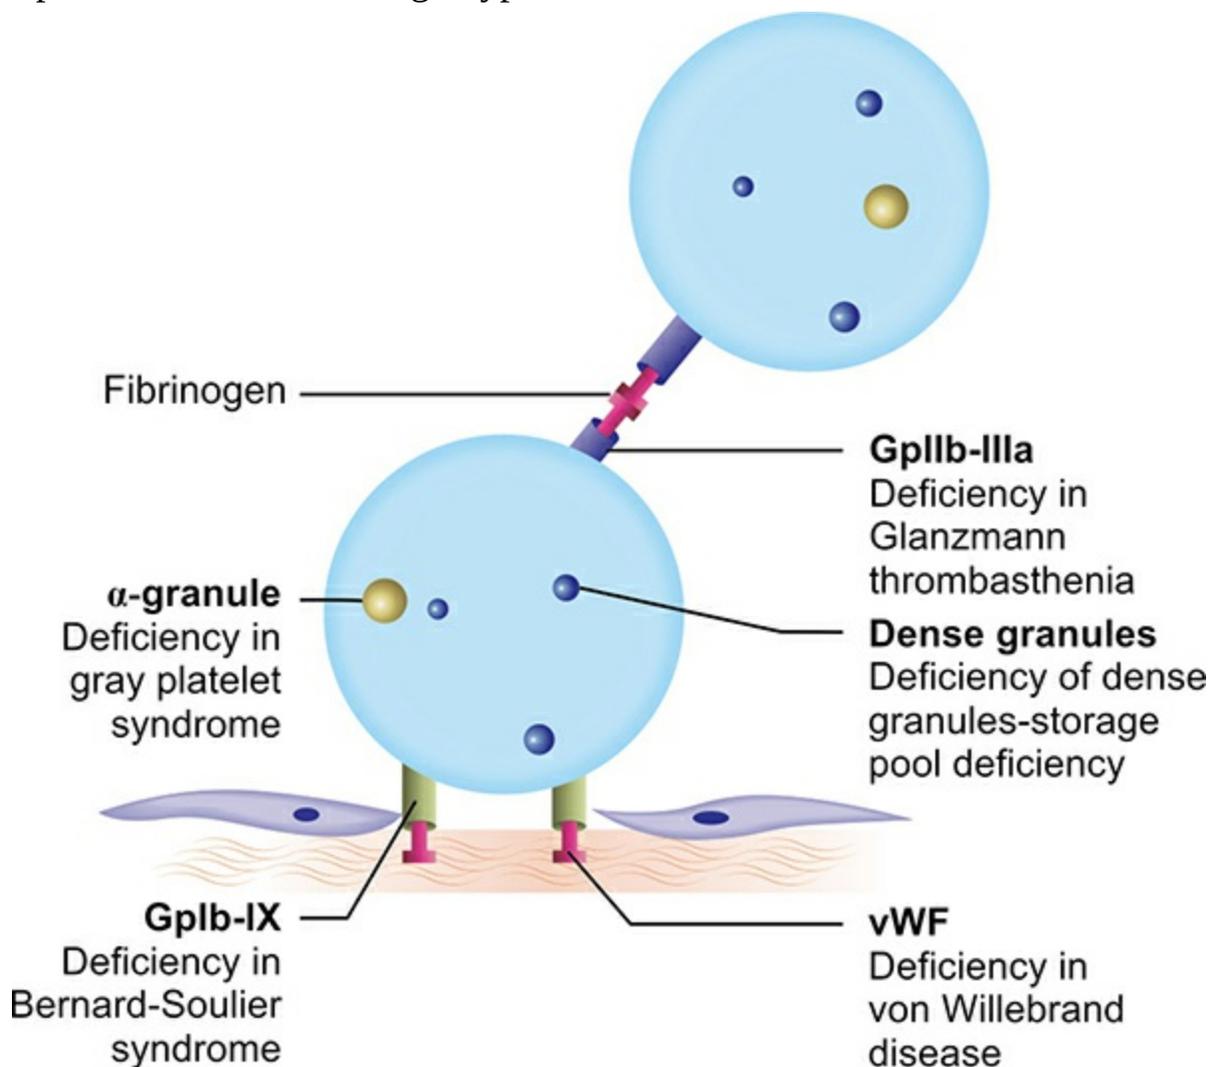

### **Definition**

Immune (idiopathic) thrombocytopenic purpura (ITP) is an autoimmune disorder characterized by increased destruction of platelets by **autoantibodies directed against platelet membrane GPIIb/IIIa and GPIb/IX.**

### **Pathogenesis**

**Q. Discuss the pathogenesis, clinical features, investigations/diagnosis and management of immune (idiopathic) thrombocytopenic purpura (ITP).**

- ITP is an *autoimmune* disorder with formation of antiplatelet antibodies, directed against membrane glycoproteins most often IIb/IIIa or Ib/IX of platelets.
- The antiplatelet antibodies can be demonstrated in approximately 80% of patients and are of the IgG type.

**Fig. 8.41:** Qualitative/functional disorders of platelets

## Clinical Features

ITP can be primary or secondary:

- **Primary:** Most cases are primary. There are two major subtypes of

primary ITP, acute and chronic (Table 8.68).

- a. Acute form is more common in children
  - b. Chronic form is characterized by the persistence of thrombocytopenia for more than 6 months and is more common in adults.
- **Secondary:** Observed in several diseases like systemic lupus erythematosus, acquired immunodeficiency syndrome (AIDS), Hepatitis C, following viral infections and as a complication of drug therapy.
  - Clinical features are not specific but are due to thrombocytopenia in general.
  - Patient has no physical signs other than those due to bleeding and anemia (following menorrhagia and epistaxis) intracranial hemorrhage (ICH), overt gastrointestinal bleeding, and hematuria, is uncommon.
  - Splenomegaly and lymphadenopathy are uncommon in primary ITP and in their presence one should consider the diagnoses other than ITP.
  - May be associated with hemolysis (**Evan's syndrome**).
  - Majority of patients with acute ITP recover within 6 months.

**Table 8.68:** Differences between clinical features of idiopathic thrombocytopenic purpura in children (acute) and adults (chronic).

	<i>Children</i>	<i>Adults</i>
Peak age of occurrence	2–4 years	15–40 years
Gender (F:M)	Equal	1.2 : 1.7
<i>Clinical presentation</i>		
• Onset	• Acute (most with symptoms <1 week)	• Insidious (most with symptoms >2 months)
• Symptoms	• Purpura (<10% with severe bleeding)	• Purpura (typically bleeding not severe)
• Platelet count	• Most <20,000/μL	• Most <20,000/μL
• Antecedent infection	Usually follows an upper respiratory viral infection	Usually no preceding history of viral infection
<i>Course</i>		
• Spontaneous remission	• 83%	• 2%
• Chronic disease	• 24%	• 43%
• Response to splenectomy	• 71%	• 66%

• Eventual complete recovery	• 89%	• 64%
<i>Morbidity and mortality</i>		
• Cerebral hemorrhage	• <1%	• 3%
• Hemorrhagic death	• <1%	• 4%
• Mortality of chronic refractory disease	• 2%	• 5%

## Investigations and Diagnosis

The diagnosis of ITP is one of exclusion. It requires only isolated thrombocytopenia (i.e. without anemia or leukopenia) without another apparent cause.

- **Platelet count** is usually **markedly reduced** (thrombocytopenia) and is below  $80 \times 10^9/L$ . Platelet count should be repeated using sodium citrate (anticoagulant) to exclude pseudothrombocytopenia caused by platelet aggregation and clumping in the presence of EDTA anticoagulant.
- **Tourniquet test (Hess test):** Positive
- **Bleeding time (BT):** Prolonged
- **Bone marrow examination:** Usually not performed in acute ITP, unless treatment becomes necessary on clinical grounds. It is important in chronic ITP to rule out thrombocytopenia resulting from bone marrow failure. Bone marrow shows moderate increase in number of both immature and mature forms of megakaryocytes. A decrease in the number of megakaryocytes argues against the diagnosis of ITP.
- **Antiplatelet antibodies:** Tests for platelet autoantibodies are not widely available but may be demonstrated in blood. However, a negative test does not exclude ITP.
- In chronic ITP, secondary causes such as HIV, hepatitis C virus infection, etc. should be excluded.

### Treatment

- Children with mild acute ITP usually do not require treatment.
- Adults with platelet counts  $>30 \times 10^9/L$  usually do not require treatment. Patients with even lower platelet counts may require treatment, if they have spontaneous bruising or bleeding.
- Indications for treatment:
  - Overt hemorrhage (treated with platelet concentrates).
  - Platelet counts below  $20,000/mm^3$ .
  - Organ or life-threatening bleeding irrespective of the circulating platelet count.

- **Platelet transfusion:** If platelet counts  $<20,000/\text{mm}^3$  or bleeding manifestations.
- **First-line therapy:** Consists of treatment with **oral corticosteroids**.
  - Indications for corticosteroids:
    - ◆ To induce remission
    - ◆ To maintain remission in chronic ITP (immune thrombocytopenic purpura).
    - ◆ Postoperatively, in patients where splenectomy failed to achieve the result.
    - ◆ Pregnant women after the 5th month of pregnancy.
  - Dosage of corticosteroids:
    - ◆ Both adults and children: Initial dose is 1–2 mg/kg of prednisolone/day. Initial dose is continued for at least 2 weeks (or if necessary 3–4 weeks), and then reduced slowly and stopped.
    - ◆ About 66% respond to prednisolone but relapse is common when the dose is reduced.
- **Second-line therapy:** It is by **splenectomy**. Majority of patients respond well and achieve a normal platelet count.
  - **Indications of splenectomy:**
    - ◆ Chronic ITP in adults who fail to responded to corticosteroids.
    - ◆ Patients requiring unacceptably high doses of corticosteroids to maintain a safe platelet count.
    - ◆ When there is severe bleeding or threatening cerebral hemorrhage (despite adequate corticosteroid therapy).
    - ◆ In the first 4–5 months of pregnancy, if steroids do not induce full remission.
  - **Mechanism of action of splenectomy:**
    - ◆ Spleen being the major site of platelet destruction, splenectomy prevents its destruction.
    - ◆ Reduces the concentration of circulating antiplatelet antibodies.
- **Third-line therapy:** Patients who fail to respond to splenectomy, a wide range of other therapies are available. Major drawbacks of these therapies are modest response rates and slow onset of action. The therapies include:
  - **High dose corticosteroids**
  - **Intravenous immunoglobulin (i.e. IgG):** It is effective. Responses are only transient (3–4 weeks).
    - ◆ Indications:
      - ◇ Acute situation prior to surgery and child birth, and in patients with intracranial bleed.
      - ◇ Patients with ITP where corticosteroid therapy and splenectomy are contraindicated.
    - ◆ Side effects: Nausea, vomiting, fever and headache. Uncommonly neutropenia and hemolytic anemia.
    - ◆ Dose: 1–2 g/kg.
  - **RhO(D) immune globulin (anti-D)**
    - ◆ Indications:
      - ◇ Patients who do not respond to steroids and may be tried before splenectomy.
    - ◆ Should be given only to Rh-positive patients.
    - ◆ Effective in patients with ITP but the effect is usually temporary, and nearly 50–75% patients relapse.
    - ◆ Dose is 75  $\mu\text{g}/\text{kg}$  intravenously.
    - ◆ Side effects: Nausea, vomiting, fever, chills and intravascular hemolysis.

- **Immunosuppressive therapy**
  - ◆ Indications:
    - ◇ Refractory cases which fail to respond to corticosteroids and splenectomy.
    - ◇ Patients with ITP where corticosteroid therapy and splenectomy are contraindicated.
  - ◆ Agents used are vinca alkaloids (vincristine, vinblastine), azathioprine, cyclophosphamide, cyclosporine and combination chemotherapy, mycophenolate mofetil.
- **Plasmapheresis:** Employed as an emergency measure to remove antibodies from the plasma.
- **TPO mimetic drugs: Eltrombopag or romiplostim. Romiplostim, 500 µg subcutaneously.**
- Specific immunomodulatory monoclonal antibodies: **Rituximab.**
- Others:
  - ◆ Danazol is an androgen with low virilising activity has been tried in idiopathic thrombocytopenic purpura.
  - ◆ Dapsone
  - ◆ Platelet transfusions are reserved for intracranial or other extreme hemorrhage, where emergency splenectomy may be justified.
- **Emergency treatment:** Necessary in case of life-threatening bleeding. It consists of intravenous administration of methylprednisolone (30 mg/kg, maximum dose 1 g) over 20 to 30 minutes along with platelet transfusion. This is followed by intravenous immunoglobulin (1 g/kg).

## THROMBOCYTOSIS

**Q. What are the common causes of thrombocytosis?**

### Definition

Platelet count more than 4,50,000/cumm is known as thrombocytosis.

### Causes (Table 8.69)

**Table 8.69: Causes of thrombocytosis.**

<i>Idiopathic/primary (autonomous production)</i>	<i>Secondary (reactive thrombocytosis)</i>
<ul style="list-style-type: none"> <li>• Myeloproliferative neoplasms               <ul style="list-style-type: none"> <li>- Essential thrombocytosis</li> <li>- Polycythemia vera</li> <li>- Chronic myeloid leukemia</li> </ul> </li> <li>• Myelodysplastic syndrome</li> </ul>	<ul style="list-style-type: none"> <li>• Iron deficiency</li> <li>• Malignancy (paraneoplastic feature)</li> <li>• Following hemorrhage: Acute or chronic blood loss</li> <li>• Following splenectomy</li> <li>• Following major surgery</li> <li>• Inflammatory disorders, e.g. rheumatoid arthritis and inflammatory bowel disease</li> </ul>

## DISORDERS OF COAGULATION (CLOTTING)

**Q. Write short note on congenital bleeding disorders.**

Hereditary coagulation disorders are listed in Box 8.25.

## **Hemophilia A (Factor VIII Deficiency)**

**Q. Discuss the etiology, classification, clinical features, diagnosis and management of hemophilia A.**

- Hemophilia A is the most common hereditary X-linked recessive disease with a reduction in the amount or activity of factor VIII (antihemophilic factor). About 30% of hemophiliacs have no family history and may be due to acquired mutations.
- Males are affected and females are carriers.
- Incidence: 1 in 10,000 males.

### ***Mode of Inheritance***

- Hemophilia A is an X-linked recessive disorder.
- Usually males are the sufferers and females are the carriers.
- Females can be hemophilic if:
  - She is born to an affected father and a carrier mother (25% risk).
  - Females with inactivation of the X-chromosome such as Turner's syndrome (45, XO)
  - She has inactivation of normal X-chromosome due to unfavorable lyonization (rare).
- Degree of deficiency of factor VIII and severity of bleeding tends to be similar in all the affected members of the same family.
- Normal level of factor VIII in the blood is 0.50–1.50 IU/mL. Hemophilia A may be classified based on the factor VIII activity in blood.

### ***Clinical Features***

- Clinical severity depends on the level of factor VIII activity and is presented in the Table 8.70.
- Excessive bleeding: Hemophilia A is characterized by excessive bleeding, but is unusual until the child is about 6 months old.
- Post-traumatic bleeding: Bleeding following trauma is characteristically 'delayed'.

- Severity of bleeding: Range from mild to severe.
- Petechiae observed in platelet and vascular disorders are not seen in hemophilia.

**Box 8.25:** Hereditary coagulation disorders.

1. von Willebrand disease
2. Hemophilia A
3. Hemophilia B
4. Hemophilia C – Inherited deficiency of factor XI (factor 11); also called Rosenthal syndrome; an autosomal recessive disorder

**Table 8.70:** Clinical classification of hemophilia A.

<i>Classification</i>	<i>Factor VIII level</i>	<i>Clinical features</i>
Mild	6–30% of normal (0.06–0.30 U/mL)	<ol style="list-style-type: none"> <li>1. Hemorrhage secondary to trauma or surgery</li> <li>2. Rare spontaneous hemorrhage</li> </ol>
Moderate	1–5% of normal (0.01–0.05 U/mL)	<ol style="list-style-type: none"> <li>1. Hemorrhage secondary to trauma or surgery</li> <li>2. Occasional spontaneous hemarthrosis</li> </ol>
Severe	≤1% of normal (≤ 0.01 U/mL)	<ol style="list-style-type: none"> <li>1. Spontaneous hemorrhage from early infancy</li> <li>2. Frequent spontaneous hemarthrosis and other hemorrhages, requiring clotting factor replacement</li> </ol>

*Bleeding into joints (hemarthrosis)*

- Frequent and spontaneous hemorrhages occur into the large joints, especially knees, elbows, ankles, wrists and hips, and are known as hemarthrosis.
- Nature of bleeding: Usually spontaneous or follows minor trauma.
- Acute stage: Affected joint is swollen, hot and tender and movements severely restricted. These changes gradually subside over a period of days.
- Consequences: Recurrent bleeding into the joints will lead to crippling deformities and disuse atrophy of muscles around the joint.

*Bleeding into muscles*

- Common sites: calf and psoas muscles.

- Consequences:
  - Psoas hematomas may compress the femoral nerve resulting in sensory disturbances over thigh and weakness of quadriceps.
  - Calf hematomas can result in contraction and shortening of the Achilles tendon.

### *Other manifestations*

- Easy bruising
- Massive bleeding following trauma (from wounds) or operative procedures (e.g. bleeding from sockets after dental extraction)
- Cerebral hemorrhage
- Hematuria and ureteric colic due to passage of blood clots.

### ***Laboratory Investigations***

- **Bleeding time is normal.**
- **Clotting time is prolonged.**
- **Platelet count is normal.**
- **Prothrombin time is normal.**
- **Activated partial thromboplastin time (APTT) is increased** (Normal 35–45 seconds) from 50 seconds to a few minutes.
- **Factor VIII assay** is required for the confirmation of diagnosis and to assess the Factor VIII levels and severity of disease.

### ***Antenatal Diagnosis***

- **Chorionic villous sampling (CVS):** Done at 8–9 weeks gestation, sexing the fetus and using informative factor VIII probes. It is the preferred method.
- **Amniocentesis:** Sexing the fetus at 16 weeks gestation by amniocentesis and, if fetus is male, a fetal blood sampling is done at about 19–20 weeks of gestation.

### **Management**

#### **A. Local treatment**

- **Wounds and bleeding from mucous membrane:** Apply local pressure and pressure bandages or sutures. Immobilize wounds by bandages, splinting etc.
- **Hematomas and hemarthrosis:**
  - **During acute stage:** Elevate the affected part and immobilize by splinting and bandages.

Pain is relieved by analgesics like acetaminophen or codeine.

- **During recovery phase:** Physiotherapy.

## **B. Replacement therapy**

- Agents used: **Factor VIII concentrate** is available as plasma-derived and recombinant products. Recombinant products are the treatment of choice and are replacing the plasma-derived factor VIII concentrate (Table 8.71).
- Route of administration: Intravenous infusion to correction of deficiency of factor VIII and to achieve normal levels.
- **Indications of replacement therapy:**
  - Early treatment of spontaneous bleeding.
  - Severe or prolonged wound and tissue bleeding.
  - Control of bleeding during and after surgery and trauma.
  - Prophylaxis: In all patients with severe hemophilia so as to prevent recurrent bleeding into joints and subsequent joint damage (arthropathy).
- Calculation of dose: Plasma factor VIII, 1 unit/kg will increase activity by 2% (0.02 IU/mL). The desired factor VIII level is about 50% (presuming the initial level to be 0). The dose is calculated as:
  - Dose of factor VIII = Desired factor level (%) × body weight (in kg) × 0.5.
- **Complications of replacement with factor VIII concentrate therapy:** Former replacement therapy with clotting factor concentrates prepared from pooled human plasma has led to other diseases in patients receiving such treatment.
  - Viral Hepatitis (hepatitis B virus, delta virus and hepatitis C virus).
  - Infection with human immunodeficiency virus (HIV).
  - Development of factor VIII inhibitors.

## **C. Nontransfusion therapy in hemophilia**

- **DDAVP (1-Amino-8-D-Arginine Vasopressin)**
  - Desmopressin (DDAVP) is a synthetic vasopressin analog that causes a transient rise in factor VIII activity by 3–5 times. It is given at a dose of 0.3 µg/kg body intravenously over 15 minutes.
  - Indication: Minor bleeding and minor surgery.
- Antifibrinolytic drugs
  - Indications: To control local hemostasis/bleeding in the gums, nasal bleeding, gastrointestinal tract, during oral surgery (e.g. dental extraction) and menstruation.
  - Drugs used: **Epsilon (ε) aminocaproic acid and tranexamic acid.**
  - **Action:** Inhibit the proteolytic activity of plasmin and results in inhibition of fibrinolysis.
  - Dose:
    - ♦ Tranexamic acid: 25 mg/kg three to four times a day.
    - ♦ EACA: Requires a loading dose of 200 mg/kg (maximum of 10 g) followed by 100 mg/kg per dose (maximum 30 g/d) every 6 hours.
  - Contraindication:
    - ♦ Not indicated to control hematuria because of the risk of formation of an occlusive clot in the lumen of genitourinary tract structures.
    - ♦ DIC.
    - ♦ Thromboembolic disease.

**Table 8.71: Doses of factor VIII for treatment of hemorrhage.**

<i>Site of hemorrhage</i>	<i>Desired factor VIII level (% of normal)</i>	<i>Factor VIII dose (U/kg body weight)</i>	<i>Frequency of dose (every no. of hours)</i>	<i>Duration (days)</i>
Hemarthrosis	30–50	~25	12–24	1–2
Superficial intramuscular hematoma	30–50	~25	12–24	1–2
Gastrointestinal tract	~50	~25	12	7–10
Epistaxis	30–50	~25	12	Until resolved
Oral mucosa	30–50	~25	12	Until resolved
Hematuria	30–100	~25–50	12	Until resolved
Central nervous system	50–100	50	12	At least 7–10 days
Retropharyngeal	50–100	50	12	At least 7–10 days
Retroperitoneal	50–100	50	12	At least 7–10 days

### **Complications**

About 15% of the patients receiving factor VIII therapy develop inhibitory antibodies that bind and inhibit factor VIII.

- **Treatment for patients with Factor VIII inhibitors:** Immune tolerance induction (ITI) is the most effective strategy of eradication of inhibitors with steroids or other immunosuppressants. Emicizumab, a bifunctional monoclonal antibody that can substitute for factor VIII is used in these cases.
- **Antibodies to AHG may occur de novo in non-hemophiliacs as part of an immunological disorder such as systemic lupus erythematosus.**
- Chronic complications
  - Arthropathy
  - HIV and HCV infection
  - Inhibitor development.

### **Preventive Therapy for Hemophilia**

- Gene therapy
- Concizumab- monoclonal antibody directed against tissue factor pathway inhibitor

## Hemophilia B

**Q. Write short essay/note on hemophilia B (Christmas disease) and its management.**

- Hemophilia B is caused by a deficiency of factor IX.
- Mode of inheritance: X-linked disorder
- Clinical features: Similar to hemophilia A.
  - Patients with severe disease: Present with muscle hematomas and hemarthrosis which progresses to crippling joint deformities.
- Diagnosis: Factor IX assay shows deficiency of factor.

### Management

- Management is similar to hemophilia A.
  - Replacement therapy:
    - ◆ Fresh frozen plasma to treat mild-to-moderated bleeding.
    - ◆ Recombinant factor IX: To treat moderate-to-severe bleeding.
      - ◇ Gene therapy: It may be effective in managing severe disease.
      - ◇ Desmopressin is ineffective.

## von Willebrand's Disease

**Q. Discuss the etiology, clinical features, investigations and treatment of von Willebrand's disease.**

- von Willebrand's disease (vWD) is characterized by defective platelet function as well as factor VIII deficiency, and both are due to a deficiency or dysfunction of von Willebrand factor (vWF).
- **Major categories:** The VWF gene is located on chromosome 12 and numerous mutations of the gene produces vWD.
  - **Quantitative deficiency in vWF:**
    - ◆ Type 1 is an autosomal dominant, relatively mild disorder.
    - ◆ Type 3 is an autosomal recessive disorder and is severe.
  - **Qualitative defects (dysfunction) in vWF:** Type 2 von Willebrand disease accounts for 25% of all cases and is usually an autosomal dominant disorder. There are several subtypes.
    - ◆ Type 2a is most commonly characterized by defective assembly of multimers.

- ◆ Type 2b is caused by synthesis of an abnormal vWF with increased affinity for platelets which results in thrombocytopenia.

### ***von Willebrand Factor (vWF)(Fig. 8.42)***

- vWF is a protein synthesized by endothelial cells and megakaryocytes.
- **Main functions:**
  1. von Willebrand factor acts as a **carrier protein** which binds to **factor VIII** and forms plasma factor VIII-vWF complex. vWF protects factor VIII and is important for its stability. It has no role in the coagulation cascade, but deficiency of vWF causes a secondary reduction of factor VIII causing coagulation defect.
  2. vWF is the most important cofactor for adhesion of platelets to the exposed subendothelial collagen matrix by GpIb/IX. Hence, the deficiency of vWF results in a defect of platelet function.

### ***Clinical Features***

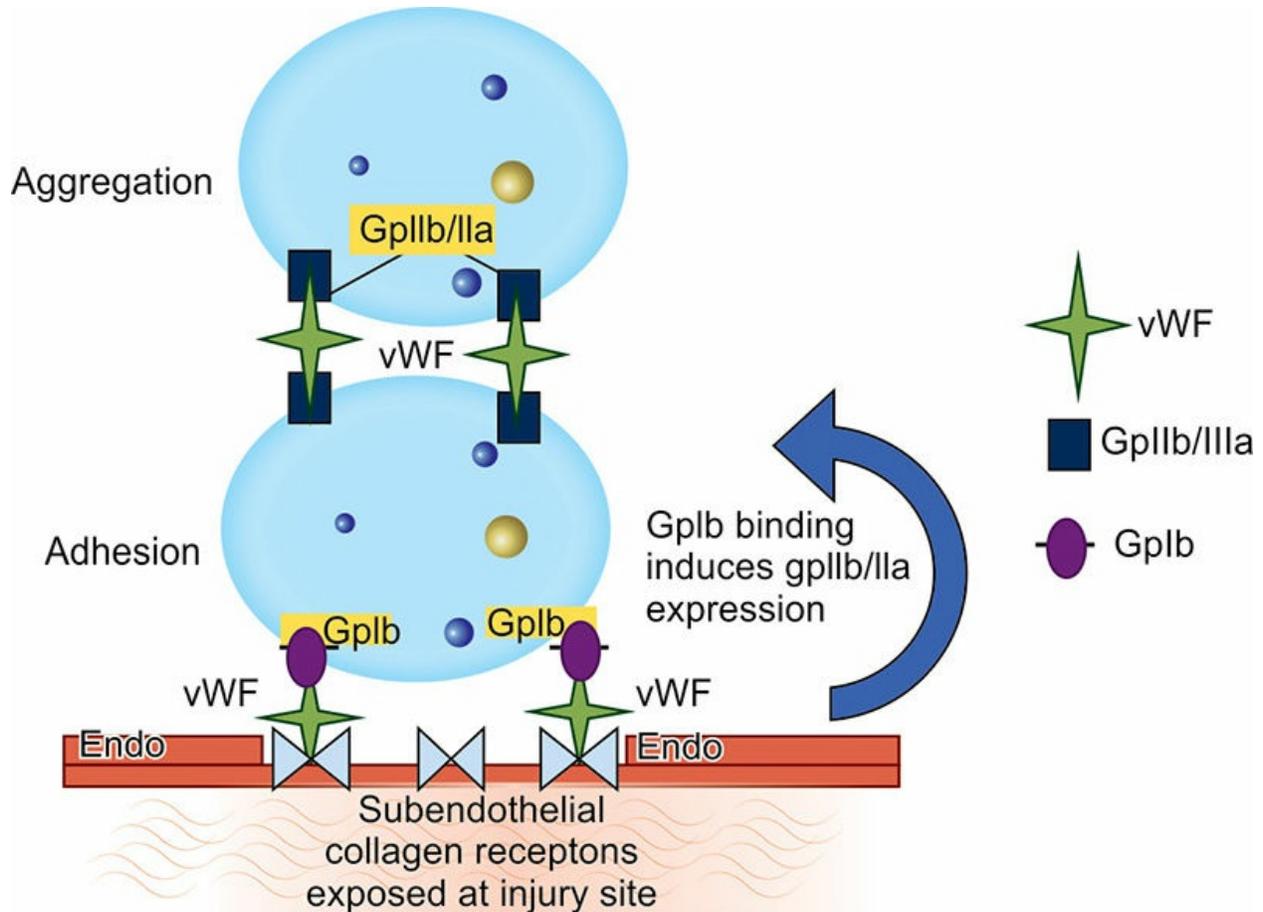

- Variable and ranges from mild asymptomatic conditions to a severe hemorrhagic disorder.
- The common symptoms are spontaneous bleeding from mucous membranes (e.g. epistaxis), excessive bleeding from wounds or menorrhagia. In severe cases, manifestations may be similar to hemophilia A.

Acquired causes of vWF deficiency are listed on Box 8.26.

### ***Laboratory Findings***

- **Platelet count** is **normal**.
- **Bleeding time** is **prolonged** despite a normal platelet count because of defect in platelet function.
- **Tourniquet test (Hess test): Positive** due to defect in platelet adhesion.
- **APTT: Prolonged** because vWF stabilizes factor VIII by binding to it. A deficiency of vWF gives rise to a secondary decrease in factor VIII levels.
- **vWF assay:** Plasma level of active vWF is **decreased**.
- **Platelet function test:** Function of vWF is assessed by **ristocetin aggregation test**. Ristocetin induces multivalent vWF multimers to bind platelet glycoprotein Ib-IX and results in bridging of platelets to each

other. The resultant clumping (agglutination) of platelets is measured by aggregometer. The degree of ristocetin-dependent platelet agglutination is a measure of vWF activity. Defective ristocetin induced platelet aggregation is diagnostic of vWF.

**Fig. 8.42:** Functions of von Willebrand factor (vWF).

### **Box 8.26:** Acquired causes of vWF deficiency.

#### Hematologic disorders

- Lymphoproliferative disorders
- Myeloproliferative neoplasms including essential thrombocytosis (ET)

#### SLE and other autoimmune disorders

#### Cardiovascular disease

- Congenital heart disease
- Aortic stenosis
- Left ventricular assist device or extracorporeal membrane oxygenation

#### Wilms tumor

#### Hypothyroidism

#### Valproic acid and other medications

## Management

### Management of bleeding:

- Mild bleeding: Managed with desmopressin.
- Severe bleeding: Controlled by intravenous cryoprecipitate or plasma-derived concentrates containing vWF and factor VIII. Recombinant activated factor VII (rFVIIa,) has also been successfully used in VWD patients with severe hemorrhage refractory to VWF replacement therapy.

### Vitamin K deficiency:

- Clinically it manifests as ecchymoses, bleeding from injection sites, bruises, gum bleeding, hematemesis, melaena or hematuria.
- Both the prothrombin time and activated partial thromboplastin time are prolonged.
- Administration of vitamin K in a dose of 5–10 mg stops bleeding within 1–2 days.
- If blood loss is severe or response to vitamin K is inadequate, transfusion of fresh blood or fresh frozen plasma is indicated.

## FIBRINOLYSIS

Causes of excessive fibrinolysis (Table 8.72).

## MICROANGIOPATHIC HEMOLYTIC STATES AND THROMBOCYTOPENIAS

This syndrome consists of two closely related entities—**thrombotic thrombocytopenic purpura (TTP)** and **hemolytic uremic syndrome (HUS)**.

### Thrombotic Thrombocytopenic Purpura

#### **Q. Discuss thrombotic thrombocytopenic purpura.**

Thrombotic thrombocytopenic purpura (TTP) is a severe microangiopathic hemolytic anemia (MAHA), characterized by systemic platelet aggregation, organ ischemia, profound thrombocytopenia (with increased marrow megakaryocytes), fragmentation of erythrocytes, fever and renal failure.

#### Table 8.72: Causes of excessive fibrinolysis.

- Obstetric: Abruption placentae, amniotic fluid embolism
- Surgical: Gastrectomy, lung resection, nephrectomy, prostatectomy, cardiopulmonary bypass, splenectomy, pancreatectomy
- Medical:

- Liver diseases (cirrhosis of liver)
- Leukemias (acute leukemia, chronic granulocytic leukemia type IV)
- Anaphylactic shock
- Autoimmune diseases (systemic lupus erythematosus)

## ***Etiology and Pathogenesis***

- Normally endothelial cells and megakaryocytes secrete normal vWF multimers into the plasma. These multimers spontaneously develop into unusually large multimers which are most effective in mediating platelet adhesion.
- A plasma protease enzyme called ADAMTS 13 ('vWF metalloprotease') regulates the activity of vWF by cleaving the hemostatically active unusually large multimers into normal multimers. Thus, ADAMTS-13 regulates the size of vWF multimers and prevents platelet adhesion.
- TTP patients have an inherited or acquired deficiency of ADAMTS-13. The deficiency leads to accumulation of unusually large multimers of vWF in plasma.
- These large multimers promote platelet adhesion or promote intravascular platelet aggregation and cause spontaneous activation of the coagulation cascade.
- This results in hyaline thrombi throughout the microcirculation, leading to tissue ischemia and infarction that are characteristic of TTP.
- Secondary causes of acute TTP: These include pregnancy, oral contraceptives, SLE, infection and drugs (ticlopidine and clopidogrel). They may or may not have associated antibodies to ADAMTS-13.

## ***Clinical Features***

The classic five symptoms of TTP are (1) microangiopathic hemolytic anemia (MAHA) with schistocytosis (at least 3 cells per 100), (2) severe thrombocytopenia, (3) transient neurologic symptoms secondary to central nervous system ischemia, (4) fever and (5) renal abnormalities including hematuria and/or proteinuria.

## ***Laboratory Findings***

- **Platelet count markedly reduced** often below 20,000/ $\mu$ L (thrombocytopenia).
- Peripheral blood smear shows fragmented red cells (called **schistocytes**) and numerous reticulocytes.

- Prothrombin time (PT), partial thromboplastin time (PTT) and fibrinogen concentration: Normal, because the coagulation system is not activated.
- Urine shows moderate proteinuria and both gross and microscopic hematuria.
- **Serum LDH: Raised** due to release from ischemic tissues.
- **ADAMTS-13 activity: Reduced** below 5–10% of normal.

### *Diagnosis*

Schistocytes and elevated serum LDH (out of proportion to the degree of hemolysis) suggest the diagnosis of TTP.

#### **Treatment**

- **Plasma exchange**
  - Daily plasma exchange (removing 40 mL/kg body weight of plasma and replacing it with equal volume of fresh frozen plasma) is the treatment of choice.
  - Provides ADAMTS-13 and removes associated autoantibody in acute TTP.
  - Continued for at least 2 days after remission, which is defined as stabilization of clinical symptoms and return to normal of platelet count and LDH levels along with rising hemoglobin level.
  - Cryoprecipitate and FFP (fresh frozen plasma) also contain ADAMTS-13 can be used.
- **Corticosteroids:** Pulsed intravenous methylprednisolone is given acutely and is generally added to plasma exchange to suppress formation of antibody.
- **Rituximab:** It is a monoclonal antibody against CD20, suppresses antibody-producing cells. It is used in those patients who are refractory to plasma exchange and corticosteroids.
- **Splenectomy:** Performed in resistant cases which remove antibody-producing cells.
- **Platelet concentrates are contraindicated.**

**Prognosis:** Untreated cases have a mortality of up to 90% but with modern management it has been reduced to about 10%.

## **Hemolytic-Uremic Syndrome (HUS)**

**Q. Discuss the clinical features, investigations and treatment of hemolytic-uremic syndrome.**

Hemolytic-uremic syndrome is distinguished from TTP by the absence of fever and neurological symptoms, the prominence of acute renal failure (uremia), frequent affection of children and different pathogenesis.

### ***Etiology and Pathogenesis***

- HUS develops following damage to the endothelium by toxins, drugs or radiation. One main cause of HUS in children and the elderly is infectious

gastroenteritis caused by *Escherichia coli* strain 0157:H7.

- *E. coli* produces a Shiga-like toxin which is absorbed from the inflamed gastrointestinal mucosa.
- The toxin enters circulation and damages endothelial cells of microvasculature, mainly in the renal glomerular capillaries and initiates platelet activation and thrombi formation.
- Red cells get trapped in the formed thrombi, undergo fragmentation resulting in schistocytes.
- Splenic trapping of the fragmented red cells causes extravascular hemolysis.

Differences between thrombotic thrombocytopenic purpura and hemolytic uremic syndrome are presented on Table 8.73.

**Table 8.73: Differences between thrombotic thrombocytopenic purpura and hemolytic uremic syndrome.**

<i>Features</i>	<i>Thrombotic thrombocytopenic purpura (TTP)</i>	<i>Hemolytic uremic syndrome(HUS)</i>
Age	Adults between 20–50 years	Children<5 years
Hemolytic anemia	With RBC fragmentation	With RBC fragmentation
Renal dysfunction	Mild to moderate	Acute renal failure
Thrombocytopenia	Present	Present
CNS symptoms	Severe	Mild
Fever	+	-

### ***Clinical Features***

- Age: HUS develops most commonly in children between 1 and 5 years of age few days after an episode of bloody diarrhea. HUS can also develop in adults following certain drugs and radiation therapy that damage endothelial cells.
- Classical presentation: **Triad of microangiopathic hemolytic anemia, thrombocytopenia and renal failure** (oliguria). Hematuria and hypertension are also common. Despite thrombocytopenia, bleeding manifestations are rare.
- Complications: Fluid overload may result in pulmonary edema and hypertensive encephalopathy.

## Investigations

- Hemoglobin levels: Decreased (anemia).
- Platelet count: Markedly reduced often below 20,000/ $\mu$ L (thrombocytopenia).
- Peripheral blood smear shows fragmented red cells (called schistocytes) and numerous reticulocytes.
- LDH: Elevated.
- Blood urea and creatinine: Elevated.
- Urine: May show proteinuria and red blood cells.
- PT and aPTT: Normal
- Stool: Culture for enterohemorrhagic *E.coli*—positive; shiga toxin—positive.

### Treatment

- Supportive care: For the renal and hematological complications.
- Antibiotics: If shigellosis is suspected/detected.
- Experimental: Eculizumab, monoclonal antibody to C5.

## Prognosis

With appropriate supportive care, they usually recover completely, but in more severe cases renal damage may result in death.

## DISSEMINATED INTRAVASCULAR COAGULATION (DIC)

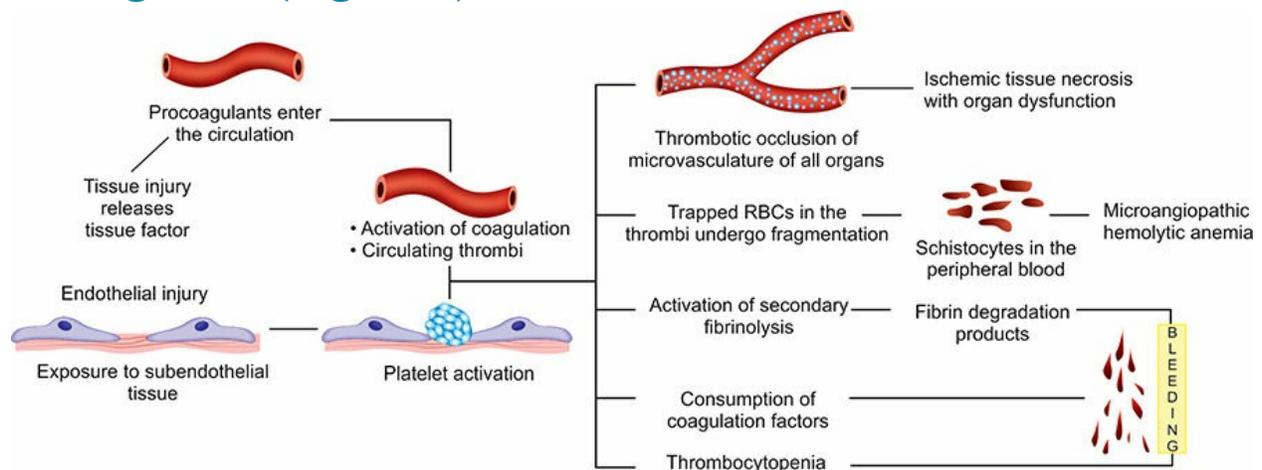

**Q. Discuss the causes, pathogenesis, clinical features, laboratory features and management of disseminated intravascular coagulation (DIC: defibrination syndrome: consumption Coagulopathy).**

Disseminated intravascular coagulation (DIC) is a widespread acute or chronic thrombohemorrhagic disorder in which a **combination of thrombosis and hemorrhage** develops as a secondary complication of a wide variety of disorders (Table 8.74).

**Table 8.74:** Major disorders associated with disseminated intravascular coagulation.

<b>1. Infections</b>	<b>4. Massive tissue injury</b>
<ul style="list-style-type: none"> <li>• Gram-negative bacterial sepsis</li> <li>• Meningococemia and other bacteria</li> <li>• Fungi, viruses, Rocky mountain spotted fever, Malaria</li> </ul>	<ul style="list-style-type: none"> <li>• Traumatic</li> <li>• Burns</li> <li>• Fat embolism</li> <li>• Surgery</li> </ul>
<b>2. Obstetric complications</b>	<b>5. Vascular disorders</b>
<ul style="list-style-type: none"> <li>• Retained dead fetus</li> <li>• Septic abortion</li> <li>• Abruptio placentae</li> <li>• Amniotic fluid embolism</li> <li>• Toxemia and preeclampsia</li> </ul>	<ul style="list-style-type: none"> <li>• Aortic aneurysm, giant hemangioma</li> </ul>
<b>3. Neoplasms</b>	<b>6. Miscellaneous</b>
<ul style="list-style-type: none"> <li>• Carcinomas of pancreas, prostate, lung, and stomach</li> <li>• Acute promyelocytic leukemia</li> </ul>	<ul style="list-style-type: none"> <li>• Snakebite, liver disease, acute intravascular hemolysis, shock, heat stroke, hypersensitivity, vasculitis</li> </ul>

## Pathogenesis (Fig. 8.43)

**Fig. 8.43:** Pathogenesis of thrombosis, ischemic tissue necrosis and bleeding in disseminated intravascular coagulation.

**Table 8.75:** Effects and signs of DIC.

<b>Organ/site</b>	<b>Due to thrombi in microvasculature</b>	<b>Due to hemorrhagic diathesis</b>
Central nervous system	Multifocal, delirium, coma	Intracerebral bleeding
Renal system	Cortical necrosis-oliguria, azotemia	Hematuria
Skin	Focal ischemic necrosis, gangrene	Petechiae, ecchymoses, bleeding at the sites of venipuncture

Gastrointestinal tract	Acute ulceration	Massive bleeding
Respiratory tract	Acute respiratory distress syndrome	
Mucous membranes		Epistaxis, gingival bleeding
Peripheral circulation	Fragmentation of trapped RBCs-Microangiopathic hemolytic anemia	

## Clinical Features

- DIC is a serious, often fatal, important clinical condition which needs an immediate diagnosis and management. The symptoms of DIC depend on the nature, intensity and duration of the underlying disorder.
- Signs and symptoms are related to the tissue hypoxia and infarction caused by the microvascular thrombosis; or with bleeding diathesis due to the depletion of factors and the activation of fibrinolytic mechanisms; or both (Table 8.75).
- Bleeding is the most common clinical feature in acute **DIC**. It may manifest as ecchymoses, petechiae or bleeding from mucous membranes or at the sites of venipuncture.
- Microvascular thrombi cause ischemic necrosis of the organ with resultant dysfunction of the involved organ and occur most often with chronic underlying diseases. Organ dysfunction may manifest as hepatic, renal, cardiac or respiratory failure or neurological disturbances. It may also result in gangrene of extremities and hemorrhagic necrosis of the skin.
- Waterhouse-Friderichsen syndrome: Occult thrombosis of adrenal vein thrombosis resulting in adrenal hemorrhage.
- Trousseau sign: Migratory venous thrombosis in cancers.
- Multiorgan dysfunction syndrome (MODS): Frequent consequence of DIC and is usually due to bleeding into organs or thrombotic alteration in various organs (hepatic, cardiac, central nervous, renal and pulmonary systems).

## Laboratory Findings (Investigations) in DIC (Table 8.76)

### **Q. Write short note on investigations to diagnose DIC.**

- Erythrocyte sedimentation rate (ESR): Low
- Peripheral smear: Presence of schistocytes.

- **Screening assays**
  - **Platelet count:** Decreased because of utilization of platelets in microthrombi.
  - **Prothrombin time:** Increased.
  - **APTT: Increased** because of consumption and inhibition of the function of clotting factors.
  - **Thrombin time (TT):** Increased because of decreased fibrinogen.
  - **Plasma fibrinogen:** Decreased.
  - Presence of schistocytes (fragmented RBCs) in the peripheral smear.
- **Confirmatory tests**
  - **FDP (fibrin degradation/split products):** Secondary fibrinolysis results in generation of FDPs, which can be measured by latex agglutination.
  - **D-dimer test:** D-dimer is formed during fibrinolysis as a result of degradation of cross-linked fibrin by plasmin. D-dimer levels are elevated and is specific for diagnosing DIC.

**Table 8.76:** Routine laboratory value abnormalities in DIC.

<i>Test</i>	<i>Abnormality</i>
Platelet count	Decreased
Prothrombin time	Prolonged
aPTT	Prolonged
Fibrin degradation products	Elevated
Protease inhibitors (e.g. protein C, AT, protein S)	Decreased

**Q. Write short note on management of DIC.**

**Management**

- Control or elimination of the underlying cause (e.g. removal of a dead fetus, placenta, etc).
- Correction of precipitating factors: For example, acidosis, dehydration, sepsis and hypoxia.
- Management of hemorrhagic symptoms: It is necessary to maintain blood volume and tissue perfusion. Hemorrhagic symptoms are managed by transfusions of platelet concentrates, FFP, cryoprecipitate and red cell concentrates.
  - Dose:
    - ◆ Platelet concentrates: 1–2 units/10 kg.
    - ◆ Fresh frozen plasma: 15–20 mL/kg.
    - ◆ Cryoprecipitate: 1 unit/10 kg.

- Drugs to control coagulation such as heparin or antifibrinolytic drugs have been tried in DIC.
  - Heparin: Low doses of continuous infusion heparin (5–10 U/kg per h) are often used in patients with thrombotic manifestations. It should be given after the correction of bleeding. Major indications for heparin therapy are:
    - ◆ Purpura fulminans during the surgical resection of giant hemangiomas and during removal of a dead fetus.
    - ◆ Acute promyelocytic leukemia.
  - Antifibrinolytic drugs: For example, EACA, or tranexamic acid prevent fibrin degradation by plasmin may reduce bleeding episodes. However, they increase the risk of thrombosis and concomitant use of heparin is indicated.

## TRANSFUSION MEDICINE

### **Q. Discuss blood transfusion, blood component transfusion and indications for transfusion therapy.**

Transfusion medicine comprises of blood and blood component/products transfusion. Blood cannot be synthesized artificially. So the source of blood is from a healthy human donor.

### **Whole Blood**

- One unit of blood collected from a donor contains 450 mL  $\pm$  10% of blood and citrate anticoagulant that also contains phosphate and dextrose.
- Whole blood provides both oxygen-carrying capacity and volume expansion. However, it is rarely used because within a few hours or days, some coagulation factors (especially factors V and VIII) and platelets decrease in quantity or lose viability.

### **Red Cell Concentrates (Packed Red Cells)**

- Packed red cells are obtained by centrifugation/sedimentation of the whole blood. All the plasma is removed and is replaced by about 100 mL of an optimal additive solution, such as SAG-M, which contains sodium chloride, adenine, glucose and mannitol.
- In the packed red cell unit, the hematocrit is between 55–65%. Since, the volume is about 330 mL; there is less risk of volume overload.
- One unit of packed red blood cells raises hemoglobin concentration by 1 g/dL.

General indications for RBC transfusion are mentioned in Box 8.27.

### **Platelet Concentrate (PC)**

- Platelet concentrate may be obtained from a single donor or pooled plasma. Platelets can also be obtained from a single donor by platelet apheresis SDP-single donor platelets.
- Platelets have ABO antigens on their surface but do not express Rh antigen. Hence, ABO matching required. But it is advisable to transfuse Rh negative persons with platelets only from Rh negative persons. One PC should increase the platelet count by 5,000–10,000/ $\mu$ L. Six units of pooled platelets or one apheresis unit should increase the platelet count by approximately 30,000/ $\mu$ L.
- Indications for platelet concentrate transfusion are mentioned in Box 8.28.

### Box 8.27: General indications for RBC transfusion.

- Replace acute blood loss due to hemorrhage or during surgery to relieve clinical features caused by insufficient oxygen delivery
- Symptomatic anemia in an euvolemic patient
  - $\beta$ -thalassemia major
  - Sickle cell anemia
  - Aplastic anemia
  - Severe anemia of any cause
- Contraindication to platelet concentrate transfusion
  - Thrombotic thrombocytopenic purpura (TTP)
  - Heparin-induced thrombocytopenia (HIT).
  - Relative contraindication: Idiopathic thrombocytopenic purpura (ITP) or post-transfusion purpura (PTP) because the survival of transfused platelets is very brief.

### Box 8.28: Indications for platelet concentrate transfusion.

Bleeding due to:

- Severe thrombocytopenia (when platelet count is less than 20,000/cu mm).
  - Immune mediated: In patients with autoimmune thrombocytopenia, it should be reserved for patients with life-threatening bleeding.
  - Secondary to bone marrow failure
    - ◆ Chemotherapy induced
    - ◆ Due to leukemia
    - ◆ Dilutional
- Abnormal platelet function
- Disseminated intravascular coagulation (DIC)
- Surgical or invasive procedures in thrombocytopenic patients

## Granulocyte Concentrates

- Indications: Severe neutropenia with definite evidence of bacterial infection
- It is not frequently employed, because it is preferable to administer the growth factors for myelopoiesis like G-CSF/GM-CSF. But it is indicated when granulocyte count is less than 500/cu mm (agranulocytosis), and to combat infections (in neonatal sepsis and chronic granulomatous disease).

## Fresh Frozen Plasma (FFP)

- The volume is about 200 mL and contains all the coagulation factors (including von Willebrand factor). Present in fresh plasma. The volume transfused depends on the clinical situation and patient size, and should be guided by laboratory assays of coagulation function. The general guide is 10–15 mL/kg per dose.
- ABO matching is essential before infusion of FFP. Rh compatibility is not required
- **Indications:** For replacement of coagulation factors in acquired coagulation factor deficiencies
  - Patients on anticoagulant drug therapy (Coumarin)
  - Antithrombin deficiency
  - Coagulopathy of liver diseases
  - Vitamin K deficiency
  - Microangiopathic hemolytic anemia including TTP, hemolytic uremic syndrome and HELLP syndrome
  - DIC.

## Cryoprecipitate

- Contains concentrated precipitate of Factor VIII, XIII, von Willebrand factor (vWF) and fibrinogen.
- Does not require cross-matching before transfusion.
- **Indications:**
  - DIC and other conditions where the fibrinogen level is very low (hypofibrinogenemia).
  - It was used for hemophilia, factor XIII deficiency, von Willebrand disease. However, it is no longer used for these disorders because of the greater risk of virus transmission compared with virus-inactivated coagulation factor concentrates.
- Various coagulations factors and their amount in one unit of cryoprecipitate are mentioned in Table 8.77.

**Table 8.77:** Various coagulations factors and their amount in one unit of cryoprecipitate.

<i>Coagulation factor</i>	<i>Quantity per unit</i>
Fibrinogen	150–250 mg
Factor VIII	80–150 units
Von Willebrand factor	100–150 units
Factor XIII	50–75 units

### Factor VIII and IX Concentrates

- These are freeze-dried preparations of specific coagulation factors prepared from large pools of plasma from many donors.
- Indications:
  - For patients with hemophilia and von Willebrand’s disease, where recombinant coagulation factor concentrates are unavailable.

### Saline-washed Red Blood Cells

Saline washing of red cells is an effective means of removing leukocytes and plasma (up to 99%). This product is largely restricted to patients with antibodies to IgA or IgE, and those requiring red cells with minimal plasma as in **thalassemia and paroxysmal nocturnal hemoglobinuria**.

### Frozen Red Blood Cells

Red blood cells can be freeze-d and stored up to 3 years by addition of glycerol as an endocellular cryoprotective agent. This procedure is used for storage of rare blood groups. Frozen red cells may be indicated for patients with history of severe allergic reactions to plasma or leukocyte factors, e.g. patients sensitized to IgA.

### Irradiated Blood Products

Cellular blood products (red cells, platelets, granulocytes) can be irradiated to a dose of 1500 rads before transfusion in order to minimize the risk of transfusion-acquired **graft-versus-host disease** in immunocompromised individuals.

### Immunoglobulins

#### *Rh Immune Globulin*

### *Indications*

- Known or suspected inoculation of Rh<sup>-</sup> mother with unknown or Rh<sup>+</sup> fetal red cells, e.g. abortion, threatened abortion, ectopic pregnancy, amniocentesis, abdominal trauma in 2nd or 3rd trimester, postpartum if new born is Rh<sup>+</sup>).
- Following transfusion of Rh<sup>+</sup> cellular blood products (e.g. platelets) to an Rh<sup>-</sup> female of child bearing age or younger.
- Acute ITP resistant to steroids.

### **Safe Transfusion Procedures**

**Q.** Write short note on precautions to be observed in blood transfusion.

### ***Pretransfusion Testing***

Before transfusion of any blood or its components, it is necessary to know whether they are compatible with the recipient's blood.

- **Donor blood:** The tests routinely carried out on donor's blood include ABO and Rh grouping, tests for HBsAg, anti-HCV, anti-HIV-1 and HIV-2 and serum alanine aminotransferase (ALT), malaria and syphilis.
- **Recipient blood:** The recipient's ABO and Rh grouping is also carried out.

### ***Compatibility Testing***

These are set of procedures which include: Review of patient's past blood bank history and records (if done earlier), ABO and Rh typing of the recipient and donor, antibody screening test of recipient's and donor's serum followed by cross-matching. It is sometimes referred to as cross-matching. However, cross-match is only a part of compatibility test.

**Cross-matching:** Cross-matching is very important before any blood transfusion. Cross-matching should be carried out to ensure that there are no antibodies in patient's serum that will react with the donor's cells when transfused. Full cross-matching requires about 45 minutes if no red cell antibodies are present, but may need hours if a patient has multiple antibodies.

- **Importance of cross-matching:**
  - It is the final check of ABO compatibility between donor and recipient.

- Detects the presence of any clinically significant, unexpected antibodies in the recipient's serum that may react with donor's cells, thereby preventing any transfusion reaction.
- **Types:** Cross-matching procedure may involve **major and minor** cross-matching. Major cross-matching consists of mixing donor's red cells with recipient's (patient's) serum; whereas minor cross-matching consists of mixing patient's red cells with donor's serum.

### ***Bedside Procedures for Safe Transfusion***

- An error of patients receiving the wrong blood is important avoidable cause of mortality and morbidity in transfusion medicine.
- Most incompatible transfusions are due to failure to adhere to standard procedures for taking correctly labeled blood samples and ensuring that the correct pack of blood component is transfused into the intended recipient.
- It is always necessary to monitor the recipient during and after transfusion so that any complications can be dealt with accordingly.

## **COMPLICATIONS OF BLOOD TRANSFUSION (TABLE 8.78)**

**Q. Write short essay/note on the complications of blood transfusion.**

### **Immunological Complications/Reactions**

#### ***Acute Hemolytic Transfusion Reaction***

- Most serious complication of blood transfusion.
- Cause: Occurs due to transfusion of incompatible donor red cells resulting in destruction of donor cells. Usually due to ABO incompatibility.

#### ***Clinical features***

- The initial symptoms may **occur within few minutes after starting the transfusion**. Patient typically develops fever with chills, pain in the lumbar region, dyspnea, pruritus, burning sensation at the site of transfusion and centrally along the vein, and chest pain.
- In an unconscious patient, more severe features like hypotension, shock,

intravascular hemolysis which results in hemoglobinuria and oliguria with acute renal failure and excessive bleeding due to DIC may develop.

**Table 8.78: Complications of blood transfusion.**

A. Immunological complications	B. Non-immunological complications
<p><b>a. Immediate reactions</b></p> <ol style="list-style-type: none"> <li>1. Acute hemolytic transfusion reactions</li> <li>2. Febrile non-hemolytic reaction</li> <li>3. Allergic reaction-urticaria</li> <li>4. Anaphylactic reactions</li> <li>5. Transfusion-related acute lung injury (TRALI)</li> </ol> <p><b>b. Delayed reactions</b></p> <ol style="list-style-type: none"> <li>1. Alloimmunization</li> <li>2. Delayed hemolytic transfusion reactions (mostly asymptomatic)</li> <li>3. Transfusion associated graft versus host disease</li> <li>4. Post-transfusion purpura</li> </ol>	<p><b>a. Immediate</b></p> <ol style="list-style-type: none"> <li>1. Circulatory overload</li> <li>2. Air embolism</li> </ol> <p><b>b. Late</b></p> <ol style="list-style-type: none"> <li>1. Iron overload: Transfusion hemosiderosis</li> <li>2. Thrombophlebitis</li> <li>3. Infections: <ul style="list-style-type: none"> <li>• Hepatitis (HBV, HCV and HDV)</li> <li>• HIV (AIDS)</li> <li>• Malaria</li> <li>• Cytomegalovirus</li> <li>• Syphilis</li> </ul> </li> </ol>

### Diagnosis

In majority of cases, this results from clerical errors like wrong labeling of the cross-match sample, improper checking or transfusion to the wrong recipient, confirmed by finding evidence of hemolysis (e.g. hemoglobinuria), and incompatibility between donor and recipient.

### Management

- Stop the transfusion immediately if there is any suspicion of serious transfusion reaction.
- Change the blood transfusion set and maintain the venous access using normal saline.
- Perform physical examination such as blood pressure, urine output and evidence of bleeding. Emergency treatment may be needed to maintain the blood pressure and renal function.
- Withdraw new blood samples from the opposite arm of the patient and send it to the blood transfusion laboratory along with the donor units to exclude a hemolytic transfusion reaction.
- Centrifuge one more blood sample from the recipient of transfusion and look for any free hemoglobin in the supernatant.
- Perform coagulation screening tests including partial thromboplastin time, platelet count, fibrinogen levels and fibrin-degradation products to exclude DIC. Laboratory evaluation for hemolysis includes the measurement of serum haptoglobin, lactate dehydrogenase (LDH) and indirect bilirubin levels.
- If hypotension develops, administer intravenous fluids and if required, vasopressors.
- Administer diuretic furosemide to maintain urine output.

## ***Febrile Non-Hemolytic Transfusion Reactions (FNHTR)***

- Common complication of blood transfusion.
- Cause: Usually develop due to presence of leukocyte antibodies in patients who have previously been transfused or pregnant. Can also occur due to release of cytokines from donor leukocytes in platelet concentrates.
- Time of occurrence: Usually occur towards the end of infusion or within hours of completing the transfusion.
- Typical signs: Flushing and tachycardia, fever ( $> 38\text{ }^{\circ}\text{C}$ ), chills and rigors.

## ***Allergic Reactions—Urticaria***

- Common but rarely severe.
- Cause: Urticarial reactions are mostly results from plasma-protein incompatibility due to the presence of antibodies in the recipient's blood to infused plasma proteins or infusion of allergens that react with IgE antibodies in the patient.

**Treatment: Stop or slow the transfusion and administer 10 mg of chlorpheniramine (chlorpheniramine) intravenously.**

## ***Anaphylactic Reactions***

- These are severe reactions which develops after transfusion of only a few milliliters of the blood component.
- Severe reactions are seen in patients who have antibodies against IgA and are often deficient in IgA. The antibodies react with IgA present in the donor blood.
- Symptoms and signs: Difficulty in breathing, coughing, nausea and vomiting, hypotension, bronchospasm, loss of consciousness, respiratory arrest, and shock.
- Treatment: Stop transfusion and maintain vascular access. Immediately administer 0.5 mg epinephrine (adrenaline) IM, and 10 mg chlorpheniramine, IV glucocorticoids and endotracheal intubation may be required in severe cases.

## ***Transfusion Related Acute Lung Injury (TRALI)***

- Cause: TRALI usually develops from the transfusion of donor plasma that contains high-titer anti-HLA antibodies that bind recipient leukocytes.

This produces aggregation of leukocytes in the pulmonary vasculature and release mediators that increase capillary permeability. Such antibodies are most frequently found in females after pregnancy and are not found in plasma of males unless they have been transfused.

- Patient develops an acute respiratory distress, either during or within 6 hours of transfusing the patient. It is characterized by fever, cough, shortness of breath and typical bilateral interstitial infiltrates on chest X-ray. The reaction occurs during or soon after transfusion and may be life-threatening.

**Treatment:** Supportive and patients usually recover without any sequelae.

### ***Delayed Hemolytic Transfusion Reactions (DHTRs)***

- These are not completely preventable.
- Cause:
  - May occur in patients previously sensitized to RBC alloantigens (such as Rh, Kidd, Kell, Duffy) by previous transfusions or pregnancies.
  - The antibody level is too low to be detected by pretransfusion compatibility testing.
  - When the patient is transfused with antigen-positive blood, there is early production of alloantibody (usually by IgG antibodies) that binds donor RBCs, resulting in destruction of the transfused donor cells.
- Occurs 3–21 days after transfusion with the incompatible blood.
- Direct Coombs' test (DAT): Positive, if carried out during hemolysis. Later, patient may show only positive indirect Coombs' test.

**Treatment:** Usually no specific therapy is required.

### ***Transfusion-associated Graft-versus-Host Disease (TA-GVHD)***

- Rare but potentially fatal complication.
- Develops 8–10 days, and death occurs at 3–4 weeks after transfusion.
- **Mechanism:** Donor blood products contain mature T lymphocytes that recognize host HLA antigens as foreign and mount an immune response and attack upon recipient's tissues. It is observed more commonly in immunocompromised recipients.
- Clinical features include fever, generalized characteristic skin rash,

jaundice (with abnormalities of liver function), diarrhea and features of pancytopenia (due to marrow failure).

- Prevention: TA-GVHD can be prevented by transfusing the irradiated blood/components in patients at risk.
- It is highly resistant to treatment with immunosuppressive therapies, including glucocorticoids, cyclosporine, antithymocyte globulin, etc.

### ***Post-transfusion Purpura***

- It is an immune-mediated thrombocytopenia that usually occurs predominantly in parous women.
- Antibodies against human platelet antigens (HPAs) are found in the patient's serum.
- It occurs 7–10 days after platelet transfusion.
- Thrombocytopenia is usually severe and may cause bleeding.
- Platelet transfusions are usually ineffective and can worsen the thrombocytopenia and hence should be avoided.

**Treatment: Treatment with high-dose (0.4 g/kg/day for 5 days). Intravenous immunoglobulin may neutralize the effector antibodies, or plasmapheresis can be used to remove the antibodies.**

### ***Alloimmunization***

- Alloimmunization usually does not cause clinical problems with the first transfusion but these may occur with subsequent transfusions. Delayed consequences of alloimmunization, include HDN (hemolytic disease of the newborn) and rejection of tissue transplants.
- Types:
  - Alloantibodies to RBC antigens
    - ◆ Detected during pretransfusion testing and may delay finding antigen-negative cross-match-compatible products for transfusion.
    - ◆ Alloimmunization may develop during pregnancy to fetal RBC antigens (i.e. D, c, E, Kell, or Duffy) inherited from the father and not shared by the mother.
  - Alloimmunization to antigens on leukocytes and platelets: It can lead to refractoriness to platelet transfusions.

### **Non-immune Complications/Reactions**

**Q. Write short note on infections transmitted by blood transfusion.**

- **Circulatory overload:** Significant in the elderly, pregnant women, those with reduced cardiac function (e.g. cardiac failure) or renal failure resulting in acute pulmonary edema.
- **Air embolism:** It used to develop in olden days when transfusion was given from the glass bottle.
- **Iron overload (transfusion siderosis)**
  - This is seen in patients who receive multiple transfusions over a period of few years (e.g. thalassemia). The excess iron gets deposited in reticuloendothelial cells of spleen, bone marrow, liver, heart and endocrine glands.
  - Iron overload can be prevented or reduced by giving iron chelating agents
- **Thrombophlebitis:** Inflammation of vein may develop in patients with indwelling catheters.
- **Infectious complications:** Transfusion of infected blood may transmit few diseases like AIDS, hepatitis (HBV, HCV and HDV), HTLV-I and II, malaria and cytomegalovirus infection. This is prevented by screening the donors for these common and ominous infections.

**Massive transfusion** is defined as transfusion of more than 10 units of red cells or replacement of 1 blood volume in 24 hours. The use of large quantities of stored blood in massive transfusions may lead to a number of complications. Among these are dilutional coagulopathy, circulatory overload, hyperkalemia, hypoglycemia, hypothermia, and rarely, citrate-induced hypocalcemia.

## Blood Groups and Diseases

- The first established disease relationship was between carcinoma of the stomach and group A.
- Duodenal ulcer is 1.4 times more common in group O patients.
- It is also reported that group A individuals have greater levels of factor VIII than group O, and hence greater complications of bleeding are seen in group O than A.
- A relationship between the Duffy (Fy) blood group and malaria is well established. It is seen in West Africa where the frequency of Fy a-b- is about 90%; these individuals are resistant to *Plasmodium vivax*. Experimentally, it has been shown that antigens Fya and Fyb act as receptors for the parasite to enter the cell.
- The Kell (K) group is associated with chronic granulomatous diseases and Rh null is implicated in autoimmune hemolytic anemia.

# STEM CELLS

**Q. Define and classify stem cells. Discuss their clinical applications.**

## Definition

Stem cells are characterized by their ability of self-renewal and capacity to generate differentiated cell lineages.

## Properties

- Self-renewal capacity
- Asymmetric replication: This is characterized by division of stem cell into:
  - One daughter cell which gives rise to differentiated mature cells and regenerating tissues
  - Other remains undifferentiated stem cell which retain the self-renewal capacity.

## Types

- **Embryonic stem cells:** During development of embryo, the blastocysts contain undifferentiated pluripotent stem cells which are called as embryonic stem cells or ES cells. These cells can form cells of all three germ cell layers.
  - Normal function: To give rise to all cells of the body.
- **Adult (somatic) stem cells:** Adult stem cells are less undifferentiated than ES cells found in adults. They are found among differentiated cells within a tissue. They are multipotent and have more limited capacity to generate different cell types than ES cells.
  - Normal function: Tissue homeostasis.
  - Use: Adult stem cells include hematopoietic stem cells (HSC) in bone marrow, peripheral blood or cord blood. They are currently the only type of stem cells commonly used to treat human diseases.
  - **Induced pluripotent stem cells (iPS cells):** This is achieved by transferring the nucleus of adult cells to an enucleated oocyte.
    - ♦ **Use:** For therapeutic cloning in the treatment of human diseases.

## Clinical Application

Some diseases in which marrow transplantation has been utilized are presented in Table 8.79.

**Table 8.79:** Diseases treated with marrow transplantation.

**Genetic diseases (allogenic BMT)**

- *Red cell disorders*
  - Thalassemia major
  - Sickle cell disease
- *Immunodeficiencies*
  - Severe combined immunodeficiency
  - X-linked agammaglobulinemia
- *Granulocyte disorders*
  - Chediak-Higashi syndrome
  - Chronic granulomatous disease
  - Kostmann syndrome
- *Enzyme deficiencies*
  - Gaucher's disease
  - Mucopolysaccharidoses
  - Leukodystrophies
- *Platelet disorders*
  - Wiskott-Aldrich syndrome
  - Glanzmann's thrombasthenia
- *Other*
  - Osteopetrosis

**Marrow failure syndromes**

**Allogenic or syngenic BMT**

- Severe aplastic anemia
- Fanconi's syndrome
- Paroxysmal nocturnal hemoglobinuria

**Malignant diseases**

**Autologous, syngenic or allogenic BMT**

- Acute leukemias
- Chronic leukemias
- Myelodysplastic syndromes
- Hodgkin's disease
- Non-Hodgkin lymphomas
- Other solid tumors

***Therapeutic***

- Hematological disorders: Leukemias, multiple myeloma and lymphoma
- Disorders with defective genes, e.g. severe combined immune deficiency.

- Other possible uses:
  - Ischemic heart disease: Stem cells are injected either into the coronary arteries or directly into the myocardium. They can differentiate into myocardial cells or new blood vessels.
  - Spinal cord lesions
  - Non-union of fractured bones
  - Parkinson disease
  - Huntington disease
  - Muscular dystrophy
  - Type 1 diabetes mellitus
  - Motor neuron disease
  - Alzheimer's disease.

### ***Other Applications***

- Useful in understanding the pathology of disease and origin of cancers.
- Monitor the development of genetic disorders.
- Test the efficacy of drugs.

## **HEMATOPOIETIC STEM CELL TRANSPLANTATION**

**Q. Write short essay/note on hematopoietic stem cells (HSC).**

**Q. Write a short note on peripheral blood stem cell transplantation.**

**Q. Write short essay/note on bone marrow transplantation and its indications.**

- **Bone marrow transplantation** was the original term used to describe the collection and transplantation of hematopoietic stem cells.
- **Hematopoietic stem cell transplantation** is a preferred term, because the peripheral blood and umbilical cord blood are also used as sources of stem cells.
- **Definition:** Hematopoietic stem cell transplantation is defined as the process of collecting and infusing hematopoietic stem cells obtained from

bone marrow (bone marrow transplantation) or peripheral blood (peripheral blood stem cell transplantation).

- **Purpose of HSC transplantation:** To repopulate or replace totally or partly recipient's hematopoietic system. HSC are self-renewing cells which can repopulate all the cell lineages in the blood.
- Major sources of hematopoietic stem cells:
  - Bone marrow: Obtained directly from bone marrow by multiple aspirations from the pelvic bones.
  - Peripheral blood (peripheral blood stem cells).
  - Umbilical cord blood.

## Indications for Hematopoietic Stem Cell Transplantation (Table 8.80)

**Q. Write short essay/note on indications for bone marrow/stem cell transplantation.**

## Categories/Types of Hematopoietic Cell Transplantation

- **Autologous ('from self')**: Stem cells obtained from the recipient (same person). The patient's own HSCs are removed and stored in the vapor phase of liquid nitrogen until required. The source of stem cells may be bone marrow or from the blood. It does not require immunosuppression. However, there is no graft-versus-tumor effect and therefore, there is increased risk of disease relapse or progression compared to allogenic HSC transplantation.
- **Allogeneic ('from different genes')**: HSCs are obtained from a donor—either related (usually an HLA-identical sibling) or from a closely HLA-matched volunteer unrelated donor (VUD).
- **Syngeneic ('from same genes')**: HSCs are obtained from an identical twin.

Main factor for a successful allogenic transplantation is finding of a HLA-matched donor, because it reduces the risk of graft rejection and graft versus host disease (GVHD).

## *Peripheral Blood Stem Cell Transplantation*

**Definition:** It is defined as transplantation of stem cells derived from the peripheral blood of a donor to a recipient (allogenic) or from the patient's

own blood (autologous).

**Steps:**

- Hematopoietic stem cells are present in the peripheral blood but in very low concentration (<0.1% of all nucleated cells). To increase their numbers, hematopoietic growth factor (G-CSF or GM-CSF) is administered to the donor (for allogenic stem cell transplant) or to the patient during recovery from intensive chemotherapy (for autologous transplant).
- Stem cells are collected from the blood by apheresis and are infused in the recipient.
- Stem cells engraft in the recipient and is characterized by the recovery of neutrophil count to  $>500 \text{ mm}^3$  for 3 consecutive days.
- Hematopoietic recovery is more rapid in peripheral hematopoietic stem cell transplantation when compared to bone marrow hematopoietic stem cell transplant.

**Umbilical cord blood:** It is a good source of HSC with no risk to either infant or mother. Possible contamination of cord blood with CMV and Epstein-Barr virus is also low due to poor transmission from placenta. However, the major disadvantage is that the number of HSCs that can be collected from cord blood is small and an adult might require multiple cord blood donors.

Origin and source of hematopoietic stem cells used for transplantation are presented in Table 8.81.

Comparison among bone marrow, peripheral blood and cord blood stem cells are presented in Table 8.82.

**Table 8.80: Indication for hematopoietic stem cell transplantation.**

**Red blood cell disorders**

- Severe aplastic anemia
- Thalassemia major
- Fanconi anemia
- Sickle cell disease
- Pure red cell aplasia

**WBC disorders**

- Leukemia
  - Acute lymphoblastic leukemia—relapse after initial chemotherapy induced remission

- Chronic myeloid leukemia, acute myeloid leukemia
- Myelodysplastic syndromes, myelofibrosis
- Lymphomas: Hodgkin lymphoma, non-Hodgkin lymphoma
- Multiple myeloma

**Solid tumors**, e.g. germ cell tumors, neuroblastoma

**Immunological disorders**

- Severe autoimmune disorders: Scleroderma, lupus erythematosus
- Immune deficiency syndromes

**Table 8.81:** Origin and source of hematopoietic stem cells used for transplantation.

- **Origin of hematopoietic stem cells**
  - Autologous
  - Syngeneic
  - Allogeneic
    - Genotypically HLA-identical siblings
    - Phenotypically HLA-identical or HLA-mismatched family members
    - Unrelated volunteer donors
- **Source of hematopoietic stem cells**
  - Bone marrow
  - Peripheral blood
  - Combination of blood and marrow
  - Umbilical cord blood

**Table 8.82:** Comparison among bone marrow, peripheral blood and cord blood stem cells.

<b>Characteristic</b>	<b>Bone marrow</b>	<b>Peripheral blood</b>	<b>Cord blood</b>
Stem cell content	Adequate	Good	Low
Risk of tumor cell contamination	High	Not applicable	Not applicable
HLA matching	Close matching	Close matching	Less restrictive
Engraftment	Medium	Fastest	Slowest
Risk of acute graft-versus-host disease (GVHD)	High	High	Lowest
Risk of chronic GVHD	Medium	Highest	Lowest

**Conditioning Regimens**

- Necessary before HSC transplantation.
- Types: **Myeloablative or non-myeloablative** (or reduced intensity).
  - **Myeloablative regimens:** Eliminates malignant cells in the marrow so that transfused HSC can populate the bone marrow and develop.
  - **Non-myeloablative regimens:** To induce immunosuppression in recipient so that engraftment of donor cells can take place. It is less toxic.
- Complications of conditioning regimens:
  - Usually develop within 30 days and includes infections, nausea, vomiting, alopecia, mucositis and interstitial pneumonia.
  - Venous-occlusive disease of liver characterized by jaundice, ascites and tender hepatomegaly.
  - Late complications: Infertility, ovarian failure and secondary malignancies (AML and solid organ malignancies).

## Autologous Stem Cell Transplant

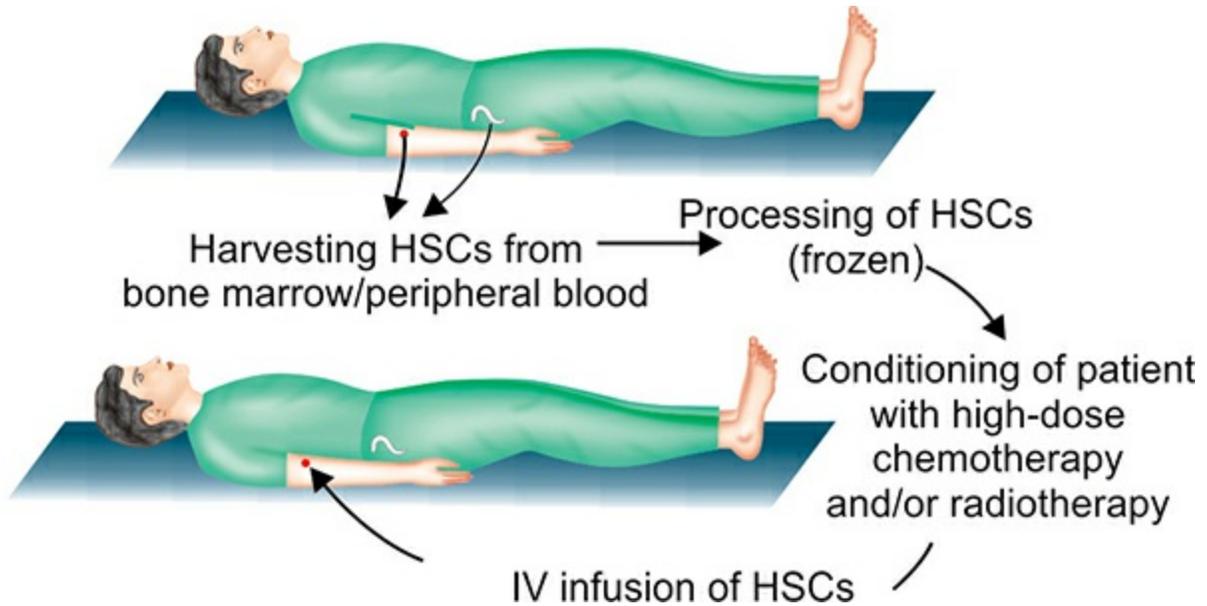

Marrow or peripheral stem cells are obtained from the patient before the high-dose therapy, frozen (cryopreserved) and then reinfused after the high-dose therapy to reconstitute marrow function.

### Different steps of autologous stem cell transplantation (Fig. 8.44)

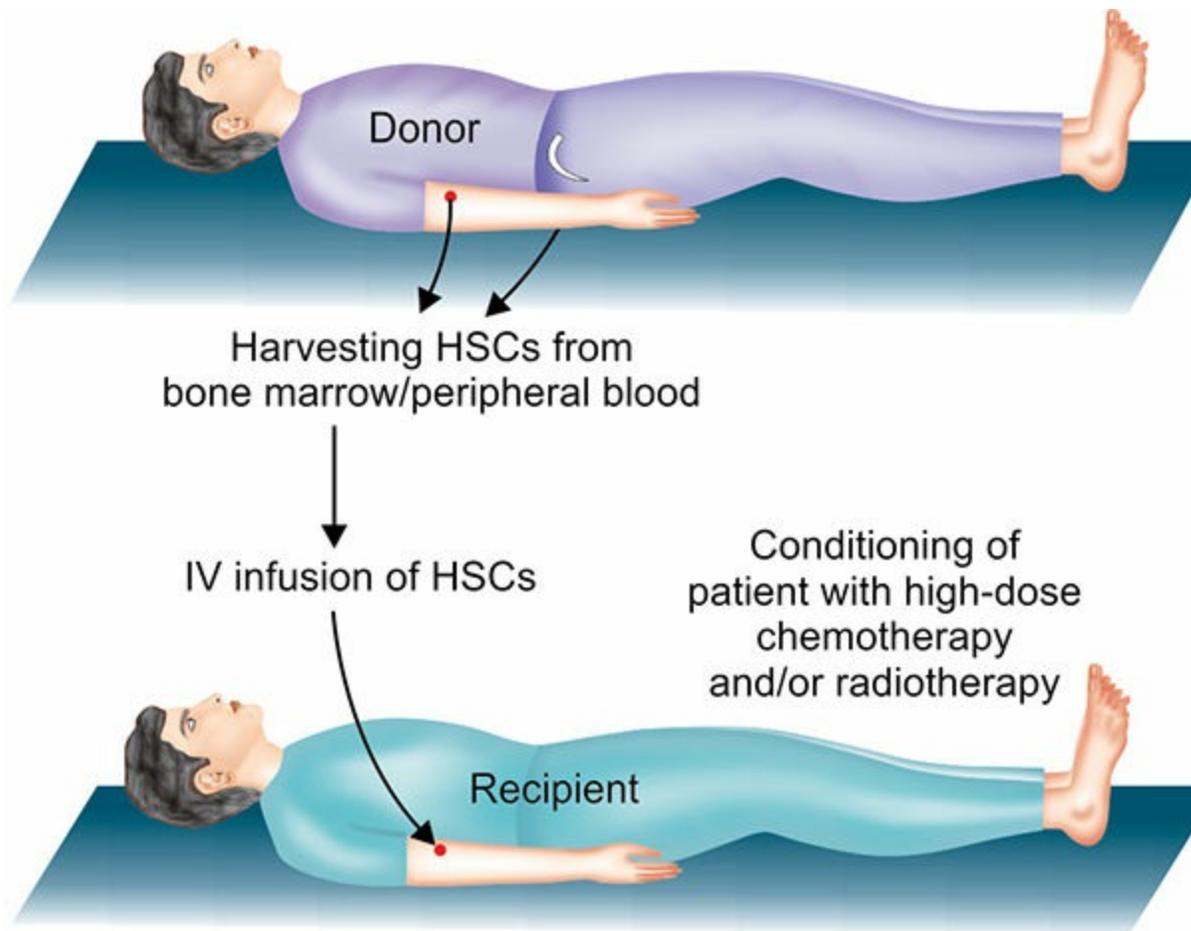

- **Harvesting:** During harvesting, bone marrow and/or peripheral HSCs (identified as CD34+ by immunophenotyping) are collected.
- **Processing of HSCs:** The collected bone marrow or peripheral blood stem cells are suspended in dimethyl sulfoxide (prevents ice crystallization in the cells) and frozen in liquid nitrogen. The HSCs can survive in frozen state for at least 5 years.
- **Conditioning:** Before the autologous transplant, the patient is given a high-dose chemotherapy and/or radiation therapy, sometimes total-body irradiation (TBI). This procedure is called conditioning, the purpose of which is to eradicate the recipient's hematopoietic and immune system and also malignant tumor cells if any. Conditioning also makes physical space available for HSCs to engraft. In contrast to allogeneic transplantation, autologous transplantation does not require immunosuppression to prevent graft versus host disease (GVHD).
- **Stem cell transplant:** The collected frozen bone marrow or peripheral

HSCs are thawed and infused intravenously like a blood transfusion. These stem cells home from the peripheral circulation to the conditioned empty marrow space. Because of conditioning the patient is pancytopenic and requires critical care. The high-dose chemotherapy also causes breakdown of the normal mucosal barriers in the mouth and gut resulting in increased susceptibility to infections and painful ulcerations.

- **Post-transplant engraftment:** During which the hematopoietic cells produce all the three formed elements of the blood.

**Fig. 8.44:** Autologous stem cell transplantation.

**Fig. 8.45:** Allogeneic stem cell transplantation.

## Allogenic Bone Marrow Transplantation

The HSCs are obtained from an HLA-matched or HLA-mismatched family member (usually a sibling) or an unrelated donor.

### Different steps of allogeneic stem cell transplantation (Fig. 8.45)

- **Harvesting:** During harvesting, collected bone marrow and/or peripheral HSCs are mixed with mature WBCs, important being lymphocytes. Mature T lymphocytes are the principal effectors of cell-mediated immunity and both therapeutic benefit and toxicities of allogeneic HSC transplant are due to immunologic reactions between donor T-cells and recipient cells.
- **Conditioning:** This step is similar to autologous HSC transplant. Immunosuppression is to allow engraftment of the transplanted HSCs. The patient's endogenous lymphocytes must be suppressed by immunosuppression so as to prevent graft versus host disease (GVHD).

- **Stem cell transplant:** The harvested HSCs are infused into the vein just like a blood transfusion. The stem cells travel and reside in the marrow and produce erythrocytes, granulocytes and platelets. This usually takes 3–4 weeks. Patient requires utmost care during this period similar to autologous transplant.
- **Engraftment:** Donor T lymphocytes help donor HSCs engraft. These T lymphocytes are mostly CD8+ and they destroy any remaining host immune cells which may reject the donor HSCs. Depletion of donor T lymphocytes before allogeneic HSC transplant significantly increases the risk of graft failure. But the greatest disadvantage due to the donor T lymphocytes is development of GVHD.

### ***Complications of Hematopoietic Stem Cell (HSC) Transplantation (Table 8.83)***

Autologous HSC transplants have fewer immunologic complications but have higher rates of relapse of the disease after transplant. Allogeneic HSC transplants have lower rates of relapse but have more immunologic complications, including GVHD, which can be fatal.

- **Infections:** Patients are susceptible to a variety of infections (bacterial, viral and fungal) due to lack of granulocytes, as well as lack of a functioning immune system. Infections may occur during three different phases after HSC transplantation.
  1. **First phase:** Infections develop due to neutropenia and damage to gastrointestinal mucosal barrier induced by conditioning agents used during transplantation. Source of infection is from oral, skin and gastrointestinal flora.
  2. **Second phase:** It develops during GVHD where T-cell function gets impaired. Patients may develop opportunistic viral and fungal infections.
  3. **Third phase:** It occurs due to chronic GVHD where both B-cell and T-cell functions are impaired. Patients may develop bacterial as well as opportunistic viral and fungal infections.
- **Organ toxicity:** The other complications include damage to GI tract, liver and lungs.
- **Interstitial pneumonitis:** This is seen in 30–40% of patients and may be fatal in some. Toxicity of radiation and chemotherapy, GVHD and viral

and pneumocystis infections are responsible.

- **Veno-occlusive disease:** VOD results from injury to hepatocytes and endothelium in zone 3 of the liver acinus and obstruction of hepatic sinusoids and venules. The clinical manifestations include jaundice, ascites and painful hepatomegaly. Tissue plasminogen activator has been used to treat VOD successfully. Severe VOD is often fatal.
- **Graft versus host disease:** GVHD is the major complication that follows allogeneic HSC transplant. This is caused by cytotoxic activity of infused donor T lymphocytes reacting against the recipient’s tissues/organs (which are considered as foreign to donor T cells).

**Table 8.83:** Complications of hematopoietic cell transplantation.

<b>Vascular access complications</b>	<b>Hepatic complications</b>
Graft failure	<ul style="list-style-type: none"> <li>• Sinusoidal obstructive syndrome</li> </ul>
<ul style="list-style-type: none"> <li>• <b>Blood group incompatibilities and hemolytic complications</b></li> </ul>	<ul style="list-style-type: none"> <li>• Hepatitis: Infectious versus noninfectious</li> </ul>
<ul style="list-style-type: none"> <li>• Acute GVHD</li> </ul>	<b>Cardiac toxicity:</b> Structural (e.g. valvular abnormalities or coronary artery disease) or functional (e.g. cardiomyopathies)
<ul style="list-style-type: none"> <li>• Chronic GVHD</li> </ul>	<b>Lung injury</b>
<b>Infectious complications</b>	<ul style="list-style-type: none"> <li>• Interstitial pneumonitis: Infectious versus noninfectious</li> </ul>

<ul style="list-style-type: none"> <li>• Adenovirus, respiratory viruses, HHV-6, -7, -8, and other viruses</li> </ul>	Growth and development: Growth retardation
<b>Gastrointestinal complications</b>	<b>Late onset nonmalignant complications</b>
<ul style="list-style-type: none"> <li>• Mucosal ulceration/bleeding</li> </ul>	<ul style="list-style-type: none"> <li>• Osteoporosis/osteopenia, avascular necrosis, dental problems, cataracts, chronic fatigue, psychosocial effects, and rehabilitation</li> </ul>
<ul style="list-style-type: none"> <li>• Nutritional support</li> </ul>	<b>Secondary malignancies:</b> Lymphoma, solid

tumors of the tongue, salivary glands, brain, thyroid, bone, malignant melanoma, squamous cell carcinoma and basal cell carcinoma

### Neurologic complications

- Three conditions are necessary for the development of GVHD:
  - An immunocompetent graft (i.e. one containing T-cells)
  - HLA mismatch (minor or major) between donor and recipient
  - An immunosuppressed recipient who cannot mount an immune response to the graft.
- ◆ Forms: GVHD can occur in two forms
  - a. Acute GVHD: If GVHD occurs before 100 days, it is termed as acute GVHD. It often affects three primary target organs simultaneously, namely skin, gastrointestinal (GI) tract and liver. It causes exfoliative dermatitis, diarrhea, hepatitis and cholestasis. It develops due to production of cytokines by Th1 cells. HLA mismatch is one of the important risk factor for its development. Treatment includes methotrexate, cyclosporine, antithymocyte globulin, corticosteroids and monoclonal antibodies against T-cells.
  - b. Chronic GVHD: Occurs after day 100 following transplantation and can affect the skin, GI tract, liver, eyes, lungs and joints. GVHD is difficult to treat and in severe cases it is usually fatal. It develops due to cytokine production by Th2 cells. Treatment includes cyclosporine and corticosteroids.

## DRUGS USED IN HEMATOLOGICAL DISEASES

### Antiplatelet Drugs (Table 8.84)

**Q.** Write short essay/note on antiplatelet drugs.

#### *Cyclooxygenase Inhibitors*

- **Aspirin** is cheap, effective and most widely used antiplatelet agent.
- **Mechanism of action:** Aspirin inhibits platelet enzyme cyclooxygenase (COX-1 and COX-2) and prevents the synthesis of thromboxane A<sub>2</sub>. This results in impairment of platelet secretion and aggregation.
- **Duration of action:** Effects of aspirin on platelet function develop within

an hour and lasts for the whole life span of platelets (~7 days).

- **Indications:** Arthritis, secondary prevention of cardiovascular events (acute coronary syndromes, stable angina) in patients with coronary artery, cerebrovascular (transient ischemic attack) or peripheral vascular disease (intermittent claudication).
- **Dose:** Usual dose is 75–325 mg once daily.
- **Side effects:** Dyspepsia to erosive gastritis or peptic ulcers with bleeding and perforation.

**Table 8.84:** Antiplatelet agents by mechanism of action and clinical use.

<b>Cyclooxygenase inhibitors</b>	
Aspirin	Coronary and cerebrovascular disease
<b>Agents that increase cAMP</b>	
Dipyridamole	Coronary, cerebrovascular, peripheral arterial disease
Pentoxifylline	Peripheral arterial disease
Cilostazol	Peripheral arterial disease
<b>ADP receptor blockers</b>	
Ticlopidine	Cerebrovascular disease
Clopidogrel	Coronary, cerebrovascular disease, PCI
Prasugrel	Coronary, cerebrovascular disease, PCI
<b>ADP mimetic</b>	
Cangrelor	Coronary, cerebrovascular disease
<b>Glycoprotein IIb/IIIa inhibitors</b>	
Abciximab	ACS, PCI
Eptifibatide	ACS, PCI
Tirofiban	ACS, PCI

(ACS: acute coronary syndrome; cAMP: cyclic adenosine monophosphate; PCI: Percutaneous coronary intervention)

### **Adenosine Diphosphate (ADP) Receptor Antagonists on Platelets (Thienopyridines)**

- Thienopyridines are drugs that selectively inhibit ADP-induced platelet aggregation by irreversibly blocking P2Y<sub>12</sub>.

- Thienopyridines include **ticlopidine, clopidogrel and prasugrel**.
- Indications: Reduces the risk of cardiovascular death, MI and stroke in patients with atherosclerotic disease.
- **Dose:**
  - Ticlopidine: 250 mg twice daily
  - Clopidogrel: 75 mg once daily. Loading dose of 300 mg of clopidogrel is given when rapid ADP receptor blockade is needed such as patients undergoing coronary stenting.
  - Prasugrel: A loading dose of 60 mg, prasugrel produces much more rapid, potent and consistent inhibition of platelet function than clopidogrel loading dose. It is followed by a maintenance dose of 10 mg once daily.
- **Side effects:**
  - Ticlopidine: Gastrointestinal and hematologic (neutropenia, thrombocytopenia and thrombotic thrombocytopenic purpura). These side effects usually occur within the first few months of starting treatment.
  - Clopidogrel and prasugrel: Gastrointestinal and hematologic side effects are rare.

### ***Adenosine Reuptake Inhibitors***

- **Dipyridamole** is a relatively weak antiplatelet agent.
- Mechanism of action:
  - Inhibits phosphodiesterase and blocks the breakdown of cyclic AMP.
- Dose: 25–75 mg three to four times a day. Dipyridamole is more commonly used along with aspirin.
- Indications: Coronary artery disease, ischemic stroke or transient ischemic attack. Rarely used at present because of dose inconvenience and side effects.
- Side effects:
  - Due to **vasodilatory effect**, it can lower the blood pressure and must be used with caution in patients with coronary artery disease.
  - Others: Gastrointestinal complaints, headache, dizziness and hypotension.

## ***Glycoprotein IIb/IIIa Receptor Antagonists (Inhibitors)***

- It includes three agents: **Abciximab, eptifibatide and tirofiban.**
- Uses: Parenteral GPIIb/IIIa receptor antagonists are used in acute coronary syndromes, unstable angina and non ST-elevatin MI percutaneous coronary interventions.
- **Side effects:** Bleeding tendencies and thrombocytopenia. Eptifibatide may produce hypotension.

## **Anticoagulants**

**Q. Classify anticoagulants. Write short essay/note on the commonly used anticoagulants.**

**Q. Write short note on:**

- Indication for anticoagulants
- Contraindication for anticoagulants.

## ***Classification of Anticoagulants (Table 8.85)***

**Table 8.85: Classification of anticoagulants.**

<b><i>Parenteral (rapidly acting)</i></b>	<b><i>Oral (slow acting)</i></b>
<ul style="list-style-type: none"> <li>• Heparin (unfractionated and low-molecular weight heparins)</li> <li>• Hirudins</li> <li>• Heparinoids</li> <li>• Indirect factor Xa inhibitors (fondaparinux and idraparinux).</li> </ul>	<ul style="list-style-type: none"> <li>• Coumarin derivatives: Warfarin sodium, dicoumarol. These are most commonly used. Bishydroxycoumarin dicoumoral, acenocoumarol (nicoumalone), ethylbiscoumacetate.</li> <li>• Indandione derivatives: Phenindione, diphenindione (not used clinically).</li> <li>• Direct thrombin inhibitors: Ximelagatran</li> </ul>

## ***Indications for Anticoagulant Therapy (Table 8.86)***

**Q. Write short note on indications for long-term anticoagulation.**

**Table 8.86: Indications for anticoagulant therapy.**

<b><i>Purpose</i></b>	<b><i>Clinical situations</i></b>
Urgent and for long-term anticoagulation: It is initiated with heparin and taken over by oral	Thrombosis and thromboembolism: <ul style="list-style-type: none"> <li>• Atrial fibrillation and cardiac disorders with</li> </ul>

anticoagulants	thromboembolism <ul style="list-style-type: none"> <li>• Deep venous thrombosis</li> <li>• Stroke in evolution and resistant transient ischemic attacks</li> <li>• Pulmonary thromboembolism</li> </ul> Others: <ul style="list-style-type: none"> <li>• Unstable angina and non-ST-elevation myocardial infarction</li> <li>• Prosthetic valves</li> <li>• Peripheral vascular disease</li> </ul>
Anticoagulants for brief periods: Heparin alone is used	Cardiac bypass surgery: <ul style="list-style-type: none"> <li>• Hemodialysis</li> <li>• Disseminated intravascular coagulation (DIC)</li> </ul>

Contraindications for anticoagulation therapy are listed in Box 8.29.

**Box 8.29:** Contraindications for anticoagulant therapy.

- Bleeding disorders, heparin-induced thrombocytopenia
- Severe hypertension, threatened abortion, hemorrhoids, peptic ulcers
- Subacute bacterial endocarditis, tuberculosis
- Ocular and neurosurgery, lumbar puncture
- Chronic alcoholics, cirrhosis, renal failure

## Heparin

### *Unfractionated heparin*

**Q. Write short note on (unfractionated) heparin.**

- **Mechanism of action:** Heparin acts as anticoagulant by activating antithrombin (previously known as antithrombin III) thereby potentiating its action. The activated antithrombin inhibits clotting enzymes, particularly thrombin and factor Xa.
- **Mode of administration:** Heparin is given parenterally. It is usually administered SC or by continuous IV infusion.
- **Dose:** Initial loading dose of 5,000–10,000 units intravenously, followed by maintenance by any one of the following:
  - Continuous intravenous.
  - Intermittent intravenous/subcutaneous.
- **Methods of anticoagulation:**

- Total anticoagulation: Continuous intravenous maintenance using an infusion pump at a rate of 1000 units/hour.
- Low-dose heparinization (e.g. prophylaxis of DVT): 5000 units 12 hourly or 8 hourly subcutaneously.
- For prophylaxis: Fixed doses of 5000 units SC two or three times daily.
- **Duration of therapy:** Variable, but usually ranges from 7 to 10 days.
- **Monitoring:** Heparin therapy is monitored using activated partial thromboplastin time (aPTT), which is maintained at 1.5 to 2 times the control value.
- **Antidote of heparin:** Protamine sulfate
- **Complications of heparin therapy:** Includes bleeding, heparin induced thrombocytopenia (HIT), osteoporosis and osteomalacia (in long-standing therapy). HIT is of two types:

#### *Heparin induced thrombocytopenia*

- **HIT type I:** Benign form develops immediately and often resolves after heparin is discontinued and is probably due to direct platelet-aggregation induced by heparin.
- **HIT type II:** The heparin binds to platelet factor 4 (PF<sub>4</sub>) released from platelets and forms a complex (heparin/PF<sub>4</sub> complex) in the circulation. The antibodies formed against these complexes activate platelets, promoting thrombosis even in the presence of marked thrombocytopenia. It develops 5 to 10 days after starting heparin therapy. Can occur with all types of heparin.

#### **Treatment of HIT Type II**

- Immediately stops all heparin administration.
- Start non-heparin anticoagulants, e.g. lepirudin—a recombinant hirudin, argatroban, danaparoid, fondaparinux and bivalirudin.
- Do not administer warfarin as it can produce gangrene of limb or necrosis of skin. Vitamin K is administered if HIT diagnosed after warfarin has already been started.
- Do not administer platelet transfusion even though there is severe thrombocytopenia

#### *Low-molecular weight heparins (LMWH)*

- LMWH are biologically active forms of conventional heparin. The molecular weights ranging from 3000 to 8000 Daltons.
- **Mode of action:** They act as anticoagulant primarily by inhibiting

activated factor X (Xa) rather than activated factor II (IIa).

- **Advantages:**
  - Can be administered subcutaneously once or twice/day.
  - Pharmacokinetics is predictable and aPTT monitoring is not needed.
  - Less immunogenic and less likely to produce thrombocytopenia.
  - Many patients with DVT (deep vein thrombosis) can be treated on an outpatient basis.
- **Disadvantage:** Higher cost.
- **Commonly available LMWH:** Enoxaparin, dalteparin and tinzaparin.

## *Warfarin*

### **Q. Write short essay/note on oral anticoagulants.**

- Water-soluble vitamin K antagonist.
- **Mode of action:** Vitamin K is necessary for the synthesis of coagulation factors such as prothrombin (factor II) and factors VII, IX and X and also protein C and protein S. Warfarin type anticoagulants prevents the conversion of vitamin K to its active hydroquinone form and interferes with the synthesis of the above vitamin K-dependent coagulation factors.
- **Monitoring:** Warfarin therapy is monitored using the **prothrombin time**.
- **Dose:**
  - Starting dose: Warfarin is started at a dose of 5 mg oral on the first day. Subsequent daily doses are adjusted according to PT (INR) which is maintained at 1.5–3 times the control value.
  - Maintenance dose: Varies from 2.5 to 7.5 mg/day.
- **Duration of therapy:** Variable and may range from 3 months to lifelong.
- **Side effects:** These include bleeding and rarely skin necrosis.
- **Antidotes of warfarin:** Injections of vitamin K<sub>1</sub>, 5 mg intravenously or fresh frozen plasma or prothrombin complex concentrate.
- **Contraindications:**
  - Severe uncontrolled hypertension
  - Severe renal or liver failure
  - Pre-existing hemostatic disorders
  - Pregnancy: It crosses the placenta and can cause fetal abnormalities.

Therefore should not be used during pregnancy.

Reversing warfarin therapy (Table 8.87)

### Direct thrombin inhibitors

#### 1. Parenteral: Hirudin

- Source: Derived from a medicinal leach.
- Recombinant form of hirudin, e.g. lepirudin, bivalirudin and desirudin.
- Mode of action: Acts directly on thrombin.
- Monitoring: By measuring aPTT.

**Table 8.87: Reversing warfarin therapy.**

Indication	Action
INR <6	Lower the dose, consider withholding one or more doses Recheck in 3 to 7 days
INR 6–10	Lower the dose and withhold 1 to 3 doses Consider administering vitamin K, 1–2 mg orally Recheck INR in 24–48 hours
INR >10	Withhold doses until INR in desired range and cause of elevation ascertained Give vitamin K, 2–4 mg orally Recheck INR in 24 hours
Serious bleeding and major overdose	Consider fresh-frozen plasma or prothrombin complex concentrate and give 5–10 mg vitamin K intravenously

Clinical indications and use of direct thrombin inhibitors is presented in Table 8.88.

#### 2. Oral

- These include ximelagatran and dabigatran etexilate
- **Dabigatran** being used for prophylaxis after hip and knee replacement. The major side effect of dabigatran is hemorrhage.
- **Idarucizumab:** *Humanized monoclonal antibody fragment (Fab) indicated in patients treated with dabigatran when reversal of the anticoagulant effects are needed for emergency surgery or urgent procedures, or in the event of life-threatening or uncontrolled bleeding.*
- **Rivaroxaban** is an orally administered drug, factor Xa inhibitor available orally administered direct factor Xa inhibitor that produces its anticoagulant effect through reversible binding with the factor Xa molecule. Rivaroxaban can inhibit both free and thrombus-associated

factor Xa.

**Table 8.88:** Clinical indications and use of direct thrombin inhibitors.

<i>Agent</i>	<i>Clinical Indication</i>	<i>Monitoring</i>
Lepirudin	HIT	aPTT
Bivalirudin	Angioplasty, PCI with HIT	ACT
Argatroban	HIT	aPTT
	HIT with PCI	ACT (activated clotting time)

### ***Indirect factor Xa inhibitors***

- These include fondaparinux and idraparinux.
- Mode of action: Increases the rate of inactivation of factor Xa by antithrombin, thereby blocking production of thrombin.
- Use: HIT-type II.

### **Fibrinolytic or Thrombolytic Agents**

**Q. Write short essay/note on fibrinolytic agents.**

**Q. Write short essay/note on thrombolytics.**

- Goal of therapy: To produce rapid dissolution of thrombus and restore the blood flow.
- Most fibrinolytic or thrombolytic agents are recombinant forms having plasminogen activator activity.
- Mechanism of Action: They convert the proenzyme, plasminogen to active enzyme plasmin. Plasmin then degrades the fibrin of thrombi and produces soluble fibrin degradation products.
- Currently approved fibrinolytic agents are:
  - Streptokinase (STK):
    - ◆ Source: It is obtained from  $\beta$ -hemolytic streptococci. It is not an enzyme and does not directly convert plasminogen to plasmin. Instead it forms a complex with plasminogen, it converts other/additional molecules of plasminogen into plasmin. Since it is obtained from bacteria, it can produce allergic reactions in about 5%

of patients.

- ◆ Uses: In acute ST-elevation myocardial infarction and pulmonary embolism.
- Urokinase (UK): It is used in patients who received STK in the past 6 months and require a thrombolytic agent for MI or pulmonary embolism. It does not produce allergic reaction.
- Acylated plasminogen streptokinase activator complex (APSAC) (anistreplase).
- Recombinant tissue-type plasminogen activator (rtPA): Also known as alteplase or activase is useful in acute thrombotic strokes (within 3 hours of onset) besides acute MI and pulmonary embolism.
- Prourokinase (pro-UK) like rtPA.
- Others: Tenecteplase, desmoteplase and reteplase.
- Indication for use of fibrinolytic agents are listed in Box 8.30.

**Box 8.30:** Indication for use of fibrinolytic or thrombolytic agents.

1. Acute myocardial infarction.
2. Massive pulmonary embolism with hypotension.
3. Acute ischemic stroke (thrombotic or embolic).
4. Acute peripheral artery occlusion.

## Erythropoietin

**Q. Write short essay/note on erythropoietin (EPO), recombinant human erythropoietin (rHuEPO) and darbepoietin alpha.**

**Q. List the ectopic sources of erythropoietin.**

- **Site of production:** This hormone is predominantly produced by the juxtatubular interstitial cells of the renal cortex and to a lesser extent in the liver.
- **Stimulus:**
  - **Hypoxia** is the most potent stimulus for EPO production. In the presence of tissue (renal) hypoxia, kidneys respond by increased production of EPO.
  - **Anemia:** Erythropoietin levels are inversely related to hemoglobin concentrations in the blood. Anemia is another important stimulant.

- **Mode of action:**

- EPO stimulates erythropoiesis by acting on the marrow erythroid progenitors to enhance their survival, proliferation and differentiation.
- EPO may also protect neuronal cells from noxious stimuli.

Ectopic sources of EPO are presented in Table 8.89.

**Table 8.89:** Ectopic sources of EPO.

<i>Polycystic kidneys</i>	<i>Cerebellar hemangioblastoma</i>	<i>Uterine leiomyoma</i>
Renal cell carcinoma	Hepatocellular carcinoma	Pheochromocytoma

### ***Recombinant Human Erythropoietin (rHuEPO)***

- It has same biological effects of endogenous erythropoietin and is available as erythropoietin- $\alpha$  and erythropoietin- $\beta$ .
- **Indications:** In the treatment of:
  - Anemia associated with chronic renal failure.
  - Anemia of chronic inflammation.
  - Anemia (hemoglobin <10 g/dL) in cancer patients given chemotherapy.
  - Zidovudine-induced anemia in HIV patients.
  - Anemic patients undergoing non-vascular surgery to reduce the need for allogeneic blood transfusions.
- **Side effects:** Hypertension, bleeding, headache, arthralgia, nausea, edema, diarrhea, increased risk of thrombosis, pure red cell aplasia and progression of cancers.

### ***Darbepoietin Alpha***

- Produced by recombinant DNA technology in Chinese hamster ovary cells.
- Half-life about 3 times rHuEPO and hence needs to be given less frequently.
- Side-effects similar to rHuEPO.
- Not approved for the treatment of zidovudine-induced anemia and for blood loss during perioperative period.

## Hemopoietic Growth Factors (HGFs)

**Q.** Write short note on hematopoietic growth factors.

### *Erythropoietin (EPO)*

Refer above discussion.

### *Granulocyte Colony Stimulating Factor (G-CSF)*

- **Indications:**
  - **Primary prophylaxis**
    - ◆ To reduce chances of febrile neutropenia following chemotherapy: When the risk of febrile neutropenia is high (>20%) as determined by age, disease characteristics and myelotoxicity of drugs used.
    - ◆ Accelerate hemopoietic recovery after chemotherapy and autologous hemopoietic cell transplantation.
  - **Secondary prophylaxis:** In patients with solid tumors with a previous history of the febrile neutropenia who require high-dose chemotherapy and any dose reduction may compromise treatment outcome.
  - **Patients with neutropenia and fever:** It may be administered to those patients with high risk of infection-related complications, prolonged (>10 days) and severe neutropenia (<100/ $\mu$ L), hypotension, multiorgan dysfunction or invasive fungal infections. It is not recommend in afebrile patients with neutropenia.
  - **Mobilizing stem cells from bone marrow:** For stem cell transplantation. Both G-CSF and GM-CSF have been used.
- **Disadvantage:** Patients undergoing chemotherapy for breast carcinoma, if treated with G-CSF may develop acute myeloid leukemia or myelodysplastic syndrome. However, the benefit outweighs the possible risks.
- **Dosage:** 15  $\mu$ g/kg daily by subcutaneous injection. Its pegylated form has a longer duration of action and requires to be given once a day.
- **Adverse effects:** Fever, bone and joint pains.

### *Granulocyte-Macrophage Colony-Stimulating Factor (GM-CSF)*

- **Action:** Increase in neutrophil, eosinophil, macrophage and sometimes lymphocyte counts.

- **Dosage:** Daily subcutaneous injection of 250 µg/m<sup>2</sup>.
- Both G-CSF and GM-CSF have similar efficacy and indications (refer G-CSF above).

### ***Thrombopoietin (TPO)***

- **Site of production:** Liver and kidney and marrow stromal cells.
- **Action:**
  - Stimulates the survival, proliferation, and differentiation of megakaryocytes and their precursors.
  - Primes mature platelets to aggregate in response to subthreshold levels of thrombin, collagen and adenosine diphosphate (ADP).
  - In cancer patients receiving chemotherapy, it has been shown to reduce the duration of postchemotherapy thrombocytopenia.
  - Thrombopoietin is undergoing clinical trials in patients with immune thrombocytopenic purpura.
- **Disadvantage:** Most patients produce antibodies against TPO and therefore, it is not recommended in treatment of any condition.

### **Vitamin K**

#### **Q. Write short note on vitamin K.**

- Vitamin K is a fat-soluble vitamin and requires bile for its absorption.
- Vitamin K is required by liver for the production of factors II, VII, IX and X, protein C and protein S.

### ***Causes of Vitamin K Deficiency***

- **Inadequate stores:** As in hemorrhagic disease of the newborn (vitamin K levels are low and are due to lack of gut bacteria and low concentrations of the vitamin in breast milk) and severe malnutrition (especially when combined with antibiotic treatment).
- **Defective absorption:** Diseases that interfere with fat absorption, e.g. obstructive jaundice owing to the lack of intraluminal bile salts, pancreatic disease or small bowel disease.
- **Oral anticoagulant drugs** which are vitamin K antagonists (warfarin therapy).

**Clinical manifestation:** Deficiency manifests as bleeding/hemorrhagic state.

**Treatment:** Shows a dramatic response to parenteral vitamin K therapy. Vitamin K may not be effective in the presence of liver cell disease.

**Dose:** Daily 10 mg of injections of vitamin K.

## Bone Marrow Examination

### **Q. Write short note on indications for and complications of bone marrow aspiration.**

Bone marrow examination is essentially done to confirm or rule out a hematologic disorder. It also helps in evaluation of non-hematological disorders (e.g. metastasis).

Bone marrow may be obtained by:

- **Aspiration:** Bone marrow aspiration is a simple, easy and safe procedure
- **Trephine biopsy** is indicated in conditions where the aspiration either fails to yield marrow or to confirm some of the diseases (where biopsy findings are diagnostic).

Sites for bone marrow aspiration are listed in Box 8.31. Indications for bone marrow aspiration (Table 8.90).

**Table 8.90:** Indications for bone marrow aspiration.

#### *A. Diagnostic*

- **Primary hematolymphoid disorders**
  - **Red cell disorders:** Nutritional anemia (e.g. megaloblastic anemia), pure red cell aplasia
  - **White cell disorders:** Subleukemic/aleukemic leukemia, diagnosis and classification of acute leukemias
  - **Megakaryocytic disorders:** ITP and other thrombocytopenias
  - **Myeloproliferative neoplasms:** Polycythemia vera, chronic myeloid leukemia, idiopathic thrombocythemia
  - **Myelodysplastic syndromes**
  - **Plasma cell neoplasms:** Multiple myeloma, Waldenström macroglobulinemia
- **Systemic diseases:** Storage disorders (e.g. Gaucher's, Niemann-Pick's disease)
- **Staging of lymphoid malignancies and solid tumors:** Lymphoma, metastatic deposits (e.g. carcinoma prostate, breast, lung, kidney)
- **Detection of infection and/or source of PUO**
  - **Parasitic disorders:** Kala-azar
  - **Fungal disorders:** Histoplasma
  - **Mycobacterial infection**
- **Iron store**

- **Miscellaneous disorders:** Pancytopenia or unexplained cytopenias

**B. Post-treatment follow-up:** To know the response to therapy and follow up in cases of leukemia, aplastic anemia and agranulocytosis

**C. Therapeutic:** Bone marrow transplant

### Box 8.31: Sites for bone marrow aspiration.

Usual sites for bone marrow aspiration are:

- Sternum
- Posterior superior iliac spine
- Iliac crest
- Anterior superior iliac spine
- Spinous process of lumbar vertebra.

In **infants**, upper end of the tibia is the ideal site for marrow aspirate.

### Box 8.32: Complications of bone marrow aspiration and biopsy.

- Local infection
- Hemorrhage
- Cardiac tamponade or mediastinitis

**Contraindications for bone marrow aspiration:** Hemophilia and congenital hemorrhagic disorders.

Complications of bone marrow aspiration and biopsy are listed in Box 8.32.

## SPLEEN

The spleen is a hematopoietic organ capable of supporting elements of the erythroid, myeloid, megakaryocytic, lymphoid, and monocyte-macrophage (i.e. reticuloendothelial).

### Splenomegaly

**Q. Write short essay/note on splenomegaly.**

**Definition:** The ‘gold-standard’ definition of splenomegaly is splenic weight: the normal adult spleen weighs about 50–250 g. The weight can only be established at splenectomy or post mortem examination. The clinical finding of a palpable spleen was considered as splenic enlargement, but up to 16% of palpable spleens have been found to be of normal size on radiological assessment.

On ultrasound examination, “craniocaudal length” is commonly used to

measure splenic size. This correlates with splenic volume. However, the upper limit of normal size varies from 11 to 14 cm.

### ***Mechanisms of Splenomegaly***

Many of the mechanisms represent exaggerated forms of normal function of spleen (Table 8.91 and Box 8.33).

**Table 8.91:** Mechanisms of splenomegaly.

<b><i>Mechanism</i></b>	<b><i>Examples</i></b>
Immune response work hypertrophy	Subacute bacterial endocarditis, infectious mononucleosis
RBC destruction work hypertrophy	Hereditary spherocytosis, thalassemia major
Congestive	Splenic vein thrombosis, portal hypertension
Myeloproliferative	Chronic myeloid metaplasia
Infiltrative	Sarcoidosis, some neoplasms
Neoplastic	Chronic lymphocytic leukemia, lymphomas
Miscellaneous	Trauma, cysts

### **Box 8.33:** Functions of spleen.

- Clearance of microorganisms and particulate antigens from the blood
- Synthesis of immunoglobulin and properdin factors
- Destruction of senescent or abnormal RBCs
- Embryonic hematopoiesis, which can be reactivated as extramedullary hematopoiesis in certain diseases (e.g. primary myelofibrosis)

### ***Diseases Associated with Splenomegaly (Table 8.92)***

**Table 8.92:** Diseases associated with splenomegaly.

#### ***Infection***

- **Acute:** Infectious mononucleosis, viral hepatitis, septicemia, typhoid, cytomegalovirus, toxoplasmosis
- **Subacute/chronic:** Miliary tuberculosis, subacute bacterial endocarditis, brucellosis, syphilis, HIV
- **Tropical/parasitic:** Malaria, leishmaniasis/kala-azar, schistosomiasis

#### ***Hematological disorders***

- **Myeloproliferative disorders:** Myelofibrosis, chronic myeloid leukemia (CML), polycythemia vera, essential thrombocytosis

- **Lymphoma:** Non-Hodgkin lymphoma (NHL), Hodgkin lymphoma
- **Leukemia:** Acute leukemia, chronic lymphocytic leukemia (CLL), hairy cell leukemia, prolymphocytic leukemia
- **RBC disorders**
  - **Congenital:** Hereditary spherocytosis, thalassemia, HbSC disease
  - **Others:** Autoimmune hemolysis, megaloblastic anemia
- **Congestive:** Cirrhosis, splenic/portal/hepatic vein thrombosis or obstruction, congestive cardiac failure

***Inflammatory diseases***

- **Collagen diseases:** Systemic lupus erythematosus, rheumatoid arthritis (Felty's)
- **Granulomatous:** Sarcoidosis
- **Neoplastic:** Hemangioma, metastasis (lung/breast carcinoma, melanoma)
- **Infiltrative:** Gaucher's disease, amyloidosis
- **Miscellaneous:** Cysts

***Causes of Asymptomatic Splenomegaly (Table 8.93)***

**Table 8.93:** Causes of asymptomatic splenomegaly.

- |   |  |
|---|--|
| <ul style="list-style-type: none"> <li>• Liver disease with portal hypertension</li> <li>• Splenic vein thrombosis</li> <li>• Agnogenic myeloid metaplasia</li> <li>• Gaucher's disease</li> <li>• Splenic cysts</li> </ul> | <ul style="list-style-type: none"> <li>• Sarcoidosis</li> <li>• Amyloidosis</li> <li>• Mild hereditary spherocytosis</li> <li>• Early stages of polycythemia vera</li> </ul> |
|---|--|

***Causes of Massively Enlarged Spleen (Table 8.94 and Fig. 8.46)***

**Fig. 8.46:** Massively enlarged spleen.

**Q. Write short essay/note on causes of massive splenomegaly.**

A spleen is considered as massively enlarged when its lower pole is within the pelvis or which has crossed the midline into the right lower or right upper abdominal quadrants.

**Table 8.94:** Causes of massively enlarged spleen.

- Chronic myeloid leukemia
- Myelofibrosis (primary or secondary to polycythemia vera or essential thrombocytosis)
- Hyper-reactive malarial splenomegaly syndrome (tropical splenomegaly syndrome)
- Gaucher's disease
- Lymphoma (mantle cell lymphoma, marginal B cell lymphoma), hairy cell leukemia
- Kala-azar (visceral leishmaniasis)
- Beta thalassemia major
- AIDS with *Mycobacterium avium* complex
- Splenic cysts

**Indications for Splenectomy (Table 8.95)**

**Table 8.95:** Indications for splenectomy.

- **Hematological:** Isolated thrombocytopenia, immune thrombocytopenic purpura (ITP), hemolytic anemia, autoimmune hemolytic anemia, warm type (AIHA), hereditary spherocytosis, thalassemia major or intermedia, neutropenia, primary myelofibrosis
- Hairy cell leukemia, splenic marginal zone lymphoma, chronic lymphocytic leukemia
- Painfully enlarged spleen
- Traumatic or atraumatic splenic rupture, blunt abdominal trauma with splenic contusion or rupture
- Splenic artery aneurysm
- Hypersplenism
- Primary treatment of an isolated splenic vascular or parenchymal lesion
- Splenic abscess, acute splenic torsion with infarction due (e.g. 'wandering spleen syndrome') splenic infarction
- Splenic vein thrombosis with bleeding esophageal varices
- Splenorenal shunting for portal hypertension

**Box 8.34:** Classical features of hypersplenism.

- Splenomegaly
- Any combination of anemia, leukopenia and/or thrombocytopenia
- Compensatory bone marrow hyperplasia
- Improvement after splenectomy

## Hypersplenism

Splenomegaly is often accompanied by hypersplenism. This is a complication of splenomegaly and not a diagnosis. The specific cause of the splenomegaly must be determined. Classical features of hypersplenism are listed in Box 8.34.

## Causes of Splenic Rupture (Table 8.96)

**Table 8.96:** Causes of splenic rupture.

**Traumatic splenic rupture:** Blunt abdominal trauma

**Atraumatic splenic rupture**

- Neoplasm: For example, leukemia, lymphoma
- Infection: For example, infectious mononucleosis, CMV, HIV, endocarditis, malaria
- Inflammatory disease/noninfectious disorders, e.g. acute and chronic pancreatitis, primary amyloidosis
- Drug and treatment related: For example, anticoagulation, G-CSF, thrombolytic therapy, dialysis
- Mechanical causes: For example, pregnancy-related, congestive splenomegaly
- Idiopathic (normal spleen)

## DISORDERS OF HEME SYNTHESIS: THE PORPHYRIAS

- The porphyrias are caused by deficiencies of enzymes involved in heme synthesis, which lead to blockade of the porphyrin pathway and subsequent accumulation of porphyrins and their precursors.
- **Cause:** Most of the porphyria is due to partial enzyme deficiencies. These enzyme deficiencies may be inherited as autosomal dominant, autosomal recessive, or X-linked traits, with the exception of porphyria cutanea tarda (PCT), which usually is sporadic.

### Classification

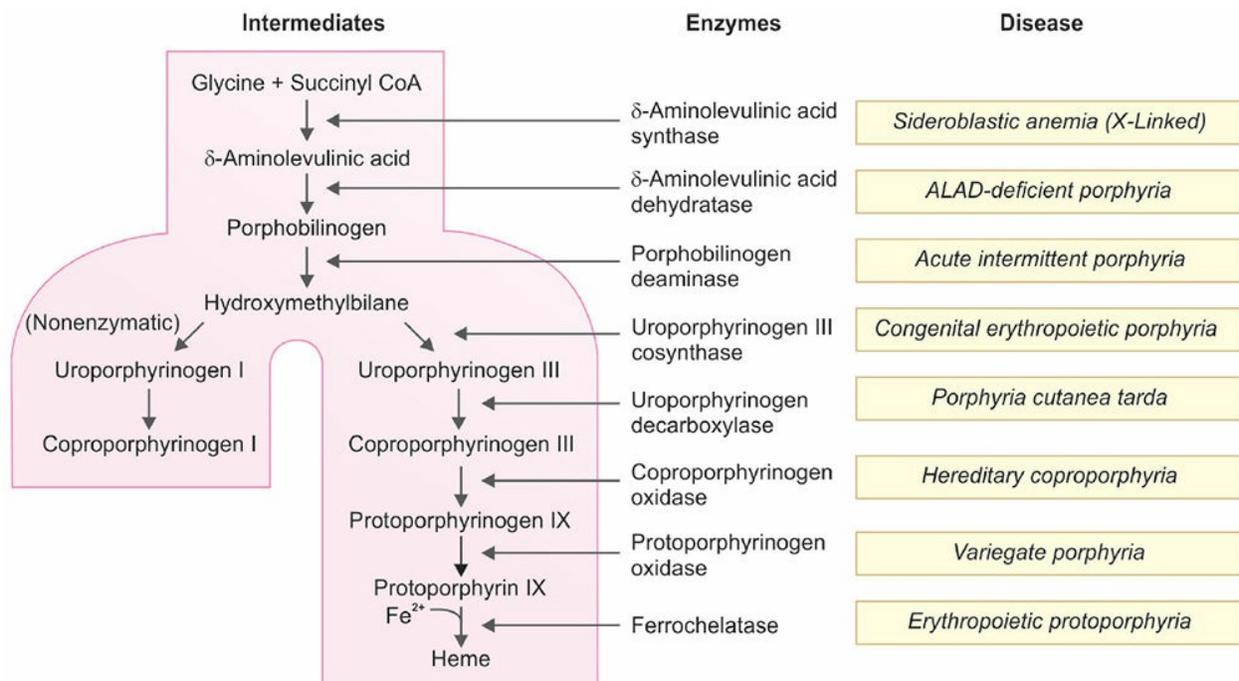

Due to deficiency of an enzyme involved in the synthesis of heme, there is build-up of porphyrins and metabolites in various tissues. It is classified depending on site of overproduction and accumulation of porphyrin but overlapping features are common. It may be classified as follows:

- Depending on the major primary site of excess production and accumulation of their respective porphyrin precursors or porphyrins: (1) **hepatic** (in the liver) or (2) **erythropoietic** (in the red cell).
- Based on the clinical manifestations **as acute or cutaneous**.

**Structure of porphyrins:** It consists of four pyrrole rings. Two molecules of  $\delta$ ALA condense to form a pyrrole ring. Depending on the structure of the side chain, porphyrins can be divided into uroporphyrins, coproporphyrins or protoporphyrins.

Intermediates accumulated and deficient enzyme in various porphyrias are depicted in Figure 8.47.

The three most common porphyrias are porphyria cutanea tarda (PCT), acute intermittent porphyria (AIP), and erythropoietic protoporphyrinemia (EPP).

**Fig. 8.47:** Intermediates accumulated and deficient enzyme in various porphyrias.

## Clinical Features

Two broad patterns of symptoms occur in the various types of porphyria (Table 8.97): (1) cutaneous photosensitivity, and (2) acute neurovisceral syndrome.

### 1. Cutaneous Photosensitivity

- These are due to excess production and accumulation of porphyrins in the skin and occur predominantly on areas of the skin that are exposed to sunlight.
- Two main patterns of skin damage are seen in the porphyrias:
  - Due to accumulation of water soluble uro- and coproporphyrins leads to blistering.
  - Due to accumulation of the lipophilic protoporphyrins leads to burning sensations in the exposed skin.
- They produce pain, erythema, bullae, skin erosions, hirsutism and hyperpigmentation. Skin also becomes sensitive to damage from minimal trauma.

**Table 8.97:** Major porphyrias and their laboratory findings.

Porphyria	Deficient enzyme	Principal symptoms	Elevated porphyrins and precursors		
			RBCs	Urine	Stool
<b>Hepatic porphyrias</b>					
5-ALA dehydratase-deficient porphyria (ADP)	ALA-dehydratase	Neurovisceral	Zn-Protoporphyrin	ALA, Coproporphyrin III	
Acute intermittent porphyria (AIP)	HMB (Hydroxy methyl bilane)-synthase	Neurovisceral		ALA, PBG, Uroporphyrin	
Porphyria cutanea tarda (PCT)	Urodecarboxylase	Cutaneous photosensitivity		Uroporphyrin, 7-carboxylate porphyrin	Isocoprop
Hereditary coproporphyria (HCP)	Copro-oxidase	Neurovisceral and cutaneous photosensitivity		ALA, PBG, Coproporphyrin III	Coproporq III
Variegate porphyria (VP)	Proto-oxidase	Neurovisceral and cutaneous photosensitivity			Coproporq III Protop
<b>Erythropoietic porphyrias</b>					
Congenital erythropoietic porphyria (CEP)	Uro-synthase	Cutaneous photosensitivity	Uroporphyrin I Coproporphyrin I	Uroporphyrin Ib Coproporphyrin Ib	Coproporq
Erythropoietic protoporphyria (EPP)	Ferrochelatae	Cutaneous photosensitivity			
X-linked protoporphyria (XLP)	ALA-synthase 2	Cutaneous photosensitivity	Protoporphyrin	—	Protoporp

## 2. Acute Neurovisceral Syndrome

- This presents with acute abdominal pain and features of autonomic dysfunction (e.g. tachycardia, hypertension and constipation). Acute motor polyneuropathy may cause quadriparesis mimicking GB syndrome. Neuropsychiatric manifestations include insomnia, anxiety, restlessness, agitation, hallucinations, hysteria, disorientation, delirium, apathy, depression and phobias.

**Triggering factors:** Porphyria can relapse and remit or follow a prolonged and unremitting course. Sometimes, it may be triggered by alcohol, fasting,

or drugs such as anticonvulsants, sulphonamides, estrogen and progesterone.

## Diagnosis

- Diagnosis and classification depends on the pattern of the porphyrins and porphyrin precursors found in blood, urine and stool (Table 8.97). Urine gets colored on exposure to sunlight (Fig. 8.48).
- Measurement of the deficient enzymes.
- Genetic testing

**Fig. 8.48:** High colored urine on exposure to sunlight in porphyria.

## Management

### *Neurovisceral*

**Acute:** The management of acute episodes is largely supportive.

- Analgesics to be given and avoid drugs that may aggravate an attack.
- **Specific management:**
  - **Intravenous glucose** inhibits ALA synthase activity leading to reduced ALA synthesis. In some cases, it can terminate acute attacks.
  - **Intravenous haem** (in various forms such as human haematin or haem arginate) infusion reduces ALA and PBG excretion by having a negative effect on ALA synthase N activity. It

relieves pain and accelerate recovery and decreases the duration of an attack and is useful in a severe attack.

- Maintain calorie and fluid intake.
- Cyclical acute attacks in females may respond to suppression of the menstrual cycle using gonadotropin-releasing hormone analogs.

### ***Cutaneous Photosensitivity Episodes***

Acute attack

- Treated symptomatically.
- Venesection (reduces urinary porphyrin) can be used for PCT (porphyria cutanea tarda) in both acute and remission phases. A prolonged course of low-dose chloroquine is effective as it helps in excretion by forming a water-soluble complex with uroporphyrins.
- Liver transplantation may be useful for severe cases.

### ***Prevention***

- Avoid sunlight (sun exposure) and skin trauma.
- Use of barrier sun creams containing zinc or titanium oxide and protective clothing.
- Oral  $\beta$ -carotene prevents formation of free radicals and provides effective protection against solar sensitivity.
- **Afamelanotide**, a synthetic analogue of alpha-melanocyte-stimulating hormone ( $\alpha$ -MSH) is useful in erythropoietic protoporphyria.

### ***Pseudoporphyria***

- In certain settings, patient develops blistering and skin fragility identical to PCT with the histological features but with normal urine and serum porphyrins. Hypertrichosis, dyspigmentation and cutaneous sclerosis do not occur. This condition is called pseudoporphyria.
- Most commonly due to medications especially NSAIDs, usually naproxen other NSAIDs and tetracycline can cause similar picture.
- Some patients on hemodialysis develop a similar PCT-like picture.

# **Rheumatology and Connective Tissue Disorders**

# CHAPTER 9

## INTRODUCTION

Initial clinical characterization of arthritis are mentioned in Box 9.1. Differences between inflammatory versus noninflammatory arthritis is presented in Table 9.1.

### Rheumatoid Factor (RF)

**Q. Write short essay/note on rheumatoid factor.**

Rheumatoid factor is an autoantibody (IgM, IgG and IgA) directed against the Fc (fragment crystallization) fragment of human immunoglobulin G (IgG).

**Box 9.1:** Initial clinical characterization of arthritis.

- **Duration:**
  - Acute (presenting within hours to days)
  - Chronic (persisting for weeks or longer)
- **Number of joints involved:**
  - Monoarticular
  - Oligoarticular/pauciarticular (2–4 joints)
  - Polyarticular (5 joints or more)
- **If more than one joint is involved:** Symmetric or asymmetric; additive or migratory
- Accurate delineation of the involved joints
- **Type:** Inflammatory or noninflammatory
- Constitutional symptoms
- **Extra-articular disease**
- Comorbid conditions

### *Significance*

- RF has **poor specificity** and is positive in **70 to 80%** of patients with rheumatoid arthritis (RA). It is appropriate and helpful only in patients suspected of having RA. It is not helpful in cases of low clinical suspicion.

**Table 9.1: Inflammatory versus noninflammatory arthritis.**

<i>Features</i>	<i>Inflammatory (Rheumatoid arthritis)</i>	<i>Non-inflammatory (Osteoarthritis)</i>
<ul style="list-style-type: none"> <li>• Age of onset</li> </ul>	<ul style="list-style-type: none"> <li>• Usually 20 to 40 years but may begin at any age</li> </ul>	<ul style="list-style-type: none"> <li>• Most commonly over 50 years of age</li> </ul>

<ul style="list-style-type: none"> <li>• Laboratory findings</li> </ul>		
<ul style="list-style-type: none"> <li>• Rheumatoid factor (RF),</li> </ul>	<ul style="list-style-type: none"> <li>• Positive</li> </ul>	<ul style="list-style-type: none"> <li>• Negative</li> </ul>

antinuclear antibody		
<ul style="list-style-type: none"> <li>Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)</li> </ul>	<ul style="list-style-type: none"> <li>Both are often raised</li> </ul>	<ul style="list-style-type: none"> <li>Usually normal but transient elevation of ESR may occur due to synovitis</li> </ul>
<ul style="list-style-type: none"> <li>White blood cell (WBC) count in the synovial fluid</li> </ul>	<ul style="list-style-type: none"> <li>WBC count is <math>&gt;2000/\text{mm}^3</math> in septic arthritis and not in rheumatoid arthritis</li> </ul>	<ul style="list-style-type: none"> <li><math>&lt;2000/\text{mm}^3</math></li> </ul>

- **High RF** titers are observed **with more severe disease** and **extra-articular disease**. The titers generally correlate with severity of disease. However, RF titers are not useful in assessing disease progression.
- It can **also be positive in many other conditions** (Table 9.2).
- 10–30% of patients with long-standing RA are seronegative.

**Table 9.2:** Conditions associated with a positive rheumatoid factor.

<i>Autoimmune rheumatic diseases (percentage)</i>	<i>Other conditions</i>
<ul style="list-style-type: none"> <li>Rheumatoid arthritis (RA) with nodules and extra-articular manifestations (100)</li> <li>Rheumatoid arthritis (overall 70)</li> <li>Sjögren's syndrome (75–95)</li> <li>Systemic lupus erythematosus (SLE) (15–35)</li> <li>Systemic sclerosis (20–30)</li> <li>Mixed essential cryoglobulinemia (90)</li> <li>Polymyositis/dermatomyositis (5–10)</li> <li>Polyarteritis nodosa (PAN)</li> <li>ANCA associated vasculitis</li> <li>Juvenile idiopathic arthritis</li> <li>Mixed connective tissue disease (50–60)</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Chronic infections:</b> Infective endocarditis, tuberculosis, leprosy, syphilis</li> <li>• <b>Viral infections:</b> Hepatitis, infectious mononucleosis</li> <li>• <b>Hyperglobulinemia:</b> Chronic liver disease, sarcoidosis</li> <li>• Interstitial lung disease, silicosis, asbestosis</li> <li>• Primary biliary cirrhosis</li> <li>• <b>Normal population</b> <ul style="list-style-type: none"> <li>– Age <math>&gt; 65</math> years</li> <li>– Relatives of people with RA</li> </ul> </li> <li>• B-cell neoplasms</li> </ul>

## Anticyclic Citrullinated Peptide Antibodies (Anti-CCPs, ACPA)

**Q. Write short note on anticitrullinated peptide antibody (Anti-CCP).**

### *Citrullinated Peptide Antigens*

- These include fibrinogen, type II collagen, alpha enolase and vimentin.
- CCPs are derived from proteins in which arginine residues are converted

to citrulline residues by an enzyme peptidyl arginine (which is abundant in inflamed synovium and in a variety of mucosal structures) during a variety of biological processes.

### ***Anticyclic Citrullinated Peptide Antibodies (ACPA)***

- These antibodies are **useful for diagnosis of RF** and may be involved in tissue injury. Many patients (about 70%) of RF have antibodies against cyclic citrullinated peptides (CCPs).
- These antibodies have **much high specificity** (93–98%) but **less sensitive** (60%) for diagnosis of RA.
- Anti-CCPs may be **detected even in asymptomatic patients** several years before the development of RA and are **associated with severe disease**. Thus, anti-CCP positive patients may require an aggressive treatment.
- Antibodies against CCPs (anti-CCPs) form immune complexes and deposit in various tissues mainly being the joints.
- Antibodies to mutated citrullinated vimentin (anti-MCV) is associated with more severe disease than anti-CCP antibodies.

### **Autoantibodies in Various Connective Tissue Diseases (CTD) (Table 9.3)**

**Q.** Write short essay on Various antibodies seen in patients with connective tissue diseases.

**Table 9.3:** Autoantibodies in various connective tissue diseases.

<b><i>Autoantibodies</i></b>	<b><i>Importance</i></b>
Rheumatoid factor	Refer Table 9.2
Anticyclic citrullinated peptide	Refer above
Antinuclear antibodies (ANA)	Refer Table 9.4
Anti-double-stranded DNA (anti-dsDNA)	<ul style="list-style-type: none"> <li>• <b>Highly specific for SLE</b>, positive in about 60% cases, positivity correlates with lupus nephritis</li> <li>• Low titers are seen in Sjögren’s syndrome, RA (rheumatoid arthritis)</li> <li>• Levels often correlate with disease activity</li> <li>• Usually absent in drug-induced SLE</li> </ul>
Antihistone	<ul style="list-style-type: none"> <li>• Sensitive for <b>drug-induced lupus</b> but not specific</li> <li>• Useful in patients with a positive ANA</li> <li>• Specific for SLE but positive in only 20–30% of cases</li> </ul>

Anti-Smith (anti-Sm)	<ul style="list-style-type: none"> <li>• Positive in 20–30% cases of SLE. <b>Highly specific</b> for SLE</li> </ul>
Anti-U1 ribonucleoproteins (RNP)	<ul style="list-style-type: none"> <li>• High titers in syndromes with features of polymyositis, lupus, scleroderma and mixed CTD (connective tissue disease)</li> </ul>
Anti-Ro (anti-SS-A)	<ul style="list-style-type: none"> <li>• Positive in <b>Sjögren’s syndrome</b> with extraglandular features</li> <li>• Positive in 40% cases of SLE and is associated with photosensitive rash and pulmonary disease. May be positive in ANA-negative lupus. Indicates higher risk of lupus nephritis</li> <li>• May be positive in neonatal lupus or congenital heart block due to maternal antibodies</li> </ul>
Anti-La (anti –SS-B)	<ul style="list-style-type: none"> <li>• Present in 10–15% cases of SLE and indicates low-risk of nephritis</li> <li>• Associated with Sjögren’s syndrome</li> </ul>
Antiphospholipid	<ul style="list-style-type: none"> <li>• Diagnostic of APLAS. Present in nearly 50% cases of SLE</li> <li>• Three types: Lupus anticoagulant (LA), anticardiolipin (aCL) and anti-<math>\beta^2</math>-glycoprotein-I (anti-<math>\beta^2</math>-GPI) antibody</li> </ul>
Anticentromere	<ul style="list-style-type: none"> <li>• Systemic sclerosis (20–35% cases).</li> <li>• CREST syndrome (calcinosis, Raynaud’s phenomenon, esophageal dysfunction, sclerodactyly and telangiectasia)</li> <li>• Primary biliary cirrhosis</li> </ul>
Antitopoisomerase I (anti-scl-70)	<ul style="list-style-type: none"> <li>• Highly specific for systemic sclerosis, found in 20–40% cases of systemic sclerosis and associated with diffuse cutaneous, pulmonary and cardiac involvements</li> </ul>
Anti-jo1	<ul style="list-style-type: none"> <li>• Present in 30% cases with polymyositis or dermatomyositis.</li> <li>• Associated with Raynaud’s phenomenon</li> </ul>
Antineutrophil cytoplasmic antibodies (ANCA)	Refer below

## Antinuclear Antibodies

**Q. Write short essay/note on antinuclear antibodies.**

**Antinuclear antibodies (ANA)** are **directed against one or more components of the cell nucleus**. The component of the nucleus includes DNA, RNA, proteins as well as complexes of proteins with nucleic acid.

## Significance

- **High titers** of ANA (>1:160) are of **more diagnostic** significance than low titers.
- Circulating **levels of ANA do not correlate with severity or activity** of the disease.
- Though these antibodies occur in many inflammatory rheumatic conditions but they can be found in low titers in normal individuals and in non-rheumatic diseases.
- ANA is **positive in several conditions** (Table 9.4).
- ANA is used as a **screening test for systemic lupus erythematosus (SLE) and systemic sclerosis (SSc)**. ANA has high sensitivity for SLE (100%) but low specificity (10–40%). A negative ANA almost rules out SLE but a positive result does not confirm it. It should not be used to monitor the course of SLE or other diseases.

**Table 9.4:** Conditions associated with a positive ANA test.

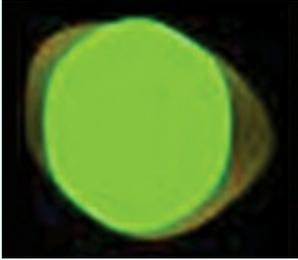

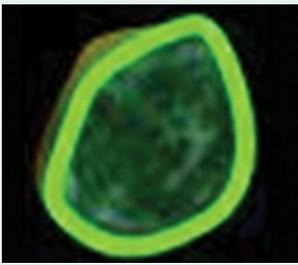

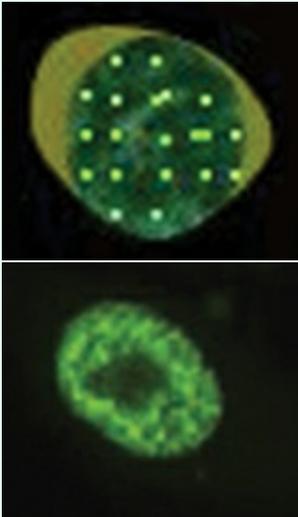

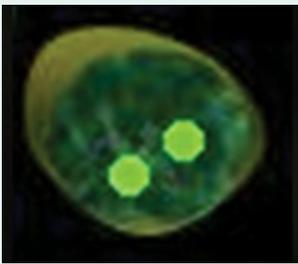

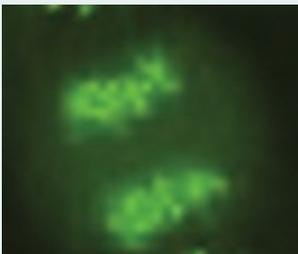

<i>Diseases where ANA is useful in diagnosis</i>	<i>Diseases where ANA is not useful in diagnosis</i>
<ul style="list-style-type: none"> <li>• Systemic lupus erythematosus (95–100%)</li> <li>• Systemic sclerosis (60–80%)</li> <li>• Sjögren’s syndrome (40–80%)</li> <li>• Drug-induced lupus (&gt;95%)</li> <li>• Mixed connective tissue disease (100%)</li> <li>• Polymyositis/dermatomyositis (30–80%)</li> <li>• Autoimmune hepatitis (100%)</li> </ul>	<ul style="list-style-type: none"> <li>• Rheumatoid arthritis (30–50%)</li> <li>• Autoimmune thyroid disease (30–50%)</li> <li>• Malignancy varies widely</li> <li>• Infectious diseases varies widely</li> </ul>

*Note:* About 5% of healthy individuals have an ANA titer > 1:80.

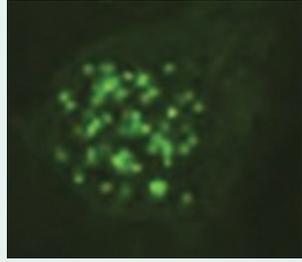

**Tests for detection:** ANAs are detected by indirect immunofluorescent staining (Table 9.5) of fresh-frozen sections of rat liver or kidney or Hep-2 cell lines (a line of human epithelial cells).

**Table 9.5:** Pattern of antinuclear antibody staining.

<i>Pattern of staining</i>	<i>Diagrammatic appearance</i>	<i>Staining pattern due to</i>	<i>Associated conditions</i>
Homogeneous or diffuse staining of the entire nucleus with or		Antibodies to nucleosomes (anti-DNP), histones (anti-	Rheumatoid arthritis, systemic lupus erythematosus (SLE) and miscellaneous

without apparent masking of the nucleoli			histone) and occasionally double-stranded DNA (anti-dsDNA)	disorders (anti-ssDNA)
Rim or peripheral staining			Antibodies to double-stranded DNA (anti-DNA) and sometimes to nuclear envelope proteins. Not seen on HEp-2	SLE
Speckled (may be coarse or fine) pattern-the presence of uniform or variable-sized speckles throughout the nucleus. Most common pattern and is least specific			Antibodies to non-DNA nuclear constituents such as Sm antigen (anti-Sm), ribonucleoprotein (anti-RNP), and SS-A (anti-SS-A) and SS-B reactive antigens (anti-SS-B)	SLE, systemic sclerosis (SS), polymyositis (PM)/dermatomyositis (DM)
Nucleolar pattern-presence of a few discrete spots within the nucleus-stains nucleoli within the nucleus, sharply separated from the unstained nucleoplasm			Antibodies to RNA (anti-nucleolar)	Most often seen in systemic sclerosis
Centromeric pattern-discrete uniform speckles throughout the nucleus. The number of speckles			Antibodies specific for centromeres (anti-centromere)	Systemic sclerosis, Sjögren syndrome, and other diseases

corresponds to a multiple of the normal chromosome number

(ds: double stranded; ss: single stranded)

## Extractable Nuclear Antibodies

**Q. Write short essay/note on extractable nuclear antibodies.**

- These are antibodies to extractable nuclear antigens (ENA) and are directed against small ribonuclear proteins (RNA).
- **Types of antibodies and associated conditions are listed in Table 9.6.**
- Their sensitivity and specificity are poor. Though used for diagnostic confirmation, they do not exclude a specific CTD.
- They do not correlate with disease activity and may be found in patients without active disease.

**Table 9.6:** Types of antibodies and associated conditions.

<i>Type of extractable nuclear antibody</i>	<i>Associated conditions</i>
• Anti-Sm	• Only in SLE and represent a serologic marker in disease classification. They are associated with renal involvement
• Antiuracil-rich 1 ribonucleoprotein (U1RNP)	• SLE and in mixed connective tissue disease
• Anti-SS-A/Ro and anti-SS-B/La	• SLE and in Sjögren's syndrome
• Anti-tRNA synthetases	• Polymyositis/dermatomyositis
• Antitopoisomerase-1 antibodies (Scl-70)	• Diffuse systemic sclerosis
• Anticentromere antibodies	• Limited systemic sclerosis

## Antineutrophil Cytoplasmic Antibodies

**Q. Write short essay/note on antineutrophil cytoplasmic antibodies (ANCA), their significance/ANCA associated disorders.**

Antineutrophil cytoplasmic antibodies (ANCAs) are heterogeneous group of IgG **autoantibodies directed against certain proteins** (mainly enzymes) in

**the cytoplasmic granules of neutrophils and lysosomes of monocytes.**

**Patterns:** On the basis of the target antigens and pattern of immunofluorescence staining, two common patterns of ANCA have been distinguished.

1. **Anti-proteinase-3 (PR3-ANCA):** It is also called cytoplasmic or cANCA. PR3 is a constituent of neutrophil azurophilic granule. It shares homology with many microbial peptides and antibodies against microbial peptides. Antibodies against proteinase-3 (PR3) form PR3-ANCAs. They produce cytoplasmic fluorescence (cANCA). They are associated with **Wegener's granulomatosis**.
2. **Anti-myeloperoxidase (MPO-ANCA):** It is also called perinuclear or pANCA. MPO is a lysosomal enzyme normally involved in producing oxygen-free radicals. Antibodies to myeloperoxidase (MPO) forms MPO-ANCAs which produces perinuclear fluorescence (pANCA). It can be induced by drugs (e.g. propylthiouracil). They are associated with **microscopic polyangiitis and Churg-Strauss syndrome**.

### **Significance**

- ANCA are **strongly associated with small-vessel vasculitis** and are useful in the diagnosis and monitoring of systemic vasculitis. For their significance in vasculitis, ANCA should be assayed both with indirect immunofluorescence (screening test) and direct ELISA for proteinase-3 or myeloperoxidase.
- **ANCA are not specific for vasculitis.** They may be positive in autoimmune liver disease, malignancy, infection (bacterial and human immunodeficiency virus, HIV), inflammatory bowel disease, chronic hepatitis, primary sclerosing cholangitis, Felty's syndrome, rheumatoid arthritis, SLE and pulmonary fibrosis.

### **Synovial Fluid in Disease States (Table 9.7)**

**Table 9.7:** Features of synovial fluid in various disease states.

	<i>Normal</i>	<i>Non-inflammatory</i>	<i>Inflammatory</i>	<i>Pyogenic</i>
Appearance	Clear	Clear	Cloudy, yellow	Turbid
Viscosity	High	High	Low	Variable, infection usually

				low
Mucus clot	Good	Good	Poor	Poor
Total WBC/mm <sup>3</sup>	< 200	200–5000	5000–50,000	> 50,000
Predominant cell	Monocytes	Monocytes	Polymorphs > 60%	Polymorphs > 80% Bacteria present
Protein	< 2–3 g/dL	< 2–3 g/dL	> 3 g/dL	> 3 g/dL
Sugar	Equal to blood sugar (BS) taken simultaneously	Equal to blood sugar (BS)	25–50% less than blood sugar	> 50% less than blood sugar

## RHEUMATOID ARTHRITIS

**Q. Discuss the etiology, pathogenesis, clinical manifestations, diagnosis, investigations, complication, and management of rheumatoid arthritis.**

Rheumatoid arthritis (RA) is the most common form of chronic inflammatory, potentially crippling arthritis with multisystem involvement affecting approximately 1% of the adult population.

### Etiology

**Q. Write short essay/note on etiology of rheumatoid arthritis.**

The cause is multifactorial and genetic, epigenetic and environmental factors play a part in the pathogenesis of RA.

- **Genetic factors:** Genetic susceptibility is a **major factor** in the pathogenesis of rheumatoid arthritis.
  - **HLA genes:** RA is linked to specific **HLA-DRB1 locus**.
  - **Non-HLA genes:** Polymorphism in *PTPN22* gene, which encodes a tyrosine phosphatase.
- **Environmental arthritogenic agents:** They are thought to **initiate the disease** process. **Smoking** and several **microbial agents** (e.g. virus, mycobacteria porphyromonas gingivalis, and *Mycoplasma*) have been suggested but not proved.
- **Autoimmunity:** The initial inflammatory synovitis, an autoimmune reaction with T cells is responsible for the chronic destructive nature of rheumatoid arthritis.

## Pathogenesis

The rheumatoid synovium behaves like a locally-invasive tumor. A cascade network of cytokines like granulocyte macrophage colony-stimulating factor (GM-CSF), interleukin (IL)-2, IL-15, IL-13, IL-17, IL-18, interferon-gamma (IFN-gamma), tumor necrosis factor (TNF) and transforming growth factor-beta (TGF-beta) are involved in the disease progression. B cells, CD4+ T cells, complement mediated immune activation play a contributory role.

## Clinical Features

**Q. Write short essay/note on clinical features of rheumatoid arthritis.**

- **Gender:** Female to male ratio is 3:1.
- **Age:** Most common age of onset is between 30 and 50 years, but the disease can occur at any age. In women in late childbearing years and in men during sixth to eighth decade.

### *Onset*

The presenting symptoms result from inflammation of the joints, tendons, and bursae. The onset varies:

- **Slow and insidious in onset:** Presents with malaise, fatigue, anorexia, weakness and generalized musculoskeletal pain.
- **Acute onset:** Sometimes RA may be very acute in onset, with morning stiffness, polyarthritis and pitting edema. This type occurs more commonly in old age.
- **Palindromic onset:** Occasionally, patient present with relapsing and remitting episodes of pain, stiffness and swelling that last for only a few hours or days alternating with symptom-free periods.
- Rarely, onset may be monoarticular.

### *Articular Manifestations*

**Q. Write short essay/note on articular manifestations of rheumatoid arthritis.**

- **Joints involved (Fig. 9.1A):** RA can affect any of the synovial (diarthrodial) joints and involvement is usually in a **symmetric distribution**. Most commonly, RA starts in the small joints, namely metacarpophalangeal (MCP), proximal interphalangeal (PIP), and

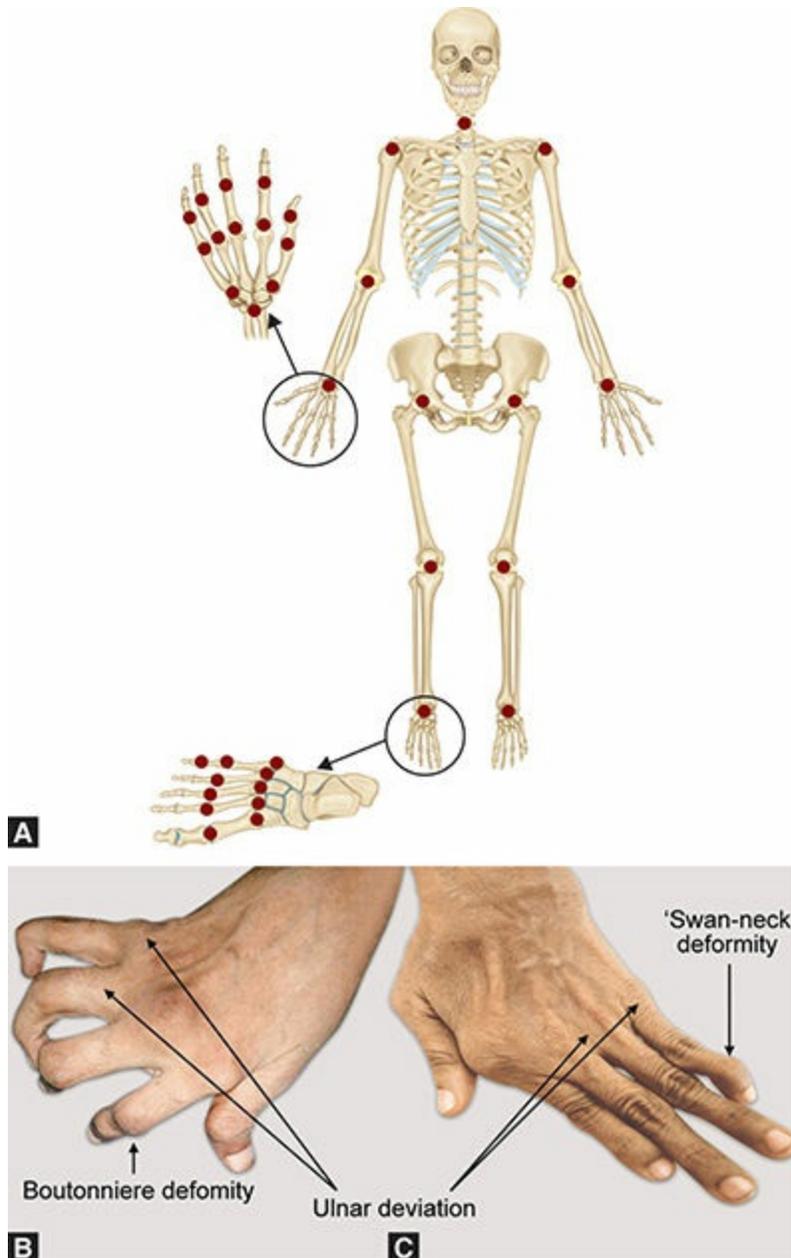

metatarsophalangeal (MTP) joints, followed by the involvement of large joints (wrists, knees, elbows, ankles, hips, and shoulders). Pitting edema over the dorsum gives rise to the “**boxing glove**” appearance. In RA, the hypertrophied synovium (also called pannus) invades and erodes contiguous cartilage, ligaments and bone.

- **Symptoms:** These include pain, swelling, and stiffness. Stiffness dominating in the mornings (‘morning stiffness’) lasting more than 1 hour is characteristic. Routine activities early in the morning like brushing teeth and combing hair may be very difficult.

**Q. Write short note on rheumatoid hand.**

**Hand and wrist (Figs. 9.1B and C):** Hands are a major site of involvement and produces significant disability.

- **The DIP joint is characteristically always spared** unless the patient also has osteoarthritis (both coexist, particularly in elderly patients).
- **Spindling of the fingers:** It is the earliest finding characterized by swelling of the proximal, but not the distal interphalangeal joints.
- **Deformities:** Destruction of the joints and soft tissues may lead to chronic, irreversible deformities.

**Figs. 9.1A to C:** Rheumatoid arthritis. (A) Pattern of joint involvement; (B and C) Shows bilateral massive swelling of tendon over the dorsal surface of wrists, muscle wasting, ulnar deviation of the metacarpophalangeal joints, and swan-neck deformity of the fingers.

- **Ulnar deviation (Figs. 9.1B and C):** It results from subluxation of the metacarpophalangeal (MCP) joints, with subluxation of the proximal phalanx to the volar side of the hand.
- **‘Swan-neck’ deformity (Figs. 9.1B and C):** It is due to hyperextension of the proximal interphalangeal joints (PIP) with flexion of the distal interphalangeal joints (DIP). At DIP joint there is

elongation or rupture of attachment of the extensor tendon to the base of the distal phalanx; this results in mallet deformity of distal joint and in addition, an extensor tendon imbalance, leading to hyperextension deformity at PIP joint.

- **‘Boutonniere’ or ‘button-hole’ deformity (Fig. 9.1C):** This deformity is due to flexion of the proximal interphalangeal (PIP) joints and extension of the distal interphalangeal (DIP) joints. Disruption of the central slip of the extensor tendon and the triangular ligament allows each of the conjoint lateral bands of the digit to slide volarly resulting in a pathologic flexion force and an extension lag; all tendons traversing the PIP joint in this setting elicit flexion of the joint.
- **‘Gamekeepers thumb’:** It is the result of hyperextension of the first interphalangeal joint and flexion of the first metacarpophalangeal joint. This leads to loss of thumb mobility and occurrence of pinch.
- **Hitchhiker’s thumb (Z-shaped deformity)** in which the thumb flexes at the metacarpophalangeal joint and hyperextends at the interphalangeal joint.
- Inflammation of the carpometacarpal joint leads to volar subluxation during contracture of the adductor hallucis.
- **‘Z’ deformity:** It is due to radial deviation of the wrist, ulnar deviation of the digits with palmar subluxation of the first MCP joint with hyperextension of the first interphalangeal (IP) joint.
- **Carpal tunnel syndrome:** Due to synovial proliferation in and around the wrists producing compression of the median nerve.
- The “bow string” sign (prominence of the tendons in the extensor compartment of the hand).

**Feet and ankle:** In most patients, feet (particularly the MTP joints) are involved early.

- **‘Broadening’ of the forefoot:** Due to swelling of the metatarsophalangeal joints.
- **Subluxation of the toes at the MTP joints (“cock-up” deformities):** leads to skin ulceration on the top of the toes and painful ambulation because of loss of the cushioning pads which protect the metatarsals heads.
- **Hallux valgus deformity** and hammer toes may be seen.

### *Larger joints*

- **Involvement of large joints (knees, ankles, elbows, hips and shoulders)** is common but generally occurs somewhat later than small joint involvement.
- Shoulder joint involvement may present as glenohumeral arthritis, rotator cuff fraying and rupture.
- **Synovial cysts:** They present as fluctuant masses around involved joints (large or small). Best examples of synovial cyst is **popliteal ('Baker's) cysts** which develops in the knee joint. The knee synovitis produces excess synovial fluid that communicates posteriorly with the cyst (between the knee joint and the popliteal space) but is prevented from returning to the joint by a one-way valve-like mechanism. Ruptured Baker's cysts can resemble a deep vein thrombosis.

### *Other joints*

- Although most of the spine is spared in RA, the **cervical spine** (atlantoaxial subluxation) can be involved producing quadriparesis.
- **Cricoarytenoid joint** involvement may present (30%) with hoarseness of voice and inspiratory stridor.

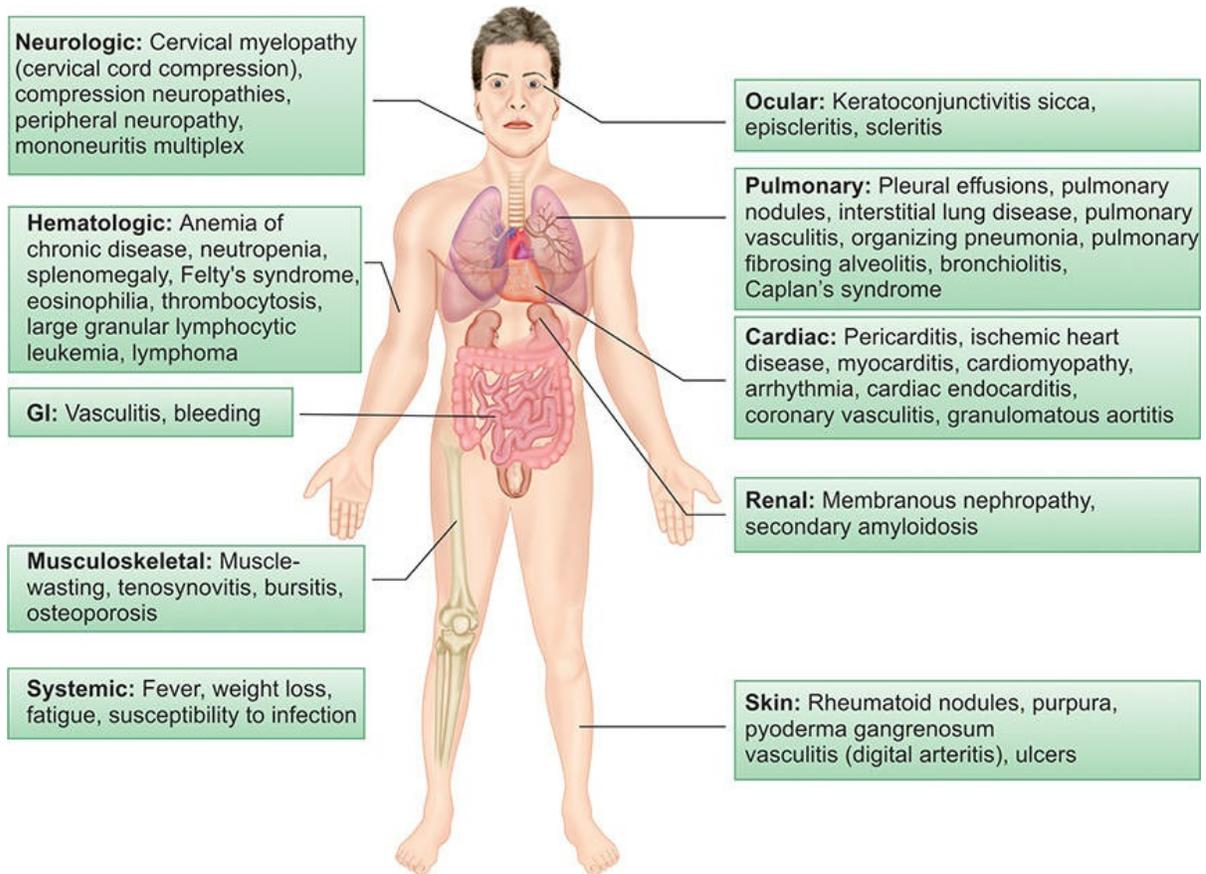

### ***Extra-articular Manifestations (Fig. 9.2)***

**Q.** Write short note on extra-articular manifestations of rheumatoid arthritis including skin manifestations.

**Constitutional:** RA is a systemic disease and features such as fatigue, weight loss, and low-grade fevers (<38°C) occur frequently. Systemic features are more common in patients who have RF or ACPA antibodies, or both.

### **Rheumatoid nodules**

- Rheumatoid nodules are usually **subcutaneous** and are typically benign.

**Fig. 9.2:** Extra-articular manifestations of RA.

- **Significance:** Nodules are seen in about one-fourth of patients with RA and, almost exclusively in those patients who are seropositive for rheumatoid factor. They are clinical predictors of more severe arthritis, sero-positivity, joint erosions and rheumatoid vasculitis.
- **Sites:** Typically occur on extensor surfaces, over joints or on areas subject to repeated trauma (particularly forearms, sacral prominences, scalp and the Achilles tendon). Rarely, they develop in lungs, pleura, heart, pericardium or in the sclera of the eye.
- **Characteristics:** On examination, rheumatoid nodules are firm and nontender (unless traumatized). They have a characteristic histologic picture (central area of fibrinoid material surrounded by a palisade of proliferating mononuclear cells), and are thought to be triggered by small vessel vasculitis.
- Methotrexate therapy can trigger a syndrome of increased nodulosis despite good control of the joint disease of RA.

## Rheumatoid vasculitis

- **RA-associated small vessel vasculitis:** It can manifest as digital infarcts, cutaneous ulcerations, palpable purpurae, distal gangrene and leukocytoclastic vasculitis. They require prompt more aggressive treatment with disease-modifying antirheumatic drugs (DMARDs).
- **Other manifestations:** Polyneuropathy, mononeuritis multiplex and visceral infarction (resulting in stroke and acute myocardial infarction) and mesenteric arteritis. **Pyoderma gangrenosum** occurs with increased frequency with RA.

## Pleuropulmonary manifestations

**Q. Write short essay/note on pleuropulmonary manifestations of rheumatoid arthritis.**

- Pleural lesions: **Pleural effusions (exudative)** occur more commonly in men and are usually small and asymptomatic. Pleural fluid is characterized by low glucose and pH.
- Pulmonary lesions:
  - **Rheumatoid nodules** especially in men; usually solid, but may calcify, cavitate or become infected.
  - **Diffuse interstitial fibrosis** causes dyspnea and may progress to cor pulmonale.
  - **Bronchiolitis obliterans** with or without organizing pneumonia.
  - **Granulomatous pneumonitis.**
  - **Pulmonary arteritis** (vasculitis) may result in infarction.
  - **Caplan's syndrome:** It is characterized by the coexistence of seropositive RA and rounded fibrotic, peripherally located nodules of 0.5–5 cm diameter in the lung along with coal worker's pneumoconiosis (CWP)/silicosis.

**Treatment induced:** Methotrexate induced lung fibrosis, immunosuppression related infections like TB.

## Cardiac manifestations

- **Pericardial effusions** are common. Rarely, long-standing pericardial disease results in a fibrinous pericarditis and constrictive pericarditis.
- Coronary artery disease due to **premature atherosclerosis**. Rarely,

**valvular involvement and conduction defects.**

### **Neurological manifestations**

- **Peripheral nerve entrapment syndromes:** For example, carpal tunnel syndrome (median nerve at the wrist), and tarsal tunnel syndrome (anterior tibial nerve at the ankle).
- **Myelopathy:** Due to spinal cord compression produced by acquired atlanto-axial dislocation.
- **Mononeuritis multiplex:** Due to vasculitis.

### **Ophthalmological manifestations**

- **Sicca complex:** Comprising keratoconjunctivitis sicca, xerostomia and salivary (parotid) gland enlargement.
- **Scleritis,** episcleritis may progress to perforation of the orbit (scleromalacia perforans).
- **Brown's syndrome:** Diplopia due to tendinitis of the superior oblique muscles.

**Felty's syndrome:** It is the triad of RA, splenomegaly, and neutropenia (refer page 678).

**Osteoporosis:** Osteoporosis secondary to rheumatoid involvements is very common especially with corticosteroid therapy and immobilization.

### **Hematological manifestations**

- **RBC:** Normocytic normochromic anemia. Causes of anemia in RA include anemia of chronic disease, anemia due to gastrointestinal bleed secondary to NSAID/steroids, methotrexate induced folate deficiency, marrow suppression due to disease/drugs and part of hypersplenism if splenomegaly present.
- **WBC:** Eosinophilia and mild leukocytosis. Neutropenia in cases of Felty's syndrome and large granular lymphocyte syndrome. Patients with RA are at an **increased risk for infections,** and this risk is further increased by some therapies.
- **Platelets:** Thrombocytosis.

**Renal involvement:** In the form of glomerulonephropathy, vasculitis, drug toxicities and secondary amyloidosis.

**Malignancies:** RA patients have an increased risk of **lymphomas.**

## Box 9.2: American College of Rheumatology (ACR) criteria for rheumatoid arthritis.

- Morning stiffness<sup>a</sup>
- Arthritis of 3 joint areas<sup>a</sup>
- Arthritis of the hands<sup>a</sup>
- Symmetric arthritis<sup>a</sup>
- Rheumatoid nodules
- Serum rheumatoid factor positive
- Radiographic changes

<sup>a</sup>These criteria must be present for more than 6 weeks. Presence of 4 criteria favors definite diagnosis of RA.

## Diagnosis

### **Q. Mention the ACR (American College of Rheumatology)/EULAR criteria for the diagnosis of rheumatoid arthritis.**

- Diagnostic criteria of rheumatoid arthritis: In 2010, a collaborative effort between the American College of Rheumatology (ACR-Box 9.2) and the ACR/European League against Rheumatism (EULAR) presented the criteria for the diagnosis of RA (Table 9.8).
- The Disease Activity Score derivative for 28 joints (**DAS28**) is used to grade severity of RA.
- Simplified Disease Activity Index (**SDAI**) and Clinical Disease Activity Index (**CDAI**) are also used in monitoring.

## Investigations

### **Q. Write short essay/note on investigations of rheumatoid arthritis.**

- **Serology**
  - **Rheumatoid factor** (refer pages 667-8)
  - **Anticyclic citrullinated protein antibodies (ACPA)**
- **Markers of acute inflammation**
  - **Anemia of chronic disease** is seen in majority of patients, and the degree of anemia is proportional to the activity of the disease.
  - **Thrombocytosis** is common, and platelet counts return to normal as

the inflammation is controlled.

- **Acute phase reactants, erythrocyte sedimentation rate and C-reactive protein levels** parallel the activity of the disease, and their persistent elevation carries poor prognosis (joint destruction and mortality).
- **WBC counts** may be raised, normal, or profoundly depressed (Felty's syndrome).
- **Other autoantibodies:** RA is associated with other autoantibodies, such as antinuclear antibodies (30% of patients) and antineutrophilic cytoplasmic antibodies, particularly of the perinuclear type (30% of patients).
- **Radiographs of the affected joints:** Radiological changes include symmetrical pattern of involvement, juxta-articular osteoporosis, soft tissue swelling, bone erosions and narrowing of the joint space.
- **Ultrasonography and MRI:** More sensitive than plain radiographs and detects soft-tissue synovitis before joint damage. *Doppler ultrasound* is useful for demonstration persistent synovitis when deciding on the need for DMARDs or assessing their efficacy.
- **Synovial fluid analysis:** White blood cell counts typically range from 5000–50,000 per microliter with approximately two-third of the cells being neutrophils with no crystals or organism. None of the synovial fluid findings are pathognomonic.

**Table 9.8:** American College of Rheumatology (ACR)/European League against Rheumatism (EULAR) classification criteria for rheumatoid arthritis: 2010.

<i>Features</i>	<i>Score</i>
<b>A. Joint involvement*</b>	
• 1 large joint (shoulder, elbow, hip, knee, ankle)	0
• 2–10 large joints	1
• 1–3 small joints (MCP, PIP, thumb IP, MTP, wrists) + involvement of large joints	2
• 4–10 small joints + involvement of large joints	3
• >10 joints (at least 1 small joint)	5
<b>B. Serology (at least one test result is needed for classification)</b>	

• Negative RF and negative ACPA	0
• Low-positive RF or low-positive ACPA ( $\leq 3$ times ULN)	2
• High-positive RF or high-positive ACPA ( $\geq 3$ times ULN)	3
<b>C. Acute-phase reactants (at least one test result is needed for classification)</b>	
• Normal CRP and normal ESR	0
• Abnormal CRP or abnormal ESR	1
<b>D. Duration of symptoms</b>	
• < 6 weeks	0
• $\geq 6$ weeks	1

(MCP: metacarpophalangeal joint; PIP: proximal interphalangeal joint; IP: interphalangeal joint; MTP: metatarsophalangeal joint; RF: rheumatoid factor; ACPA: anticitrullinated protein antibodies; ULN: upper limit of normal; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate)

- Above criteria yields a score of 0–10. **A score of  $\geq 6$  required for definitive diagnosis of RA.**
- A score of < 6/10 are not classifiable as RA, but their status to be reassessed over time.

## **Q. Write short essay on treatment of rheumatoid arthritis.**

### **Management**

#### **General Measures**

There is no cure for rheumatoid arthritis, which is a lifelong disease process requiring lifelong treatment. **The goal of therapy is disease remission and to maintain this remission** by continuing therapy.

- **Rest and splinting** of the involved joints during the acute stage.
- **Physiotherapy:** Helps in mobilization and prevention of contractures.

#### **Medical Therapy**

Three types of medical therapies are used in the treatment of RA: (1) NSAIDs, (2) glucocorticoids, and (3) DMARDs (both conventional and biologic).

1. **Nonsteroidal anti-inflammatory drugs (NSAIDs):** NSAIDs produce **symptomatic relief** because of its **analgesic and anti-inflammatory properties**. However, they do not alter the underlying disease process. Therefore, they are not used without the concomitant use of DMARDs. Their **chronic use should be minimized** because of its side effects such as gastritis/peptic ulcer disease and impairment of renal function.
2. **Glucocorticoids:** These are the most potent anti-inflammatory treatments available and cause dramatic and rapid improvement. Not only they produce symptomatic improvement, but also significantly decrease the radiographic progression of RA. However, the long-term therapy is associated with multisystem toxicities.
  - **Prednisolone** is the most commonly used glucocorticoid and is administered orally.
  - **Bridge therapy:** In ‘bridge therapy’, glucocorticoids are used first to shut off inflammation rapidly and then to taper them as the DMARD is taking effect.
  - **Pulse therapy:** Remission is induced with IM (intramuscular) depot methylprednisolone 80–120 mg if synovitis persists beyond 6 weeks. Intraarticular long-acting glucocorticoids (e.g. triamcinolone hexacetonide) are used to reduce synovitis.
3. **Disease modifying antirheumatic drugs (DMARDs).**

**Q. Write short note on disease modifying antirheumatic drugs (DMARDs) including its indications and current status.**

DMARDs have the ability to inhibit greatly the disease process to modify or change the disabling potential of RA. DMARDs are so named because in most of the cases they are able to slow or prevent structural (radiographic) progression of RA.

**Box 9.3:** Conventional DMARDs used in RA.

- Methotrexate (MTX)
- Hydroxychloroquine
- Sulfasalazine
- Leflunomide
- Azathioprine
- Gold (auranofin)
- Minocycline
- D-penicillamine

**Conventional DMARDs used in RA (Box 9.3)**

- Conventional DMARDs exhibit a delayed onset of action and take 2–6 months to exert their full effect.
- Start DMARD therapy early in the disease process. Early in the course of disease, most patients should be started on a combination of DMARDs and analgesics. Before using DMARDs, complete blood count, serum creatinine, aminotransferases, and screening for hepatitis C, hepatitis B, and latent tuberculosis infection. A chest radiograph should be obtained prior to initiating treatment with MTX.

**Methotrexate:** Currently, methotrexate is the DMARD of choice (considered as ‘gold standard’ drug) for RA and is the anchor drug for most combination therapies.

- **Mechanism of action** in RA: At the dosages used for RA, methotrexate stimulates extracellular release of adenosine from cells, which has anti-inflammatory and immunomodulatory properties. Enzymes inhibited by methotrexate in RA include **thymidylate synthetase (TS) and 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) transformylase**. It should not be prescribed in pregnancy.
- **Dose:** Usually given orally in the starting dose of 2.5–7.5 mg/week as a single dose. **If there is no positive response** within 4–8 weeks, and there is no toxicity, the dose should be **increased by 2.5–5 mg/week** each month to 15–25 mg/week before considering, the treatment a failure. Oral absorption of methotrexate is variable. If oral treatment is not effective, it is given by subcutaneous injections. It should be monitored with full blood counts and liver biochemistry.
- **Folic acid**, 1 to 4 mg/day (or 5 mg once a week, on the day following methotrexate dose), reduces most methotrexate associated toxicities (e.g. gastrointestinal intolerance, stomatitis, hepatotoxicity, hyperhomocysteinemia, alopecia) without apparent loss of efficacy.

If methotrexate alone does not sufficiently control RA, it is combined with other DMARDs.

**Other DMARDs**

- **Hydroxychloroquine** is used usually in combination with other DMARDs, particularly methotrexate. It is given orally at a dose of 200–400 mg daily. It is the least toxic DMARD but also the least effective as monotherapy. Regular monitoring (every 6 months to a year) by ophthalmoscopy to detect any signs of retinopathy, bull’s eye maculopathy should be done.
- **Sulfasalazine:** It is effective when given in doses of 1–3 g daily. Monitoring of blood cell

counts is recommended, particularly WBC counts, in the first 6 months. Combination of sulfasalazine + hydroxychloroquine+ methotrexate is referred to as triple therapy.

- **Leflunomide** is a pyrimidine antagonist, also inhibits enzyme **dihydroorotate dehydrogenase**, interfering with cell signal transduction. It has a very long half-life and is given daily in a dose of 10–20 mg. The most common toxicity is diarrhea, which may respond to dose reduction. Leflunomide is teratogenic and hepatotoxic. It is used as monotherapy or in combination with methotrexate and other DMARDs.
- **Others:** These include minocycline, gold salts, penicillamine and cyclosporine are used sparingly now.

### **Biologic DMARDs/Biologicals**

#### **Q. List the biologicals used in the treatment of rheumatoid arthritis (RA).**

- They are usually given along with methotrexate or other conventional DMARDs.
- **Disadvantages: High cost and long-term toxicities**, notably **infections** (especially cellulitis, septic joints, tuberculosis, histoplasmosis, coccidioidomycosis, and *Listeria*) and **demyelinating syndromes**

#### *TNF- $\alpha$ Blockers*

- **Etanercept**, a recombinant TNF receptor fusion protein. Administered subcutaneously in a dose of 25 mg twice weekly.
- **Infliximab** is a mouse/human chimeric monoclonal antibody against TNF- $\alpha$ . It is given intravenously (3–10 mg/kg) every 4–8 weeks.
- **Adalimumab** is a recombinant human IgG1 monoclonal antibody directed against TNF- $\alpha$ . It is administered subcutaneously in a dose of 40 mg every other week.

#### *IL-1 Receptor Blocker*

- **Anakinra**, a recombinant human interleukin-1 receptor antagonist. It is given subcutaneously in a dose of 100 mg daily.

#### *Anti-CD20 Antibodies.*

#### **Q. Write short note on rituximab.**

- **Rituximab** is a genetically engineered chimeric murine/human monoclonal antibody directed against the CD20 molecule found on the surface of B cells. It is given intravenously as two infusions 2 weeks apart for the treatment of patients with refractory RA.

#### *T-cell Agent*

- **Abatacept** is a recombinant fusion protein of the extracellular domain of human CTLA4 and a fragment of the Fc domain of human IgG1. It is administered by intravenous infusion every 4 weeks in a dose of approximately 10 mg/kg.
- **Tofacitinib**, the orally administered Janus kinase inhibitor, can also be used in combination with MTX or as monotherapy.

**Immunosuppressants:** These are used as third-line drugs for RA that recurs or does not respond to second-line agents. These include cyclophosphamide and azathioprine. However, in RA with acute vasculitis causing serious organ involvement, intravenous administration of cyclophosphamide may be lifesaving.

### **Surgery**

Surgical therapy may improve pain and disability when there is failure of medical therapy. It is useful in maintenance of joint function, and prevention and correction of deformities. Surgical procedures of the joint include (a) synovectomy of the inflamed joint before joint damage; (b) osteotomy to correct the deformity and relieve pain in the upper end of the tibia, and excision of the lower end of

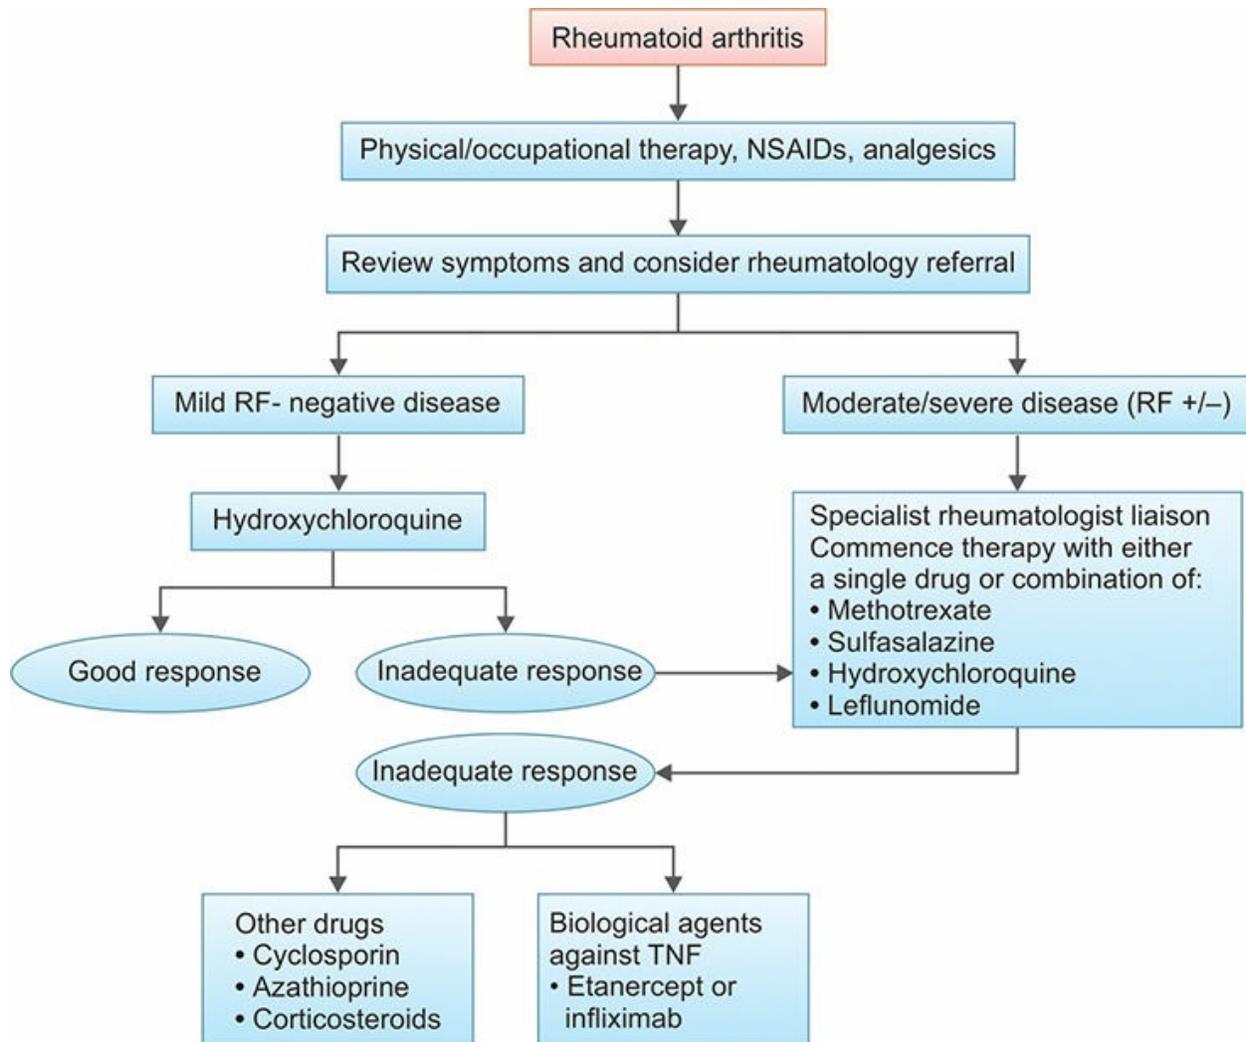

the ulna; (c) arthrodesis of the joint to relieve pain in the atlanto-axial joint, wrists, ankle and subtalar joints; (d) excision arthroplasty and (e) joint replacement.

**Physiotherapy, Rehabilitation and Assistive Devices**

Exercise and physical activity improve muscle strength. Judicious use of wrist splints can decrease pain.

Treatment algorithm for rheumatoid arthritis is presented in Flowchart 9.1.

**Flowchart 9.1:** Treatment algorithm for rheumatoid arthritis.

**Felty’s Syndrome**

**Q. Write short essay/note on Felty’s syndrome and its components.**

- Felty’s syndrome is the triad of RA, neutropenia and splenomegaly.
- It is seen in patients with long-standing chronic, severe and sero-positive RA.

## ***Clinical Features (Box 9.4)***

**Box 9.4:** Clinical features of Felty's syndrome.

- Features of RA (rheumatoid arthritis)
- Splenomegaly
- Lymphadenopathy
- Skin pigmentation
- Fever
- Weight loss
- Features of neutropenia and thrombocytopenia
- Recurrent infections and chronic leg ulcers
- Vasculitis
- Subcutaneous nodules
- Carpal tunnel syndrome
- Higher risk of Hodgkin's lymphoma

## ***Laboratory Findings***

- **Blood:** Neutropenia  $<1500/\text{mm}^3$ , anemia and thrombocytopenia.
- **Rheumatoid factor (RF):** High titers.
- **Circulating immune complexes (CIC):** Increased levels.

### **Treatment**

- Do not require special specific therapy; instead **treat underlying severe RA**. Immunosuppressive agents particularly methotrexate and azathioprine are beneficial.
- G-CSF and GM-CSF can be tried.
- **Splenectomy is indicated in:** Severe and persistent neutropenia ( $< 500 \text{ cells}/\text{mm}^3$ ), recurrent or serious bacterial infections, chronic, nonhealing leg ulcers, hypersplenism producing severe anemia or thrombocytopenic hemorrhage.

## ***Prognosis***

Poor with an increased mortality due to increased incidence of severe infection.

## **Non-steroidal Anti-inflammatory Drugs**

**Non-steroidal anti-inflammatory drugs** are the most widely used drugs, but they have an increased risk of cardiovascular disease. Oral NSAIDs are used for the management of pain due to inflammation.

**Mechanism of NSAID action:** Arachidonic acid (AA) is derived from membrane phospholipid and its **metabolism occurs along two major**

enzymatic pathways namely cyclooxygenase pathway (produces prostaglandins by the cyclooxygenase) (COX) and lipoxygenase pathway (produces leukotrienes by 5-lipoxygenase).

**Q. Write short essay/note on COX enzymes and COX-2 inhibitors.**

### ***Traditional NSAIDs versus COX-2 Inhibitors***

- **Traditional NSAIDs** (e.g. ibuprofen, diclofenac, and naproxen) exert their anti-inflammatory effect by inhibiting synthesis of prostaglandin from arachidonic acid by blocking both COX enzymes. They do not have a disease-modifying effect in either osteoarthritis or inflammatory rheumatic diseases. Inhibition of COX-1 is required for anti-inflammatory and analgesic effects, but can damage the mucosa of stomach and duodenum and is associated with an increased risk of upper gastrointestinal ulceration, bleeding and perforation. Simultaneous administration of omeprazole (20 mg daily) or misoprostol (200 µg twice or 3 times daily) reduces the risk of NSAID-induced ulceration and bleeding. Other side-effects include fluid retention, renal impairment due to inhibition of renal prostaglandin production, and rashes.
- **COX-2 (cyclooxygenase-2) selective NSAIDs** (e.g. celecoxib, etoricoxib, etodolac, rofecoxib and valdecoxib) selectively inhibit COX-2. They have **analgesic and anti-inflammatory properties similar to traditional NSAIDs**. However, they are much less **likely to cause gastrointestinal toxicity** and have **minimal antiplatelet effects**. Similar to traditional NSAIDs, they can produce significant changes in renal function, and hence, should be cautiously used in patients with diabetes, dehydration and congestive heart failure. They **play an important role in the management of inflammation and pain caused by arthritis**. It has been observed that there is a higher risk of myocardial infarction and stroke (thromboembolic complications) in patients using COX-2 inhibitors compared to traditional NSAIDs. Hence, two COX-2 inhibitors namely rofecoxib and valdecoxib have been withdrawn.

### **Differences between Rheumatic Arthritis and Rheumatoid Arthritis (Table 9.9)**

**Q. Write short note on differentiation of rheumatic arthritis from rheumatoid arthritis.**

# SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

**Q. Discuss the clinical manifestations, diagnosis and management of systemic lupus erythematosus (SLE).**

- Systemic lupus erythematosus (SLE) is a chronic, **multisystemic autoimmune** disease that results from **immune system-mediated tissue damage** and is characterized by the presence of **broad spectrum of autoantibodies**.
- **Arthralgia and rashes** are the **most common clinical features**, whereas **cerebral and renal diseases** constitute **most serious problems**.

**Table 9.9:** Differences between rheumatic arthritis and rheumatoid arthritis.

	<i>Rheumatic arthritis</i>	<i>Rheumatoid arthritis</i>
Onset	Acute	Subacute/chronic
Joints involved	Major joints (e.g. knee), rarely involves small joints of hands/wrists/feet.	[Small joints, e.g. palm-finger (MCP) joints, joints of the wrist/feet]
Joints spared	Spares hip joints	Spares distal interphalangeal (DIP) joint
Spine	Not involved	C1, C2 involved
Presentation	Migratory	Non-migratory, static
Morning stiffness	+/-	+++
Pattern of involvement	Asymmetrical	Symmetrical
Cause	Poststreptococcal	Immune
Deformities	Rare (Jaccouds)	Common
Nodules	Rare, located only subcutaneously, painless	Common, painful, located periarticular, pleura, internal organs
Criteria used for diagnosis	Jones	ACR/EULAR
Antibodies	ASO	RF/ACPA
Treatment	Penicillin/aspirin +/- steroids	DMARDS/biologics
Other systems involved	Cardiac, basal ganglia	All systems involved

(ASO: antistreptolysin O; ACR: American College of Rheumatology; EULAR: European League against Rheumatism; RF: rheumatoid factor; ACPA: anticyclic citrullinated protein antibodies; DMARD: disease modifying antirheumatic drugs)

- **Age:** It usually occurs in young women between **20 to 30 years**, but may manifest at any age.
- **Sex:** It predominantly affects **women**, with female-to-male ratio of 9:1.

## Clinical Features (Table 9.10)

**Q.** Write short essay/note on clinical features of systemic lupus erythematosus (SLE).

**Table 9.10:** Common clinical manifestations of SLE.

System involved	%	Clinical manifestations	
		Common	Uncommon
<b>Systemic</b>	95	Fatigue, malaise, fever, anorexia, nausea, weight loss	Generalized lymphadenopathy
<b>Musculoskeletal</b>	95	Arthralgias/myalgias, non-erosive polyarthritis myopathy	Myositis
<b>Cutaneous</b>	80	Photosensitivity, malar rash ('butterfly' rash), oral ulcers, alopecia, discoid rash, Raynaud phenomenon, livedo reticularis, panniculitis, splinter hemorrhages	Angioedema, bullous lupus, cutaneous vasculitis thromboembolic manifestations
<b>Hematological</b>	85	Anemia, leukopenia (<4000/ $\mu$ L), lymphopenia (<1500/ $\mu$ L), thrombocytopenia (100,000/ $\mu$ L), lymphadenopathy, splenomegaly, hemolytic anemia	
<b>Neurologic</b>	60	Delirium, psychosis, seizures, mono/polyneuropathy, mood disorder, headache	Cranial neuropathy, chorea
<b>Cardiopulmonary</b>	60	Pericarditis/pericardial effusions, coronary artery disease, pleurisy/pleural effusions, lupus pneumonitis, pulmonary hypertension	Myocarditis, Libman-Sacks endocarditis, pulmonary hemorrhage
<b>Renal</b>	30 to 50	Proteinuria 500 mg/24 h, cellular casts, nephrotic syndrome, renal failure	
<b>Gastrointestinal</b>	40	Non-specific symptoms (nausea, mild pain, diarrhea), bleeding or perforation, abnormal liver enzymes	Mesenteric vasculitis (with or without ischemia), colitis, splenomegaly
<b>Thrombosis</b>	15	Venous and arterial	
<b>Ocular</b>	15	Sicca syndrome, conjunctivitis, episcleritis, retinal vasculitis	Optic neuritis, uveitis, retinitis

## ***Musculoskeletal Manifestations***

- Arthralgia and nonerosive arthritis are most common (> 85%). Commonly involves proximal interphalangeal and metacarpophalangeal joints of the hand, along with the knees and wrists.
- In about 10% of patients, **deformities result from damage to periarticular** tissue, a condition termed **Jaccoud's arthropathy**.

## ***Cutaneous Manifestations***

- **Classic malar rash** consists of erythematous (flat or raised) facial rash with a **butterfly distribution** across the malar and nasal prominences and sparing of the nasolabial folds (Fig. 9.3) and is seen in 30–60% of patients. Butterfly rash is **often triggered by sun exposure**.

**Fig. 9.3:** Systemic lupus erythematosus with malar rash and alopecia.

- **Discoid lupus** is a benign variant of lupus in which **only the skin is involved**. Discoid rash consists of erythematous, slightly raised patches with adherent keratotic scaling and follicular plugging. Discoid rash

without any systemic features occurs in discoid lupus erythematosus (DLE). Only 5% of patients with DLE have SLE; however, as many as 20% SLE patients have DLE. This rash is primarily seen on the face and scalp.

- Generalized photosensitivity (skin rash on exposure to sunlight) and alopecia.

### ***Mucous Membrane Manifestations***

Recurrent crops of small, painful ulcerations on the oral or nasal mucosa. Dryness secondary to Sjögren's syndrome.

### ***Hematologic Manifestations***

Antibodies that target each of the cellular blood elements are responsible for hematological changes.

- RBC: Normocytic normochromic **anemia**, reflecting chronic illness. **Hemolytic anemia:** Coombs' test positive or microangiopathic hemolysis.
- WBC: **Leukopenia**, particularly lymphopenia
- Platelets: **Idiopathic/immune thrombocytopenic purpura** induced by antiplatelet antibodies.
- Antibodies to clotting factors can contribute to impaired clot formation and hemorrhage.

### ***Renal Manifestations***

#### **Q. Write short note on renal manifestations of SLE.**

- Kidney may be **involved in 30–50%** of SLE patients and is one of the most important organs involved.
- **Often asymptomatic** in most lupus patients, particularly initially. Hence, **urinalysis should be done** in any person suspected of having SLE followed by regular urinalysis and blood pressure monitoring.
- Characterized by proteinuria (>500 mg/24 hours) and/or cellular (red cell) casts.
- Histological classification of lupus nephritis (Table 9.11).

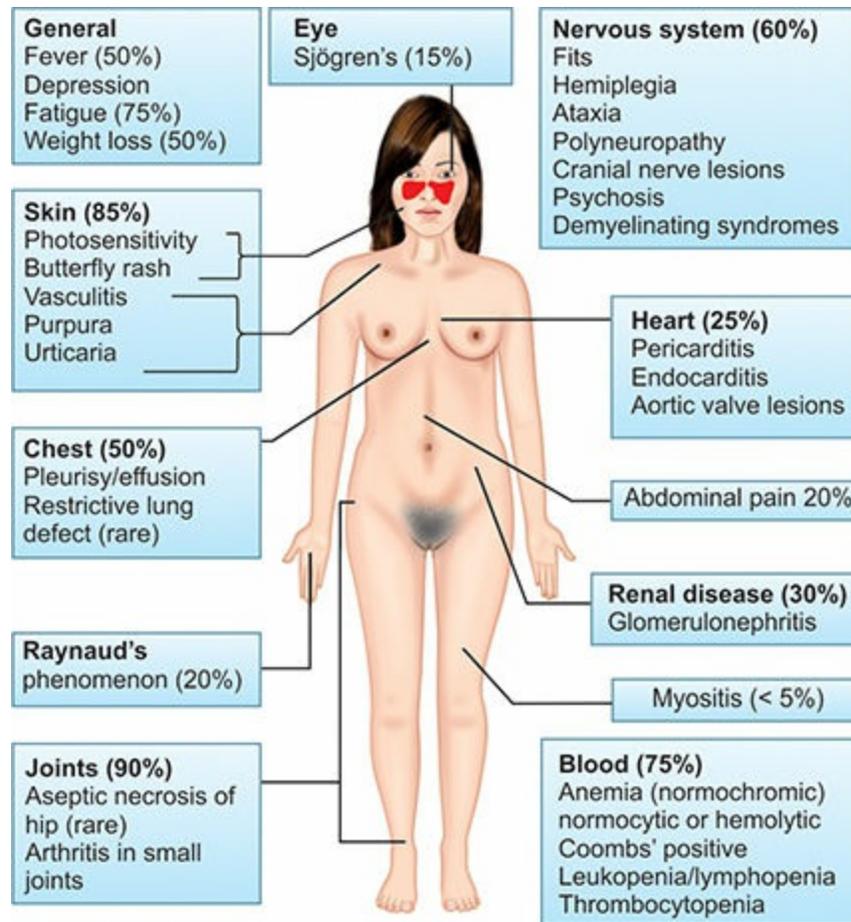

**Table 9.11:** ISN/RPS classification of lupus nephritis.

<i>Class</i>	<i>Histological type</i>
--------------	--------------------------

• I	Minimal mesangial lupus nephritis (Light microscopy: Normal glomeruli)
• II	Mesangial proliferative LN (few isolated subepithelial/endothelial deposits visible by IF or electron microscopy)
• III	Focal lupus nephritis (<50% glomeruli, subendothelial deposits)
– IIIA	Active lesions
– IIIA/C	Active and chronic lesions
– IIIC	Chronic lesions
• IV	Diffuse lupus nephritis >50% glomerul involved, segmental and global lesions
– IV–S (A)	Active lesions—Diffuse segmental proliferative lupus nephritis
– IV–G (A)	Active lesions—Diffuse global proliferative lupus nephritis
– IV–S (A/C)	Active and chronic lesions—Diffuse segmental proliferative and sclerosing lupus nephritis
– IV–G (A/C)	Active and chronic lesions—Diffuse global proliferative and sclerosing lupus nephritis
– IV–S (C)	Chronic in active lesions with scars—Diffuse segmental sclerosing lupus nephritis
– IV–G (C)	Chronic in active lesions with scars—Diffuse segmental global lupus nephritis
• V	Membranous lupus nephritis
• VI	Advanced sclerosing lupus nephritis

### ***Neuropsychiatric Features***

- Nervous system involvement in SLE produces both neurologic and psychiatric manifestations.
- Clinical features include cognitive dysfunction (due to SLE cerebritis), headache and seizures, psychiatric features including depression and psychosis. Peripheral nervous system involvement can cause neuropathy. Cranial nerve and ocular involvement due to vasculopathy.

**Fig. 9.4:** Clinical features of systemic lupus erythematosus (SLE).

### ***Cardiac Manifestations***

- **Pericarditis most frequent;** serious manifestations are myocarditis and **Libman-Sack** (noninfective endocarditis involving the mitral valve) endocarditis.
- **Increased risk for myocardial infarction,** usually due to accelerated atherosclerosis and vasculitis.

### ***Pulmonary Manifestations***

- **Pleural lesions:** Pleurisy with or without pleural effusion—most common pulmonary manifestation. Pleural effusion is exudative with low C3 and ANA test positive in the pleural fluid.
- **Lung lesions:** Pneumonitis (exclude infection before ascribing a lung lesion to SLE), shrinking lung syndrome, interstitial inflammation leading to fibrosis and intra-alveolar hemorrhage.

## ***Gastrointestinal Features***

Non-specific diffuse abdominal pain (caused by autoimmune peritonitis and/or intestinal vasculitis), nausea sometimes with vomiting and diarrhea. Increases in serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT). Mesenteric vasculitis can cause infarction or perforation of small intestine.

### **Box 9.5:** Causes of death in SLE.

- **Infections and renal failure:** Cause of death in the first decade of disease
- **Thromboembolic events:** Cause of death in the second and later decades
- **Cardiovascular:** Due to premature atherosclerosis

## ***Ocular Manifestations***

- Sicca syndrome (Sjögren's syndrome) and nonspecific conjunctivitis are common.
- Serious manifestations are retinal vasculitis (can cause infarcts and cytoid bodies) and optic neuritis. Complications of glucocorticosteroid therapy include cataracts (common) and glaucoma.

## ***Other Manifestations***

Kikuchi-Fujimoto disease (splenomegaly, lymphadenopathy), antiphospholipid syndrome, osteoporosis, and complement deficiencies are associated with SLE. Increased risk of hematologic malignancies (particularly non-Hodgkin's lymphoma) and possibly lung and hepatobiliary cancers.

Clinical features are summarized diagrammatically in Figure 9.4. Causes of death in SLE are listed in Box 9.5.

## **Laboratory Findings**

**Purpose:** (1) To establish or rule out the diagnosis, (2) follow the course of disease, and (3) to identify adverse effects of therapies.

## ***Autoantibodies in SLE***

**Q.** Write short essay/note on the various autoantibodies in systemic lupus erythematosus (SLE).

- SLE is characterized by the production of **several diverse autoantibodies**.

Some antibodies are against different nuclear and cytoplasmic components of the cell that are not organ specific. Other antibodies are directed against specific cell surface antigens of blood cells.

- **Importance of autoantibodies:** (1) **Diagnosis and management** of patients with SLE, and (2) responsible for **pathogenesis of tissue damage**.

**Table 9.12:** Autoantibodies in patients with systemic lupus erythematosus (SLE).

<ul style="list-style-type: none"> <li>• Antinuclear antibodies (ANA)</li> <li>• Anti-dsDNA (ds = double stranded)</li> <li>• Anti-Sm (Anti-Smith)</li> <li>• Anti-RNP</li> <li>• Anti-Ro (SSA)</li> <li>• Anti-La (SSB)</li> </ul>	<ul style="list-style-type: none"> <li>• Antihistone</li> <li>• Antiphospholipid</li> <li>• Antierythrocyte</li> <li>• Antiplatelet</li> <li>• Antineuronal</li> <li>• Antiribosomal</li> </ul>
---	---

#### *Types of antibodies (Table 9.12)*

- **Antinuclear antibody (ANA):** Best screening test and > 90% of the patients show a positive test. However, a positive test is not specific for SLE. It can be positive in some normal individual (especially elderly), other autoimmune diseases, acute viral infections, chronic inflammatory processes and with certain drugs.
- **Anti-double-stranded DNA (Anti-dsDNA)** antibodies are common in SLE. **Anti-Sm antibodies are highly specific** for SLE. Rising levels of anti-dsDNA and low levels of complement (C3 and C4) usually reflect disease activity.
- **Rheumatoid factor** is positive in 30%.

#### *Other Tests*

- **Complete blood count:** Essential and aids in diagnosis and management. **Anemia** (normocytic normochromic and Coombs' positive), **leucopenia**, **lymphopenia** and **thrombocytopenia** may be present.
- **Activated partial thromboplastin time (aPTT):** **Prolonged** in the presence of pathogenic **antiphospholipid antibodies**. These antibodies give a false-positive result in the serologic test for syphilis.
- **Erythrocyte sedimentation rate (ESR):** Nonspecific indicator of systemic inflammation. It is often monitored in many patients to know the

disease activity.

- **C-reactive protein (CRP):** It is an acute phase reactant which is relatively uninformative and normal in SLE. It does not usually rise with disease activity unless there is infection, arthritis or serositis.
- **Urinalysis:** When there is active nephritis, urinalysis shows proteinuria, hematuria and cellular (red and white blood cell casts in the urinary sediment suggest proliferative GN) or granular casts. Blood urea nitrogen and serum creatinine are elevated in acute kidney injury. If there is proteinuria, urine albumin/creatinine ratio should be measured. Renal biopsy confirms renal involvement.
- **Complement levels:** Low levels of C3 indicate active disease especially nephritis.
- **LE cell:** Phagocytic leukocyte (neutrophil or macrophage) that has engulfed the denatured nucleus of an injured cell is positive. Rarely done nowadays.

### **Imaging**

- Chest X-ray: To exclude other pathology, for cardiac size and in lung disease.
- High resolution CT: To demonstrate fibrotic lung.
- Magnetic resonance imaging (MRI) of brain or spinal cord in cases with central nervous system disease involvement.

## **Diagnostic Criteria for Systemic Lupus Erythematosus**

**Q. Write short essay/note on diagnostic criteria/revised American Rheumatism Association criteria for systemic lupus erythematosus (SLE).**

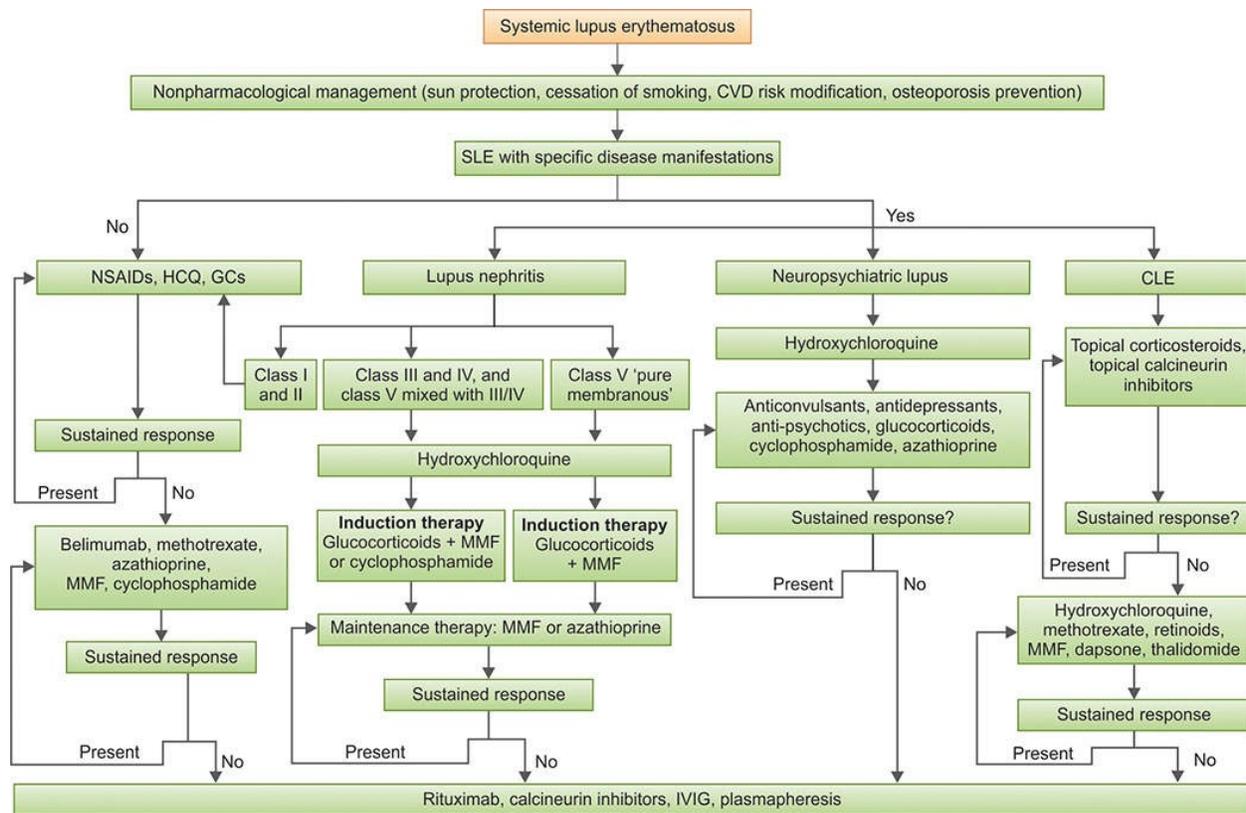

The clinical presentation of SLE is so variable that the American College of Rheumatology has established a complex set of criteria (Table 9.13). The presence of 4 of the 11 ACR criteria yields a sensitivity of 85% and a specificity of 95% for SLE.

**Table 9.13:** Revised criteria for classification of systemic lupus erythematosus (American College of Rheumatology Criteria): 1997.

<b>Criteria</b>	<b>Description</b>
1. Malar rash	Fixed erythema, flat or raised, over the malar eminences tending to spare the nasolabial folds
2. Discoid rash	Erythematous raised patches with adherent keratotic scaling and follicular plugging
3. Photosensitivity	Skin rash as a result of unusual reaction to sunlight, by patient history or physician observation
4. Oral ulcers	Oral or nasopharyngeal ulceration, usually painless, observed by physician
5. Arthritis	Non-erosive arthritis involving two or more peripheral joints
6. Serositis	Pleuritis or pleural effusion or Pericarditis or pericardial effusion
7. Renal disorder	Persistent proteinuria >0.5 g/day or >3 + if quantitation not performed or cellular casts (red blood cell, hemoglobin, granular, tubular, or mixed)
8. Neurologic disorder	Seizures: In the absence of offending drugs or known metabolic derangements (e.g. uremia, ketoacidosis, or electrolyte imbalance) or Psychosis: In the absence of offending drugs or known metabolic derangements
9. Hematologic disorder	Hemolytic anemia with reticulocytosis or leucopenia (<4000/mm <sup>3</sup> ) total on two or more occasions or lymphopenia (<1500/mm <sup>3</sup> ) on two or more occasions or thrombocytopenia (<1,00,000/mm <sup>3</sup> ) in the absence of offending drugs
10. Immunologic disorder	Anti-DNA antibody to native DNA in abnormal titer, or Anti-Sm—presence of antibody to Sm nuclear antigen, or Positive finding of antiphospholipid antibodies based on: (1) an abnormal serum level of IgG or IgM anticardiolipin antibodies, (2) a positive test for lupus anticoagulant using a standard test, or (3) a false-positive serologic test for syphilis known to be positive for at least 6 months and confirmed by negative <i>Treponema pallidum</i> immobilization or fluorescent treponemal antibody absorption test
11. Antinuclear antibody	An abnormal titer of antinuclear antibody by immunofluorescence or an equivalent assay at any point in time and in the absence of drugs known to be associated with drug-induced lupus syndrome

*Presence of any four or more criteria of the 11 (serially or simultaneously, during any period of observation) is diagnostic of SLE.*

**Flowchart 9.2:** Treatment algorithm for systemic lupus erythematosus.

(NSAIDs: nonsteroidal anti-inflammatory drugs; HCQ: hydroxychloroquine; GCs: glucocorticoids; CLE: cutaneous lupus erythematosus; MMF: mycophenolate mofetil)

## Management (Flowchart 9.2)

### Q. Write short essay/note on management of systemic lupus erythematosus.

#### General

- To avoid known triggers of disease exacerbation, such as ultraviolet light, smoking cessation.
- Need for adequate rest.

#### Conservative therapies for management of non-life-threatening disease

In patients with fatigue, pain, and autoantibodies of SLE, but without major organ involvement are managed by analgesics (NSAIDs), antimalarials (**hydroxychloroquine**, chloroquine, and quinacrine) and **low-dose corticosteroids**. Skin lesions and arthritis also respond to hydroxychloroquine. Photosensitive skin lesions need application of sun-screen lotions.

#### Life-threatening SLE: Proliferative forms of lupus nephritis

- Life-threatening SLE or patients with severe symptoms should receive **corticosteroids**.
- Acutely ill patients and patients with active proliferative glomerulonephritis may be treated with prednisone at 60 mg daily or 1 g of intravenous methylprednisolone administered daily for 3 days.
- **Immunosuppressive agents:** These include azathioprine, methotrexate, cyclophosphamide, mycophenolate mofetil and are also useful in controlling severe disease. They are particularly useful in patients with renal involvement. A combination of intravenous cyclophosphamide and steroids is the most effective regimen. Following intravenous cyclophosphamide, oral mycophenolate mofetil is an alternative to maintain remission. Drugs targeting B-cell pathways, such as belimumab and rituximab are used in refractory cases.

**Systemic Lupus International Collaborating Clinics (SLICC) Classification 2012 criteria\*** (Table 9.14).

**Table 9.14:** Systemic Lupus International Collaborating Clinics (SLICC) Classification 2012 criteria.

*Lupus nephritis proved by biopsy and ANA or anti-DNA or at least 4 criteria (1 needs to be immunological)*

<b>Clinical</b>	<b>Immunological</b>
• Acute cutaneous LE	• ANA
• Chronic cutaneous LE	• Anti-dsDNA
• Oral ulcer	• Anti-Sm
• Alopecia	• aPL antibodies
• Synovitis	• Low complement
• Serositis	• Direct Coombs' test positive
• Renal	
• Neurologic	
• Hemolytic anemia	
• Leukopenia/lymphopenia	
• Thrombocytopenia	

Differences between rheumatoid arthritis and systemic lupus erythematosus are presented in Table 9.15.

**Table 9.15:** Differences between rheumatoid arthritis and systemic lupus erythematosus.

<b>Features</b>	<b>Rheumatoid arthritis</b>	<b>Systemic lupus erythematosus</b>
Smoking	Predisposing factor	No relation
Female:Male	3:1	9:1
Type of arthritis	Erosive	Non-erosive
Deformities	Common	Rare, Jaccoud's arthropathy (10%)
Systemic involvement	Relatively less	Marked
Nodules	Rheumatoid nodules	Absent
Malar (skin) rash	Nil	Striking feature: malar rash, discoid rash

Photosensitivity	Absent	Photosensitivity present
Oral ulcer and alopecia	Absent	Present
Spine involvement	Involves cervical spine	Rare
Pyoderma gangrenosum	May develop	Rare
Renal involvement	Uncommon	Common and severe
Platelet abnormality	Thrombocytopenia	Thrombocytopenia
Serology	RA factor and ACPA	ANA and anti-dsDNA
Criteria for diagnosis	ACR/EULAR	SLICC/ACR
Response to DMARDs	Present	Less response

(ACPA: anticyclic citrullinated peptide antibodies; ANA: antinuclear antibodies; ds: double stranded; ACR: American college of rheumatology; EULAR: European league against rheumatism; SLICC: systemic lupus international collaborating clinics (SLICC) classification)

## Drug-induced Lupus

### **Q. Write short essay/note on drug-induced lupus.**

It is a syndrome consisting of positive ANA associated with symptoms such as fever, malaise, arthritis or intense arthralgias/myalgias, serositis, and/or rash.

**Etiology:** The syndrome develops during therapy with certain medications and includes:

- **Drugs:** Antiarrhythmics (e.g. procainamide, diltiazem, disopyramide, and propafenone), antihypertensive (e.g. hydralazine), methyl dopa, angiotensin-converting enzyme inhibitors, beta blockers, antithyroid propylthiouracil, antipsychotics (e.g. chlorpromazine and lithium), anticonvulsants (e.g. carbamazepine and phenytoin), antibiotics (e.g. isoniazid, minocycline, and macrodantin), antirheumatic (e.g. sulfasalazine), diuretic (e.g. hydrochlorothiazide) and antihyperlipidemics (e.g. lovastatin and simvastatin).
- **Biologic agents:** Interferons and TNF inhibitors.

**Symptoms:** Usually resolve after discontinuation of the offending drug.

Box 9.6 lists the features that differentiates drug-induced lupus from SLE.

**Box 9.6:** Features that differentiate drug-induced lupus from SLE.

Drug-induced lupus

- Less female predilection than SLE
- Kidneys or brain involvement rare, less cutaneous involvement.
- Antinuclear antibodies positive; antihistone antibodies positive (95%); autoantibodies to dsDNA absent
- C<sub>3</sub> levels normal

# SPONDYLOARTHROPATHIES (SPONDYLOARTHRITIDES) (SPAS)

**Q.** Write short essay/note on spondyloarthropathies.

**Q.** Write short essay/note on seronegative spondyloarthropathies (SSA).

**Definition:** The spondyloarthropathies (SpAs) are a **group of related inflammatory joint diseases** (Box 9.7) that **share clinical features and genetic susceptibility**.

**Box 9.7:** Diseases included under spondyloarthropathies (SpAs).

1. Ankylosing spondylitis (AnS)
2. Reactive arthritis (ReA) (including Reiter's syndrome)
3. Psoriatic arthritis (PsA)
4. Arthropathy associated with inflammatory bowel disease
5. Undifferentiated spondyloarthritis

## Common Features of SpAs

The similarities in clinical features and genetic predisposition suggest that these disorders share pathogenic mechanisms.

### 1. Common clinical features:

- Strong predilection for the **spine**, in particular the **sacroiliac joints**. **Inflammatory back pain** due to sacroiliitis and spondylitis.
- **Tendency for new bone formation** at sites of chronic inflammation, with **joint ankylosis** as a consequence.
- If **peripheral arthritis** occurs, it is usually in the **lower extremity and asymmetrical**.
- **Predilection for sites of tendon insertion into bone (enthesitis)**. **Enthesitis** is inflammation at sites where tendons, ligaments or joint capsules attach to bone and is one of the **most specific clinical manifestations** of the SpAs.
- RF negative; hence, known as '**seronegative**'.

### 2. Common genetic predisposing factor: All subsets have an association with **HLA-B27 allele**.

## Ankylosing Spondylitis

**Q.** Write short essay/note on ankylosing spondylitis, rheumatoid spondylitis or Bekhterev-Strümpell-Marie disease.

Ankylosing spondylitis (AnS) is a chronic inflammatory disorder of unknown causes that primarily affects the axial skeleton (predominantly sacroiliac joints and spine). The peripheral joints and extra-articular structures are also

frequently involved.

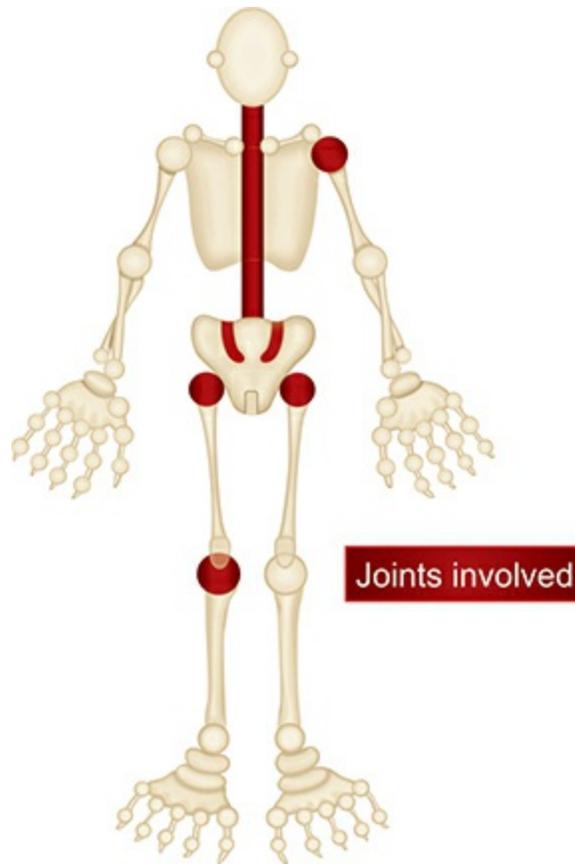

**Age and gender:** Usually begins in the second or third decade; male to female ratio is between 2:1 and 3:1.

### ***Clinical Features***

**Targets in ankylosing spondylitis** (Fig. 9.5): Mainly involves spine, sacroiliac joints and large peripheral joints in an asymmetrical pattern.

#### *Involvement of lumbar spine*

- Classical presentation is the **insidious onset of inflammatory low back pain**. The pain is dull and located in the lower lumbar regions or gluteal region and shows nocturnal exacerbation.
- Back pain persists for > 3 months. It is accompanied by **early-morning stiffness** that typically **improves with activity/exercise** and **exacerbated by inactivity**.
- **Physical examination:** Physical examination of the spine shows loss of spinal mobility in all directions and pain on sacroiliac stressing.
- **Modified Schober test:** Used to measure lumbar spine flexion. The patient stands upright with heels together. Two marks are made on the spine; one at the lumbosacral junction (identified by a horizontal line between the posterosuperior iliac spines) and other 10 cm above. The patient then bends forward maximally with knees fully extended. The distance between the two marks is measured. This distance increases by >5 cm in the case of normal mobility and by <4 cm in the case of decreased mobility.

**Fig. 9.5:** Pattern of joint involvement in ankylosing spondylitis.

### *Involvement of sacroiliac joint*

The tests mentioned below produce stress and pain in the sacroiliac joint.

- **Patrick's test** (figure of 4 test): Pain in the sacroiliac joints may be elicited either by direct pressure or by maneuvers that stress the joint, namely, Patrick's test. One leg is guided into 'figure of 4' position with the ipsilateral ankle resting across the contralateral thigh. The ipsilateral knee is then pressed downwards with one hand while providing counter pressure with the other hand on the contralateral anterior superior iliac spine.
- **FABER (flexion abduction external rotation) maneuver:** Patient lies supine while the examiner flexes and externally rotates the hip.
- **Gaenslen's maneuver:** The examiner extends the hip by letting the leg dangle off the side of the examining table.
- Occiput to wall test (**Flesch test**): Normally zero, in AnS it is increased.

### *Peripheral joints-enthesitis*

- Enthesitis is inflammation at the sites of tendon/ligament insertions.
- **Heel pain** due to inflammation at the **Achilles tendon** (Achilles tendinitis) and **plantar fascia** (plantar fasciitis) at calcaneal insertions is common. Like arthritis, enthesitis is also aggravated by rest and improved with activity.
- Other sites of enthesitis include superior and inferior aspects of patella, metatarsal heads and spinal ligament insertions on vertebral bodies.

#### *Other sites*

- Involvement of the thoracic spine, costovertebral joints and costosternal joints leads to chest pain, reduced expansion of chest (<5 cm) and thoracic kyphosis.
- Involvement of the cervical spine produces neck pain and a forward stoop of the neck.
- Peripheral arthritis usually occurs late and asymmetric. Involvement of hips and shoulders result in pain and limitation of movement.
- **Dactylitis (sausage digits)** is characterized by diffuse swelling of toes or fingers.

#### *Extra-articular manifestations (Table 9.16)*

**Table 9.16:** Extra-articular manifestations of ankylosing spondylitis.

<ul style="list-style-type: none"> <li>• Acute anterior uveitis (Iritis)</li> <li>• Inflammatory bowel disease</li> <li>• Aortic insufficiency, cardiac conduction defects and heart failure</li> <li>• Psoriasis</li> <li>• Pulmonary fibrosis and cavitation (apical)</li> </ul>	<ul style="list-style-type: none"> <li>• Osteoporosis</li> <li>• Myelopathy secondary to atlantoaxial subluxation and spinal fracture</li> <li>• Cauda equina syndrome</li> <li>• Amyloidosis</li> </ul>
--	--

#### ***Investigations***

- Erythrocyte sedimentation rate (ESR) and C-reactive protein: Raised.
- Tests for rheumatoid factor (RF): Negative.
- Anti-cyclic citrullinated peptide (CCP) and antinuclear antibodies (ANAs): Negative.
- **HLA-B27: Present in > 90% cases.** High sensitivity and specificity.
- MRI and bone scan: They can detect early sacroiliitis.

## *Radiographic Findings*

### *X-ray*

- **Sacroiliac joint:** The medial and lateral cortical margins of both sacroiliac joints lose definition owing to erosions. They show irregularity and loss of cortical margins (blurring of the cortical margins of the subchondral bone), erosions in the joint line, and ‘pseudowidening’ of the joint space. Subsequently, it shows subchondral sclerosis, joint space narrowing and fusion, bony ankylosis reflecting complete bony replacement of the sacroiliac joints.
- **Lumbar spine:** Radiographs of the spine may show anterior ‘**squaring**’ (loss of the normal anterior concavity of the lumbar vertebra), ‘shiny corners’ (subchondral sclerosis at the upper edge of the vertebral body), or even ‘barreling’ of one or more vertebral bodies due to erosion and sclerosis of the anterior corners of vertebrae with subsequent erosion. These are manifestations of enthesitis.
  - **Bridging syndesmophytes** are areas of calcification that follow the outermost fibers of the annulus and may also be seen in AS. Progressive ossification may lead to formation of **marginal syndesmophytes** make the diagnosis clear. They are observed as bony bridges connecting successive vertebral bodies anteriorly and laterally. In advanced disease, ossification of the anterior longitudinal ligament and facet joint fusion may also be seen. Eventually, the changes may result in a ‘**bamboo spine**’ (Fig. 9.6), so called because the multiple bridging syndesmophytes (bridging the intervertebral spaces) can mimic the appearance of bamboo.

**Fig. 9.6:** Bamboo spine in ankylosing spondylitis.

- Diffuse osteoporosis of spine and atlantoaxial dislocation can be seen as late feature. Erosive changes may be observed in the symphysis pubis, the ischial tuberosities and peripheral joints.

### ***Magnetic Resonance Imaging (MRI)***

MRI is **much more sensitive** for detection of early sacroiliitis than X-ray and can also detect inflammatory changes in the lumbar spine.

### ***Diagnostic Criteria (Box 9.8)***

#### **Management**

- Early diagnosis is important to maintain posture and range of motion.
- Regular exercises is started with active and passive physiotherapy before syndesmophytes have formed.
- Symptomatic relief of pain and stiffness can be obtained with long-acting or slow-release NSAID or an NSAID suppository improves sleep, peripheral arthritis and enthesitis are managed with NSAIDs or local steroid injections. Indomethacin is the most effective drug and may be given up to a maximum dose of 100 mg/day. Systemic glucocorticoids have limited role.
- **Sulfasalazine and methotrexate** are useful to control effective for peripheral arthritis but not for spinal disease.
  - Peripheral arthritis and enthesitis are managed with NSAIDs or local steroid injections. Rarely systemic corticosteroids may be necessary.

**Box 9.8:** Modified New York Criteria (1984) for ankylosing spondylitis.

#### ***Clinical criteria***

- Low back pain and stiffness for >3 months that improve with exercise but are not relieved by rest
- Limitation of motion of the lumbar spine in both sagittal and frontal planes
- Limitation of chest expansion

### **Radiologic criteria**

- Sacroilitis: Grade  $\geq 2$  bilateral or grade 3 or 4 unilateral

### **Grading**

Definite AS (ankylosing spondylitis) if the radiologic criterion is associated with at least one clinical variable

Probable ankylosing spondylitis (AS) if:

- The three clinical criteria are present
- The radiologic criterion is present without the clinical criteria

### **Anti-tumor necrosis factor therapy**

Biologic agents, such as monoclonal antibodies to TNF- $\alpha$  (**infliximab, adalimumab, certolizumab, golimumab**) or the soluble TNF receptor (**etanercept**) are options for patients with active ankylosing spondylitis who are not satisfactorily responded to NSAIDs. Duration of treatment is 2–3 years.

#### *Dosage*

- Infliximab: 3–5 mg/kg body weight intravenously every 6–8 weeks.
- Etanercept: 25 mg subcutaneously twice a week initially/50 mg once weekly.
- Adalimumab: 40 mg biweekly by subcutaneous injection.
- Golimumab: 50 or 100 mg every 4 weeks, given by subcutaneous injection.

#### *Others*

- Reconstructive surgery
- Pamidronate
- Control of uveitis by local steroid drugs.

## **Reactive Arthritis**

**Q. Write short essay/note on reactive arthritis and its causes.**

**Q. Write a short note on Reiter's syndrome.**

- Reactive arthritis (ReA) refers to **acute nonpurulent arthritis** (aseptic arthritis) **complicating an extra-articular infection** elsewhere in the body, most typically enteric (GIT) or urogenital (GU tract) infections.
- **Classical triad of Reiter's syndrome** is (1) **nonspecific urethritis**, (2) **conjunctivitis** and (3) **arthritis**. However, the term is no longer in common use.

## ***Etiology***

- **GIT infections:** Common enteric organisms that trigger include *Salmonella typhimurium*, *Shigella flexneri* and *Yersinia enterocolitica*.
- **GUT infection:** Common urogenital organisms are *Chlamydia trachomatis* or *Ureaplasma urealyticum*.
- More than 75% of ReA patients have the histocompatibility antigen HLA-B27.

## ***Clinical Features***

- **Age and gender:** Predominantly a disease of young (18–40 years) men, with a male preponderance of 15:1.
- **Constitutional symptoms** are common and include fatigue, malaise, fever, and weight loss.
- **Arthritis:** Arthritis is typically an acute, asymmetrical, lower limb (e.g. knees, ankles, midtarsal and MTP joints) arthritis and occurs 1 to 3 weeks after the GIT or GUT infection, arthritis usually persists for 3–5 months. Enthesitis is common.
- **Dactylitis** or ‘**sausage digit**,’ is a diffuse swelling of a solitary finger or toe may also be seen. It is the result of inflammatory changes affecting the joint capsule, entheses, periarticular structures, and periosteal bone.
- Sacroiliitis may be seen in 25% patients.
- **Extra-articular features**
  - **Urogenital lesions:** Urethritis and prostatitis in males, cervicitis or salpingitis in females.
  - **Mucocutaneous lesions:** *Circinate balanitis* (a painless erythematous lesion of the glans penis), *keratoderma blennorrhagica* (hyperkeratotic lesions on the palms of the hands or the soles of the feet) and nail dystrophy.
  - **Ocular disease:** Common and includes conjunctivitis, anterior uveitis and acute iritis.
  - **Others:** Cardiac conduction defects, aortic regurgitation, central or peripheral nervous system lesions, and pleuropulmonary infiltrates.
- Usually a self-limiting course of 3–12 months. About 50% of patients develop recurrent bouts of arthritis and 15–30% develop chronic arthritis

or sacroiliitis.

## ***Investigations***

- Erythrocyte sedimentation rate (**ESR**) and acute-phase reactants: Usually **raised**.
- **Peripheral blood:** Anemia and polymorphonuclear leukocytosis.
- **Synovial fluid:** Characteristic synovial fluid is **leucocyte-rich** (> 2000 white blood cells/mL with a predominance of neutrophils) and may contain multinucleated macrophages (Reiter's cells).
- **HLA-B27: Positive** in more than 75% of cases.
- Serum tests for rheumatoid factor and antinuclear antibodies: Negative.
- **Urethritis:** Confirmed in the 'two-glass test' by demonstration of mucoid threads in the first-void specimen that clears in the second specimen.

## ***Radiological features***

- Shows periarticular osteoporosis, joint space narrowing and proliferative erosions in chronic or recurrent disease.
- Periostitis, especially of metatarsals, phalanges and pelvis, and large, 'fluffy' calcaneal spurs at the insertion of the plantar fascia.
  - Sacroiliitis (less common than ankylosing spondylitis) is often asymmetrical and sometimes unilateral.
  - Syndesmophytes are predominantly coarse and asymmetrical, often extending beyond the contours of the annulus ('non-marginal').

## **Management**

- **Acute attack:**
  - Treated with rest, oral NSAIDs and analgesics. Indomethacin, 75–150 mg/d in divided doses, is the initial treatment of choice.
  - Intra-articular or local steroid injections and rarely systemic steroids in severe cases.
- **Non-specific chlamydial urethritis:** Treated with **doxycycline or ciprofloxacin** or a single dose of azithromycin course.
- No role of antibiotics in reactive spondyloarthritis secondary to enteric infections.
- **Sulfasalazine, azathioprine and methotrexate** may be useful in patients with disabling relapsing and remitting arthritis.
- **DMARDs:** For patients with persistent marked symptoms, recurrent arthritis or severe keratoderma blennorrhagica.
- Anterior uveitis is a medical emergency and treated by topical, subconjunctival or systemic corticosteroids.
- **TNF- $\alpha$  blocking agents** are the drugs of next choice in severe and persistent disease.

## Psoriatic Arthritis

### **Q. Write short note on psoriatic arthritis.**

- Psoriatic arthritis (PsA) is a seronegative inflammatory arthritis that characteristically occurs in patient with psoriasis, a past or family history of psoriasis or with characteristic nail changes.
- Occurs in about 7–20% of patients of psoriasis.

**Types:** Wright and Moll described five patterns of psoriatic arthritis (Box 9.9)

Newer pattern of psoriatic arthritis is described in **HIV patients**.

### **Box 9.9:** Patterns of psoriatic arthritis.

1. Asymmetric inflammatory oligoarthritis
2. Symmetric polyarthritis similar to RA (rheumatoid arthritis)
3. Arthritis of the DIP (distal interphalangeal) joints
4. Psoriatic spondylitis
5. Arthritis mutilans

## ***Clinical Features***

It presents with pain and swelling affected joints and enthesitis.

- **Asymmetrical inflammatory oligoarthritis:** Most characteristically occur in the hands and feet, when synovitis is associated with tenosynovitis, enthesitis and inflammation of intervening tissue resulting in a **‘sausage-shaped digit’ or dactylitis**. Usually, less than four joints are involved (oligoarthritis).
- **Symmetrical polyarthritis:** It is more common in women and may strongly resemble RA.
- **Arthritis of the DIP joints:** Uncommon and affects men more than women. It involves finger DIP joints and surrounding periarticular tissues, and is accompanied by nail dystrophy.
- **Psoriatic spondylitis:** Presents similar to AS but with less severe involvement. It is typically unilateral or asymmetric in severity.
- **Arthritis mutilans** is a severe, deforming erosive arthritis accompanied by prominent cartilage and bone destruction results in marked instability of fingers and toes. The encasing skin appears invaginated and ‘telescoped’ and the finger can be pulled back to its original length.

**Skin lesions:** Characteristic skin lesion of psoriasis may be present (refer page 1155).

**Nail changes (Fig. 9.7):** Psoriatic nail dystrophy, onycholysis, pitting, and hyperkeratosis observed in nearly 80% patients with arthritis.

**Fig. 9.7:** Sausage digits in psoriatic arthritis and psoriatic nails.

**Uveitis:** Unilateral or bilateral and generally chronic.

**Table 9.17:** Distinguishing clinical features of psoriatic arthritis from rheumatoid arthritis.

	<i>Psoriatic arthritis</i>	<i>Rheumatoid arthritis</i>
Psoriasis	+	-
Symmetric involvement	+	++
Asymmetric involvement	++	+
Enthesopathy	+	-
Dactylitis	+	-
Nail dystrophy, psoriatic skin lesions	+	-
HIV association	+	-
DIP (distal interphalangeal) involvement	+	-
Inflammatory LBA (low backache)	+	-
Sacroiliac joint involvement	+	-

(+: present; -: absent)

## **Diagnosis**

- Acute phase reactants (ESR and CRP): Raised in active disease.
- Rheumatoid factor and antinuclear antibodies: Negative.
- Radiological findings: May be normal or show erosive change with joint space narrowing similar to those of RA, but osteoporosis is relatively less common. Distal interphalangeal joints may show **'pencil-in-cup' changes** (Fig. 9.8) because of marked resorption of bone. Other findings include enthesitis with periosteal reaction, sacroiliitis and spondylitis.
- MRI and ultrasound with power Doppler are used to detect synovial inflammation and inflammation at the enthuses (enthesitis).

Distinguishing clinical features of psoriatic arthritis from rheumatoid arthritis (Table 9.17).

**Fig. 9.8:** X-ray of hand shows pencil-in-cup appearance in psoriatic arthritis.

## **Management**

- NSAIDs and analgesics may be sufficient to control symptoms in mild disease.
- Local synovitis may be treated by intra-articular corticosteroid injections.
- DMARDs for persistent synovitis unresponsive to conservative treatment. Sulfasalazine or methotrexate slows the development of joint damage.

- Anti-TNF- $\alpha$  agents (e.g. etanercept, golimumab, infliximab and adalimumab) should be considered for patients with active synovitis who respond inadequately to standard DMARDs.
- Hydroxychloroquine must be avoided as it can cause exfoliative skin reactions.
- **Alefacept** is a fusion protein of soluble lymphocyte function antigen 3 with Fc fragments of IgG1. It is used for moderate-to-severe psoriasis and associated arthritis.

## Enteropathic Arthritis

### **Q. Write short essay/note on spondyloarthropathy associated with inflammatory bowel disease.**

- Also called as enteropathic arthritis associated with inflammatory bowel disease (ulcerative colitis and Crohn's disease).
- An acute inflammatory oligoarthritis occurs in 10–20% of patients with inflammatory bowel disease (IBD).
- More often in patients with Crohn's disease than in those with ulcerative colitis.

### ***Clinical Features***

#### *Peripheral arthritis*

- The arthritis is asymmetrical, inflammatory, nonerosive polyarthritis and mainly involves lower-limb joints (knees, ankles, hips).
- The clinical activity of the peripheral arthritis parallels the activity of the gut inflammation. Effective treatment of the GI disease usually controls the joint disease as well.
- It is not associated with HLA-B27 and follows a transient course.

#### *Sacroiliitis*

- It is clinically and radiologically similar to classic AS.
- It can manifest before or after the onset of IBD and there is no correlation between activity of the spondylitis and bowel disease.
- HLA-B27 is found in 50% of patients and it follows a chronic course.

**Others:** Enthesitis, dactylitis and extra-articular manifestations of IBD.

#### **Treatment**

- NSAIDs to be used cautiously because they may worsen diarrhea.
- A monoarthritis is treated by intra-articular corticosteroids.
- Sulfasalazine more effective as it may help both bowel and joint disease. Azathioprine and methotrexate may also be used.

- TNF- $\alpha$  blocking drug infliximab used for IBD can help the arthritis.

## Differences between inflammatory and mechanical low back pain (LBP) (Table 9.18)

**Q. What features in the history and physical examination are helpful in differentiating inflammatory LBP in AS from mechanical LBP?**

### Seronegative Arthritis

**Q. Write short note on seronegative arthritis and its causes.**

Arthritis can be divided into seropositive and seronegative.

- Seropositive arthritis refers to the presence of rheumatoid factor and anti-CCP in the blood.
- Seronegative arthritis generally called ‘seronegative spondyloarthropathy’ and include ankylosing spondylitis, psoriatic arthritis and reactive arthritis.

## VASCULITIS

**Q. Define and classify vasculitis.**

**Definition:** Vasculitis refers to a heterogeneous group of disorders that is characterized by destructive inflammation of blood vessel walls. The lumen of the inflamed blood vessels is liable to occlude or rupture or develop a thrombus, and this is associated with ischemia of the tissues supplied by the involved vessel.

### Classification (Fig. 9.9)

Vasculitis may involve a single organ (e.g. skin), or it may involve several organ systems. One of the basis for classifying the vasculitides is the size of the predominant blood vessels involved (Box 9.10).

### Clinical Manifestations

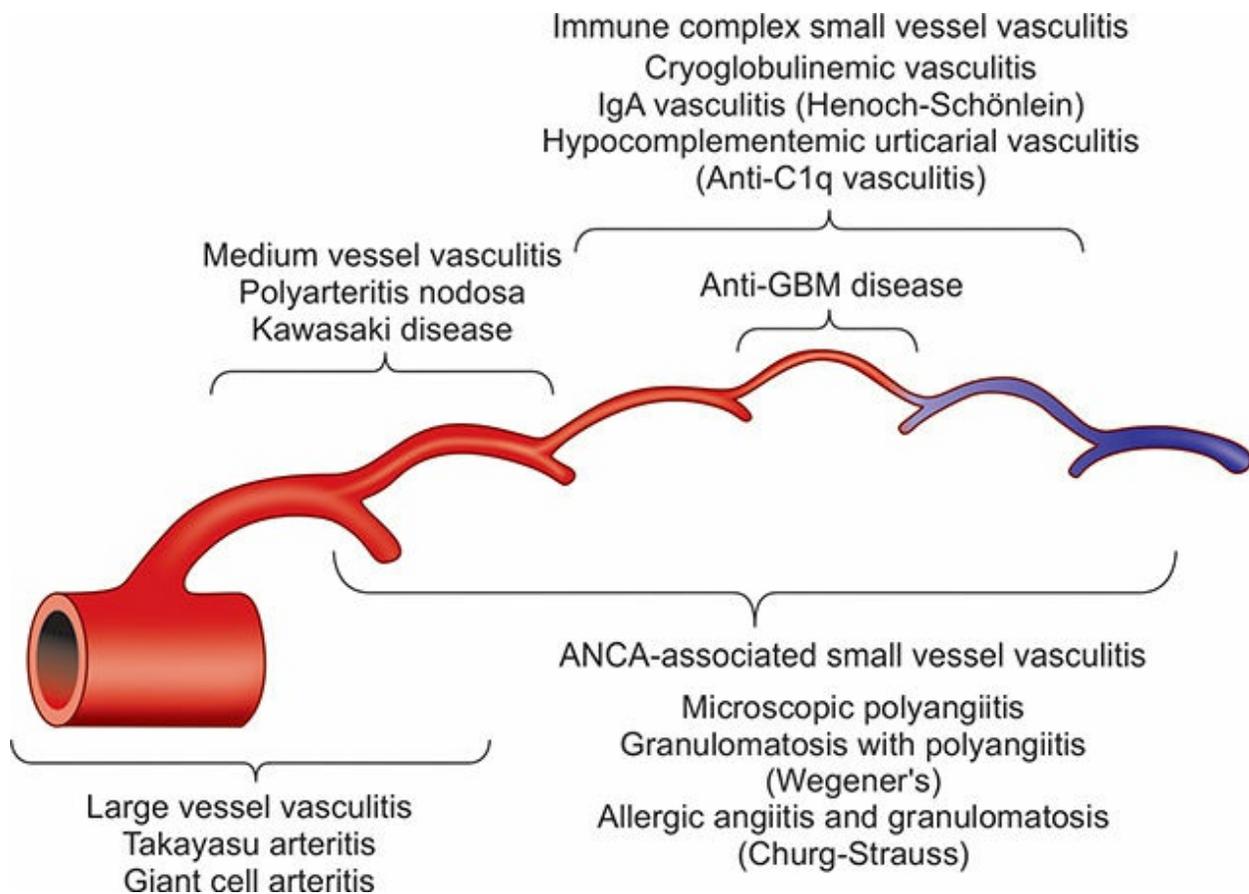

**Q. Write short essay/note on clinical features of vasculitis.**

**Constitutional symptoms:** Fever, weight loss, malaise, arthralgias/arthritis (common to vasculitides of all vessel sizes). Typical clinical manifestations of large, medium, and small vessel vasculitis are presented in Table 9.19 and vasculitis associated with granulomatous inflammation is listed in Table 9.20.

---

**Table 9.18:** Differences between inflammatory and mechanical low back pain (LBP).

<i>Features</i>	<i>Inflammatory LBP</i>	<i>Mechanical LBP</i>
Age at onset	< 40 years	Any age
Type of onset	Insidious	Acute
Symptom duration	> 3 months	< 4 weeks
Morning stiffness	> 60 minutes	< 30 minutes
Nocturnal pain	Frequent	Absent
Effect of exercise	Improvement	Exacerbation
Sacroiliac joint tenderness	Frequent	Absent
Back mobility	Loss in all planes	Abnormal flexion
Chest expansion	Often decreased	Normal
Neurologic deficits	Unusual	Possible

**Fig. 9.9:** Classification of vasculitis.

**Box 9.10:** Classification of the primary vasculitides according to size of

predominant blood vessels involved (Chapel Hill Consensus Conference).

**Predominantly large-vessel (aorta and its major tributaries) vasculitis**

- Giant cell arteritis
- Takayasu arteritis
- Cogan syndrome

**Predominantly medium-vessel (medium and small-sized arteries and arterioles) vasculitis**

- Polyarteritis nodosa
- Primary central nervous system disease
- Buerger disease

**Predominantly small-vessel (small arteries, arterioles, venules and capillaries) vasculitis**

- ANCA-associated small-vessel vasculitis
  - Granulomatosis with polyangiitis (Wegener granulomatosis)
  - Microscopic polyangiitis
  - Churg-Strauss syndrome (allergic angiitis and granulomatosis)
  - Drug-induced ANCA-associated vasculitis
- Immune complex mediated
  - Cutaneous leukocytoclastic angiitis ('hypersensitivity' vasculitis)
  - Henoch-Schönlein purpura
  - Urticarial vasculitis

**Table 9.19:** Typical clinical manifestations of vasculitis.

<i>Large</i>	<i>Medium</i>	<i>Small</i>
Limb claudication	Cutaneous nodules	Purpura
Asymmetric blood pressures	Ulcers	Vesiculobullous lesions
Absence of pulses	Livedo reticularis	Urticaria
Bruits	Digital gangrene	Glomerulonephritis
Aortic dilation	Mononeuritis multiplex	Alveolar hemorrhage
Renovascular hypertension	Microaneurysms	Cutaneous extravascular
	Renovascular hypertension	Necrotizing granulomas
		Splinter hemorrhages
		Uveitis/episcleritis/scleritis

**Table 9.20:** Vasculitis associated with granulomatous inflammation.

Giant cell arteritis	Churg-Strauss syndrome
Takayasu's arteritis	Primary angiitis of the central nervous system
Cogan's syndrome	Buerger's disease
Wegener's granulomatosis (granulomatosis with polyangiitis)	Rheumatoid vasculitis

## Giant Cell Arteritis (GCA)

**Q. Write short essay/note on temporal arteritis, cranial arteritis or giant cell arteritis.**

Giant cell arteritis (temporal arteritis or cranial arteritis) is **inflammatory granulomatous arteritis** of large and medium sized **arteries in the head and neck**. It can involve aorta and its primary and secondary branches.

**Age and gender:** It is a disease of the elderly and average **age at onset is 70**. It is extremely rare below 60 years of age. Female to male ratio is about 3:1.

**Vessels involved:** One or more branches of the carotid artery (e.g. **temporal artery**, occipital, ophthalmic, posterior ciliary arteries and vertebral arteries). Can involve multiple arteries, aorta and its branches.

### *Clinical Features*

- **Onset** may be gradual or sudden.
- **Systemic manifestations:** Severe malaise, tiredness, **fever, anemia, fatigue** and weight loss.
- **Severe headache:** Most severe and often localized along the course of the superficial temporal artery or occipital region. Arteritis often occurs in the carotid/temporal arteries. On palpation, **the involved artery is tender, thickened** and cord-like or **nodular**. It may be accompanied tenderness of the scalp or of the temple.
- **Jaw claudication:** When chewing, eating or talking, due to ischemia of the masseter muscles.
- **Visual symptoms:** These include loss of visual acuity, reduced color perception and papillary defects. It can even present as **sudden blindness** in one eye due to occlusion of the posterior ciliary artery.
- **Neurological manifestations:** It occurs in about 30% of patients and includes transient ischemic attacks, brainstem infarcts and hemiparesis.

### *Investigation*

- **Normochromic, normocytic anemia.**
- **ESR is raised** (50–120 mm/h) and the **CRP very high.**
- **Temporal artery biopsy** from the affected side is the **definitive diagnostic test**. Characteristic biopsy findings are fragmentation of the internal elastic lamina with necrosis of the media, mixed inflammatory

cell infiltrate and granulomatous inflammation of the intima and media with giant cells.

- Ultrasound or arteriography: It may be used for guiding the biopsy. Duplex ultrasonography can detect the characteristic appearance.

#### Treatment

**Corticosteroids** are the treatment of choice and should be commenced urgently in suspected giant cell arteritis to prevent the risk of visual loss. It responds dramatically within 24–48 hours of starting corticosteroids. Prednisolone is given at a dose of 40–60 mg/day. NSAIDs should not be used.

## Polymyalgia Rheumatic (PMR)

### **Q. Write short note on polymyalgia rheumatic.**

PMR is characterized by pain, aching, and stiffness in the muscles of the neck, shoulders, and hip-girdle area that are usually much worse in the morning. PMR is closely associated with GCA (giant cell arteritis).

### ***Criteria for the Diagnosis of PMR (Box 9.11)***

#### Treatment

- **Corticosteroids:** Prednisolone (10–15 mg/day) is rapidly effective. Symptoms are relieved within 48–72 hours and the ESR normalizes after 7–10 days.

### **Box 9.11:** Criteria for the diagnosis of PMR (Polymyalgia rheumatic).

- Age > 50 years
- Aching and stiffness for at least 1 month, affecting at least two of the three areas (i.e. shoulders, neck, and pelvic girdle)
- Morning stiffness lasting at least 1 hour
- ESR > 40 mm/hour
- Exclusion of other diseases except GCA (giant cell arteritis)
- Rapid response to prednisone (20 mg/day)
- All of the above criteria must be met to diagnose PMR

## Classic Polyarteritis Nodosa (PAN)

### **Q. Write short essay on the clinical features, diagnosis and management of classic polyarteritis nodosa (PAN).**

**Definition:** Polyarteritis nodosa is also called classic polyarteritis nodosa is a systemic, necrotizing vasculitis of small and medium-sized muscular arteries that spares the smallest blood vessels (e.g. arterioles, venules or

capillaries). It characteristically involves the **renal and visceral arteries** and is not associated with glomerulonephritis.

Two additional features that distinguish PAN from other forms of systemic vasculitis are:

1. **Confinement of the disease to the arterial rather than the venous circulation.**
2. **Absence of granulomatous inflammation.**

**Organ systems involved:** Commonly involves **skin, kidneys, heart, liver, and gastrointestinal tract. PAN does not involve pulmonary arteries.**

About 30% of patients with PAN have **chronic hepatitis B** with HBsAg-HbsAb complexes in affected vessels.

### *Clinical Features*

**Q. Write short note on the clinical features of polyarteritis nodosa (PAN).**

- Age and gender: Peak incidence between **40 to 50 years of age**. Predominantly affects middle aged males (M:F=2:1).
- **Subacute onset of constitutional vague symptoms** such as fever, weight loss, weakness, malaise and arthralgias are present in > 50% of cases. Others include lower extremity nodules and ulcerations, mononeuritis multiplex, and intestinal angina (postprandial pain caused by the involvement of mesenteric vessels).
- **Absence of pulmonary artery involvement** helps distinguish PAN from most cases of vasculitis.

### *Diagnosis*

- Anemia, thrombocytosis, and raised acute phase reactants.
- **Hepatitis B surface antigen (HBsAg):** It may be positive.
- p-ANCA: Present in about 20% of cases.
- **Arteriograms:** Demonstrates **aneurysms of small and medium-sized arteries** in the kidney, liver, and visceral vasculature.
- **Biopsy:** Presence of characteristic findings of **vasculitis** of involved organ confirms the diagnosis. Biopsy of symptomatic organs such as nodular skin lesions, painful testes, and nerve/muscle reveals vasculitis. Microscopy shows destruction of the blood vessel wall by inflammatory

cells, accompanied by **fibrinoid necrosis**.

#### Treatment

- **Glucocorticoids and cytotoxic agents:** In idiopathic PAN, remissions or cures is achieved by high doses of glucocorticoids alone. Cyclophosphamide is indicated when PAN is refractory to corticosteroids or when there is serious involvement of major organs.
- PAN with hepatitis B: Antiviral therapy used in combination with glucocorticoids and plasma exchange.

## Microscopic Polyangiitis

**Q. Write short note on microscopic polyangiitis.**

**Definition:** Microscopic polyangiitis (MPA) is the most common ANCA-associated necrotizing vasculitis with **few or no immune complexes** in the involved vessels. It affects **small vessels** (capillaries, venules or arterioles).

### *Clinical Features*

- **Age and gender:** Most common age of onset is 40–60 years. More common in males than females.
- Microscopic polyangiitis is the most common cause of the **pulmonary-renal syndrome**, i.e. alveolar hemorrhage and glomerulonephritis. Alveolar hemorrhage associated with hemoptysis and respiratory compromise.
- The five most common clinical manifestations of MPA are: (1) **glomerulonephritis** (~80% of patients), (2) **weight loss** (> 70%), (3) **mononeuritis multiplex** (60%), (4) **fever** (55%), and (5) a variety of **cutaneous findings**-cutaneous vasculitis (> 60%).
- Other features: Migratory arthralgias or arthritis (either pauciarticular or polyarticular), **palpable purpura**, sometimes with skin ulcerations, nodules, livedo reticularis, and digital gangrene may be seen.

### *Diagnosis*

- p-ANCA is positive in most patients, although c-ANCA may also be present in 40% cases.

#### Treatment

- **Combination of cyclophosphamide and glucocorticoids:** It is the cornerstone of treatment regimens, because most patients with MPA have major organ involvement such as glomerulonephritis, alveolar hemorrhage, or vasculitic neuropathy. Cyclophosphamide may be administered on either a daily or intermittent basis.

- **'Pulse' methylprednisolone** (1 g/d for 3 days) may be considered for patients with severe organ involvement at diagnosis.
- In severe cases (e.g. renal failure or diffuse alveolar hemorrhage), additional use of plasmapheresis is beneficial.
- Other treatment regimens: This includes methotrexate, azathioprine and intravenous immunoglobulin.

## Churg-Strauss Syndrome

### **Q.** Write short essay/note on Churg-Strauss syndrome.

- Churg-Strauss syndrome (CSS) or *allergic angiitis and granulomatosis* is a rare syndrome that affects small to medium sized arteries and veins of multiple organ systems.
- **Hallmarks:** It is characterized by **asthma, peripheral and tissue eosinophilia, extravascular granuloma** formation, and **systemic vasculitis**.

### **Classic Clinical Features (Box 9.12)**

**Box 9.12:** Classic clinical features of Churg-Strauss syndrome.

- Allergic rhinitis and nasal polyposis
- Reactive airway disease
- Peripheral eosinophilia (10–60% of all circulating leukocytes)
- Fleeting pulmonary infiltrates and occasional alveolar hemorrhage
- Vasculitic neuropathy
- Congestive heart failure
- Mononeuritis multiplex and stroke
- Coronary arteritis and myocarditis are the principal causes of morbidity and mortality

### **Investigations**

- Striking **eosinophilia** >10% (>1000 cells/ $\mu$ L) in peripheral blood.
- Raised ESR fibrinogen, or  $\alpha^2$ -globulins and CRP. Increased IgE levels.
- Urine: RBC casts and proteinuria.
- Positive antinuclear cytoplasmic antibodies against myeloperoxidase (**p-ANCA**) in ~48% of cases.
- Chest X-ray: May show infiltrates and pleural effusion.
- Biopsy: Three histologic criteria for the diagnosis: (1) the presence of necrotizing vasculitis, (2) tissue infiltration by eosinophils, and (3)

extravascular granuloma.

#### Treatment

- High-dose steroids and cyclophosphamide, followed by maintenance therapy with low-dose steroids. Some cases may require addition of cytotoxic drugs.
- In severe cases, anti-TNF- $\alpha$  agents like infliximab and etanercept are used.

## Granulomatosis with Polyangiitis (Wegener's Granulomatosis)

**Q. Write short essay on clinical features, diagnosis and treatment of granulomatosis with polyangiitis (Wegener's granulomatosis).**

**Definition:** Granulomatosis with polyangiitis is a distinct clinicopathologic entity characterized by **necrotizing vasculitis**, which involves the **upper respiratory tract**, the **lungs**, and the **kidneys**.

It is one of the most common forms of systemic vasculitis. It involves small to medium-sized blood vessels. It affects both the arterial and venous circulations.

### *Clinical Features*

**Age and gender:** It usually presents during **fourth to fifth decade**. **Males** are affected more often than females.

- **Nasal involvement:** Found in about 90% of patients. These include nasal crusting, epistaxis (bleeding), paranasal sinus pain, sinusitis, nasal mucosal ulceration and obstruction. Inflammation of nasal cartilage may lead to nasal septal perforation and collapse of the nasal bridge ('saddle nose' deformity). Erosive sinus disease and subglottic stenosis (narrowing of the trachea due to inflammation just below the vocal cords) are highly characteristic of granulomatosis with polyangiitis.
- **Lesions in the mouth:** Two classic mouth lesions are **gum inflammation** ('strawberry gums') and **tongue ulcers**.
- **Deafness** due to inner ear involvement and **proptosis** due to inflammation of the retro-orbital tissue, diplopia due to entrapment of the extra-ocular muscles, and loss of vision due to optic nerve compression may occur.
- **Lung involvement** may produce cough, hemoptysis (due to alveolar hemorrhage) and dyspnea.
- **Renal involvement** occurs in the form of rapidly progressive glomerulonephritis, resulting in proteinuria, hematuria, red blood cell casts

in the urine and renal failure.

- **Other manifestations:** These include palpable purpurae, conjunctivitis, episcleritis, scleritis, cranial neuritis and mononeuritis multiplex.

## **Diagnosis**

- **ESR: Markedly elevated.**
- **Non-specific abnormalities:** These include mild anemia, leukocytosis and mild hypergammaglobulinemia (particularly of the IgA class). Complement levels will be normal or elevated.
- **Serum antiproteinase-3 ANCA (c-ANCA): Positive** in about 90% of patients.
- **Chest radiograph:** It may show pulmonary infiltrates and nodules that may cavitate.
- **Imaging** of the upper airways or chest with MRI: It can be useful in localizing abnormalities.
- **Lung biopsy:** Used for confirmation of the diagnosis. It shows the characteristic necrotizing granulomatous vasculitis.
- **Renal biopsy:** It may show a segmental necrotizing crescentic glomerulonephritis, with no immunoglobulin deposition ('Pauci-immune').

**Treatment:** Treatment is similar to that for microscopic polyangiitis (refer page 693).

## **Behçet's Disease/Syndrome**

**Q. Write short essay/note on symptoms, diagnosis and treatment of Behçet's disease.**

**Behçet's syndrome** is characterized by triad of (1) **recurrent episodes of oral/mouth ulcers**, (2) **genital ulcers**, and (3) **eye inflammation (i.e. iritis)**.

Pathologic process is a vasculitis (leukocytoclastic) that may affect small, medium, and large vessels in either the venous or the arterial circulation in any organ.

### **Clinical Features**

**Diagnostic criteria:** Diagnostic criteria of International Study Group for Behçet's syndrome is presented in Box 9.13. However, the spectrum of

Behçet's syndrome consists of many manifestations (e.g. neurological involvement seen in 5% of patients, recurrent thrombosis) that are not included in these criteria.

- **Positive pathergy test:** Highly specific to Behçet's disease but may be positive in only 50% of Behçet's patients. It involves pricking the skin with a needle and looking for evidence of pustule development within 48 hours.
- ESR and CRP raised but not autoantibodies.

**Box 9.13:** Diagnostic criteria for Behçet's syndrome.

### **One required manifestation**

- Recurrent oral ulceration: Aphthous or herpetiform, at least three times in 12 months, usually deep and multiple, and last for 10–30 days. This is the cardinal clinical feature.

**plus**

### **At least two of the following:**

- Recurrent genital ulceration occurs in 60–80% of cases.
- Characteristic eye lesions: Anterior or posterior uveitis or retinal vasculitis or cells in vitreous on slit-lamp examination.
- Characteristic skin lesions: Erythema nodosum, pseudofolliculitis, papulopustular lesions and acneiform nodules.
- Positive pathergy test

### **Treatment**

- Oral and genital ulceration: Topical steroid preparations (soluble prednisolone mouthwashes, steroid pastes). Thalidomide (100–300 mg/day for 28 days initially) is very effective for resistant oral and genital ulceration but is teratogenic and neurotoxic.
- Colchicine can be effective for erythema nodosum and joint pain.
- Steroids and immunosuppressants and ciclosporin are indicated for chronic uveitis and rare neurological complications. Anti-TNF agents can be used to control severe uveitis and serious neurological manifestations and gastrointestinal Behçet's disease.

## **Henoch-Schönlein Purpura IgA Vasculitis**

**Q. Write short note on Henoch-Schönlein purpura and anaphylactoid purpura.**

- Henoch-Schönlein purpura (also referred to as IgA vasculitis or **anaphylactoid purpura**), is the commonest systemic small-vessel vasculitis caused by Ig A dominant immune complex deposition following an infectious trigger. It often occurs after upper respiratory tract infections.
- Usually occurs in **children** (> 90% of cases) and young adults.

### ***Diagnostic Criteria***

**Usual presentation:** Often present with the **tetrad** of:

1. **Purpura (vasculitic/non-thrombocytopenic/palpable purpura):** Palpable and found over the **buttocks and lower legs (Fig. 9.10)**.
2. **Arthralgia or arthritis:** Most patients develop a transient non-migratory polyarthralgias in the absence of frank arthritis and resolves without permanent damage to joints.
3. **Gastrointestinal involvement:** Seen in about 70% of pediatric patients. It is characterized by recurrent colicky abdominal pain associated with nausea, vomiting, diarrhea, or constipation, and the **passage of blood** and mucus per rectum. In some cases, there may be intussusceptions.
4. **Renal involvement:** Seen in 10–50% of patients. It usually produces mild glomerulonephritis causing proteinuria, microscopic hematuria, with red blood cell casts in the urine. It usually resolves spontaneously without treatment.

**Prognosis:** HSP is self-limited most of the time. The vast majority of cases resolve within 6–8 weeks. Adult cases are sometimes more recalcitrant (not responsive to treatment).

**Fig. 9.10:** Palpable purpura over lower legs in Henoch-Schönlein purpura.

## ***Investigations***

- Acute phase reactants are elevated. Serum IgA levels are elevated.
- **Skin biopsy:** Findings are **pathognomonic**. It demonstrates leucocytoclastic vasculitis in capillary venules and direct immunofluorescence of the skin biopsy shows **IgA** immune complexes deposit in the small vessels.

### **Treatment**

- Usually a self-limiting disorder that settles spontaneously without specific treatment.
- Patients respond to bed rest and NSAIDs.
- Corticosteroids and immunosuppressive therapy may be indicated when HSP is severe disease, particularly in the presence of nephritis.

## **Cogan Syndrome (CS)**

An immune-mediated condition that primarily affects young adults, is associated with ocular inflammation (usually interstitial keratitis) and audiovestibular dysfunction.

## **Buerger Disease (Thromboangiitis Obliterans)**

Classic patient is a **young male smoker**.

## ***Diagnosis***

- Recognition of the compatible clinical findings—digital ischemia without involvement of other organs. A major hallmark of Buerger disease is its confinement to the extremities.
- Identification of the typical pattern of vascular involvement by angiography.
- Major risk factor is tobacco exposure.
- Absence of fibrinoid necrosis (it is a hallmark of most systemic vasculitides).

## ***Clinical Features***

- Initially, nonspecific pains in the calf, foot, or toes.
- Later, the progression of thrombosis and vasculitis can lead to horrific pain in the digits and limbs and ultimately to gangrene and tissue loss, through either autoamputation or elective amputation.

The only effective intervention in Buerger disease is **complete smoking cessation**.

## **Takayasu Arteritis**

**Q. Write short essay/note on Takayasu arteritis.**

- Takayasu arteritis, named for the Japanese ophthalmologist who first described the ocular manifestations in 1908.
- It is a **large-vessel vasculitis of unknown** cause that chiefly affects **women during their reproductive years**.
- **Sites:** Most common sites are the **aorta** (65%) and the **left subclavian arteries** (93%).
- **Presentation:**
  - Vascular manifestations include: **Bruit, claudication, hypertension, light-headedness** (associated with vertebral or carotid artery disease), **unequal blood pressures in the extremities**, carotidynia, aortic regurgitation, and loss of a pulse. Absence pulses in upper limbs (called as reverse coarctation).
  - **Bruits:** Most frequent over the carotid arteries, but also often develop in the supraclavicular or infraclavicular space (reflecting subclavian disease), along the flexor surface of the upper arm (from axillary artery)

disease), or in the abdomen (from renal or mesenteric artery vasculitis). Many patients have multiple bruits.

- A **widened pulse pressure** and diastolic murmur along the right sternal border may signal the aortic regurgitation that develops in 20% of patients. Stroke, angina, and congestive heart failure affect a significant minority of patients.
- **Cardiac complications:** Hypertension, congestive heart failure, angina, and aortic regurgitation.
- About 50% of patients develop **constitutional or musculoskeletal symptoms**. Asthenia, weight loss, fever, myalgia, and arthralgia occur commonly.

Criteria for the diagnosis of Takayasu arteritis (Box 9.14).

**Box 9.14:** American College of Rheumatology classification Criteria for Takayasu Arteritis.

1. Onset at age < 40 years
2. Limb claudication
3. Decreased brachial artery pulse
4. Unequal arm blood pressures (> 10 mm Hg)
5. Subclavian or aortic bruit
6. Angiographic evidence of narrowing or occlusion of the aorta or its primary branches, or large limb arteritis

\*The presence of three or more of the six criteria is sensitive (91%) and specific (98%) for the diagnosis of Takayasu arteritis.

## ***Investigations***

- Elevated erythrocyte sedimentation rates or C-reactive protein values during phases of active disease.
- Anemia and thrombocytosis
- Vascular abnormalities can be imaged by conventional angiography, MRI, MRA, CT angiography, or ultrasonography. Conventional angiography is the ‘gold standard’ for precisely delineating the stenosis, occlusions, and aneurysms.

**Treatment:** Glucocorticoids.

Differences between giant cell arteritis and Takayasu’s arteritis (Table 9.21).

**Q. Write short note on differences between giant cell arteritis and Takayasu's arteritis.**

**Table 9.21: Comparison of giant cell arteritis and Takayasu's arteritis.**

<i>Feature</i>	<i>Giant cell arteritis</i>	<i>Takayasu's arteritis</i>
Female-male ratio	2:1	8:1
Age range (years)	50	< 40
Average age of onset (years)	72	25
Visual loss	10–30%	Rare
Involvement of aorta or its major branches	25%	100%
Pathology	Granulomatous arteritis	Granulomatous arteritis
Pulmonary artery involvement	No	Possible
Renal hypertension	Rare	Common
Claudication	Uncommon	Common
Ethnic groups with highest incidence	Scandinavians	Asians
Corticosteroid responsive	Yes	Yes
Bruits present	Minority	Majority
Surgical intervention	Rarely needed	Commonly needed

## OSTEOARTHRITIS

**Q. Write short essay/note on pathogenesis and clinical features and management of osteoarthritis/degenerative joint diseases.**

Osteoarthritis (OA) is the most common form of arthritis. OA refers to a **clinical syndrome of joint pain** accompanied by **varying degrees of functional limitation** and reduced quality of life.

OA is a **noninflammatory, slowly progressive joint disease**, mainly **involving the cartilage**. It shows **progressive destruction of articular cartilage** of weight-bearing joints of **genetically susceptible older persons**. It leads to narrowing of joint, subchondral bone thickening, and finally **nonfunctioning, painful joint**.

### Joints Affected

- **Weight bearing joints** (knee, hips and cervical and lumbar segments of the spine).
- **Non-weight bearing** distal interphalangeal (DIP) joints, thumb bases (first

CMC joints and trapezioscapoid joints), first MTP joints, lower cervical and lumbar facet joints, knees, and hips.

## Etiology

Osteoarthritis (OA) is a **multifactorial disease** having both genetic and environmental components (Table 9.22).

**Table 9.22:** Risk factors for incidence and progression of osteoarthritis.

<b>Risk factors</b>	
Age	<ul style="list-style-type: none"> <li>• Normal ageing process causes increased progression</li> </ul>
Trauma	<ul style="list-style-type: none"> <li>• Collateral ligament, meniscal tears and joint fractures</li> </ul>
Occupation	<ul style="list-style-type: none"> <li>• Heavy physical work (e.g. dockers, miners and farmers)</li> </ul>
Exercise	<ul style="list-style-type: none"> <li>• High impact sports</li> </ul>
Gender	<ul style="list-style-type: none"> <li>• Men under the age of 50 and women over 50</li> </ul>
Genetics	<ul style="list-style-type: none"> <li>• Genetic susceptibility to the disease. Genes involved in <b>prostaglandin</b> metabolism and <b>Wnt</b> (Wingless-related integration site)-signaling pathway</li> </ul>
Obesity	<ul style="list-style-type: none"> <li>• Strongest modifiable risk factor</li> </ul>
Diet	<ul style="list-style-type: none"> <li>• Lower vitamin C and D blood levels</li> </ul>
Bone density	<ul style="list-style-type: none"> <li>• Increasing bone density</li> </ul>

## Types of Osteoarthritis (Box 9.15)

### Box 9.15: Types of osteoarthritis.

**Idiopathic or primary osteoarthritis:** It develops as aging process and may affect few (oligoarticular) or many joints.

- Localized: Most commonly affects the hands, feet, knee, hip, and spine.
- Generalized: Involves three or more joint sites

**Secondary osteoarthritis:** It appears in younger individuals with predisposing condition.

- Previous injuries/trauma to a joint
- Congenital or developmental deformity of a joint(s)
- Secondary to systemic disease [e.g. diabetes, marked obesity, acromegaly, hypothyroidism, neuropathic (Charcot) arthropathy]
- Calcium pyrophosphate dihydrate deposition disease (CPPD)
- Bone and joint disorders including rheumatoid arthritis, gouty arthritis, septic arthritis, and Paget disease of bone and osteonecrosis

## Identifiable Causes of Osteoarthritis (Table 9.23)

**Table 9.23: Identifiable causes of osteoarthritis.**

<p><b>Congenital disorder (hip)</b></p> <ul style="list-style-type: none"> <li>• Legg-Calvé-Perthes disease</li> <li>• Acetabular dysplasia</li> <li>• Slipped capital femoral epiphysis</li> </ul>	<p><b>Metabolic disorders</b></p> <ul style="list-style-type: none"> <li>• Hemochromatosis</li> <li>• Wilson disease</li> <li>• Ochronosis (alkaptonuria)</li> </ul>
<p><b>Inborn error of connective tissue</b></p> <ul style="list-style-type: none"> <li>• Ehlers-Danlos syndrome</li> <li>• Marfan syndrome</li> </ul>	<p><b>History of a septic joint</b></p>
<p><b>Post-traumatic (knee)</b></p> <ul style="list-style-type: none"> <li>• Anterior cruciate ligament tear</li> <li>• Meniscus tear with or without prior meniscectomy surgery</li> </ul>	<p><b>Postinflammatory</b> Underlying rheumatoid arthritis</p>

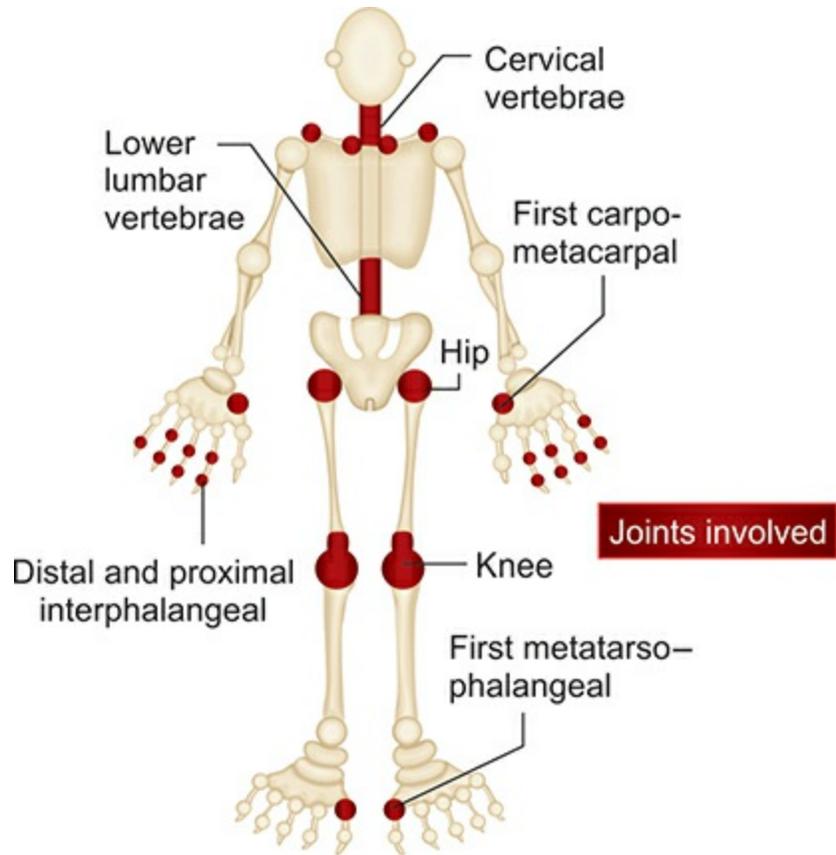

## Clinical Manifestations

**Age of onset:** Usually after age 40.

Joints affected in osteoarthritis (Table 9.24 and Fig. 9.11)

**Table 9.24: Joints affected in osteoarthritis.**

<i>Commonly affected joints</i>		<i>Uncommonly affected joints</i>
Cervical and lumbar spine	Hip	Shoulder
First carpometacarpal joint	Knee	Wrist
Proximal interphalangeal joint	Subtalar joint	Elbow
Distal interphalangeal joint	First metatarsophalangeal joint	Metacarpophalangeal joint

**Fig. 9.11:** Pattern of joint involvement in osteoarthritis.

**Fig. 9.12:** Osteoarthritis showing Heberden's nodes (on DIP) and Bouchard's nodes (on PIP).

**Fig. 9.13:** Radiological features of osteoarthritis.

## ***Signs, symptoms and diagnostic features of osteoarthritis (Box 9.16)***

**Box 9.16:** Signs, symptoms and diagnostic features of osteoarthritis.

### **Symptoms**

- Joint pain that increases with activity
- Stiffness: Morning stiffness relatively brief (for < 30 minutes) and self-limited
- Gelling

### **Physical findings**

- Crepitus (a grating sensation) on active motion
- Bony enlargement at the joint margin, hard bony enlargements, called **Heberden's nodes** (on DIP) and/or **Bouchard's nodes** (on PIP) (Fig. 9.12)
- Decreased range of motion
- Malalignment
- Tenderness to palpation over the joint
- Absence of warmth

### **Synovial fluid analysis**

- Clear fluid
- Noninflammatory synovial fluid ( $<1000$  WBC/mm<sup>3</sup>)
- Normal viscosity

**Erythrocyte sedimentation rate** normal for age

**Negative** serologic tests for **antinuclear antibody** and **rheumatoid factor**

### **Radiographic features**

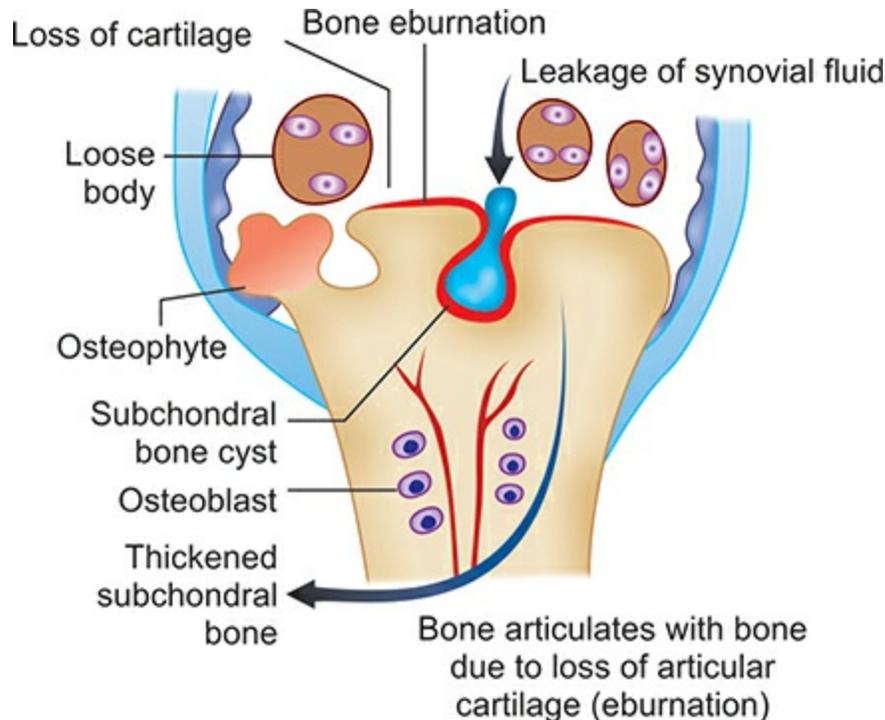

Nonuniform joint space narrowing (Fig. 9.13)

Subchondral eburnation (bony sclerosis)

Marginal osteophytes (spur) formation

Subchondral cysts

Diagrammatic representation of joint changes in osteoarthritis is shown in Figure 9.14.

**Fig. 9.14:** Diagrammatic representation of joint changes in osteoarthritis.

## **Prevention**

Preventing the onset of OA requires lifestyle changes.

- **Primary prevention:** These include:
  - Weight control: Maintaining or reducing weight.
  - Occupational injury prevention: Avoiding repetitive joint use and its injuries.
  - Sports injury prevention: Precautions to prevent injury such as warming up and using proper equipment.
- **Secondary prevention.**
  - Early diagnosis so that appropriate early intervention can be

utilized. **However, this is difficult in OA since no effective biomarkers are available to determine the progression of the disease.**

- **Tertiary prevention.** Reduce, delay the onset of complications and disability. The strategies include: self-management (weight control, physical activity, education); home help programs; cognitive behavioral interventions; rehabilitation services and medical surgical treatments.

## Therapeutic Options in Osteoarthritis (Table 9.25)

**Table 9.25:** Therapeutic options in osteoarthritis.

<p><b>Non-pharmacological treatment</b></p> <p>Education (patient and spouse or family) Social support Physiotherapy (physical therapy) Occupational therapy Weight loss Exercise Orthotic devices Laser Pulsed EMF (Electromagnetic field therapy) Ultrasound Transcutaneous electrical nerve stimulation (TENS) Acupuncture Nutrients Herbal remedies Vitamins/minerals</p>	<p>Hormones Psychotropic drugs SYSADOA (Symptomatic Slow Acting Drugs for OA (avocado/soybean unsaponifiables (ASU), chondroitin, diacerein and glucosamine) Topical NSAIDs Topical capsaicin</p> <p><b>Intra-articular treatment</b></p> <p>Corticosteroids Hyaluronans Tidal irrigation</p> <p><b>Surgical</b></p> <p>Arthroscopy Osteomy UKR (unicompartmental knee replacement) TKR (total knee replacement)</p>
<p><b>Pharmacological treatment</b></p> <p>Paracetamol/acetaminophen NSAIDs (Non-steroidal anti-inflammatory drugs) [plus misoprostol or a proton pump inhibitor] COX-2 inhibitors (cyclo-oxygenase-2 selective non-steroidal anti-inflammatory drugs) Opioid analgesics</p>	<p><b>Drugs in the pipeline</b></p> <p><i>Inhibition of breakdown of cartilage by collagenolytic enzymes or matrix metalloproteinases (MMPs)—Doxycycline</i> <i>Therapy that stimulates repair activity by chondrocytes</i> <i>Bisphosphonates</i> <i>Growth factors</i> <i>Cathepsin K inhibition</i></p>

**Q. Write short essay/note on management of osteoarthritis.**

## SYSTEMIC SCLEROSIS (SCLERODERMA)

**Q. Write a note/essay on scleroderma systemic sclerosis.**

**Q. Discuss the clinical manifestations, diagnosis and management of systemic sclerosis.**

Systemic sclerosis (SSc) is a **chronic multisystem disease** of connective tissue **affecting the skin, musculoskeletal system, internal organs** (e.g. gastrointestinal tract, lungs, heart and kidneys) and vasculature. Scleroderma literally means 'hard skin' and the hallmark of SSc is thickening and **hardening of the skin** (scleroderma) due to skin fibrosis.

## Classification

Systemic sclerosis is classified and subdivided into two principal subsets defined largely by the anatomic skin distribution and associated with distinct clinical and laboratory manifestations.

- **Diffuse cutaneous systemic sclerosis (DCSS: 30% of cases):** It is associated with progressive skin thickening, starting in the fingers and ascending from distal to proximal extremities, the face, and the trunk. These patients have a risk of early pulmonary fibrosis and involvement of kidney and other systems.

**Q. Write short note on CREST syndrome and its clinical features.**

- **Limited cutaneous systemic sclerosis (LCSS: 70% of cases).** Usually these patients have long-standing Raynaud's phenomenon before other manifestations. Skin involvement progresses slowly and remains limited to the fingers (sclerodactyly), distal extremities, and face, without involvement of trunk. Few of these patients have prominent Calcinosis cutis, **Raynaud's phenomenon, Esophageal dysmotility, Sclerodactyly** (scleroderma of the fingers), and **Telangiectasia**, which is termed **CREST syndrome**. CREST syndrome generally show slow progression.

**Age and gender:** Peak incidence is between 30 and 50 years of age with female to male ratio of 3:1.

**Etiology:** The cause is poorly understood. There is associations with alleles at the HLA locus have been found. There is immunological dysfunction of T lymphocytes, especially Th1 and Th17 subtype.

## Clinical Features

**Q. Write short note on symptoms and signs of systemic sclerosis.**

## ***Skin Manifestations***

- **Limited disease or CREST syndrome:** Skin involvement restricted to sites distal to the elbow or knee (apart from the face).
- **Diffuse disease:** Skin involvement proximal to the knee and elbow and on the trunk.

*Changes in skin (Figs. 9.15A to C)*

**Figs. 9.15A to C:** Systemic sclerosis. (A and B) show shiny, thickened skin of hands and feet; (C) Shows mask like face with decreased oral aperture.

Symmetrical and bilateral skin thickening is the hallmark of SSc

- **Early stage:** Shows non-pitting edema of fingers and flexor tendon sheaths.
- **Later stages:** Skin becomes shiny, firm, thickened, and distal skin creases disappear. After many years, the skin may become thin, atrophic and tightly bound to underlying subcutaneous tissue.
- **Hyperpigmentation:** Skin generally becomes hyperpigmented. In dark-skinned individuals, vitiligo-like areas of hypopigmentation may occur.

Because pigment loss spares the perifollicular areas, the skin may develop a **‘salt-and-pepper’** appearance most prominently on the upper back and chest.

- **Changes in facial skin:** Produces a beak-like nose, ‘mask-like’ face, and decreased oral aperture (microstomia).
- **Other manifestations:** These include flexion contractures, ulcers over fingertips and bony prominences (due to breakdown of atrophic skin), telangiectasia, calcinosis cutis and dry coarse skin.

### ***Musculoskeletal Manifestations***

- Range from mild arthralgias to frank nonerosive arthritis with synovitis resembling rheumatoid arthritis.
- Generalized arthralgia, morning stiffness and flexor tenosynovitis are common.
- Muscle weakness and wasting due to disuse atrophy, myopathy and myositis.
- Restricted hand/limb function associated with contractures of the joints is due to sclerosis of skin rather than joint disease.
- Bone resorption is most common in the terminal phalanges, where it causes loss of the distal tufts (acro-osteolysis) (pseudoclubbing).

### ***Vascular Manifestations***

- Involvement of the vasculature is **universal feature** of SSc.
- **Raynaud’s phenomenon** is an **episodic reversible vasoconstriction of the vessels of the digits** (fingers and toes) that can result in ischemia of the digits. It occurs in all patients with SSc and can precede other features by many years. This is the first manifestation of the disease in almost every patient.
  - **Triggering factors:** Factors which trigger attack include exposure to cold, a decrease in temperature, emotional stress, and vibration. Typical attacks start with pallor (vasoconstriction), followed by cyanosis (ischemia) of variable duration and erythema (reperfusion) develops spontaneously or with rewarming of the digit.
- A **diffuse vasculopathy of peripheral arteries** (in the extremities) may cause narrowing or occlusion of the vessel lumen leading to tissue ischemia. This may produce skin ulceration over pressure areas, localized

areas of infarction and pulp atrophy at the fingertips.

- Vascular disease is fundamental to organ damage and subsequent malfunction of the heart (cardiomyopathy), lung (pulmonary hypertension), kidney [scleroderma renal crisis (SRC)], and other organs in SSc.

### ***Gastrointestinal Manifestations***

Gastrointestinal disease in scleroderma usually involves both the upper and lower gastrointestinal tract but clinical expression is highly variable.

- **Esophageal involvement:** It can manifest as reflux with erosive esophagitis, dysphagia and odynophagia, strictures, and dilatation and atony of lower esophagus.
- **Stomach involvement:** It results in dilatation, atony and delayed gastric emptying. Recurrent occult upper gastrointestinal bleeding may occur due to antral vascular ectasia (**'watermelon' stomach**) (Fig. 9.16).
- **Small and large bowel involvement:** It results in intermittent abdominal distension, abdominal pain, constipation, intestinal obstruction, malabsorption (due to bacterial overgrowth) and steatorrhea. **Pseudo-obstruction** is a known complication.

### ***Pulmonary Manifestations***

- It is a major cause of morbidity and mortality. Main forms of lung disease: (1) inflammatory alveolitis leading to interstitial fibrosis and (2) pulmonary arterial hypertension.
- Pulmonary hypertension presents with rapidly progressive dyspnea, right heart failure and angina.

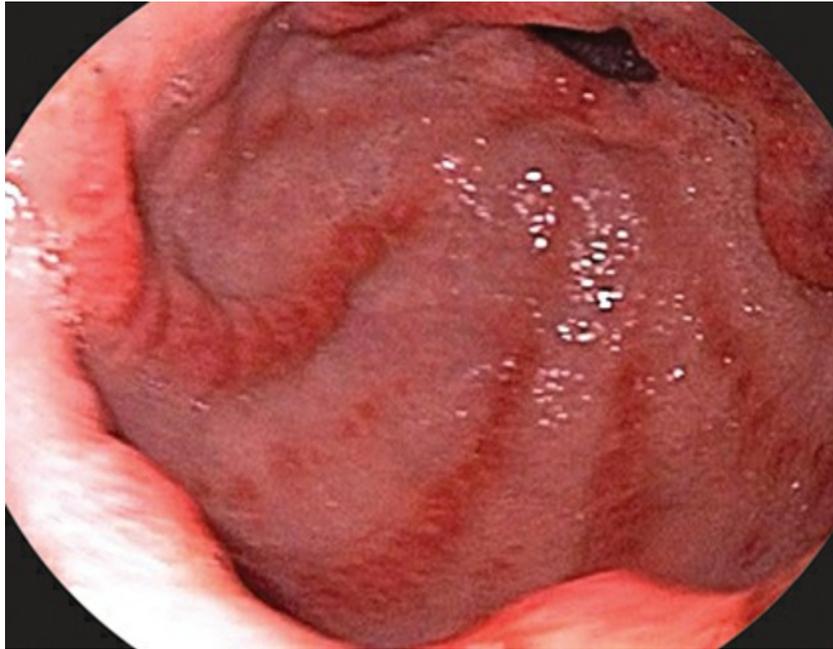

### ***Other Manifestations***

- **Renal involvement:** Occurs in only a minority of patients and can be acute or chronic. Acute hypertensive renal crisis (scleroderma renal crisis-SRC) characterized by sudden onset of malignant hypertension and renal failure was used to be the most common cause of death. At present, this is not the case because ACE inhibitors with dialysis and renal transplantation has improved the outlook.
- **Cardiac involvement:** Myocardial fibrosis may cause arrhythmias, conduction defects and cardiomyopathy. Occasionally, pericarditis with or

without effusion may develop.

**SSc sine scleroderma:** Sometimes systemic features occur without skin involvement.

**Localized scleroderma:** Localized form without systemic involvement (morphea).

**Fig. 9.16:** Gastric antral vascular ectasia (watermelon stomach) in scleroderma.

## Diagnosis (Box 9.17)

**Box 9.17:** Criteria for diagnosis of scleroderma.

- Thickened (sclerodermatous) skin changes proximal to the metacarpophalangeal joints
- OR
- At least two of the following:
    - Sclerodactyly
    - Digital pitting (residual loss of tissue on the finger pads due to ischemia)
    - Bibasilar pulmonary fibrosis

## Investigations

- **ESR:** Elevated.
- **IgG levels:** Raised.
- **Anemia:** It may be due to: (1) **chronic disease**, (2) **iron deficiency** due to gastrointestinal bleed, (3) **folate and B<sub>12</sub> deficiency** due to blind loop syndrome and (4) **microangiopathic hemolytic anemia** due to renal involvement.
- **Urea and creatinine:** Raised in acute kidney injury.
- **Urine** microscopy and if there is proteinuria, measurement of urine albumin/creatinine ratio.
- **Autoantibodies associated with scleroderma** (Table 9.26)

**Table 9.26:** Autoantibodies associated with scleroderma.

<i>Autoantibody</i>	<i>Prevalence</i>
Antinuclear antibody	> 95%
Anti-Scl-70 (anti-topoisomerase I)	20–40%
Anti-centromere	20–40%
Anti-RNA polymerases	4–20%
Anti-B23	10%
Anti-Pm-Scl	2–10%
Anti-U3-RNP (anti-fibrillarin)	8%
Anti-U1-RNP	5%
Anti-Th/To	1–5%

- **Rheumatoid factor:** Positive in 30%.
- **Nailfold capillary changes:** Visualization of capillaries of the skin at the nailfold by diascopy gives insight into a patient’s microvasculature status. Nailfold capillary dropout and dilated capillary loops are seen in nearly every patient with scleroderma but are not specific for scleroderma.
- **Imaging**
  - **Chest X-ray:** For changes in cardiac size and evidence of lung disease.
  - **X-ray of hands:** For deposits of calcium around fingers. In severe cases, erosion and absorption of the distal phalanges (acro-osteolysis).
  - **Barium swallow:** To demonstrate impaired esophageal motility. Scintigraphy, manometry, impedance, and upper GI endoscopy are also useful.

- **High-resolution CT:** To demonstrate interstitial lung disease.
- **Other investigations:** Echocardiography for cardiac involvement and pulmonary hypertension.

### Treatment

There is no cure and no treatment can halt or reverse the fibrotic changes produced in systemic sclerosis. Treatment should be organ-based to ameliorate the effects of the disease on target organs.

- **General measures:**
  - Education, counseling and family support.
  - Regular exercises and skin lubricants.
  - Monitoring of blood counts, renal functions and analysis of urine on regular basis.
- **Control of Raynaud’s syndrome and digital ulcers**
  - Raynaud’s phenomenon: **Avoid triggering factors.** Use hand warmers, and oral vasodilators (**calcium-channel blockers**, ACE inhibitors, angiotensin receptor blockers). Parenteral vasodilators (prostacyclin analogues and calcitonin gene-related peptide) may be beneficial in severe digital ischemia.
  - **Digital ulcers:** Endothelin 1 antagonist bosentan promotes healing of digital ulcers. If ulcers become infected, antibiotics may be required.
  - **Surgical management:** Lumbar **sympathectomy**, radical micro-arteriolysis (digital sympathectomy), and thoracic sympathectomy may be beneficial.
- **Hypertension:** Treated aggressively with **ACE inhibitors**, even if renal impairment is present.
- **Esophageal reflux:** Treated with **proton pump inhibitors** and anti-reflux agents, but prokinetic drugs are rarely useful.
- **Intestinal involvement:** Symptomatic malabsorption requires nutritional supplements. Antibiotics may be necessary for small intestinal bacterial overgrowth syndromes, and metoclopramide or domperidone may be useful for symptoms of pseudo-obstruction.
- **Joint involvement:** Treated with analgesics and/or NSAID. If synovitis is present, immunosuppressants such as methotrexate can be used.
- **Pulmonary hypertension:** Treated with oral vasodilators, oxygen and warfarin. Advanced cases require prostacyclin therapy (inhaled, subcutaneous or intravenous) or the oral endothelin-receptor antagonists (bosentan and sitaxsentan). Low-dose oral corticosteroids and cytotoxic drugs (e.g. cyclophosphamide or azathioprine) are indicated when myositis or pulmonary fibrosis is co-exist.
- D-Penicillamine: May reduce skin thickening and also systemic involvement.

## Prognosis

Prognosis is highly dependent on the extent of major organ disease.

Can be predicted to some extent by the degree of skin involvement:

- Limited scleroderma has a normal life expectancy, about 90% 5-year survival rate.
- Diffuse skin disease have only about a 70–80% 5-year survival rate.

# SJÖGREN'S SYNDROME

**Q. Discuss the classification, clinical manifestations, diagnosis and management of Sjögren's syndrome (SS).**

It **mainly affects the exocrine** (salivary and lachrymal) **glands** and is characterized by the immune-mediated destruction of exocrine glands with secondary development of **keratoconjunctivitis sicca** (dry eyes) and **xerostomia** (dryness of the mouth).

## Classification

- **Primary:** Sjögren's syndrome' (sicca syndrome): It occurs in the absence of any underlying connective tissue disorder.
- **Secondary:** It occurs in association with other autoimmune disorders. These include rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis (scleroderma), mixed connective tissue disease, primary biliary cirrhosis, vasculitis and chronic active hepatitis.

**Age and gender:** Usual age of onset is **40 to 50 years**, with **female** to male ratio of 9:1.

Mechanisms of tissue destruction: Lymphocytic infiltration and immune-complex deposition.

## Clinical Features (Table 9.27)

**Q. Write short note on keratoconjunctivitis sicca.**

## Laboratory Investigations

- **Schirmer tear test:** This is the most commonly used test for the diagnosis of SS. It measures wetting of standardized tear test strips by tear flow over 5 minutes. A standard tear test (absorbent) paper strips is placed between the eyeball and inside of the lower eyelid. Normal result is more than 10 mm of wetting in 5 minutes and if wetting is <10 mm in 5 minutes it indicates defective tear production.
- **Rose Bengal staining.** Staining of the eyes with rose Bengal may show punctate or filamentary keratitis over the area not covered by the open eyelid.
- **Biopsy:** If the diagnosis remains in doubt, it can be confirmed by biopsies of the salivary gland or of the lip (labial minor salivary gland). They show

a focal infiltration by lymphocytes and plasma cells. Minor salivary gland biopsy remains a highly specific test for the diagnosis of SS.

**Table 9.27: Major clinical manifestations of Sjögren syndrome.**

<i>Organ</i>	<i>Manifestations</i>
Mouth	Oral dryness (xerostomia), soreness, caries, periodontal disease, oral candidiasis, parotid swelling
Eyes (keratoconjunctivitis sicca)	Ocular dryness (xerophthalmia), corneal ulcers, conjunctivitis and blepharitis (lack of lubricating tears)
Nose and throat	Nasal dryness, chronic cough
<b>Extraglandular manifestations</b>	
Skin	Cutaneous dryness, palpable purpura, urticarial lesions, Raynaud phenomenon
Joints	Arthralgias, non-erosive symmetric arthritis
Lungs	Obstructive chronic lung disease, interstitial pneumopathy
Cardiovascular	Raynaud phenomenon, pericarditis, autonomic disturbances
Liver	Associated hepatitis C virus infection, primary biliary cirrhosis, type 1 autoimmune hepatitis
Kidneys	Renal tubular acidosis type I (distal), glomerulonephritis
Peripheral nerve	Mixed polyneuropathy, pure sensitive neuropathy, mononeuritis multiplex
Central nervous system	White matter lesions, cranial nerve involvement (V, VIII, and VII), myelopathy
Ears	Sensorineural hearing loss
Thyroid	Autoimmune (Hashimoto's) thyroiditis
General symptoms	Low-grade fever, generalized pain, myalgias, fatigue, weakness, fibromyalgia, polyadenopathies, depression, anxiety, increased risk of non-Hodgkin's lymphoma

- **Tests for salivary gland involvement:** Other diagnostic tests include sialometry (to measure salivary flow), sialography, and scintigraphy. Newer imaging techniques such as ultrasound, MRI or MR sialography of the major salivary glands are also useful.
- **Common laboratory abnormalities**
  - Most patients have an elevated ESR, raised immunoglobulin levels (hypergammaglobulinemia), and circulating immune complexes.
  - Autoantibodies
    - ◆ Rheumatoid factor: Usually positive (75–90%).

- ◆ Antinuclear antibodies: Positive in 80% of cases.
- ◆ Anti-mitochondrial antibodies: Positive in 10%.
- ◆ Anti-Ro (SSA) antibodies: Positive in 60–90% (in 10% of cases of RA and secondary Sjögren’s syndrome). This antibody can cross the placenta and cause congenital heart block.
- ◆ Anti-La (SSB) antibodies: Present in 40%.
- Others: Leucopenia, thrombocytosis.

### Treatment

- Management is symptomatic.
- **Ocular symptoms:** Symptomatic treatment is with artificial tears. Lachrymal substitutes (e.g. hypromellose) during the day and more viscous ophthalmologic lubricating ointment at night. Cyclosporine emulsion may be useful in ocular dryness.
- **Oral symptoms:** Best replacement for xerostomia is water, lubricating agents and saliva-replacement solutions. Stimulation of saliva flow by sugar-free chewing gum or lozenges may be of help. Vaginal dryness is treated with lubricants such as K-Y jelly.
- **Muscarinic agonists** (pilocarpine and cevimeline) have been recently used for the treatment of sicca symptoms in SS. They stimulate the M1 and M3 receptors present on salivary glands and tear glands leading to increased secretory function.
- Hydroxychloroquine is helpful for fatigue and arthralgia.
- Glucocorticoids and immunosuppressive agents are reserved for potentially severe disease. Corticosteroids are used to treat persistent salivary gland swelling or neuropathy.
- Biological agents, including infliximab, interferon- $\alpha$  and anti-CD20 antibodies (rituximab) are tried.

## Overlap Syndromes and Mixed Connective Tissue Disease (MCTD)

**Q. Write short note on definition of mixed connective tissue disease/overlap syndromes.**

**Overlap syndromes** are diseases in which clinical or laboratory signs and symptoms of another defined connective tissue disease occur, such as systemic lupus erythematosus, scleroderma, rheumatoid arthritis, Sjögren’s syndrome, Churg–Strauss arteritis, thrombotic thrombocytopenic purpura, antiphospholipid antibody syndrome and autoimmune thyroid disease.

**Mixed connective-tissue disease (MCTD)** is a disorder with overlapping clinical features of systemic lupus erythematosus, scleroderma, and myositis, with the presence of a distinctive antibody against **U1-ribonucleoprotein (RNP)**.

## CRYSTAL ARTHROPATHIES

### Gout

**Q. Discuss the etiology, clinical manifestations, diagnosis and management of gout.**

**Q. Write short essay on the various causes, clinical manifestations, investigations and management of hyperuricemia.**

Gout is a **heterogeneous group of inflammatory diseases** characterized by **hyperuricemia** (plasma urate level above 6.8 mg/dL) and **monosodium urate crystal deposition in and around synovial joints and kidneys.**

### ***Etiology of Gout and Hyperuricemia (Box 9.18)***

**Box 9.18:** Classification of hyperuricemia.

#### **Urate overproduction**

- **Primary hyperuricemia**
  - Idiopathic
  - Complete or partial deficiency of HGPRT
  - Superactivity of PRPP synthetase
- **Secondary hyperuricemia**
  - Excessive purine consumption
  - Myeloproliferative or lymphoproliferative disorders
  - Hemolytic diseases
  - Psoriasis
  - Glycogen storage diseases: types 1, 3, 5, and 7

#### **Uric acid under excretion**

- **Primary hyperuricemia**
  - Idiopathic
- **Secondary hyperuricemia**
  - Decreased renal function
  - Metabolic acidosis (ketoacidosis or lactic acidosis)
  - Dehydration
  - Diuretics
  - Hypertension
  - Hyperparathyroidism
  - Drugs including cyclosporine, pyrazinamide, ethambutol and low-dose salicylates
  - Lead nephropathy

#### **Overproduction and under excretion**

- Alcohol use
- Glucose-6-phosphatase deficiency
- Fructose-1-phosphate-aldolase deficiency

(HGPRT: hypoxanthine guanine phosphoribosyltransferase; PRPP: 5'-phosphoribosyl-1-

pyrophosphate)

**Q. Write short note on causes of hyperuricemia.**

Uric acid is the end product of purine metabolism, which is eliminated only in the urine. Humans do not have uricase, an enzyme which degrades uric acid. Usually, there is a balance between uric acid production and tissue deposition of urates.

### ***Clinical Features***

The natural history of gout has four stages:

1. **Asymptomatic hyperuricemia:** It is a state in which serum urate exceeds the level of solubility but symptoms of crystalline deposition have not occurred. Appears at puberty in males and after menopause in females.
2. **Acute gouty arthritis:**
  - Acute gouty arthritis usually follows decades of asymptomatic hyperuricemia. Usually the **first attack** occurs in a **middle-aged male**.
  - **Presentation:** It appears as **sudden excruciating** (agonizing) **joint pain, swelling, intense redness** and tenderness of the **first metatarsophalangeal (MTP) joint (termed *podagra*) (Fig. 9.17)**. Other joints that can be involved are tarsal joints, ankles, knees and wrists. Gout can also cause bursitis and tenosynovitis.

**Fig. 9.17:** Acute gouty arthritis involving the first metatarsophalangeal (MTP) joint (termed podagra).

- **Systemic symptoms:** The acute attack may be accompanied by fever, chills, and malaise, leukocytosis and raised ESR.
  - **Factors which precipitate acute attack** are those that cause fluctuations (rapidly raising or lowering) in serum urate levels. These include overindulgence in certain high-purine foods, alcohol ingestion, starvation, dehydration certain drugs (e.g. diuretic, salicylates, urate-lowering drugs allopurinol and radiographic contrast agents), trauma and surgery.
  - **Termination of attack:** Even if not treated, acute attacks of gout are usually self-limited, subside spontaneously and first several acute attacks last for 5 to 8 days. Recovery is usually associated with desquamation of the overlying skin. There is no damage to any organ system during the acute attack.
3. **Intercritical gout:** With resolution of the attack, patients enter an interval termed the ‘intercritical period’. It is the asymptomatic period between the first acute attack and subsequent attacks. During this period, the previously affected joints are free of symptoms. Despite this, monosodium urate crystal deposition continues.

**Q. Write short essay/note on chronic tophaceous gout.**

**4. Chronic tophaceous gout (tophi and chronic gouty arthritis)**

- Eventually the untreated patient progresses to chronic polyarticular gout (advanced gout). This stage usually develops after several years (10 or more years) of acute gouty arthritis, which may lead to severe crippling disease.
- The intensity of pain in chronic is not severe compared to that of acute attacks.
- **Most characteristic lesion** of advanced gout is **subcutaneous tophus**. It results from deposition of crystals in cartilage, synovial membranes, tendons and soft tissues. It can occur anywhere in the body but are most common in the fingers, wrists, ears (helix and antihelix), knees, and olecranon bursa.

*Nephropathy*

Occurs in 90% of patients with gouty arthritis. Two types of parenchymal renal damage can occur.

- **Urate nephropathy:** It is characterized by deposition of urate crystals in the interstitial tissue. It may lead to albuminuria, isosthenuria or renal failure.
- **Obstructive uropathy (nephrolithiasis):** Chronic hyperuricemia may be complicated by formation of uric acid renal stone with blockage of urine flow. The factors favoring stone formation are hyperuricosuria, overproduction of purine, increased ingestion of purine, uricosuric drugs and acidic urine.

*Other features:* Hypertension is a risk factor for development of gout and gout may be associated with increased incidence of hypertension and cardiovascular disorders.

**Investigations**

- **Joint fluid microscopy:** Most specific and diagnostic test but is technically difficult. Synovial fluid examined by compensated polarized microscopy shows **urate crystals**. These crystals are bright yellow in color and appear as slender, **needle shaped, negatively birefringent structures**.
  - **Acute gout:** Synovial fluid is turbid due to the greatly elevated cell

count (> 90% neutrophils).

- **Chronic gout:** More variable but occasionally it appears white due to the high crystal load. Crystals may be seen between attacks.
- **Serum uric acid:** Raised hyperuricemia (>7.0 mg/dL in males and > 6.0 mg/dL in females) does not confirm the diagnosis. However, levels may be normal (in 50% cases) during an acute attack.
- **Serum urea, creatinine:** Monitoring is needed to detect any signs of renal impairment.
- Raised ESR and CRP and neutrophilia are observed during acute gout, and they return to normal as the attack subsides.
- **Plain radiographs:** Usually normal in acute gout. In chronic or tophaceous gout, well-demarcated rounded or oval punched out erosions with hypertrophic calcified 'overhanging edge' (**Martel sign**) are characteristically observed. RA causes marginal erosions within the limits of the joint capsule.

### **Q. Write short note on management of acute attack of gout.**

#### **Management**

##### ***Treatment of acute attack***

- **NSAIDs:** They rapidly relieve pain and swelling during the acute attack and are the agents of choice. Commonly used drugs include indomethacin (75 mg immediately, then 50 mg 6–8 hours), naproxen (750 mg immediately, then 500 mg every 8–12 hours), *diclofenac* (75–100 mg immediately, then 50 mg every 6–8 hours) and fenoprofen. NSAIDs may cause renal impairment.
- Local ice packs can produce symptomatic relief.
- **Oral colchicine:** It is the second drug of choice which acts by inhibiting microtubule assembly in neutrophils. It is very effective at a dose of 1.2 mg immediately, then 0.6 mg every 6–12 hours. Side effects include diarrhea or colicky abdominal pain.
- **Corticosteroids:** If patient cannot tolerate NSAIDs or colchicine, oral prednisolone (20–30 mg/day) or intramuscular or intra-articular depot methylprednisolone may be tried.
- **ACTH gel:** A single injection of intramuscular ACTH gel (25 to 80 IU) is useful for terminating an acute attack of gout.
- **Interleukin 1 inhibitors:** Anakinra, canakinumab have been tried.

#### ***Prophylaxis***

##### ***Dietary advice***

- Avoid alcohol intake, especially beer, which is high in purines and fructose. Carbonated soft drinks are also rich in fructose.
- Avoid meat and shellfish.
- Controlled weight reduction if patient is obese.
- Avoid use of thiazides or loop diuretics.

## Drugs for Prophylaxis

### Urate-lowering therapy

It is indicated (Box 9.19) in patients who develop more than one acute attack within one year and those with complications. Xanthine oxidase inhibitors are used in urate overproducers while Uricosuric agents are used in urate underexcretors.

**Box 9.19:** Indications for urate-lowering drugs.

Hyperuricemia associated with increased uric acid production

- Urinary uric acid excretion of 1000 mg or more in 24 hours
- Very high levels of serum uric acid
- Hyperuricemia associated with HGPRT deficiency or PRPP synthetase over activity
- Uric acid nephropathy
- Nephrolithiasis
- Prophylaxis before cytolytic therapy
- Evidence of bone or joint damage

(HGPRT: hypoxanthine guanine phosphoribosyl-transferase; PRPP: 5'-phosphoribosyl-1-pyrophosphate) Prophylaxis

- **Allopurinol** is the drug of first choice. It is an xanthine oxidase inhibitor that blocks the conversion of xanthine into uric acid. Thus it reduces uric acid production and serum uric acid levels rapidly.
  - **Indication:** Should be used when the attacks are frequent and severe (despite dietary changes), associated with renal impairment or tophi, or when NSAIDs or colchicine are difficult to tolerate.
  - **Dosage:** 300–900 mg daily.
  - **Common side effects:** These include gastrointestinal intolerance and skin rashes. Allopurinol hypersensitivity syndrome is the most severe reaction characterized by fever, skin rash, eosinophilia, hepatitis, progressive renal insufficiency, and death.
- **Febuxostat** is a non-purine selective inhibitor of xanthine oxidase, is a new urate lowering drug that is possibly well tolerated, safer in renal impairment and superior to allopurinol. Dose is 40–120 mg/day.
- **Uricosuric agents** like **probenecid**, **benzbromarone**, **lesinurad**, and **sulfinpyrazone** are indicated in selected cases (when uric acid excretion in the urine is below 600 mg/day). Uricosuric drugs are risky if urinary urate excretion is already > 800 mg/24 hours. These are contraindicated in those with urate calculi. Uricosurics are ineffective in renal impairment (creatinine clearance < 50 mL/minute).
- Uricase, analogs as **pegloticase** and **rasburicase** are used to promote depletion of body urate pools.

## Calcium Pyrophosphate Dihydrate Deposition Disease

**Q. Write short essay/note on pseudo-gout; calcium pyrophosphate dihydrate deposition disease; pyrophosphate arthropathy.**

Calcium pyrophosphate dihydrate (CPPD) deposition disease is a condition

associated with deposition of calcium pyrophosphate dihydrate (CPPD) crystals within articular and hyaline cartilage.

### ***Common Causes (Box 9.20)***

**Box 9.20:** Common causes of calcium pyrophosphate dihydrate crystal deposition disease.

---

Idiopathic (most frequent): Occurs in association with aging  
Complication of primary osteoarthritis  
Long-term consequence of mechanical joint trauma or knee meniscectomy  
Familial  
Associated with systemic metabolic disease, e.g. hyperparathyroidism, dialysis-dependent renal failure, hemochromatosis, hypomagnesemia

---

### ***Clinical Features***

- May be asymptomatic or may result in a variety of clinical presentations.
- A **common presentation** is **acute inflammatory arthritis** that resembles acute gout. Hence, also known as ‘**pseudogout**’. However, in contrast to gout it is more common in elderly women and usually affects the knee followed by the wrist, shoulder, ankle and elbow. Examination of joint reveals a warm, tender erythematous joint with signs of a large effusion. Fever is common.
- **Trigger factors:** These include trauma, intercurrent illness and surgery.
- **Chronic arthropathy:** It may also occur in association with CPPD crystal deposition disease.

### ***Investigations***

- **Examination of synovial fluid:** CPPD crystals can be demonstrated using compensated polarized microscopy and helps in differentiation from gout. CPPD crystals are generally **rhomboid-shaped and positively birefringent**. They appear blue when parallel to the long axis of the compensator and yellow when perpendicular. The synovial fluid is turbid and may be uniformly blood-stained.
- **X-rays of the affected joint:** It may show calcification in hyaline cartilage and/or fibrocartilage (chondrocalcinosis).

### **Basic Calcium Phosphate Crystal Deposition**

- Basic calcium phosphate (BCP) deposition disease is due to the deposition

of **hydroxyapatite or apatite crystals** and other basic calcium phosphate salts (e.g. octacalcium phosphate, tricalcium phosphate) in soft tissues.

- **Main sites of deposits:** BCP crystal deposits are mainly seen in tendons, ligaments and hyaline cartilage. In the shoulder, it may manifest as calcific tendinitis of the rotator cuff.
- **Fluids for crystal detection:** BCP crystals may be detected as **nonbirefringent globular clumps within leukocytes** in synovial and bursal fluids. Under light microscopy BCP crystal clumps stain positive with the calcium-binding dye such as alizarin red S.

## Therapeutics for Crystal Deposition Disease (Table 9.28)

### MISCELLANEOUS

#### Relapsing Polychondritis (RP)

- **Immune-mediated** condition associated with **inflammation in cartilaginous structures and other connective tissues** throughout the body.
- **Sites:** These include **ears, nose, joints, respiratory tract, and others.**

**Table 9.28:** Therapeutics for crystal deposition disease.

NSAIDs or COX-2 inhibitors	Hydroxychloroquine for refractory chronic inflammation
Intra-articular corticosteroids	TLR2 antagonism for CPPD-associated degenerative arthropathy
Systemic corticosteroids	Oral calcium supplementation to suppress PTH levels
ACTH	ANKH anion channel blockade (probenecid)
Prophylactic low-dose colchicine	NPP1 inhibition
Methotrexate for refractory chronic inflammation and recurrent pseudogout	TG2 inhibition
Oral magnesium (for patients with hypomagnesemia)	Polyphosphates
<b>Novel therapy</b>	Promotion of crystal dissolution by alkaline phosphatase or polyamines
Phosphocitrate	
Caspase-1 or IL-1 antagonism for CPPD crystal-induced inflammation	

- **Associated with diseases:** Thirty percent occur in association with disease such as systemic vasculitis (particularly Wegener granulomatosis), connective tissue disorder (e.g. rheumatoid arthritis or systemic lupus erythematosus), or a myelodysplastic syndrome.
- **Presentation:** Patients can present with respiratory obstruction, aortitis and mitral regurgitation.

**Treatment:** Steroids and in severe disease immunosuppressive agents are used.

## Still's Disease (Systemic Juvenile Idiopathic Arthritis)

**Q.** Write short note on Still's disease/juvenile idiopathic arthritis (JIA).

- Inflammatory arthritis is rare in children. **Systemic juvenile idiopathic arthritis (JIA)**, formerly known as Still's disease, is a systemic disorder **occurring in children**. It presents with fever, rash, arthritis, hepatosplenomegaly and serositis.
- **Subtypes:** Depending on the extent of involvement.
  - **Oligoarticular JIA:** More common (60%), occurs predominantly in females, affect large joints in an asymmetrical pattern. It may be associated with uveitis and many show ANA-positivity.
  - Rheumatoid factor-negative **polyarthritis:** Heterogeneous form, polyarticular with more extensive joint involvement.
- **Lab tests:** It shows raised ESR and CRP, negative rheumatoid factor, neutrophilia, and thrombocytosis.

**Treatment:** Corticosteroids, methotrexate, TNF blockers, IL-1 inhibitors and tocilizumab.

- **Prognosis:** Oligoarthritis has good prognosis. Polyarticular have a poorer prognosis.

## Adult-Onset Still's Disease (AOSD)

**Q.** Write short note on adult-onset Still's disease.

- A rare multisystemic inflammatory disorder of unknown cause (form of Still's disease) that occurs in adults.
- **Clinical features:** Similar to juvenile idiopathic arthritis, it presents with triad of high-spiking fever, rash and arthralgia.
  - **Fever:** Transient, lasting less than for 4 hours and is most commonly

**quotidian or double quotidian** in pattern (rabbit ears pattern).

- **Rash:** Maculopapular (Salmon-colored), mainly observed on the proximal limbs and trunk.
- **Arthralgia:** Most frequently affects knee, wrist and ankle joints.
- **Other manifestations:** These include splenomegaly, hepatomegaly and lymphadenopathy.

• **Investigations:**

- **Marked elevation of the serum ferritin** (above 3000 mg/mL) found in more than 70% of patients.
- **Reduced level (< 20%) of glycosylated fraction of ferritin** is a more useful marker.
- **RF and ANA: Negative.**
- Yamaguchi's diagnostic criteria for Adult-Onset Still's Disease (AOSD) is presented in Table 9.29.

**Table 9.29: Yamaguchi's criteria for the diagnosis of Adult-Onset Still's Disease (AOSD).**

<i>Major criteria</i>	<i>Minor criteria</i>
Arthralgias >2 weeks	Sore throat
Fever >39° intermittent, >1 week	Lymphadenopathy and /or Splenomegaly
Typical rash*	Abnormal liver function tests
WBC > 10,000/cumm (>80% granulocytes)	Negative rheumatoid factor and ANA
Diagnostic combination	
<b>Exclusion criteria</b>	<b>Diagnosis</b>
Infections	5 criteria with at least 2 major
Malignancy	
Rheumatic disease	

\*Evanescent, salmon-pink, maculopapular eruption, predominant on the proximal limbs and trunk

**Treatment:** Most patients respond to corticosteroids. DMARDs may be necessary and given as steroid-sparing agents.

## Nonarticular Rheumatism

**Q. Write short note on nonarticular rheumatism, and four forms of the disorder.**

- Nonarticular rheumatism is not actually a true arthritis. It refers to aches and pains that arise from structures outside of joints.
- **Forms:** Four forms namely **tendinitis, bursitis, FMS (fibromyalgia syndrome), and the myofascial pain syndrome.**
- **Common types of tendinitis and bursitis:**
  1. **Tennis elbow:** Pain over the lateral epicondyle of the elbow due to inflammation of the tendons of the wrist extensor muscles that insert at this location.
  2. **Golfer's elbow:** Pain over the medial epicondyle due to inflammation of the wrist flexor tendons that insert at this location.
  3. **Shoulder impingement syndrome:** It is due to impingement of the tendons of the rotator cuff with shoulder abduction or flexion. It can be associated with supraspinatus tendinitis, subacromial bursitis, or rotator cuff tears.
  4. **Housemaid's knee:** It is prepatellar bursitis produced due to repetitive trauma or overuse such as kneeling. Another common region for bursitis is over the greater trochanter of the lateral hip.

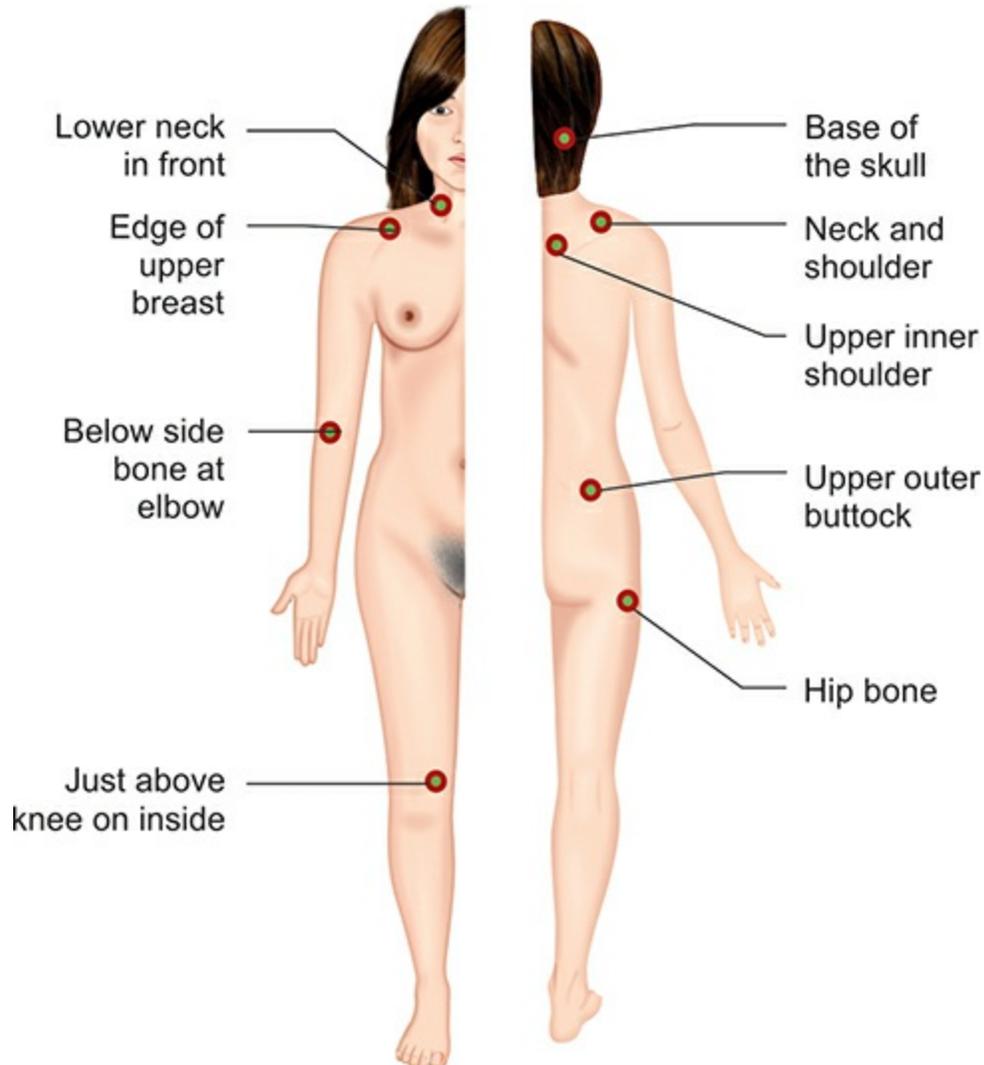

### ***Fibromyalgia Syndrome***

**Q. Write short note on the criteria for diagnosis of fibromyalgia syndrome (FMS).**

Fibromyalgia syndrome is characterized by chronic widespread pain, and is defined as pain for more than three months both above and below the waist.

- **Diagnostic criteria for FMS**
  - At least 3 months of widespread pain that is bilateral, above and below the waist.
  - It includes axial skeletal pain and pain to palpation at a minimum of 11 of 18 predefined tender points (refer below).
  - The diagnosis of other diseases does not exclude the diagnosis of FMS.
- **Physical examination:** Normal except for tender points in precise locations. Usually these points are tender bilaterally.
  - **Tender points** (Fig. 9.18): Typically located at the occiput, at the midportion of the trapezius, the origin of the supraspinatus, low anterior cervical region, second costochondral junction, lateral

epicondyle, outer upper quadrant of the buttocks, greater trochanter region, and medial knee area.

**Fig. 9.18:** Trigger points in fibromyalgia.

- **Differential diagnosis:** Medical illnesses that may exhibit symptoms similar to those of FMS include: Celiac sprue, hepatitis C, hyperparathyroidism, hypothyroidism, and polymyalgia rheumatica (PMR).

## OSTEOPOROSIS

**Q. Write short essay/note on risk factors, prevention and treatment of osteoporosis.**

Osteoporosis is the most common bone disorder and is a component of the

fragility syndrome.

## Definition

- It is a bone disease characterized by low bone mass and micro-architectural disruption of bone tissue that leads to increased bone fragility and fracture risk.
- **WHO definition:** Osteoporosis is defined as a bone mineral density (BMD) of 2.5 standard deviations (SDs) below the young healthy adult mean value (T-score  $\leq -2.5$ ) or lower as measured by DXA (dual-energy X-ray absorptiometry). The term 'established osteoporosis' includes the presence of a fragility fracture. There is inverse relationship between bone mineral density and fracture risk in postmenopausal women and older men. However, this definition should not be applied to young women, men or children.
- **National Institute of Health (NIH) definition:** Osteoporosis is defined as a skeletal disorder characterized by compromised bone strength, which predisposes an individual to an increased risk of fracture.
- **Osteopenia:** It is the term used when the BMD values lies between  $-1$  and  $-2.5$  SDs below the young adult mean.

## Epidemiology

Most common bone disorder. More common in women (4:1). More common in Caucasian population than in other races.

## Pathogenesis

- In osteoporosis, there is **loss of bone mass**, despite **normal mineralization**. In contrast, **osteomalacia** occurs when **bone is not being properly mineralized**, despite the normal production of bone matrix.
- Osteoporosis develops due to an **imbalance in bone remodeling**. It can be due to increased breakdown of bone (**absorption of bone**) by osteoclasts and/or decreased bone formation by osteoblasts. The process of **mineralization of new bone matrix** remains normal.
- Osteoporosis affects both **trabecular** (long thick bones, e.g. femur) and **cortical bone** (high surface area, thin bones e.g. spine). When it affects trabecular bones, **reabsorption of bone** is the main mechanism.
- Genetic factors play important role and multiple genes are involved,

including collagen type 1A, vitamin D receptor and estrogen receptor genes.

- Nutritional factors, sex hormone status and physical activity also play a role. Cigarette smoking is an independent risk factor.

## Classification of Osteoporosis

- **Generalized osteoporosis (Table 9.30):** It involves the entire skeleton. It may be
  - **Primary** or
  - **Secondary** to variety of conditions
- **Localized:** Limited to certain bone or region (e.g. disuse osteoporosis of a limb).

**Table 9.30: Causes of generalized osteoporosis**

### Primary

- Idiopathic
- Postmenopausal
- Senile

### Secondary

- Endocrine disorders
  - Addison disease
  - Type 1 diabetes mellitus
  - Hyperparathyroidism
  - Hyperthyroidism
  - Hypothyroidism
  - Pituitary tumors
  - Cushing's syndrome
  - Acromegaly
- Hypogonadal states
  - Turner's syndrome
  - Klinefelter's syndrome
  - Female hypogonadism
  - Premature and primary ovarian failure
  - Anorexia nervosa
  - Hypothalamic amenorrhea
  - Hyperprolactinemia
- Nutritional and gastrointestinal disorders
  - Hepatic insufficiency, severe liver disease, especially biliary cirrhosis
  - Pernicious anemia

- Subtotal gastrectomy
- Malabsorption syndromes
- Malnutrition
- Parenteral nutrition
- Vitamin C, D deficiencies
- Rheumatologic disorders
  - Rheumatoid arthritis
  - Ankylosing spondylitis
- Hematologic disorders/malignancy
  - Multiple myeloma
  - Lymphoma and leukemia
  - Malignancy with parathyroid hormone (PTHrP) production
  - Hemolytic anemias (e.g. thalassemia)
  - Systemic mastocytosis
  - Hemophilia
  - Disseminated carcinoma
- Drugs
  - Alcohol
  - Anticoagulants (e.g. heparin)
  - Anticonvulsants
  - Chemotherapy
  - Corticosteroids
  - Proton pump inhibitors
  - Ciclosporin, tacrolimus
- Miscellaneous
  - Homocystinuria
  - Immobilization
  - Osteogenesis imperfecta
  - Pulmonary disease

## Clinical Features

- **Risk of fracture:** Osteoporosis can be clinically silent and does not have specific symptoms. However, it increases the risk of bone fractures and fracture is the only cause of symptoms and thereby **increases the morbidity and mortality** in elderly.
- **Fragility fracture:** It is a low-trauma fracture, i.e. mechanical forces (situations) that would not ordinarily result in fracture in healthy people. They typically occur in trabecular bone. The most common sites are:
  - **Spine (vertebrae):** Sudden severe back pain (in the spine) that radiates around to the front suggests **vertebral crush fracture** (compression

fracture).

- **Hip (proximal femur):** Fractures of the **proximal femur** usually occur in elderly persons falling on their side or back. Usually requires prompt surgery.
- **Wrist (distal radius): Colles' fractures** follow a fall on an outstretched arm.
- Other sites include arm (humerus), pelvis, ribs, and other bones.

## Investigations and Diagnosis

**Conventional plain radiograph:** It is useful along with CT or MRI, for detecting complications of osteopenia (reduced bone mass; pre-osteoporosis), such as fractures. However, radiography is relatively insensitive for detection of early disease as it requires a substantial amount of bone loss (about 30%) to be apparent on X-ray images. The radiographic features of osteoporosis are cortical thinning and increased radiolucency.

**Bone biopsy: Tetracycline labeling of the skeleton** on bone biopsy determines the rate of skeletal growth. However, the current use of BMD tests, in combination with hormonal evaluation and biochemical markers of bone remodeling, has replaced the bone biopsy.

**Biochemical markers:** They provide an index of the overall rate of bone remodeling. Markers for bone formation include serum bone-specific alkaline phosphatase, serum osteocalcin, serum propeptide of type I procollagen. Markers for bone resorption urine and serum cross-linked N-telopeptide, urine and serum cross-linked C-telopeptide and urine total free deoxypyridinoline.

**Bone mineral density (BMD):** It is a measure of the mineral content of bone. It is mostly calcium, but also comprises potassium, manganese, magnesium, strontium, selenium, and other minerals. The diagnosis of osteoporosis can be made by measuring the bone mineral density (BMD).

- **Dual energy X-ray absorptiometry (DXA):** It is the most commonly used technique to measure BMD. Two low dose X-rays are directed to the area of interest. It measures areal bone density (mineral/surface area rather than a true volumetric density), usually spine (lumbar) and hip (proximal femur). It uses low doses of radiation and is the 'gold standard' for the diagnosis of osteoporosis. Results from DXA are expressed as either the T-score or the Z-score.

- **Quantitative ultrasound:** This has many advantages in assessing osteoporosis being quick, easy and cheaper than other methods and does not need ionizing radiation. It is used as a screening procedure prior to DXA assessment and is not used for diagnostic purposes. The calcaneus is the most common skeletal site for quantitative ultrasound assessment.
- **Quantitative CT scanning:** It assesses true volumetric mineral density in mg/cm<sup>3</sup>. It gives separate estimates of BMD for trabecular and cortical bone. It is more expensive and requires higher radiation than other techniques.

**Other investigations:** These may be necessary to exclude other diseases or identify contributory factors associated with osteoporosis. These include thyroid function test, vitamin D levels and myeloma screen.

### Treatment of Osteoporosis

The aim of treatment is to reduce the risk of fracture. Treatment plan for osteoporosis includes 1) diagnosis of individuals at highest risk, 2) exclusion of secondary causes of osteoporosis and 3) selecting appropriate treatment.

#### Prevention

**Lifestyle changes:** Methods to prevent osteoporosis include:

- **Nutrition:** Sufficient daily **calcium** intake (1200–1500 mg/day) and vitamin D.
- **Cessation of smoking.**
- Reduction in alcohol intake.
- **Increase weight bearing exercise:** They increase bone mass density and also helps to prevent falls. At least 30 minutes weight bearing exercise 3x per week is needed to increase bone density. Osteoporosis orthosis helps to prevent spine fractures and support the building up of muscles.
- Fall prevention can help prevent osteoporosis complications.

**Box 9.21:** NICE guidelines for use of biphosphates in osteoporosis.

- 1st line: Use a bisphosphonate
- 2nd line: If no improvement, try a different bisphosphonate
- 3rd line: If no improvement, try strontium

### Pharmacological Management

**Q. Write short note on drugs used in osteoporosis.**

Drug treatments can reduce the risk of fracture **by up to 50%**.

The two main classes of drugs used namely: 1) antiresorptive agents and 2) anabolic agents.

1. **Antiresorptive agents (Box 9.21):** They block bone resorption by inhibiting the activity of osteoclasts. These include bisphosphonates, denosumab, raloxifene, and calcitonin.
  - **Bisphosphonates:** These drugs are essentially analogues of pyrophosphate and include alendronic acid, risedronate, clodronate, pamidronate, etidronate. Usually taken **weekly**, and

with plenty of water. **Poorly absorbed from the gut.**

- Should be taken on an empty stomach, as they can bind to calcium in food, after which, the drug cannot be absorbed.
- Only about 10% of the oral dose is absorbed under normal circumstances.
- Alendronate, risedronate, ibandronate, pamidronate and zoledronic acid are effective for both the prevention and treatment of osteoporosis.
- **Adverse drug reactions:** These include: GI upset, esophagitis, bone pain, headache and fever rarely osteonecrosis of jaw.

- **Hormone-replacement therapy (HRT)**

- No longer used as mainstream treatment. Used if other treatments are not tolerated or effective.
- It may be useful in women in post-menopausal osteoporosis. Most effective when started early in menopause, and to be continued for > 5 years.
- Disadvantages: (1) Bone loss continues, and is possibly increased upon stopping HRT and (2) increases the risks of cardiovascular disease and stroke.
- Estrogen analogs: Estrogen replacement therapy is good for prevention of osteoporosis. However, it is not recommended unless there are other indications for its use. In hypogonadal men testosterone has been shown to give improvement in bone quantity and quality.
- **Raloxifene, Bazedoxifene:** It is a selective estrogen receptor modulators (SERMs) that act on the estrogen receptors throughout the body in a selective manner. Raloxifene has an advantage of reducing the risk of invasive breast cancer. SERMs have been proven effective in clinical trials.

- **Calcitonin:** It directly inhibits osteoclastic bone resorption activity via the calcitonin receptor on the surface of osteoclasts. It acts by inhibiting actin cytoskeleton which is needed for the osteoclastic activity.

2. **Bone anabolic agents:** They stimulate bone formation by acting primarily on osteoblasts. These include parathyroid hormone and teriparatide.

- **Teriparatide and abaloparatide:** It acts like parathyroid hormone and stimulates osteoblasts and increases their activity. Mostly used for patients with established osteoporosis, those with low BMD or several risk factors for fracture or cannot tolerate the oral bisphosphonates. It is given as a daily injection with the use of a pen-type injection device.
- **Sodium fluoride:** It produces skeletal changes such as pronounced bone density with increased number and thickness of trabeculae, cortical thickening, and partial obliteration of the medullary space.

3. **Other agents**

- **RANKL inhibitors: Denosumab** is a fully human monoclonal antibody that mimics the activity of osteoprotegerin. It binds to RANKL, thereby preventing RANKL from interacting with RANK and reducing its bone resorption. Anti-sclerostin antibody (romosozumab) is in trials.
- **Strontium ranelate:** It is an alternative oral treatment, belonging to a class of drugs called 'dual action bone agents' (DABAs). It has proven efficacy, especially in the prevention of vertebral fracture. Strontium ranelate is taken as a 2 g oral suspension daily.

**Supplements:** Dietary supplements are given as adjuncts to pharmacological therapy. These include (1) **calcium** and (2) **vitamin D**.

# ANTIPHOSPHOLIPID ANTIBODY (APLA) SYNDROME (HUGHES SYNDROME)

**Q. Write short note on antiphospholipid antibody (APLA) syndrome and antiphospholipid antibodies.**

- Antiphospholipid antibody (APLA) syndrome or antiphospholipid syndrome (APS) is characterized by the **presence of a family of antibodies** in the patient's plasma known as antiphospholipid antibodies (autoantibodies directed against phospholipids) and a syndrome of **hypercoagulability**. This prothrombotic disorder is also associated with thrombocytopenia.
- The term **antiphospholipid antibody is misleading** because these antibodies react with plasma proteins which themselves bind and form complexes with negatively charged phospholipids. So, in contrast to the terminology antiphospholipid, there is no direct binding of antibodies to phospholipids.

## Types of Antiphospholipid Antibody Syndrome

1. **Primary antiphospholipid syndrome:** They do not have any predisposing cause and their only manifestation is hypercoagulable state.
2. **Secondary antiphospholipid syndrome:** These are found in association with autoimmune diseases, like systemic lupus erythematosus. Because of this association, they were formerly known as lupus anticoagulant syndrome.

## Clinical Features

It is the commonest acquired hematologic cause of recurrent thromboembolic events. Clinical manifestations chiefly are due to a direct or indirect effect of venous or arterial thrombosis and/or pregnancy morbidity (Table 9.31).

## Diagnosis

**Types of antiphospholipid antibodies:** Antiphospholipid antibodies are a heterogeneous group of autoantibodies directed against phospholipids-binding proteins. Many plasma proteins (e.g. prothrombin,  $\beta_2$ -glycoprotein) bind to anionic phospholipids resulting in different antiphospholipid antibodies. Antiphospholipid antibodies (APAs) may include (1) **lupus anticoagulant (LA) antibody**, (2) **anticardiolipin antibody (aCL)**, or (3) **anti- $\beta_2$ -glycoprotein-I (anti- $\beta_2$ -GPI) antibody**.

**Table 9.31: Clinical manifestations of antiphospholipid antibody syndrome.**

<i>Organ/System</i>	<i>Manifestation</i>
<b>Venous thrombosis and related consequences</b>	Deep vein thrombosis <b>Cutaneous:</b> Livedo reticularis (Fig. 9.19) <b>Lung:</b> Pulmonary embolism, pulmonary hypertension Superficial thrombophlebitis Thrombosis in various other sites
<b>Arterial thrombosis and related consequences</b>	<b>Neurologic:</b> Stroke, transient ischemic attack <b>Cardiac:</b> Myocardial ischemia (infarction or angina), valvular vegetation (Libman-Sacks endocarditis) <b>Cutaneous:</b> Leg ulcers and/or digital gangrene Arterial thrombosis in the extremities Ophthalmologic: Retinal artery thrombosis/amaurosis fugax Ischemia of visceral organs or avascular necrosis of bone Multi-infarct dementia
<b>Neurologic manifestations of uncertain etiology</b>	Migraine; epilepsy; chorea; cerebellar ataxia; transverse myelopathy
<b>Renal manifestations</b>	<b>Renal artery/renal vein/glomerular thrombosis</b> , renal microangiopathy, renal infarction, acute renal failure, hematuria
<b>Osteoarticular manifestations</b>	Arthralgia; arthritis
<b>Obstetric manifestations</b>	Preeclampsia; eclampsia
<b>Fetal manifestations</b>	Early fetal loss (<10 weeks); late fetal loss (10 weeks); premature birth among the live births
<b>Hematologic manifestations</b>	Thrombocytopenia, autoimmune hemolytic anemia

**1. Lupus anticoagulant (LA) antibody:**

- It is named lupus as it was first detected in patients with systemic lupus erythematosus (SLE).
- It was called anticoagulant because it paradoxically prolongs the clotting times by coagulation assays in vitro (e.g. prolongation of APTT).
- However, the term lupus anticoagulant is a misnomer, because it is more frequently found in patients without lupus and is not anticoagulant and is associated with a hypercoagulable state rather than bleeding.
- For LA screening, two or more phospholipid-dependent coagulation tests are necessary. These include (1) activated partial thromboplastin time, (2) dilute Russell viper venom time (DRVVT) and (3) kaolin clotting time.

2. **Anticardiolipin antibody (aCL):** They target cardiolipin (a bovine cardiac protein) and are detected by immunoassays.

3. **Anti- $\beta^2$ -glycoprotein-I (anti- $\beta^2$ -GPI) antibody:** They are directed against  $\beta^2$ -glycoprotein I and may be causal in APLA syndrome.

**Significance**

- LA antibodies are more specific, whereas aCL antibodies are more sensitive for antiphospholipid syndrome. IgG aCL antibodies are more specific than IgM type.

- Antiphospholipid antibodies may be detected in 10% of normal population and 30–50% of SLE patients. They can also be found in patients with infections such as human immunodeficiency virus and during therapy with medications (e.g. chlorpromazine).

**Fig. 9.19:** Livedo reticularis-mottled reticulated vascular pattern that appears as a lace-like purplish discoloration of the skin. It is due to swelling of the venules caused by obstruction of capillaries.

## Criteria for Diagnosis: APLA Syndrome (Box 9.22)

### Management

#### *Treatment of Venous Thrombosis*

- Patients with APS have a high risk of recurrent thromboembolism. Hence, they should receive antithrombotic therapy.
- **Anticoagulation** with unfractionated heparin or low-molecular-weight heparin (LMWH), and oral warfarin, for acute venous thromboembolism (VTE). This is followed by long-term oral warfarin to a target international normalized ratio (INR) of 2 to 3, alone or in combination with 80 mg of aspirin daily. Duration of treatment is probably lifelong.
- Steroids are often added to the above treatment.
- In severe generalized thrombosis, plasmapheresis or intravenous immunoglobulin may be necessary.

**Box 9.22:** Antiphospholipid antibody syndrome classification criteria (revised Sapporo classification criteria).

#### **Vascular thrombosis**

- Arterial, venous, or small vessel

#### **Pregnancy morbidity**

- One or more fetal deaths
- One or more premature births due to severe preeclampsia or placental insufficiency
- Three or more first trimester losses

## PLUS

- Lupus anticoagulant
- Anticardiolipin IgG or IgM (medium to high titer)
- Anti-beta<sub>2</sub> glycoprotein-1 IgG or IgM on two occasions 12 weeks (or more) apart

A definite diagnosis of antiphospholipid syndrome is made if the patient has one clinical and one laboratory criteria.

### *Prevention of Recurrence of Arterial Thrombosis*

- Aspirin 325 mg/day or warfarin (INR between 1.4 to 2.8).

### *Prophylaxis of any Thrombotic Episode*

- Aspirin for preventing thrombosis in females with previous pregnancy loss.
- Modification of other risk factors (e.g. hypercholesterolemia, smoking).

### *Management of Pregnancy in patients with Antiphospholipid Syndrome*

- **Attempted conception:** Start aspirin 80 mg daily.
- **Confirmed intrauterine pregnancy** by ultrasound, start heparin (5,000–10,000 units every 12 hours) or low-molecular-weight heparin in prophylactic doses (enoxaparin 1 mg/kg, dalteparin 5000 units once a day) and continue till late in the third trimester.
- **Females with a history pregnancy losses:** The goal is to prevent recurrent pregnancy loss. Two or more early pregnancy losses, or one or more late pregnancy losses without any previous history of thrombosis should receive combination of aspirin and heparin (unfractionated or low molecular weight) during pregnancy.

**Treatment of APS-associated bleeding:** It depends on the site and severity of bleeding.

- For anticoagulation bleeding, withdraw the anticoagulant and give an antidote (e.g. protamine).
- For thrombocytopenia bleeding, give platelet transfusions.

## Catastrophic Antiphospholipid Syndrome

- History of APS and/or aPL.
- Three or more new organ thromboses within a week.

### **Treatment**

- Intravenous heparin along with high-dose corticosteroids.
- Early addition of plasma exchange and/or intravenous immunoglobulin (400 mg/kg qd) or CD20 monoclonal antibody rituximab, ofatumumab, veltuzumab, and ocrelizumab (375 mg/m<sup>2</sup> per week for 4 weeks) in patients who do not respond promptly to heparin and corticosteroids.

- **Prognosis:** Despite treatment, mortality is about 50%.

## INFLAMMATORY MUSCLE DISEASES

**Q. Write short note on inflammatory muscle diseases.**

### Common Inflammatory Muscle Diseases (Table 9.32)

**Idiopathic inflammatory myopathies** consist of three major types: (1) **polymyositis**, (2) **dermatomyositis** and (3) **inclusion body myositis**.

## Polymyositis and Dermatomyositis

**Q. Write short note on polymyositis and dermatomyositis.**

### *Idiopathic Polymyositis*

**Onset:** Gradual. Commonly between 40 and 60 years of age.

**Table 9.32: Common inflammatory muscle diseases.**

<i>Infective forms</i>	<i>Autoimmune (Idiopathic)</i>	
Viral: Coxsackie B, influenza, Epstein-Barr virus, HIV Bacterial: <i>Streptococcus</i> , <i>Staphylococcus</i> , clostridia, mycobacteria Fungal: Candidiasis, coccidioidomycosis, cryptococcosis Protozoal: Toxoplasmosis Helminthic: Trichinosis, cysticercosis	<b>Generalized forms</b> <ul style="list-style-type: none"> <li>• Dermatomyositis</li> <li>• Polymyositis</li> <li>• Inclusion body myositis</li> <li>• Overlap syndromes</li> <li>• Eosinophilic myositis</li> <li>• Granulomatous myositis</li> <li>• Necrotizing myopathy (paraneoplastic)</li> </ul>	<b>Focal forms</b> <ul style="list-style-type: none"> <li>• Monomelic myositis</li> <li>• Eosinophilic myositis</li> <li>• Macrophagic myofasciitis</li> <li>• Orbital myositis</li> </ul>

### Clinical manifestations

- **Symmetrical proximal muscle weakness:**
  - **Sites affected:** Usually affects the **lower limbs** (hips and thighs) **than the upper limbs** (shoulder girdle muscles). The distal muscles, facial muscles are not usually affected.
- **Others:** Involvement of pharyngeal, laryngeal and respiratory muscles can lead to dysphonia and respiratory failure.
- **Systemic features:** Fever, weight loss and fatigue are common.
- **Investigation:** Muscle biopsy shows fiber necrosis, regeneration and inflammatory cell infiltrate.

### *Idiopathic Dermatomyositis*

**Q. Write short note on dermatomyositis.**

- Dermatomyositis characterized by **polymyositis** along **with** characteristic **skin changes**. The skin changes may occur before or after the muscle

syndrome.

- **Skin changes:** These include
    - **Gottron's papules:** Scaly, erythematous or violaceous, psoriaform plaques occurring over the extensor surfaces of PIP and DIP joints.
    - **Heliotrope rash:** Violaceous discoloration of the eyelid may be seen along with periorbital edema.
    - **Shawl sign or the V sign:** Occurrence of erythematous macules distributed in a 'shawl' pattern over the upper back, chest and shoulders.
    - **Periungual telangiectasias:** Periungual nail-fold capillaries are enlarged and tortuous.
    - **Mechanic's hand:** Fissured, scaly and hyperkeratotic hand.
  - **Others:** Ulcerative vasculitis and calcinosis (calcium deposition) of the subcutaneous tissue seen in about 25% of cases. In the long term, muscle fibrosis and contractures of joints occur.
  - **Increased risk of malignancy:** Few patients with dermatomyositis above 60 years of age have an underlying malignancy. The most common being ovarian and gastric carcinoma, and lymphoma.
  - **Amyopathic dermatomyositis or dermatomyositis sine myositis:** Presence of pathognomonic skin lesion without muscle involvement.
  - **Investigation:** Muscle biopsy shows necrosis of muscle (single fibers or in groups), perifascicular atrophy, and infiltration with lymphocytes.
- Table 9.33 lists the differences between dermatomyositis, polymyositis and inclusion-body myositis.

## Diagnosis

- **ESR and CRP:** Usually raised.
- **Serum autoantibody studies:** **Antinuclear antibodies** frequently positive.
- **Muscles enzymes:** Raised levels of **serum creatine kinase (CK)**, **aldolase**, serum glutamic oxaloacetic transaminase (SGOT), lactate dehydrogenase (LDH) and serum glutamic pyruvate transaminase (SGPT).
- **Autoantibodies** directed against cytoplasmic RNA synthetases, other cytoplasmic proteins and RNP found in about 30% of patients. Only antihistidyl-tRNA synthetase (anti-Jo-1antibody) is a diagnostic marker

and is found in 20% of patients with polymyositis/dermatomyositis.

**Table 9.33:** Differences between dermatomyositis, polymyositis and inclusion-body myositis.

<i>Features</i>	<i>Dermatomyositis</i>	<i>Polymyositis</i>	<i>Inclusion-body myositis</i>
Sex	F > M	M = F	M >> F
Age of onset	Any	20 years +	50 years +
Onset	Subacute/acute	Chronic	Chronic
Distribution of weakness	Proximal	Proximal	Proximal + distal + asymmetric (typically quadriceps + finger flexors)
Muscle pain/swelling	In acute cases	No	No
Skin involvement	Often	No	No
Raynaud's arthralgia	Frequent	Infrequent	No
Dysphagia	In severe cases	Infrequent	Occasional
Association with cancer	Up to 20%	Probably no	No
Cardiac involvement	Yes	No	No
Interstitial lung disease	Associated with anti-Jo	Associated with anti-Jo	No

- **Electromyography (EMG):** It can confirm the presence of myopathy and exclude neuropathy.
- **MRI:** It can be used to detect abnormally inflamed muscle.
- **Needle muscle biopsy:** Characteristic changes: fiber necrosis, regeneration and lymphocytic inflammatory cell infiltrate. Open biopsy helps in more thorough assessment.
- **Screening for malignancy:** These include CXR (chest X-ray), mammography, pelvic/abdominal ultrasound, PET scan, urine microscopy and circulating tumor markers.

#### Management

- **Corticosteroids:** The treatment of choice is prednisolone (dose of 1 mg/kg daily) till patient shows significant improvement. High-dose intravenous methylprednisolone (1 g/day for 3 days) may be necessary in patients with respiratory or pharyngeal weakness.
- **Additional immunosuppressive therapy:** If no improvement with prednisolone, azathioprine (2–3 mg/kg/day) may be added. It also has some steroid-sparing effect. Other steroid-sparing agents include methotrexate, azathioprine, ciclosporin, cyclophosphamide mycophenolate mofetil,

tacrolimus and MMF.

- **Intravenous immunoglobulin:** It may be effective in refractory or rapidly progressive cases.

Causes of acute and chronic arthritis are listed in Box 9.23.

**Q. Write short note on causes of polyarthritis.**

**Box 9.23:** Causes of acute and chronic arthritis.

**Acute monoarthritis**

- **Inflammatory:** Crystal disease (e.g. gout), infectious disease, spondyloarthropathy, rheumatoid arthritis
- **Mechanical/inflammatory:** Trauma, avascular necrosis

**Acute polyarthritis**

- **Infectious:** Bacterial, HIV
- **Non-infectious:** Rheumatoid arthritis, spondyloarthropathy, other connective tissue diseases, crystal (gout), sarcoidosis, malignancy, leukemia, sickle cell anemia

**Chronic monoarthritis**

- **Inflammatory:** Crystal disease, infectious disease (e.g. tuberculosis, fungal), spondyloarthropathy, rheumatoid arthritis
- **Non-inflammatory:** Osteoarthritis, avascular necrosis, neuropathic arthropathy, villonodular synovitis

**Chronic polyarthritis**

- **Inflammatory:** Rheumatoid arthritis, spondyloarthropathy, other connective tissue diseases
- **Mechanical:** Osteoarthritis
- **Crystal:** Gout
- **Metabolic:** Infiltrative, metabolic, hypothyroidism
- **Malignancy**

Causes of low back pain (Box 9.24).

**Q. Write short note on causes of low back pain.**

**Box 9.24:** Causes of low back pain.

- |                                       |                                 |                   |
|---------------------------------------|---------------------------------|-------------------|
| • Mechanical back pain                | • Prolapsed intervertebral disc | • Osteoarthritis  |
| • Vertebral fracture                  | • Paget's disease of bone       | • Spinal stenosis |
| • Spondylolysis and spondylolisthesis | • Metastases to bone            | • Arachnoiditis   |

# Gastroenterology

# CHAPTER 10

## SYMPTOMATOLOGY AND EVALUATION OF GASTROINTESTINAL DISEASE

### Anorexia (Table 10.1)

**Q.** Write short note on common causes of loss of appetite (anorexia).

### Vomiting

**Definition:** Vomiting is a **complex reflex and involves both autonomic and somatic neural pathways.**

- **Nausea** is a feeling of wanting to vomit and often precedes actual vomiting.
- **Retching** is a strong involuntary unproductive effort to vomit. It is associated with contraction of abdominal muscles but without expulsion of stomach contents through the mouth.

**Mechanism of vomiting:** Synchronous contraction of the diaphragm, intercostal muscles and abdominal muscles raises intra-abdominal pressure. This is combined with relaxation of the lower esophageal sphincter and causes forcible ejection of contents of the stomach.

### *Common Causes of Nausea and Vomiting (Table 10.2)*

**Q.** Write short note on common causes of persistent vomiting and CNS causes of vomiting.

### Table 10.1: Common causes of anorexia.

**Infections:** Viral fever, tuberculosis

**Endocrine diseases:** Hypothyroidism, hyperparathyroidism, Addison's disease, panhypopituitarism

**Liver disease:** Hepatitis, cirrhosis

**Renal disease:** Chronic renal failure

**Malignancies:** Any malignant tumors, e.g. carcinoma stomach, pancreas. Leukemias and lymphomas

**Psychiatric causes:** Depression, **anorexia nervosa**

**Table 10.2: Common causes of nausea and vomiting.**

**Abdominal causes**

**Mechanical obstruction**

Gastric outlet obstruction, small bowel obstruction\*

**Motility disorders**

- Functional dyspepsia gastroesophageal reflux disease (GERD)\*
- Gastroparesis\*

**Other intra-abdominal causes**

- Acute appendicitis, acute cholecystitis, acute hepatitis, acute mesenteric ischemia, eosinophilic gastroenteritis and gastric and duodenal ulcer disease\*

**Drugs**

**Aspirin and other nonsteroidal anti-inflammatory drugs**

**Anti-diabetic agents**

**Anti-gout drugs**

**Anti-microbials:** Acyclovir, anti-tuberculosis drugs, erythromycin, sulfonamides, tetracycline

**Cancer chemotherapy:** Cisplatin, cytarabine, dacarbazine, etoposide, 5-fluorouracil, methotrexate

**Cardiovascular drugs:** Antiarrhythmics, antihypertensives, beta-blockers, calcium channel blockers, digoxin, diuretics

**Central nervous system drugs:**

Antiparkinsonian drugs (levodopa and other dopamine agonists, anticonvulsants

**Others:** Theophylline

**Infectious causes**

Acute gastroenteritis: Viral, bacterial

Nongastrointestinal (systemic) infections

**Metabolic and endocrine causes**

Acute intermittent porphyria, diabetes mellitus, diabetic ketoacidosis, hyperparathyroidism and other causes of hypercalcemia\*

Addison's disease, hyperthyroidism, hyponatremia, hypoparathyroidism, pregnancy

**Central nervous system causes**

Demyelinating disorders, disorders of the autonomic system, hydrocephalus, meningitis, migraine headaches\*

Intracerebral lesions with edema (projectile vomiting): Abscess, hemorrhage, infarction, neoplasm\*

**Labyrinthine disorders**

- Labyrinthitis\*
- Motion sickness

Ménière's disease\*

**Other causes**

- Anxiety and depression\*
- Cyclic vomiting syndrome\*
- Ethanol abuse\*

Cardiac disease:

- Congestive heart failure
- Myocardial infarction

- Functional disorders and bulimia nervosa\*

- Myocardial ischemia

\* Indicates causes of persistent vomiting

## ***Rumination Syndrome/Merycism (Box 10.1)***

### **Box 10.1: Features of rumination syndrome.**

- Rumination is a functional disorder resembles vomiting but does not involve an integrated somatovisceral response coordinated by the emetic center.
- It consists of the repetitive effortless regurgitation of small amounts of recently ingested food into the mouth followed by re-chewing and re-swallowing or expulsion.

## ***Complications of Chronic Vomiting***

### *Emetic injuries to the esophagus and stomach*

- Mild erythema to erosions and ulcerations.
- Abrupt retching or vomiting episodes may produce longitudinal mucosal and even transmural lacerations at the level of the gastroesophageal junction. When the lacerations are associated with acute bleeding and hematemesis, the clinical condition is described as the **Mallory-Weiss syndrome**.
- **Boerhaave's syndrome** refers to spontaneous rupture of the esophageal wall, with free perforation and secondary mediastinitis.
- Dental caries and erosions may result from chronic vomiting.

### *Spasm of the glottis and aspiration pneumonia*

- In patients with diminished consciousness, or in an older person or patient with a depressed cough reflex, may be associated with aspiration of gastric contents into the bronchi, resulting in acute asphyxia and a subsequent risk of **aspiration pneumonia**.

### *Fluid, electrolyte, and metabolic alterations*

- **Hypochloremic alkalosis** is usually the first metabolic abnormality to develop and is attributable to loss of fluid and hydrogen and chloride ions. Hypokalemia, hypernatremia and dehydration can occur.

### *Nutritional deficiencies*

Nutritional deficiencies may result from reduced caloric intake or loss of nutrients in the vomitus.

## Q. Write short note on treatment of vomiting.

### Treatment

1. **Supportive measure: Correction of fluid and electrolyte balance**
2. **Medication:**
  - **Phenothiazines and related drugs:** Prochlorperazine 5 to 10 mg thrice daily
  - **Dopamine antagonists:** Metoclopramide 10 mg 30 minutes before meals and at bedtime. Side effects include drowsiness and extrapyramidal effects. Domperidone (10 mg thrice daily) has no CNS side effects.
  - **Antihistaminic agents**, e.g. diphenhydramine.
  - **Serotonin 5-HT<sub>3</sub> receptor** antagonists: Useful in chemotherapy associated emesis. Examples ondasetron and granisetron.
  - **Neurokinin-1(NK-1)** receptor antagonist, e.g. aprepitant (oral) and fosaprepitant (parenteral) indicated only in chemotherapy-induced nausea and vomiting.
  - **Motilin receptor agonists:** Erythromycin intravenously in boluses of 200 to 400 mg every four to five hours.
  - **Synthetic cannabinoids:** Bethane (muscarinic receptor agonist), Nabilone and dronabinol.
  - **Glucocorticoids:** Especially in raised intracranial tension (ICT), and chemotherapy induced emesis.
  - **Gastric electrical stimulation** in refractory cases

## Hiccough

### Q. Write short note on the causes and symptomatic treatment of hiccough.

The symptom of hiccups (hiccoughs, singultus) is an involuntary, intermittent, spasmodic contraction of the diaphragm and intercostal muscles and glottic closure. Its causes are listed in Table 10.3.

**Table 10.3: Causes of hiccough.**

<ul style="list-style-type: none"><li>• Hasty ingestion of food and fluids</li><li>• <b>Hyponatremia</b></li><li>• <b>Uremia</b></li><li>• Irritation of the phrenic nerve: Due to compression by tumors, esophagitis pericarditis, mediastinitis, surgery of thorax and abdomen</li><li>• Cerebrovascular accidents (especially <b>lateral medullary syndrome</b>), encephalitis, brain tumors</li></ul>	<ul style="list-style-type: none"><li>• Diabetic ketoacidosis, renal failure, respiratory failure and electrolyte imbalance</li><li>• Local irritation of the diaphragm: Due to gaseous distension of stomach and intestines, subphrenic abscess, peritonitis and acute myocardial infarction</li><li>• Psychogenic</li><li>• Unknown</li></ul>
---	---

### Symptomatic treatment

- Advised to drink cold water, swallowing a teaspoon of dry sugar
- Apply pressure over the eyeballs
- Perform Valsalva maneuver
- Rebreathing into a paper bag
- Drugs (Box 10.2)
- Local infiltration of phrenic nerve with procaine
- Acupunctur

### **Box 10.2: Drugs used for the treatment of hiccough.**

- Chlorpromazine 25–50 mg orally or intramuscularly
- Domperidone 10 mg thrice daily
- Metoclopramide 10 mg thrice daily
- Xylocaine viscus 15 mL thrice a day
- Baclofen 5–10 mg thrice a day
- Nifedipine, haloperidol, phenytoin, olanzapine, nefopam and gabapentin can be used

## **Constipation**

**Q. Write short note on define and common causes of constipation.**

**Definition:** Constipation is defined as persistent, difficult, infrequent passage of hard stools, or seemingly incomplete defecation/evacuation. Many patients may also complain of excessive straining or lower abdominal fullness/discomfort.

### ***Criteria for Functional Constipation (Box 10.3)***

**Risk factors:** Advanced age, female gender, low level of physical activity, low socioeconomic status, nonwhite ethnicity and use of certain medications.

### **Box 10.3: Rome III criteria for functional constipation.**

Two or more of the following six must be present\*

1. Straining during at least 25% of defecations
2. Lumpy or hard stools in at least 25% of defecations
3. Sensation of incomplete evacuation for at least 25% of defecations
4. Sensation of anorectal obstruction/blockage for at least 25% of defecations
5. Manual maneuvers to facilitate at least 25% of defecations (e.g. digital evacuation, support of the pelvic floor)
6. Fewer than three defecations/week

\*Criteria fulfilled for the previous three months with symptom onset at least six months prior to diagnosis

## ***Causes of Constipation (Table 10.4)***

### ***Investigations***

It is neither possible nor appropriate to investigate all patients with constipation.

### ***Initial visit***

- Routine biochemistry: Serum calcium, serum glucose, and thyroid function tests
- Complete blood count
- Examination of stool including occult blood
- Digital rectal examination
- Proctoscopy and sigmoidoscopy or colonoscopy: To detect anorectal disease or exclude carcinoma colon (in patients older than 50 years or those with alarm situations such as blood in stool or anemia or weight loss or new onset of symptoms).

### **Table 10.4: Causes of constipation.**

#### **Primary Causes of Constipation**

##### ***Gastrointestinal Disorders***

- **Dietary:** Lack of fiber and/or fluid intake
- **Motility:** Irritable bowel syndrome, slow-transit constipation
- **Structural:** Carcinoma colon, diverticular disease, Hirschsprung's disease
- **Defecation:** Anorectal disease such as Crohn's, fissures, hemorrhoids

#### **Secondary Causes of Constipation**

##### ***Medications***

- Antacids
- Anticholinergic agents (e.g. antiparkinsonian drugs, antipsychotics, antispasmodics, tricyclic antidepressants)
- Anticonvulsants (e.g. carbamazepine, phenobarbital, phenytoin)
- Calcium-channel blockers (e.g. verapamil)
- Diuretics (e.g. furosemide)
- Iron supplements
- Nonsteroidal anti-inflammatory drugs (e.g. ibuprofen)
- Mu-opioid agonists (e.g. fentanyl, loperamide, morphine)

##### ***Metabolic and Endocrinologic Disorders***

- Diabetes mellitus

- Heavy metal poisoning (e.g. arsenic, lead, mercury)
- Hypercalcemia
- Hyperthyroidism
- Hypokalemia
- Hypothyroidism

#### **Neurologic and Myopathic Disorders**

- Amyloidosis
- Autonomic neuropathy
- Dermatomyositis
- Multiple sclerosis
- Parkinsonism
- Progressive systemic sclerosis
- Shy-Drager syndrome
- Spinal cord injury

*If these investigations are normal, a 1 month trial of dietary fiber and/or laxatives is advised.*

### **Next visit**

If symptoms persist, barium studies or CT colonography is indicated to look for structural disease. Colonic transit studies, anorectal manometry and defecography are performed in only in resistant cases without a structural disease.

### **Q. Write short note on management of constipation.**

#### **Treatment**

- Regular exercise and adequate fluid intake.
- Treat the underlying cause or eliminate offending medication.
- **Fiber supplementation:** If there is no secondary cause, increasing the fiber content of the diet and fluid intake. A fiber supplement such as wheat bran or psyllium and mucilaginous seeds and seed coats (e.g. ispaghula husk) with water 2 to 4 times per day.
- **Laxatives (Table 10.5):** They should be restricted to severe cases. Osmotic laxatives act by increasing colonic inflow of fluid and electrolytes by osmotic activity. This softens the stool and stimulates colonic contractility. The stimulatory laxatives act by stimulating colonic contractility and by causing intestinal secretion. Prucalopride is effective in refractory constipation.

**Table 10.5: Various laxatives.**

<i><b>Emollient laxatives</b></i>	<i><b>Stimulant laxatives (stimulate motility)</b></i>	<i><b>Osmotic laxatives</b></i>	<i><b>Others</b></i>
-----------------------------------	--	---------------------------------	----------------------

	<i>and intestinal secretion)</i>		
<ul style="list-style-type: none"> <li>• Docusate salts</li> <li>• Mineral oil</li> <li>• Other agents, e.g. polyethylene glycol and lubiprostone (a synthetic bicyclic fatty acid).</li> </ul>	<ul style="list-style-type: none"> <li>• Phenolphthalein</li> <li>• Bisacodyl</li> <li>• Anthraquinones-senna and dantron (only for the terminally ill)</li> <li>• Docusate sodium</li> <li>• Prucalopride</li> <li>• Castor oil</li> </ul>	<ul style="list-style-type: none"> <li>• Magnesium sulfate</li> <li>• Lactulose/Lactitol</li> <li>• Macrogols</li> </ul>	<ul style="list-style-type: none"> <li>• Guanylate cyclase-C receptor agonists (linaclotide, plecanatide)</li> <li>• Lubiprostone</li> <li>• Misoprostol</li> <li>• Colchicine</li> <li>• Prucalopride</li> </ul>

**Q. Write short note on lactulose (discussed under hepatic encephalopathy on page... of Chapter 11).**

- Lactulose is an osmotic laxative which consists of semisynthetic disaccharide of fructose and lactose. It is neither digested nor absorbed in the small intestine and retains water. It is broken down to osmotically more active products by the bacteria present in the colon.
- **Suppositories**, e.g. bisacodyl and glycerol
- **Enemas**: These include sodium biphosphate, arachis oil, docusate sodium, hypertonic phosphate and sodium citrate

## Chronic Blood and Mucus in the Stools

**Q. Write short note on the causes of chronic blood and mucus in the stools. Mention the investigations done in such cases.**

### *Causes (Table 10.6)*

#### *Investigations*

- **Stool examination**
  - Macroscopy: Fresh blood/altered blood/foul smelling/bulky/floats in water/mucus.
  - Microscopy (Table 10.7)
- **Proctoscopy**: To detect any ulcers or tumors of rectum and hemorrhoids.
- **Sigmoidoscopy**: To detect any ulcers/tumors in the sigmoid colon.
- **Colonoscopy**: To visualize colon.

- **Barium enema:** To identify any growth or filling defects, strictures, ulcers and diverticulae.
- **Biopsy:** Of an ulcer or growth.

**Table 10.6: Causes of chronic blood and mucus in the stools.**

<ul style="list-style-type: none"> <li>• Dysentery               <ul style="list-style-type: none"> <li>– Amebic dysentery</li> <li>– Bacillary dysentery</li> </ul> </li> <li>• Inflammatory bowel disease               <ul style="list-style-type: none"> <li>– Ulcerative colitis</li> <li>– Crohn’s disease</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Intestinal tuberculosis</li> <li>• Carcinoma: Large bowel (rectum, sigmoid and colon)</li> <li>• Diverticulitis</li> <li>• Mesenteric vascular disease</li> <li>• Necrotizing enterocolitis</li> </ul>
---	---

**Table 10.7: Microscopic components that can appear in stool.**

<ul style="list-style-type: none"> <li>• Ova</li> <li>• Trophozoites</li> <li>• Red blood cells</li> <li>• Bacteria</li> <li>• Culture and sensitivity: Grows the organism</li> </ul>	<ul style="list-style-type: none"> <li>• Cysts</li> <li>• Pus cells</li> <li>• Macrophages</li> </ul>
---	---

## Occult Blood in the Stool

### **Q. Write a short note on occult blood in the stool.**

- Stool may appear normal (i.e. no melena) in patients with gastroduodenal bleeding of up to 50–100 mL/day.
- Blood loss in stool of a normal individual varies from 0.5 mL/day to 1.5 mL/day. Occult blood tests begin to become positive usually when blood loss is around 2 mL/day.
- **Test for detection of occult blood in stool**
  - **Guaiaac test:** Gastrointestinal tract bleeding is often intermittent. Hence, this test should be performed for several successive days. This test is negative in a person on iron or bismuth.
  - **Other tests:** Fecal immunochemical tests and heme-porphyrin test.

### **Conditions with Occult Blood in Stool (Table 10.8)**

### **Q. Write a short note on causes of occult blood in the stool.**

## Weight Loss (Table 10.9)

**Q. Write short note on the common causes of weight loss.**

## Glossitis

**Q. Write short note on the causes of glossitis.**

**Definition:** Glossitis is defined as inflammation of the tongue.

### Causes

B-complex deficiency, megaloblastic anemia (pernicious anemia), oral candidiasis, herpes, cirrhosis, iron deficiency anemia, pellagra, scarlet fever, syphilis, chemical irritants, drug reactions, amyloidosis, sarcoidosis, infections, and vesiculo-erosive diseases

## Clinical Features

- Patients may complain of lingual pain (glossodynia) or burning sensation (glossopyrosis).
- Atrophic glossitis is a sign of protein-calorie malnutrition and muscle atrophy and is commonly found in older adults.
- Median rhomboid glossitis manifests as an asymptomatic, well-defined erythematous patch in the mid-posterior dorsum of the tongue.

## Dyspepsia

**Q. Write short note on the causes and differential diagnosis of dyspepsia.**

Dyspepsia is derived from the Greek words *dys* and *pepse* and literally means 'difficult digestion'

- Dyspepsia is a collective description of a variety of gastrointestinal symptoms (Table 10.10).
- **Ulcer dyspepsia:** Dyspeptic symptoms associated with peptic ulcer.
- **Non-ulcer dyspepsia** (functional dyspepsia): No cause can be found.
- **Flatulent dyspepsia:** Usually due to a functional disorder. Symptoms include early satiety, flatulence, bloating and belching predominate.

## Table 10.8: Conditions with occult blood in stool.

Upper gastrointestinal bleeding

Esophageal varices, esophagitis, peptic ulcer disease, gastritis, malignancy

Lower gastrointestinal bleeding	Hemorrhoids, malignancy, diverticulitis, inflammatory bowel disease, celiac sprue
Drugs	Aspirin or steroids (rare)
Others	Hookworm infestation, mesenteric vascular disease

### Table 10.9: Common causes of weight loss.

#### Types of weight loss

- **Physiological:** Due to dieting, exercise, starvation, or decreased nutritional intake (e.g. old age).
- **Pathological/involuntary**
  1. Endocrine and metabolic disorders: Diabetes mellitus, hyperthyroidism, pheochromocytoma, Addison's disease, panhypopituitarism
  2. Gastrointestinal disorders: Malabsorption, tropical sprue, chronic pancreatitis, inflammatory bowel disease (ulcerative colitis and Crohn disease), parasitic infestations.
  3. Chronic infections: Tuberculosis, HIV, fungal infections, amebic abscess
  4. Malignancy: Stomach, colon, pancreas, liver, lung, lymphoma, leukemia.
  5. Psychiatric illness: Anorexia nervosa, depression, schizophrenia
  6. Renal disease: Chronic renal failure, infective endocarditis.
  7. Cardiac disorders: Chronic congestive heart failure
  8. Respiratory disorders: Emphysema, empyema, chronic obstructive pulmonary disease (COPD)
  9. Rheumatological: Rheumatoid arthritis
  10. Idiopathic

### Table 10.10: Symptoms of dyspepsia.

Postprandial fullness	Bloating in the upper abdomen
Early satiation	Nausea
Epigastric pain	Vomiting
Epigastric burning	Belching

#### ***Causes (Table 10.11)***

### **Nonulcer Dyspepsia (Functional Dyspepsia, Nervous Dyspepsia; Nonorganic Dyspepsia)**

**Q. Discuss the etiology clinical features, investigations and management of nonulcer dyspepsia (functional dyspepsia, nervous dyspepsia; nonorganic dyspepsia).**

**Definition:** Chronic dyspepsia in the absence of organic disease.

Second most common functional gastrointestinal disorder (after irritable

bowel syndrome).

### ***Etiology***

- It is dyspepsia in the absence of organic disease and even on detailed investigation, no cause can be found.
- Etiology is poorly understood but probably due to a spectrum of mucosal, motility and psychiatric disorders.
- Symptoms are probably due to disturbances in the motor function of the gastrointestinal tract similar to that occurring in the irritable bowel syndrome. Both irritable bowel syndrome and nonulcer dyspepsia often exist together in the same patient.
- *Helicobacter pylori* infection should be excluded, because it may be responsible for symptoms in few patients.

### ***Clinical Features***

- Usually occurs in young (<40 years of age) females.
- Symptoms and subtypes described in Table 10.12.
- Morning symptoms of pain and nausea on walking are characteristic.
- Features suggestive of irritable bowel syndrome such as pellet-like stools and feeling of incomplete evacuation after defecation may be observed.
- History may reveal stress factors such as worries, financial problems, employment and family affairs.
- On examination, no diagnostic signs, except for inappropriate abdominal tenderness on abdominal palpation.
- All the organic causes of dyspepsia like peptic ulcer disease, drug ingestion, depression pregnancy, alcohol abuse, etc. should be excluded.
- In older patients intra-abdominal malignancy should be excluded which may present with alarming features such as weight loss, anorexia, dysphagia and hematemesis or melena.

**Table 10.11: Causes of dyspepsia.**

#### ***Luminal Gastrointestinal Tract***

- Chronic gastric or intestinal ischemia
- Food intolerance
- Functional dyspepsia

- Gastroesophageal reflux disease
- Gastric or esophageal neoplasms
- Gastric infections (e.g. cytomegalovirus, fungus, tuberculosis, syphilis)
- Gastroparesis (e.g. diabetes mellitus, post-vagotomy, scleroderma, chronic intestinal pseudo-obstruction, postviral, idiopathic)
- Irritable bowel syndrome
- Peptic ulcer disease
- Parasites (e.g. Giardia lamblia, Strongyloides stercoralis)

### **Medications**

Acarbose, aspirin, other nonsteroidal anti-inflammatory drugs (including cyclooxygenase-2 selective agents), colchicine, digitalis preparations, estrogens, ethanol, glucocorticoids, iron, levodopa, niacin, narcotics, nitrates, orlistat, potassium chloride, quinidine, sildenafil, theophylline

### **Pancreaticobiliary Disorders**

- Biliary pain: Cholelithiasis, choledocholithiasis, sphincter of Oddi dysfunction
- Chronic pancreatitis
- Pancreatic neoplasms

### **Systemic Conditions**

Adrenal insufficiency, congestive heart failure, diabetes mellitus, hyperparathyroidism, myocardial ischemia, pregnancy, renal insufficiency, thyroid disease

**Table 10.12: Rome III criteria for functional dyspepsia.**

#### **Causes of vitamin A deficiency.**

Includes one or more of the following:

- |  |   |
|--|---|
| <ol style="list-style-type: none"> <li>1. Botherome postprandial fullness</li> <li>2. Early satiation</li> </ol> | <ol style="list-style-type: none"> <li>3. Epigastric pain</li> <li>4. Epigastric burning</li> </ol> |
|--|---|

and

No evidence of structural disease (including at upper endoscopy) that is likely to explain the symptoms.

Subgroups according to Rome III criteria

- **Epigastric pain syndrome (EPS):** Pain centered in the upper abdomen as the predominant symptom.
- **Postprandial distress syndrome (PDS):** Unpleasant or troublesome nonpainful sensation (discomfort) centered in the upper abdomen is the predominant symptom. This may be accompanied by upper abdominal fullness, early satiety, bloating and nausea.

Any one of the first two criteria 1 or 2 is for EPS while any one last two criteria 3 or 4 is for PDS.

## **Investigations**

The history often suggests the diagnosis.

- *Helicobacter pylori* infection should be serologically excluded in all patients.

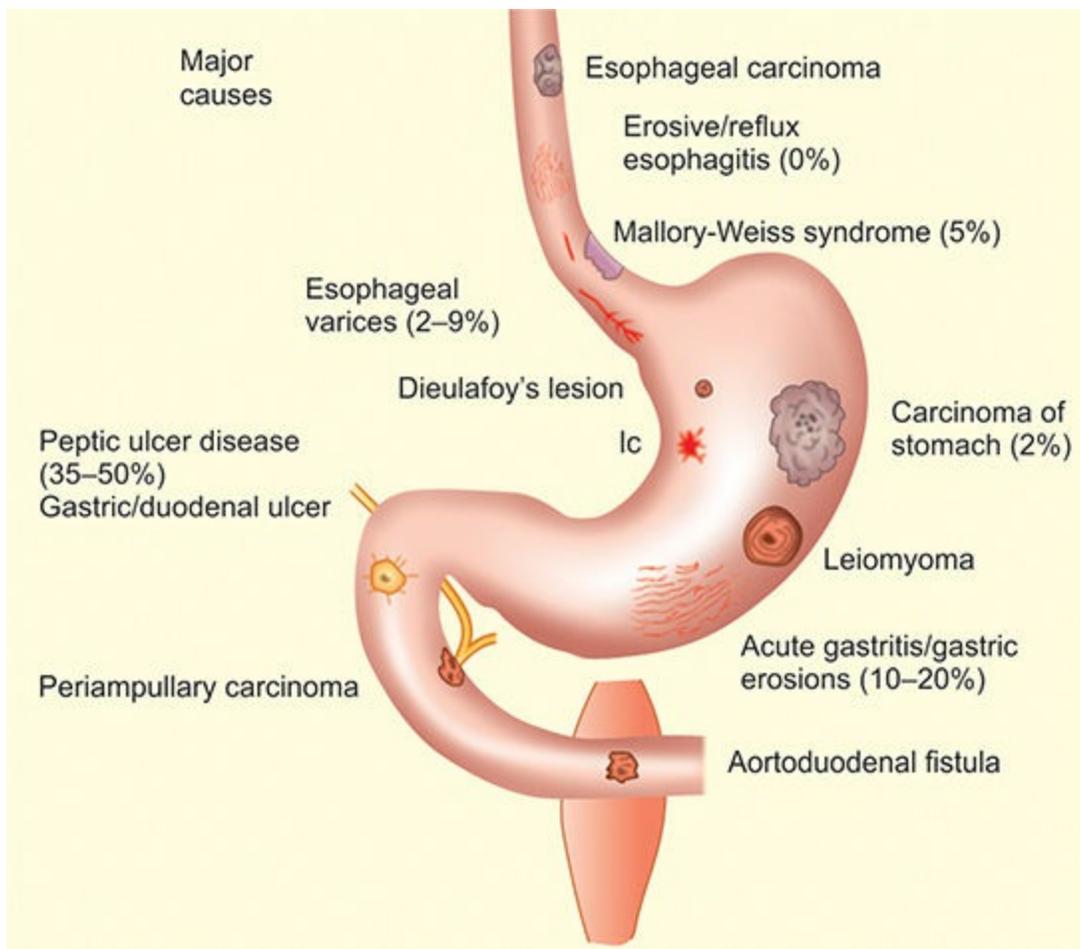

- Exclusion of organic causes by following investigations:
  - Blood count, ESR and occult blood in stools
  - Liver function tests (to exclude alcoholism)
  - Pregnancy test
  - Barium meal
  - Ultrasound scan may detect gallstones.
- Indications for endoscopy in patients with chronic dyspepsia/ RED FLAGS are listed in Box 10.4.

**Box 10.4:** Indications for endoscopy in patients with chronic dyspepsia/RED FLAGS.

- Age >60 years
- Dysphagia/previous peptic ulcer disease, odynophagia
- Clinically significant weight loss (>5% usual body weight over 6 to 12 months)
- Protracted vomiting
- Melena
- Anemia
- Palpable mass
- Jaundice
- Family history of stomach cancer.

**Management (Fig. 10.1)**

- Explanation, reassurance and lifestyle changes.
- Advice to avoid cigarette smoking and alcohol use.
- Symptoms if associated with an identifiable cause of stress resolve with appropriate counseling.
- Psychological factors influencing on gut function should be explained and may require psychological treatment.
- Idiosyncratic and restrictive diets are not beneficial, but reducing intake of fat and coffee may help.
- If endoscopy is non-contributory, empirical treatment is advised.
  - Prokinetic drugs, such as metoclopramide (10 mg 3 times daily) or domperidone (10–20 mg 3 times daily), may be given before meals for nausea, vomiting or bloating.
  - Mosapride or itopride may also be tried.
  - H<sub>2</sub>-receptor antagonists or proton-pump inhibitors if night pain or heartburn is troublesome.
  - H. pylori eradication therapy if test is positive and may be effective in some patients with functional dyspepsia.
  - Selective serotonin reuptake inhibitors may be effective in some patients.
  - Low dose tricyclic agents (e.g. amitriptyline) may be of help in up to two-thirds.
  - SSRI (selective serotonin re-uptake inhibitor) medication is tried in refractory cases

**Fig. 10.1:** Causes of acute upper gastrointestinal hemorrhage.

### ***Distinguishing Features of Nonulcer Dyspepsia and Ulcer Dyspepsia (Table 10.13)***

**Table 10.13:** Distinguishing features of nonulcer dyspepsia and ulcer dyspepsia.

<b>Characteristics</b>	<b>Non-ulcer dyspepsia</b>	<b>Ulcer dyspepsia</b>
Nature of pain	Not episodic	Episodic (periodicity)
Duration of pain	Throughout the day	Occurs only on empty stomach
Relief of pain	Not affected by antacids	Relieved by antacids
Relation of pain with vomiting	Pain is not relieved by vomiting and patient cannot eat afterwards	Pain relieved by vomiting and patient can eat immediately
Relation pain to food	Pain provoked by food	Pain relieved by food
Location of abdominal pain	Diffuse referred to more than one site	Localized referred to epigastrium

Relation of pain to sleep

Pain at night, waking the patient from sleep is rare

Pain at night, waking the patient from sleep is common

## GASTROINTESTINAL BLEEDING

**Q. Enumerate the etiology/causes and investigations of upper gastrointestinal bleeding. Discuss how you will manage a case of esophageal varices.**

**Q. Write short essay on causes of hematemesis.**

### Upper Gastrointestinal (UGI) Bleeding

It is the bleeding proximal to the duodeno-jejunal junction (ligament of Treitz).

#### *Etiology (Table 10.14 and Fig. 10.1)*

Peptic ulcers are the most common cause of UGI bleeding (up to about 50%).

#### *Clinical Features (Table 10.15)*

**Presentation:** Patient usually presents with either hematemesis (vomiting of blood or coffee-ground material) and/or melena (black, tarry stool).

- **Hematemesis: Color of the vomitus** depends on how long the blood has been in the stomach and the severity of bleeding.
  - **Red** with clots when bleeding is severe and bright red indicates rapid and sizeable bleeding.
  - **Black** ('coffee grounds') when less severe and bleeding is small.
- **Melena:** It is the passage of **black, tarry, foul-smelling stools** containing altered blood. The characteristic color and smell are due to the action of digestive enzymes and bacteria on hemoglobin. It usually occurs when more than 60 mL blood is lost and blood has been present in the upper gastrointestinal tract for at least 14 h (and as long as 3–5 days). Occasionally it develops due to hemorrhage from the right side of the colon.
  - Severe/massive acute upper gastrointestinal bleeding can sometimes cause maroon or bright red stool due to passage of frank blood per rectum (**hematochezia**).

- **Occasionally**, presentation with **symptoms of blood loss only**. These include
  - **Acute loss with intravascular volume depletion**: Dizziness, extreme pallor and shock.
  - **Chronic loss**: With symptoms of anemia.

Differences between hematemesis and hemoptysis is presented in Table 10.16.

**Table 10.14:** Various causes of upper gastrointestinal (UGI) bleeding.

**Esophageal causes**

- Esophageal varices (e.g. due to portal hypertension) usually occur from the lower 5 cm of esophagus.
- Erosive esophagitis
- Esophageal carcinoma
- Mallory-Weiss syndrome

**Gastroduodenal causes**

- Peptic ulcer (gastric and duodenal) disease
- Erosive gastritis (e.g. after ingestion of NSAIDs and alcohol) or duodenitis
- Stress ulcers occurring with **shock, sepsis, or severe trauma**
- **Curling ulcers** in the proximal duodenum with **severe burns or trauma**.
- Carcinoma stomach
- Gastric antral vascular ectasia (GAVE), also described as watermelon stomach, Dieulafoy’s lesion
- Angiodysplasia or vascular malformations (Heydes syndrome in aortic stenosis)
- Rupture of aortic aneurysm or aortic duodenal fistula following aortic graft. Cushing ulcer associated with elevated intracranial pressure

**Other cause**

- Coagulation defects
- Cameron’s lesions: Linear erosions or ulcerations in the proximal stomach at the end of a large hiatal hernia, near the diaphragmatic pinch
- Hemobilia
- Hemosuccus pancreaticus

**Table 10.15:** Features suggesting probable source of upper GI bleeding.

<i>History of</i>	<i>Probable source of bleeding</i>
<ul style="list-style-type: none"> <li>• Features suggestive of peptic ulcer</li> </ul>	Peptic ulcer disease
<ul style="list-style-type: none"> <li>• Jaundice, pedal edema, abdominal distension, splenomegaly, ascites, dilated abdominal veins</li> <li>• Features of liver cell failure, e.g. spider nevi, palmar erythema, jaundice and gynecomastia</li> </ul>	Esophageal varices

• Alcohol or drug (NSAIDs) ingestion, trauma, burns or sepsis	Gastric erosions
• Heavy alcohol intake or vomiting	Mallory-Weiss tear
• Dysphagia and weight loss prior to bleeding	Malignant (stomach or esophageal cancer)/intra-abdominal tumor
• Tenderness or a mass	

**Table 10.16:** Differences between hematemesis and hemoptysis.

<i>Features</i>	<i>Hemoptysis</i>	<i>Hematemesis</i>
Definition	Coughing out of blood	Vomiting out of blood
Content and color	Mixed with sputum and bright red in color	Mixed with food particles and coffee-ground in color
Contents	Frothy, associated sputum	No froth, associated food particles
Associated symptoms	Cough, dyspnea	Nausea, vomiting, retching, abdominal discomfort
Melena	Rare	Common
Reaction	Alkaline (blue litmus remains unchanged)	Acidic (blue litmus remains unchanged)

**Q. Write short essay on evaluation and treatment/management of upper gastrointestinal bleeding.**

## *History*

### *Physical Examination: Look for*

- Vital signs, orthostatic hypotension
- Abdominal tenderness
- Skin, oral examination
- Stigmata of liver disease
- *Rectal examination:*
  - Objective description of stool/blood
  - Assess for mass, hemorrhoid.

Differences between upper and lower GI bleed are presented in Table 10.17.

**Table 10.17:** Differences between upper and lower GI bleed.

<i>Features</i>	<i>Upper GI tract bleed</i>	<i>Lower GI tract bleed</i>
Site of bleeding	Above ligament of Treitz	Below ligament of Treitz
Clinical	Hematemesis or melena	Hematochezia/rarely melena

presentation		
Nasogastric aspiration shows	Blood	Clear fluid
Bowel sounds	Hyperactive	Normal
BUN (blood urea nitrogen)/creatinine ratio	Increased	Normal

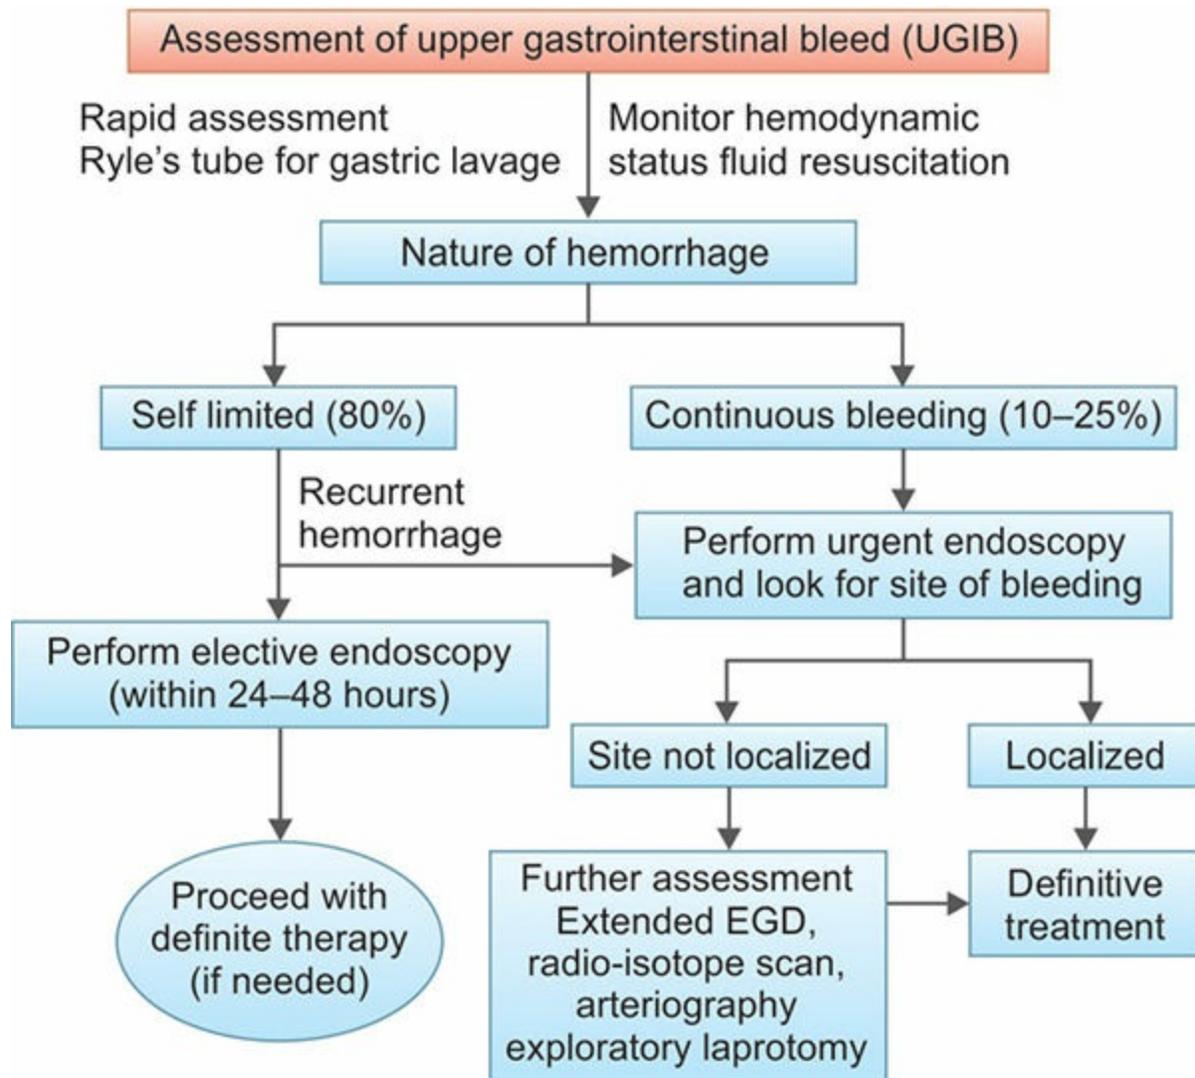

## ***Basic Investigations***

- Complete blood count
  - Chronic bleeding leads to anemia, but the hemoglobin concentration and the hematocrit level may be normal after sudden, major bleeding until hemodilution occurs.
  - Low platelet count: Suggests chronic liver disease, dilution, or hematologic disorder.
- **Blood urea nitrogen (BUN) and creatinine:** The blood urea nitrogen level increases to greater extent than the creatinine level because of increased intestinal absorption of urea after breakdown of blood proteins. An elevated blood urea with normal creatinine concentration implies severe bleeding.
- **Liver function tests.** They may show evidence of chronic liver disease.
- **Prothrombin time:** It may be prolonged in patients with chronic liver disease or in coagulation disorders or patients on anticoagulated therapy.
- **Cross-matching:** Potential infusion of packed red blood cells.

**Q. Write short essay on management and drugs used in upper gastrointestinal bleeding.**

Assessment of upper GIT bleed is presented in Flowchart 10.1

**Flowchart 10.1:** Assessment of upper gastrointestinal bleed (UGIB)

## Management

**Medical resuscitation and replenishment of intravascular volume:** In case of massive bleeding, resuscitation measures should be initiated simultaneously with the initial assessment.

- **Intravenous access:** The first step is to gain intravenous access using at least one large-bore (14- or 16-gauge) intravenous catheters for essentially all patients so that normal saline can be infused as fast as necessary to maintain hemodynamic stability.
- **Fluid resuscitation:** Adequate resuscitation and hemodynamic stabilization is essential prior to endoscopy (saline). Vasopressors if persistent hypotension.
- **Blood product transfusions:** Initiate blood transfusions if the hemoglobin is  $<7$  g/dL to maintain the hemoglobin at a level of  $\geq 9$  g/dL. Patients with active bleeding and a low platelet count ( $<50,000/\mu\text{L}$ ) should be transfused with platelets. Patients with a coagulopathy with a prolonged prothrombin time with  $\text{INR} >1.5$  should be transfused with fresh frozen plasma (FFP).

### Initial clinical assessment:

- **Circulatory status:** Severe bleeding causes tachycardia, hypotension and oliguria. Closely observe with hourly pulse, blood pressure, postural hypotension urine output and level of consciousness.
- **Evidence of liver disease:** May be present in patients with decompensated cirrhosis.

- Comorbidity: Such as cardiorespiratory, cerebrovascular or renal may be worsened by acute bleeding and also increase the hazards of endoscopy and surgical operations.

**Gastric lavage:** This procedure has been abandoned in present day.

- **Procedure:** Gastric lavage is performed by instilling 500 mL of ice-cold or tap water every 30–60 minutes.
- **Advantages** of nasogastric or orogastric tube helps to localize the site of upper GI bleeding. Determine the type of material whether red blood or coffee-ground. Assess the rate, severity, persistency, and recurrence of the bleeding. Clear the blood from stomach for better endoscopic visualization prior to endoscopy. Remove blood → reduces the risk of encephalopathy in patients with liver disease. Dilute acid-pepsin in stomach → reduces bleeding from erosions. Minimize the risk of aspiration
- **Prognostic score:** Rockall score is based upon age, the presence of shock, comorbidity, diagnosis, and endoscopic stigmata of recent hemorrhage.

## Endoscopy

### *Pre-endoscopic pharmacotherapy*

For nonvariceal UGIB (upper gastrointestinal bleeding)

- IV proton pump inhibitor: 80 mg bolus, 8 mg/hr drip (esomeprazole).
- Rationale: Suppress acid, facilitate clot formation and stabilization.

*Goal of endoscopic therapy:* To stop acute bleeding and reduce the risk of recurrent bleeding.

- Early endoscopy (within 24 hours) is recommended for most patients with acute UGIB.
- Achieves prompt diagnosis, provides risk stratification and hemostasis therapy in high-risk patients.

### *Endoscopic hemostasis therapy*

It includes (1) epinephrine injection, (2) thermal electrocoagulation, and (3) mechanical (hemoclips). Combination therapy is superior to monotherapy.

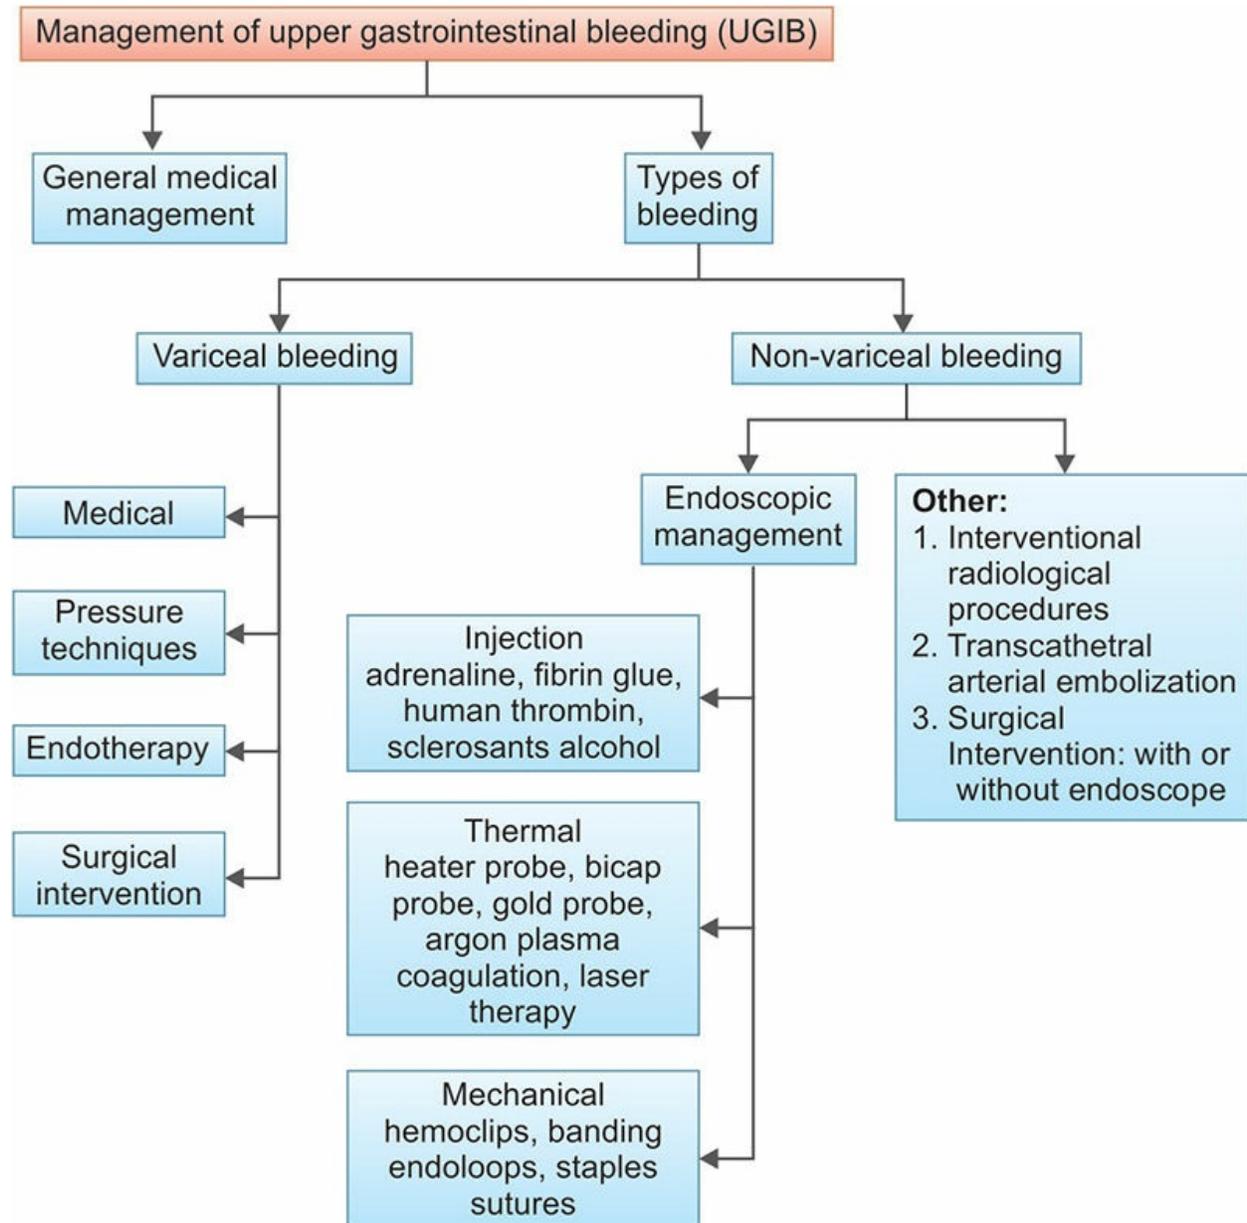

Nonvariceal UGIB: Postendoscopy management (Box 10.5)

**Box 10.5:** Postendoscopy management of nonvariceal UGIB.

- Patients with ulcers requiring endoscopic therapy should receive PPI x 72 hours.
- Determine *H. pylori* status in all ulcer patients.
- Discharge patients on PPI (once to twice daily), duration dictated by underlying etiology and need for NSAIDs/aspirin.
- In patients with cardiovascular disease on low dose aspirin: Restart as soon as bleeding has resolved.

Management of upper GI tract bleeding is summarized in Flowchart 10.2.

**Flowchart 10.2:** Management of upper GI tract bleeding.

(CV: cardiovascular prevention; NSAID: non-steroidal antiinflammatory drugs; PPI: proton pump inhibitors; H2 RA: Histamine H2-receptor antagonists)

## Variceal Bleeding

Occurs in 1/3 of patients with cirrhosis. In 1/3 initial bleeding episodes are fatal. Among survivors, 1/3 will rebleed within 6 weeks. Only 1/3 will survive 1 year or more. Management of variceal bleed is discussed in Chapter 11.

## Lower GI (LGI) Bleed

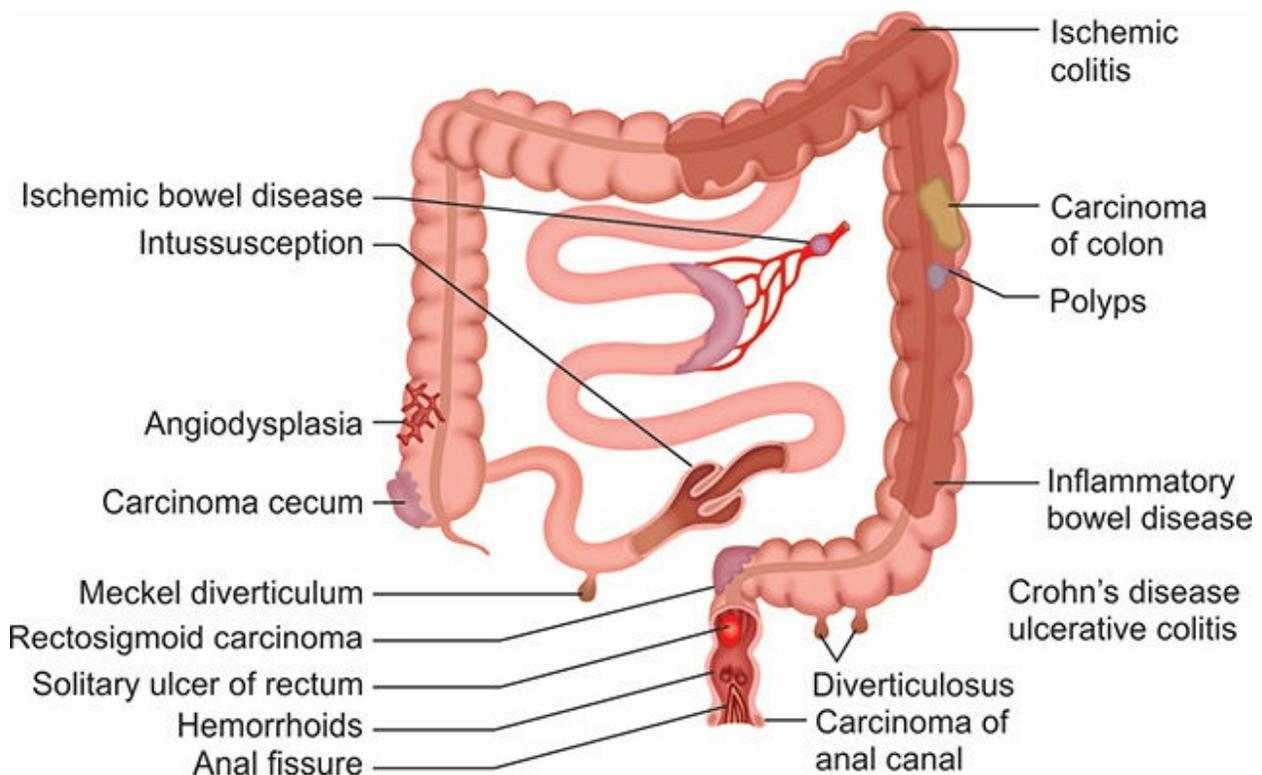

**Q. Write short essay on causes of lower gastrointestinal bleeding.**

LGI bleeding generally signifies bleeding from the colon or anorectum. In patients with severe hematochezia, first consider possibility of UGIB. About 10–15% of patients with presumed LGIB are found to have upper GIB.

**Etiology (Table 10.18 and Fig. 10.2)**

**Table 10.18: Causes of vitamin A deficiency.**

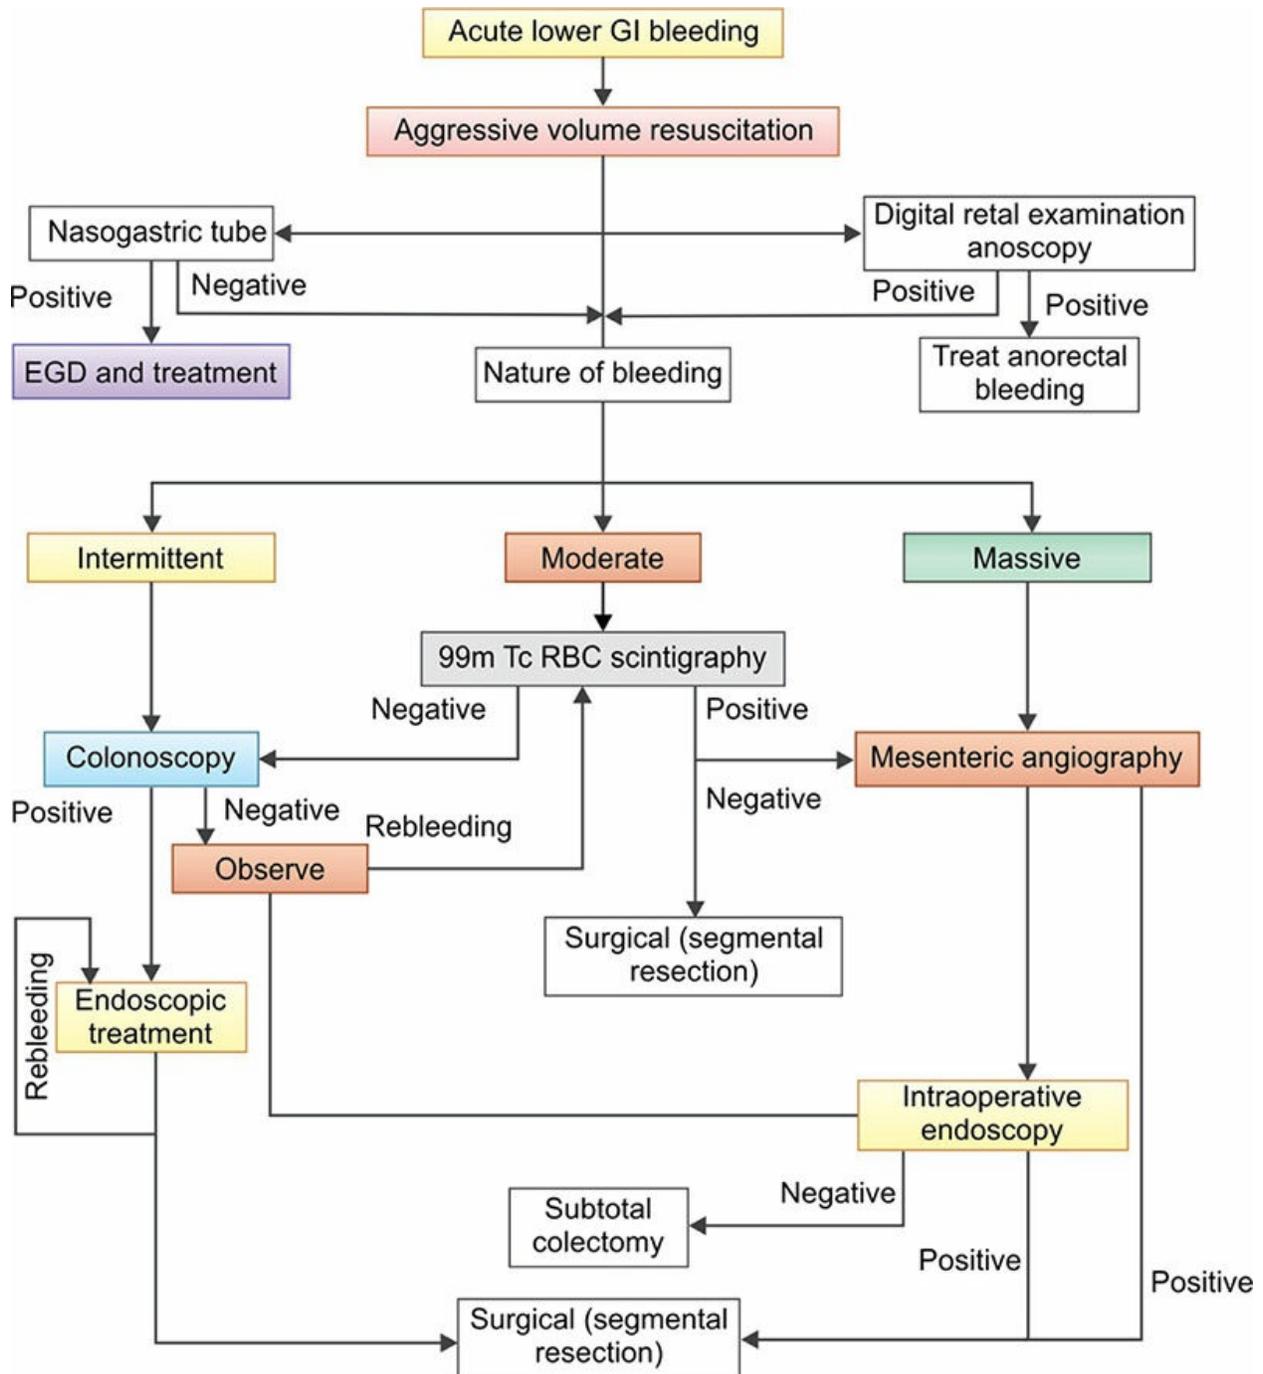

Diverticulosis (main cause)	Angioectasias
Hemorrhoids anal fissures, ulcer	Colitis (IBD, infectious, ischemic)
Neoplasms	Post-polypectomy
Dieulafoy's lesion	Radiation colitis, small bowel bleed
	Unknown causes-10%

**Fig. 10.2:** Causes of lower gastrointestinal bleed (LGIB)

**Management of LGI Bleed (Flowchart 10.3)**

**Flowchart 10.3:** Management of lower gastrointestinal bleeding.

## APPROACH TO DIARRHEA

**Q. Enumerate the common cause of diarrhea in the tropics.**

**Definition:** Daily bowel movements of three or more times are considered to be abnormal. The upper limit of stool weight is 200 g daily. Although stool

weight usually considered as a ‘scientific’ definition of diarrhea, diarrhea should not be defined solely in terms of fecal weight.

- **Acute diarrhea** is defined as abrupt onset of increased frequency and/or fluidity of bowel movements.
- **Chronic diarrhea** is defined as passage of loose stools with or without increased stool frequency for more than 4 weeks.

### Large-Volume versus Small-Volume Diarrhea

- Normal rectosigmoid colon functions as a storage reservoir.
- **Left colonic disorders:** Inflammatory or motility disorders involving the left colon compromises this rectosigmoid reservoir capacity and results in **frequent small-volume bowel movements**.
- **Right colonic or small bowel disorders:** In diarrhea due to disorders of the right colon or small bowel and if the rectosigmoid reservoir is intact, individual **bowel movements are less frequent and larger**.

Frequent, small, painful stools may point to a source in the distal colon, whereas painless large-volume stools suggest a right colonic or small bowel source.

### Secretory versus Osmotic Diarrhea (Table 10.19)

- **Secretory diarrhea:** It results from malabsorption or secretion of electrolytes (secretory diarrhea).
- **Osmotic diarrhea:** It results from intestinal malabsorption of ingested nonelectrolytes.
- Osmotic diarrhea constitutes small number of cases whereas secretory diarrhea forms the much larger number of cases.
- In secretory diarrhea, sodium, potassium, and accompanying anions account almost entirely for stool osmolality. In contrast, in osmotic diarrhea poorly absorbable solutes within the lumen of the intestine account for much of the osmotic activity of stool water.

**Table 10.19:** Secretory versus osmotic diarrhea.

<i>Type of diarrhea</i>	<i>Causes</i>	<i>Examples</i>
Secretory diarrhea	Exogenous secretagogues	Enterotoxins (e.g. cholera)
	Endogenous secretagogues	Neuroendocrine tumors (e.g. carcinoid syndrome)

	Absence of ion transporter	Congenital chloridorrhea
	Loss of intestinal surface area	Intestinal resection, diffuse intestinal mucosal disease
	Intestinal ischemia	Diffuse mesenteric atherosclerosis
	Rapid intestinal transit	Intestinal hurry following vagotomy
Osmotic diarrhea	Ingestion of poorly absorbed agent	Magnesium ingestion
	Loss of nutrient transporter	Lactase deficiency

## Watery versus Fatty versus Inflammatory Diarrhea

- **Watery diarrhea:** It implies a defect primarily in water absorption as a result of increased electrolyte secretion or reduced electrolyte absorption (secretory diarrhea) or ingestion of a poorly absorbed substance (osmotic diarrhea).
- **Fatty diarrhea:** It implies defective absorption of fat and perhaps other nutrients in the small intestine.
- **Inflammatory diarrhea:** It implies the presence of one of a limited number of inflammatory or neoplastic diseases involving the gastrointestinal tract.

## Causes of Diarrhea in the Tropics (Table 10.20)

**Table 10.20:** Causes of diarrhea in tropics.

<i>Gastroenteritis induced by toxin</i>	<i>Gastroenteritis induced by changes in mucosa</i>
<ul style="list-style-type: none"> <li>• Performed toxins: <i>Staphylococcus aureus</i>, <i>Bacillus cereus</i></li> <li>• Mucosal changes without invasion: Rotavirus, Norwalk agent</li> </ul>	<ul style="list-style-type: none"> <li>• Enterotoxins produced in the intestine, <i>Clostridium perfringens</i>, <i>Vibrio cholerae</i>, Enterotoxigenic <i>Escherichia coli</i>, Enterohemorrhagic <i>E. coli</i>, <i>Clostridium difficile</i></li> <li>• Invasion of mucosa/inflammatory (invasion or cytotoxin) dysentery <ul style="list-style-type: none"> <li>– <i>Salmonella spp</i>, <i>Shigella spp</i>, Enterohemorrhagic <i>E. coli</i>, Enteroinvasive <i>E. coli</i>, <i>Campylobacter jejuni</i>, <i>Yersinia enterocolitica</i>, <i>Entameba histolytica</i></li> </ul> </li> <li>• Other causes: Mushrooms, Heavy metals (arsenic), Monosodium glutamate</li> </ul>

## Causes of Chronic Diarrhea (Table 10.21)

**Q. Write short note on causes of chronic diarrhea.**

**Table 10.21: Causes of chronic diarrhea.**

<b>Fatty diarrhea</b>	<b>Watery diarrhea</b>
<p><b>1. Malabsorption syndromes</b></p> <ul style="list-style-type: none"> <li>• Mucosal diseases (e.g. celiac disease, Whipple’s disease)</li> <li>• Mesenteric ischemia</li> <li>• Short bowel syndrome</li> <li>• Small intestinal bacterial overgrowth</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Osmotic diarrhea</b> <ul style="list-style-type: none"> <li>– Carbohydrate malabsorption</li> <li>– Osmotic laxatives</li> </ul> </li> <li>• Secretory diarrhea</li> <li>• Bacterial toxins</li> <li>• Congenital syndromes (e.g. congenital chloridorrhea)</li> <li>• Disordered motility, regulation                             <ul style="list-style-type: none"> <li>– Diabetic autonomic neuropathy</li> <li>– Irritable bowel syndrome</li> <li>– Postsympathectomy diarrhea</li> <li>– Postvagotomy diarrhea</li> </ul> </li> <li>• Diverticulitis</li> <li>• Endocrinopathies: Addison’s disease, carcinoid syndrome, gastrinoma, hyperthyroidism, mastocytosis, medullary carcinoma of thyroid, pheochromocytoma, somatostatinoma, VIPoma</li> <li>• Laxative abuse (stimulant laxatives)</li> <li>• Medications and toxins</li> </ul>
<p><b>2. Maldigestion</b></p> <ul style="list-style-type: none"> <li>• Inadequate luminal bile acid concentration</li> <li>• Pancreatic exocrine insufficiency</li> </ul>	
<p><b>Inflammatory diarrhea</b></p> <ul style="list-style-type: none"> <li>• Diverticulitis</li> <li>• Infectious diseases                             <ul style="list-style-type: none"> <li>– Invasive bacterial infections (e.g. tuberculosis, yersiniosis)</li> <li>– Invasive parasitic infections (e.g. amebiasis, strongyloidosis)</li> <li>– Pseudomembranous colitis (<i>Clostridium difficile</i> infection)</li> <li>– Ulcerating viral infections (e.g. cytomegalovirus, herpes simplex virus)</li> </ul> </li> <li>• Inflammatory bowel diseases: Crohn’s disease, ulcerative colitis</li> <li>• Ischemic colitis</li> <li>• Neoplasia: Carcinoma of colon, lymphoma</li> <li>• Radiation colitis</li> </ul>	

**Food Poisoning (refer pages 130-2)**

**Approach to the Patient with Acute Diarrhea**

**Q. Discuss the evaluation and management of acute diarrhea.**

**Assessment of the Patient**

- Degree of dehydration
- Evidence of specific cause
- Necessity of any diagnostic tests

- Requirement for any treatment

### **History (Table 10.22)**

#### **Physical Examination**

- Examine for signs of dehydration to assess the severity of the diarrhea. These include examination of pulse, blood pressure (including postural change), skin turgor, dryness of mucous membranes (e.g. mouth), mental status and breathing.
- Severity of dehydration (Table 10.23)
- Electrolyte imbalances: Assess muscle strength and muscle reflexes which may be reduced in hypokalemia.
- Examination of abdomen to exclude any surgical cause (e.g. intestinal obstruction).

#### **Laboratory Investigations**

Laboratory investigations usually do not help in the management acute diarrhea.

- **Total WBC count:** Presence of high leukocyte count with shift to left suggests invasive bacterial infection.
- **Electrolytes and acid-base status:** It should be done in patients with severe dehydration. Severe diarrhea produces metabolic acidosis.
- **Blood cultures:** To be performed when bacteremia or a systemic infection is suspected.
- **Stool examination:** Grossly bloody or mucus in the stool suggests an inflammatory process. In severe cases stool should be examined for the presence of leukocytes, red cells and cysts or trophozoites/parasites. In cholera *V.cholerae* show the characteristic darting motility. Stool with leukocytes consider inflammatory causes (*Shigella*, *Salmonella*, *Campylobacter*, *E. coli*, *Entamoeba* and *Clostridium difficile*).
- **Stool culture**

**Table 10.22:** Features to be noted during taking history in a patient with acute diarrhea.

1. Duration of diarrhea
2. Travel or use of antibiotics

3. Having food outside in the recent past and time since consumption
4. Any other family member or close associated affected
5. *Associated features*: Pain abdomen, fever, vomiting, tenesmus
6. *Stool*: Frequency of loose stools, volume, appearance of stools (e.g. rice water), presence of blood or mucus in the stools
7. Urine output
8. Any alteration in the level of consciousness
9. Occupation of the patient

**Table 10.23: Severity of dehydration.**

<b>Features</b>	<b>Mild</b>	<b>Moderate</b>	<b>Severe</b>
Urine output	Decreased	Decreased	Markedly decreased
<b>Physical examination</b>			
Level of consciousness	Normal	Normal	Depressed
Mental status	Normal/irritable	Lethargic	Comatose
Skin	Normal	Cool	Cool and mottled
Skin turgor	Normal	Reduced with skin tenting	Markedly reduced
Mouth/oral mucosa	Dry	Markedly dry	Parched
Eyes	Normal	Sunken (sunken fontanelle in infants)	Markedly sunken
Pulse rate	Normal or mild increase	Tachycardia, feeble	Marked tachycardia
Blood pressure	Normal	Postural/orthostatic fall	Hypotension and frank shock
Respiration	Normal	Normal	Acidotic
<b>Investigations</b>			
Urine specific gravity	<1.020	>1.020	>1.035
Blood urea	Normal	Normal to raised	High

Systemic complications of acute diarrheal disease is presented in Table 10.24

**Table 10.24: Systemic complications of acute diarrheal disease.**

<b>Complication</b>	<b>Associated organism</b>
Sepsis	<i>Shigella</i> species, Nontyphoidal <i>Salmonella enterica</i> , <i>Campylobacter fetus</i>
Hemolytic-uremic syndrome	<i>Shigella</i> species, Shiga toxin-

	producing <i>Escherichia coli</i>
Guillain-Barré syndrome	<i>Campylobacter jejuni</i>
Reactive arthritis	<i>Campylobacter species</i> , <i>Salmonella species</i> , <i>Shigella flexneri</i>

## Small Bowel versus Large Bowel Diarrhea (Table 10.25)

**Table 10.25:** Differences between small bowel and large bowel diarrhea.

Features	Small bowel diarrhea	Large bowel diarrhea
Characteristic of diarrhea	Large-volume, watery diarrhea	Frequent, small volume, often painful bowel movements
Associated clinical features	Abdominal cramping, bloating and gas formation	Gripping pain in lower abdomen
Fever	Uncommon	Present
Tenesmus	Absent	Present
Blood or mucus stools	Not common	Common
Inflammatory cells and red blood cells in stools	Absent	Present

### Management (Flowchart 10.4)

Most of acute diarrhea is self-limited and fluid and electrolyte replacement are of most important in all cases.

#### Rehydration

- Severe diarrhea produces dehydration especially in the very young and very old.
- Toxin-induced diarrhea produces stools that are usually isotonic. Concentrations of sodium and chloride are slightly less than that of plasma while bicarbonate concentration is double that of plasma. The stools also contain significant amount of potassium.
- In inflammatory diarrhea the electrolyte loss is of less compared to toxigenic diarrhea.

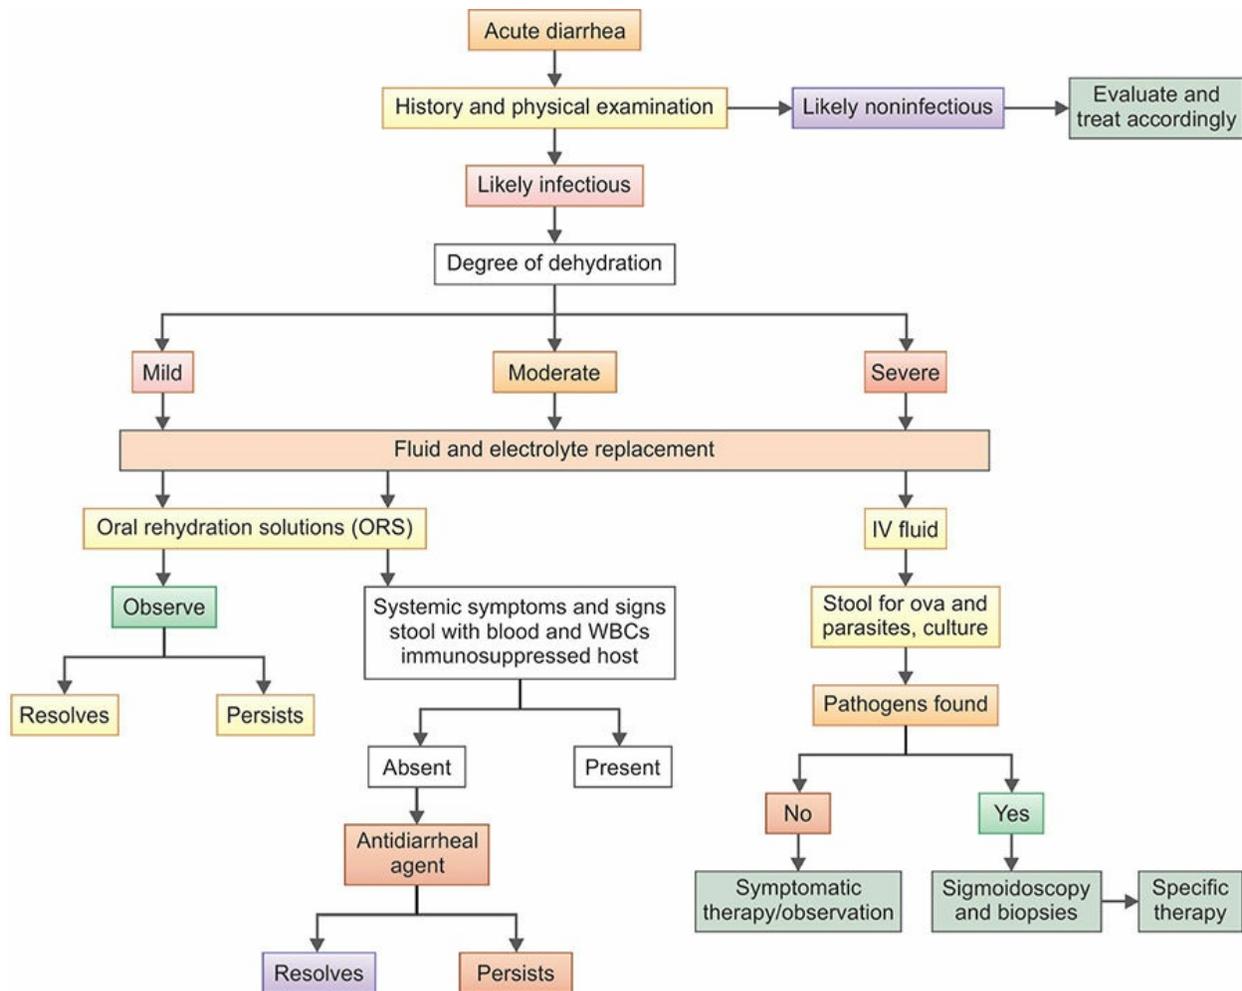

#### Oral rehydration solution (ORS)

Used for mild to moderate dehydration.

#### Intravenous fluids

- Used when there is moderate-to-severe dehydration.
- Usually Ringer's lactate is administered.
- In severe cases, fluids are administered at a rate of 20 mL/kg/hour for the first 2–3 hours. If the patient improves, reduce the rate to 10 mL/kg/hour for the next 2–4 hours.
- Concurrently start oral rehydration therapy.

**Flowchart 10.4:** Approach to the management of acute diarrhea

### **Absorbants**

Kaolin absorbs the toxin and may be of use in few patients. However, it does not affect the course of the disease.

### **Antimotility drugs**

- Used for symptomatic treatment of toxin-induced diarrhea in adults only. It should not be used in young children and elderly.
- It can be given in inflammatory diarrhea along with antibiotics. These include:
  - Opiates (e.g. morphine and codeine): They may cause respiratory depression.
  - Diphenoxylate/atropine combination: May cause respiratory depression and anticholinergic side effects.
  - Loperamide: Dose is 2 tablets of 4 mg each initially, then 2 mg after each unformed stool, not to exceed 16 mg/day for  $\leq 2$  days.
  - Bismuth subsalicylate: It acts as an antisecretory agent. Dose is 1 tablet every 30 minutes for a total of 8 doses or 60 mL every 6 hourly.

### **Antisecretory agents: Racecadotril**

- Reduces the hypersecretion of water and electrolytes into the intestinal lumen.
- Inhibits enkephalinase (an enzyme that degrades enkephalins)

- Dose: 100 mg thrice daily. To be given to patients with acute, watery diarrhea only.
- Contraindication: Renal insufficiency, pregnancy and breastfeeding.

### **Antispasmodics**

Mild antispasmodics such as dicyclomine, hyoscine may be used in patients with significant abdominal cramps.

### **Antibiotics: Indications**

- Symptomatic patients with inflammatory diarrhea (high fever, toxicity, abdominal pain).
- Acute febrile dysentery illness.
- Diarrhea caused by *Campylobacter jejuni*. Early use of erythromycin or azithromycin limits the duration of illness.
- Commonly used antibiotics: Quinolones (norfloxacin 400 mg and ciprofloxacin 500 mg both given twice daily or levofloxacin 500 mg given once a day) for 3–5 days.
- Cholera: Doxycycline in a dose of 300 mg as single dose. Alternatives include trimethoprim-sulphamethoxazole, furazolidone and norfloxacin.

### **Specific Treatment once Cause Identified**

Nonspecific drug therapy for chronic diarrhea is presented in Table 10.26.

**Table 10.26:** Nonspecific drug therapy for chronic diarrhea.

<b>Drug class</b>	<b>Agent</b>
Opiates (mu opiate receptor selective)	Codeine, Diphenoxylate, Loperamide, Morphine, Tincture of opium
Enkephalinase inhibitor (delta opiate receptor effects)	Racecadotril
Alpha-2 adrenergic agonist	Clonidine
Somatostatin analog	Octreotide
Bile acid-binding resin	Cholestyramine, Colesevelam, Colestipol
Fiber supplements	Calcium polycarbophil, Psyllium

## **Traveler's Diarrhea**

### **Q. Write short note on traveler's diarrhea.**

Traveler's diarrhea is the leading cause of illness in travelers. Usually a short-lived and self-limited.

### **Etiology**

- Causative agents: Various pathogens causing travelers' diarrhea are listed in Table 10.27. Most important pathogens are *Escherichia coli* and enteroaggregative *E. coli*; rotavirus and norovirus.

- Source of infection: Main source of infection are food and water contaminated with fecal matter.

**Table 10.27: Various causes of traveler’s diarrhea.**

<b>Bacteria (50–75%)</b>	<b>Viruses (0–20%)</b>	<b>Parasites (0–10%)</b>
<i>Enterotoxigenic Escherichia coli</i>	<i>Norovirus (winter vomiting bug)</i>	<i>Giardia lamblia</i>
<i>Enteroaggregative E. coli</i>	Rotavirus	<i>Cryptosporidium</i>
<i>Campylobacter jejuni</i>		<i>Entamoeba histolytica</i>
<i>Shigella</i>		
<i>Salmonella (non-typhoid)</i>	No pathogens (10–50%)	

### **Clinical Features**

- Usually involves intercontinental travelers.
- Symptoms: Abrupt in onset, watery diarrhea lasting 2–5 days, abdominal cramps, nausea, vomiting, anorexia and fever.
- Signs: Diffuse tenderness over abdomen.

#### **Treatment**

- Usually self-limited and requires no treatment.
- Dehydration is corrected by oral rehydration supplements.
- Drugs:
  - Antidiarrheal agents and antibiotics are only rarely required.
  - If there is fever or bloody diarrhea advise norfloxacin or ciprofloxacin. Azithromycin is used in patients who are allergic to quinolones
  - Rifaximin (a poorly absorbed rifampicin derivative) is very effective against non-invasive bacterial pathogens.

#### **Prevention**

- Drugs: Doxycycline 100 mg/day for a few weeks. Norfloxacin/ciprofloxacin/rifaximin once a day.
- Probiotics may be useful

## **DISEASES OF THE ESOPHAGUS**

### **Dysphagia**

**Q. Write short essay/note on causes and investigation (evaluation) and management of dysphagia.**

Dysphagia, from the Greek dys (difficulty, disordered) and phagia (to eat), refers to the sensation that food is hindered in its passage from the mouth to the stomach.

## ***Causes of Dysphagia***

### *Oropharyngeal dysphagia*

Processes that affect the mouth, hypopharynx, and upper esophagus. The patient often is unable to initiate a swallow and repeatedly has to attempt to swallow. Patients frequently describe coughing or choking when they attempt to swallow. Causes of oropharyngeal dysphagia are listed in Table 10.28.

**Table 10.28: Causes of oropharyngeal dysphagia.**

<i>Neuromuscular causes</i>	<i>Structural causes</i>
<ul style="list-style-type: none"> <li>• Amyotrophic lateral sclerosis (ALS)</li> <li>• Multiple sclerosis</li> <li>• Muscular dystrophy</li> <li>• Myasthenia gravis</li> <li>• Parkinson’s disease</li> <li>• Polymyositis or dermatomyositis</li> <li>• Stroke</li> <li>• Thyroid dysfunction</li> </ul>	<ul style="list-style-type: none"> <li>• Carcinoma</li> <li>• Infections of pharynx or neck</li> <li>• Osteophytes and other spinal disorders</li> <li>• Prior surgery or radiation therapy</li> <li>• Proximal esophageal web</li> <li>• Plummer–Vinson syndrome</li> <li>• Thyromegaly</li> <li>• Zenker’s diverticulum</li> </ul>

### ***Esophageal dysphagia (Table 10.29)***

**Table 10.29: Common causes of esophageal dysphagia.**

<i>Motility (Neuromuscular) disorders</i>	<i>Structural (Mechanical) disorders</i>
<p><b>Primary disorders</b></p> <ul style="list-style-type: none"> <li>• Achalasia</li> <li>• Diffuse esophageal spasm</li> <li>• Hypertensive LES</li> <li>• Ineffective esophageal motility</li> <li>• Nutcracker (high-pressure) esophagus</li> </ul>	<p><b>Intrinsic</b></p> <ul style="list-style-type: none"> <li>• Carcinoma and benign tumors</li> <li>• Diverticula</li> <li>• Eosinophilic esophagitis</li> <li>• Esophageal rings and webs (other than Schatzki ring)</li> <li>• Foreign body</li> <li>• Lower esophageal (Schatzki) ring</li> <li>• Medication-induced stricture</li> <li>• Peptic stricture</li> </ul>
<p><b>Secondary disorders</b></p> <ul style="list-style-type: none"> <li>• Chagas’ disease</li> </ul>	<p><b>Extrinsic</b></p> <ul style="list-style-type: none"> <li>• Mediastinal mass</li> </ul>

- Reflux-related dysmotility
- Scleroderma and other rheumatologic disorders
- Spinal osteophytes
- Vascular compression

## ***Differential Diagnosis of Dysphagia***

Approach to the patient with dysphagia is presented in Flowchart 10.5.

### ***Investigations***

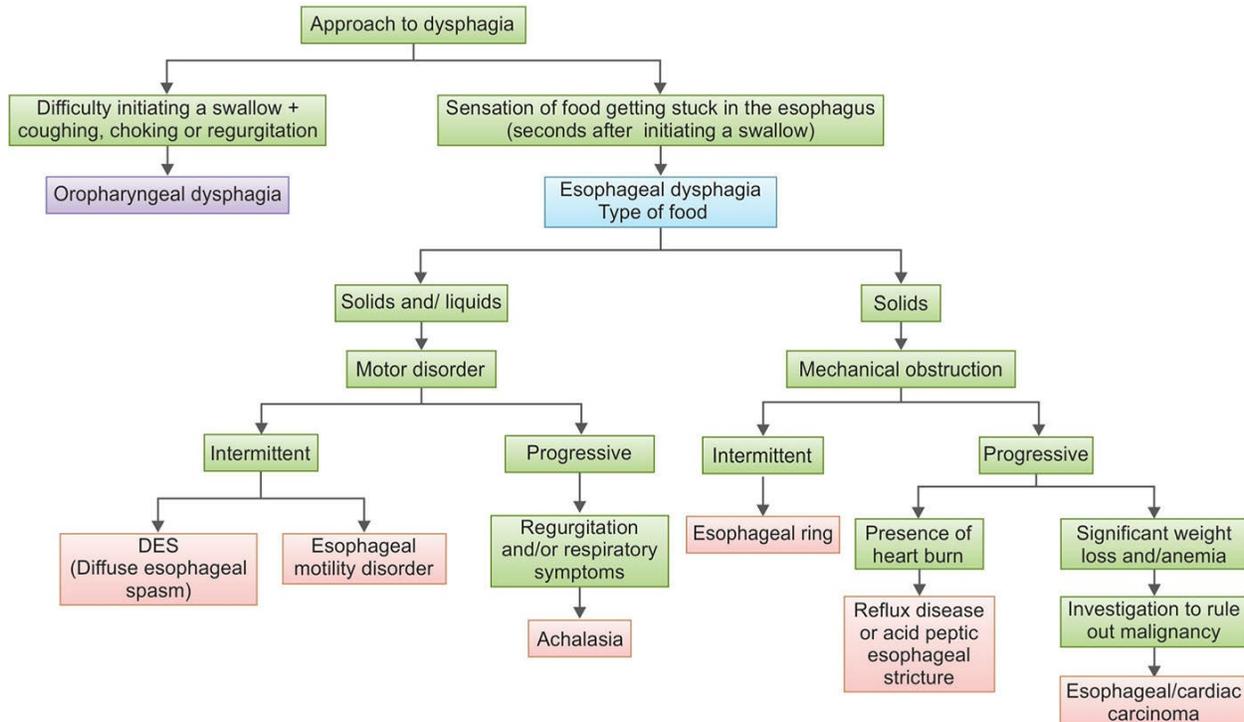

- Hemoglobin and peripheral smear for anemia.
- Chest radiograph detect retrosternal goiter, mediastinal lymph nodes, aortic aneurysms, primary and secondary malignancy of lungs.
- Esophagoscopy allows removal of foreign body, visualization and biopsy of tumors, ulcers, strictures, etc.
- CT scan of thorax
- Biopsy from the growth, ulcer or inflamed mucosa.
- Barium swallow detect tumors as filling defects or strictures (rat tail appearance).
- Esophageal motility studies (esophageal manometry).

### **Odynophagia**

**Q. Write short note on the causes for odynophagia.**

Odynophagia, or painful swallowing, is specific feature for esophageal involvement. It usually reflects an inflammatory process in the esophageal mucosa. Its severity varies. It may be a dull retrosternal ache on swallowing to a stabbing pain with radiation to the back so severe that the patient cannot eat or even swallow their own saliva.

**Flowchart 10.5:** Approach to the patient with dysphagia

## Causes of Odynophagia (Table 10.30)

*Plummer-Vinson Syndrome, (discussed on pages 568 of Chapter 8)*

**Q. Write short note on Plummer-Vinson Syndrome (Patterson-Brown-Kelly syndrome) and its characteristic features/sideropenic dysphagia.**

### Treatment

- Iron deficiency anemia is treated with iron. It may resolve dysphagia.
- Endoscopy:
  - Dysphagia may require endoscopic dilatation.
  - Follow-up endoscopy at regular intervals to detect development of carcinoma

## Gastroesophageal Reflux Disease (GERD)

**Q. Describe the etiopathogenesis, complications and management of gastroesophageal reflux disease (GERD).**

**Q. Write short essay on reflux esophagitis and its management.**

### Definition

- Gastroesophageal reflux disease (GERD) is a consequence of the failure of

the normal antireflux barrier to protect against frequent and abnormal amounts of gastroesophageal reflux (GER; i.e. gastric contents moving retrograde effortlessly from the stomach to the esophagus).

- Spectrum of injury to the esophagus includes *esophagitis*, *stricture*, *Barrett's esophagus*, and *adenocarcinoma*.

**Table 10.30: Causes of odynophagia.**

**Caustic ingestion:** Acid, alkali

**Pill-induced Injury**

- Alendronate and other bisphosphonates
- Aspirin and other NSAIDs
- Iron preparations
- Potassium chloride (especially slow-release form)
- Tetracycline and its derivatives
- Quinidine
- Zidovudine

**Infectious Esophagitis**

- *Viral:* Cytomegalovirus, Epstein-Barr virus, herpes simplex virus, human immunodeficiency virus
- *Bacteria:* Mycobacteria (tuberculosis or Mycobacterium avium complex)
- *Fungal:* Candida albicans, histoplasmosis
- *Protozoan:* Cryptosporidium, Pneumocystis

**Severe Reflux Esophagitis**

**Esophageal Carcinoma**

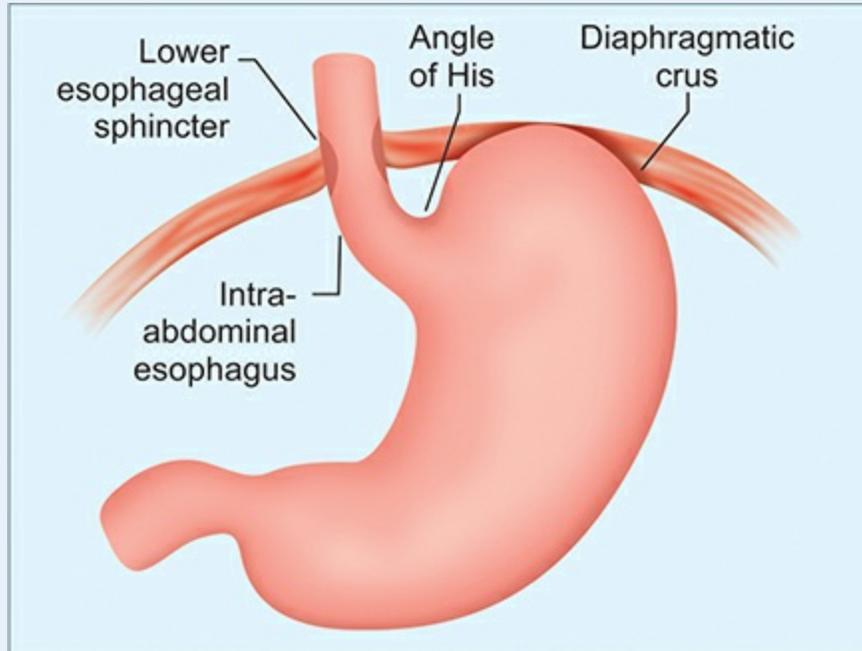

## Pathophysiology

**Normal defense mechanisms preventing reflux and reflux esophagitis**

Several defense mechanisms prevent the reflux of gastric contents into the esophagus.

- **Antireflux barrier at the gastroesophageal junction (Fig. 10.3):** This consists of (1) lower esophageal sphincter (LES), at the lower end of esophagus, below the diaphragm, (2) striated muscles of the crural diaphragm, (3) phrenoesophageal ligament (4) oblique entrance of the esophagus into the stomach (angle of His), (5) attachment of the lower esophageal sphincter (LES) to the crural diaphragm: Intra-abdominal pressure reinforces the LES tone.
- **Esophageal clearance mechanisms:** Reflux of gastric contents into the esophagus occurs in healthy persons and are normally cleared by esophagus in a two-step process:
  - Volume clearance by peristaltic function: After acid reflux from stomach, the esophageal peristalsis returns the refluxed fluid to the stomach.
  - Neutralization of acid by bicarbonate in the swallowed saliva: The small amounts of residual acid refluxed into the esophagus is neutralized by weakly alkaline (bicarbonate) contained in swallowed saliva.
- **Epithelial defensive factors:** The esophageal mucosa contains mainly 3 lines of defense.

1. **Pre-epithelial barrier:** Consisting of (1) small unstirred water layer (2) bicarbonate from swallowed saliva and (3) secretions of submucosal glands.
2. **Epithelial defense:** Consisting of cell membranes and tight intercellular junctions, buffers, and ion transporters.
3. **Postepithelial defense:** Consists of the blood supply to the esophagus.

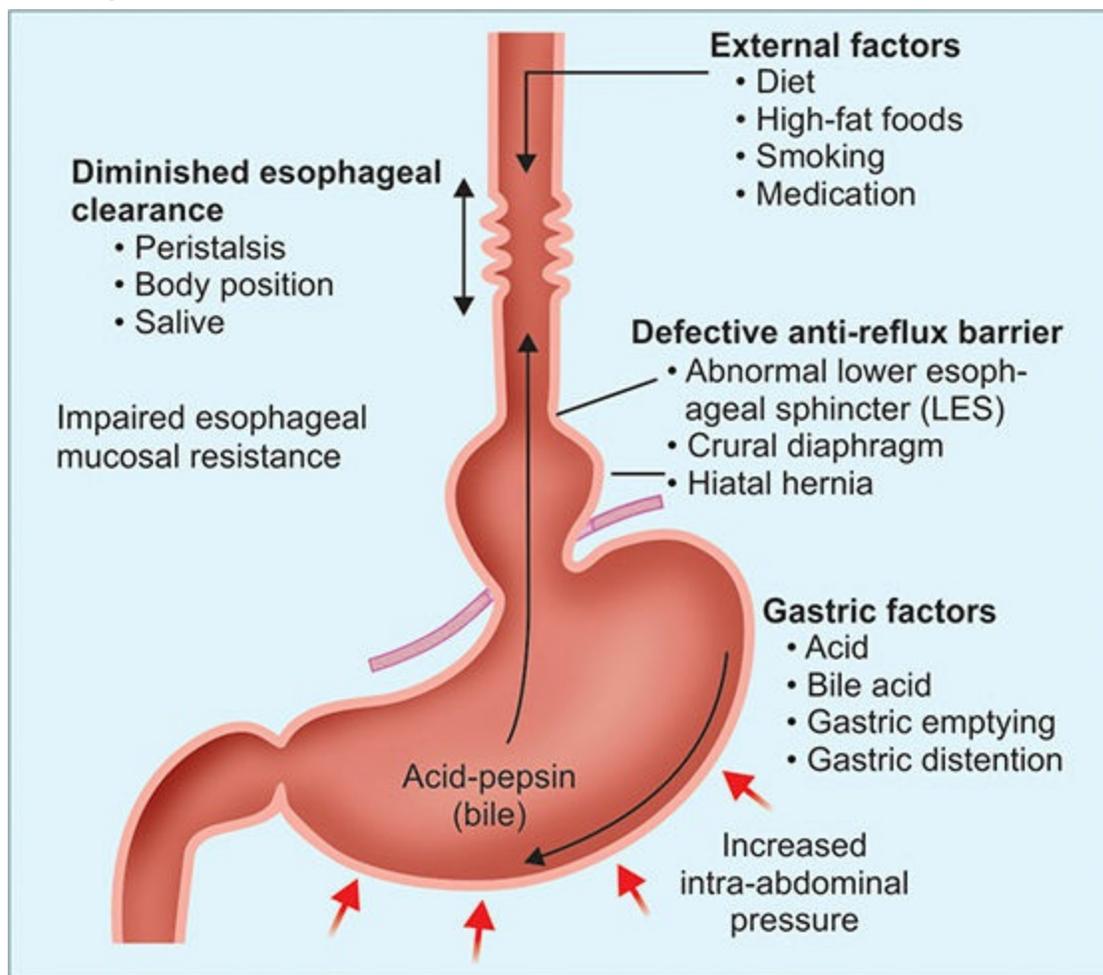

**Fig. 10.3:** Anatomy of normal antireflux barrier at the lower esophagus

### ***Causes of Disruption of Normal Defense Mechanisms (Fig. 10.4)***

- **Defective anti-reflux barriers**

- **Hiatus hernia (sliding type):** This is characterized by sliding of the esophagogastric junction through the diaphragm. This results in increased exposure of the esophagus to acid and may lead to esophagitis, Barrett's esophagus or peptic strictures.
- **Abnormalities of lower esophageal sphincter (LES):** Transient relaxation and reduced tone of LES can result in regurgitation, especially when intra-abdominal pressure is increased.
  - ◆ Cigarette smoking, chocolate, alcohol, fatty foods and caffeine causes relaxation and reduction of tone of LES.
  - ◆ Cardiomyotomy and vagotomy reduces the efficiency of the LES.
  - ◆ Drugs (aminophyline,  $\beta$ -agonists, nitrates, calcium channel blockers) reduce the tone of LES.
- Crural diaphragm

- **Increased the intra-abdominal pressure:** It may occur during pregnancy, obesity, ascites, weight lifting and straining.
- **Prolonged/delayed esophageal clearance of refluxed acid:** It may be due to (1) impaired peristalsis, (2) reduced salivation and (3) body position. Poor esophageal clearance leads to increased acid exposure time. Impaired production of saliva may be observed in smokers and Sjögren's syndrome.
- **Defective gastric emptying:** It increases the gastric content available for reflux. It may be due to gastric outlet obstruction, anticholinergic drugs and fatty food.

**Fig. 10.4:** Pathophysiological factors associated with the development of gastroesophageal reflux disease (GERD).

## ***Clinical Features***

**Classical triad of symptoms** is (1) heartburn, (2) acid regurgitation, and (3)

epigastric pain.

- **Heartburn:** It is the classic symptom of GERD. Patients usually complain of a burning feeling, rising from the stomach or lower chest and radiating toward the neck, throat, and occasionally the back. It occurs postprandially, particularly after large meals or after ingesting spicy foods, citrus products, fats, chocolates, and alcohol. The supine position and bending over may exacerbate heartburn.
- **Acid regurgitation:** Effortless regurgitation of acidic fluid, especially after meals and worsened by stooping or the supine position is highly suggestive of GERD.
- **Epigastric pain:** Sometimes radiating through to the back.

#### *Other symptoms*

- **Odynophagia** (painful swallowing).
- **Dysphagia:** Dysphagia is reported by more than 30% of individuals with GERD. Transient to solids (due to esophageal spasm) or persistent dysphagia to solids (due to strictures).
- Less common symptoms associated with GERD include water brash, burping, hiccups, nausea, and vomiting.
- Iron deficiency anemia may occur due to blood loss.

#### *Extraesophageal symptoms*

- Atypical chest pain which may be severe and can mimic angina.
- Upper respiratory tract: Hoarseness, sore throat, sinusitis, otitis media, chronic cough, laryngitis.
- Pulmonary: The prevalence of GERD in asthmatics is estimated between 34% and 89%. Other pulmonary diseases associated with GERD include aspiration pneumonia, interstitial pulmonary fibrosis, chronic bronchitis, and bronchiectasis.

*Associated conditions:* Pregnancy (reducing LES pressure due to the effects of estrogen and progesterone and possibly mechanical factors from the gravid uterus), scleroderma, achalasia cardia, Zollinger–Ellison syndrome.

**Table 10.31:** Alarm symptoms or signs of GERD.

- |   |  |
|---|--|
| <ul style="list-style-type: none"><li>• Dysphagia</li><li>• Weight loss</li></ul> | <ul style="list-style-type: none"><li>• Persistent heartburn</li><li>• Odynophagia</li></ul> |
|---|--|

- Gastrointestinal bleeding
- Nausea and vomiting, early satiety
- Anemia
- Family history of cancer

**Table 10.32: Complications of GERD.**

- |   |   |
|---|---|
| <ul style="list-style-type: none"> <li>• Esophagitis</li> <li>• Hemorrhage and bleeding (hematemesis, melena)</li> <li>• Esophageal ulceration</li> <li>• Esophageal strictures</li> <li>• Barrett's esophagus</li> </ul> | <ul style="list-style-type: none"> <li>• Adenocarcinoma esophagus</li> <li>• Aspiration pneumonia</li> <li>• Iron deficiency anemia</li> <li>• Dental caries</li> </ul> |
|---|---|

*Alarm symptoms or signs (Table 10.31)*

## **Complications of GERD (Table 10.32)**

### **Barrett's Esophagus**

#### **Q. Write short answer on Barrett's esophagus**

Barrett's esophagus is a **pre-malignant condition**, in which the **normal squamous lining of the lower esophagus is replaced by columnar mucosa** (columnar lined esophagus; CLO). The columnar mucosa may show areas of intestinal metaplasia (with goblet cells). It is an adaptive response to chronic gastroesophageal reflux and is often asymptomatic. The risk of esophageal cancer depends on the severity and duration of reflux and it may be detected when the patient presents with esophageal cancer. It is more common in men, obese and above the age of 50. It is weakly associated with smoking but not with alcohol intake.

**Diagnosis:** It needs multiple systematic biopsies which may show intestinal metaplasia and/or dysplasia.

#### **Management**

**Regular endoscopic surveillance** to detect dysplasia at an early stage. Currently recommendation are as follows:

- Barrett's esophagus with intestinal metaplasia, but without dysplasia: Should undergo endoscopy at 3–5 yearly intervals if the length of the Barrettic segment is 3 cm and at 2–3 yearly intervals if the length is >3 cm.
- *Low-grade dysplasia:* It should be endoscoped at 6-monthly intervals.

Treatment is indicated only for symptoms of reflux or complications (e.g. stricture).

**Endoscopic therapies:** Such as radiofrequency ablation or photodynamic therapy, can induce regression. However, they are used only for patients with dysplasia or intramucosal cancer.

**High-grade dysplasia or intramucosal carcinoma:** Treatment options are either esophagectomy or

endoscopic therapy, with a combination of endoscopic resection of any visibly abnormal areas and radiofrequency ablation of the remaining Barrett's mucosa, as an 'organ-preserving' alternative to surgery.

### **Investigations (Table 10.33)**

Diagnostic endoscopy should be performed in patients who fail to respond to therapy or have alarm symptoms or signs.

- **Endoscopy:** It is useful for the detection of
  - **Erosive esophagitis** which would be visualized and confirmed by biopsy.
  - **Complications:** Peptic stricture and Barrett's esophagus (confirmed by biopsy)
- **Barium radiography:** It has no role in the diagnosis of GERD. Barium swallow and meal examination is useful for appreciation of gastroesophageal anatomy and may be important in the diagnosis of hiatus hernia.
- **24-hour pH recording:** It is the 'gold standard' for diagnosis of GERD. Prolonged measurement of pH is the most accurate method for the diagnosis of gastroesophageal reflux particularly in patients with atypical symptoms and with normal endoscopies.
- **Esophageal manometry:** Useful to exclude achalasia and other motility disorders.
- **Resting ECG and stress ECG:** To rule out ischemic heart disease (IHD).

**Table 10.33:** Diagnostic tests for gastroesophageal reflux disease.

#### **Tests for Reflux**

- Intraesophageal pH monitoring (catheter or catheter-free system)
- Ambulatory impedance and pH monitoring (nonacid reflux)
- Barium esophagogram

#### **Tests to Assess Symptoms**

- Empirical trial of acid suppression
- Intraesophageal pH monitoring with symptom analysis

#### **Tests to Assess Esophageal Damage**

- Endoscopy
- Wireless capsule endoscopy
- Esophageal biopsy

#### **Tests to Assess Esophageal Function**

- Esophageal manometry
- Esophageal impedance

**Q. Write short note on management/treatment of gastroesophageal reflux disease (GERD)/reflux esophagitis.**

**Treatment**

**General measures**

These are lifestyle modifications as listed in Box 10.6.

*Medical treatment*

Inhibition of gastric acid secretion is the cornerstone of the treatment of acute GERD.

**Antacids (for details refer page 743):** Liquid antacids buffer acid and increase LES. They are used in the dose of 10–15 mL, 1 and 3 hours after meal and at bedtime or as needed. They relieve heart burn in mild cases.

**Histamine (H<sub>2</sub>)-receptor antagonists (for details refer page 743):** They decrease acid secretion. These drugs include cimetidine (800 mg bid, 400 mg qid) or ranitidine (150 mg qid), or famotidine (20–40 mg bid) daily to be given with meals and before bed time, for at least 6 weeks (in mild cases).

**Proton pump inhibitors (PPIs) (for details refer page 743):** They decrease acid secretion and gastric volume. They are superior to histamine (H<sub>2</sub>)-receptor antagonists. These include omeprazole (20–40 mg/day), lansoprazole (15–30 mg/day), pantoprazole (40 mg/day), esomeprazole (20–40 mg/day) and rabeprazole (10–20 mg/day). Maintenance doses may be necessary for 6–8 months.

- Present evidence does not support the common practice of using metoclopramide or domperidone 10 mg thrice daily either as monotherapy or an adjunct to acid suppression therapy. Its significant adverse effects argue against the use of this drug in GERD.
- *H. pylori* eradication does not have any therapeutic value.
- Dilatation of esophageal strictures.
- Anemia is treated with oral iron or blood transfusion.

*Surgical treatment*

**Indications:** (1) failure to respond to medical therapy, (2) patients not willing to take long-term PPIs or intolerant to PPIs (3) patients with severe symptom, and (4) patients with regurgitation.

*Surgical measures*

- **Surgical resection of esophageal strictures.**
- **Anti-reflux surgery:** Laparoscopic fundoplication (additional valve mechanism) yields results comparable to continued PPI therapy

**Box 10.6: Lifestyle modifications in the treatment of GERD.**

- Avoid foods such as fatty food, alcohol, mint, tomato-based foods, spicy foods, coffee, tea and acidic foods.
- Avoid late night meals before retiring.
- Avoid weight lifting, stooping and bending at waist.
- Elevation of the head of the bed in patients with regurgitation or heartburn during night.
- Weight reduction
- Stop smoking, alcohol
- Frequent feeds of small volume.

## Hiatus Hernia

### Q. Write short note on hiatus hernia.

It is the herniation of elements of the abdominal cavity (part of stomach) through the diaphragm into the thoracic cavity.

### Types (Figs. 10.5A to D)

- **Sliding or type I hiatus hernia:** It is the most common type. In this type, the gastroesophageal junction and the fundus of stomach slide upward above the diaphragmatic hiatus.

**Figs. 10.5A to D:** Types of hiatus hernia. (A) Normal esophagus and stomach; (B) Type I (sliding); (C) Type II (paraesophageal/rolling); (D) Type III (mixed paraesophageal) hiatus hernia.

- **True paraesophageal (rolling) or type II hiatus hernia:** It is uncommon. In this type, location of gastroesophageal junction is in its normal position, but the fundus and parts of the greater curvature of the stomach herniate into the mediastinum alongside the esophagus.
- **Mixed paraesophageal hernia or type III:** In this type, gastroesophageal junction and a large part of the stomach herniate into the mediastinum.

**Predisposing factors:** Obesity, pregnancy and ascites. Occurs in 33% of normal adults and 50% of elderly.

### Clinical Features

- Majority of hiatus hernia are asymptomatic. Hiatus hernia predisposes to gastroesophageal reflux disease (GERD), and hence, symptoms of GERD may be present.
- Type I: Usually asymptomatic or present with symptoms of heartburn or acid regurgitation.
- Type II and III may present with epigastric pain, chest pain, substernal

fullness, shortness of breath, nausea, or vomiting.

### **Investigations**

- **Plain radiograph of the chest:** Hernia may be visible as a gas bubble, often with a fluid level behind the heart.
- **Barium swallow/meal:** It is the best method of diagnosis and demonstrates the presence of gastroesophageal junction in the thorax.
- **Endoscopy.**

### **Management**

- Asymptomatic hiatus hernias do not require any treatment. Surgical repair of hernia is required in selected cases with gastroesophageal reflux.
- Symptomatic rolling hiatus hernias require surgical repair because it is potentially liable to undergo volvulus as a dangerous complication.

**Surgical treatment:** (1) Repair of the diaphragmatic defect, and (2) fixing the stomach in the abdominal cavity (fundoplication) combined with an antireflux procedure.

## **Achalasia of the Esophagus**

**Q. Write short note on achalasia cardia and its diagnosis/investigations.**

Achalasia is characterized by **esophageal aperistalsis** and results from progressive degeneration of ganglion cells in the myenteric plexus in the esophageal wall, causing failure of relaxation of the hypertonic lower esophageal sphincter in response to the swallowing wave. Failure of propagated esophageal contraction results in progressive dilatation of the gullet.

**Cause:** Unknown. Autoimmune, neurodegenerative and viral etiologies have been suggested. Reduction in nitric oxide synthase containing neurons is detected by immunohistochemical staining in the lower esophageal sphincter. There is degeneration of ganglion cells within the sphincter and the body of the esophagus. Infection with *Trypanosoma cruzi* in Chagas' disease causes a syndrome that is clinically similar to achalasia.

### **Clinical Features**

- **Age and gender:** Occurs equally in males and females and at all ages but is rare in childhood.
- **Dysphagia:** It develops slowly, is initially intermittent and characteristically for both liquids and solids from the onset (worse for

solids). Dysphagia is eased by drinking liquids, and by standing and moving around after eating.

- **Episodes of chest pain:** Spontaneous chest pain occurs due to esophageal spasm which may be misdiagnosed as cardiac.
- **Regurgitation of food from the dilated esophagus:** As the disease progresses, dysphagia worsens and caused poor emptying of the esophagus. This may produce nocturnal pulmonary aspiration and aspiration pneumonia.
- Heartburn does not occur because the closed esophageal sphincter which prevents gastroesophageal reflux.
- Achalasia **predisposes to squamous carcinoma of the esophagus.**

### ***Investigations***

- **Chest X-ray:** Shows a dilated esophagus. Sometimes fluid level may be observed behind the heart. There is absence of fundic gas shadow.
- **Barium swallow:** There is absence of peristalsis and often synchronous contractions in the body of the esophagus. There is tapered narrowing of the lower esophagus producing a ‘bird’s beak’ appearance due to failure of the sphincter to relax.
- **Manometry** shows high-pressure, non-relaxing lower esophageal sphincter with poor contractility of the esophageal body.
- **Endoscopy:** It should be performed because carcinoma of the cardia can mimic the presentation and radiological and manometric features of achalasia (‘pseudo-achalasia’).

### **Management**

Treatment for achalasia is palliative.

#### ***Endoscopic***

- **Endoscopic dilatation of the LES (lower esophageal sphincter)**
- **Endoscopically directed injection of botulinum toxin** into the lower esophageal sphincter (intersphincteric injection).

#### ***Surgical***

- **Surgical myotomy (Heller’s operation)**
- **Peroral endoscopic myotomy (POEM)**

## **DISEASES OF THE STOMACH AND**

# DUODENUM

**Q. Discuss the etiology, pathogenesis, pathology, clinical features, investigations and management of peptic ulcer disease or acid peptic disease.**

## Peptic Ulcer Disease (PUD)

### *Definition*

An ulcer in the gastrointestinal (GI) tract may be defined as a break in the lining of the mucosa, with appreciable depth at endoscopy or histologic evidence of involvement of the submucosa.

### *Sites of Peptic Ulcer*

Any portion of the GI tract exposed to acidic gastric juices.

- **Duodenum: More common in the first portion of the duodenum** (anterior or posterior wall) **than in the stomach.** Occasionally occurs at both anterior and posterior sites ('kissing' ulcers).
- **Stomach:** Lesser curvature near the junction (transitional zone) of the body and antrum.
  - Proximal ulcers: Located in the body of the stomach.
  - Distal ulcers: Located in the antrum and angulus of the stomach.
- **Gastroesophageal junction of esophagus**
- **Anastomotic site:** Occurs in patients who have undergone a distal gastric resection. Occur at margins of the gastroduodenal anastomosis/gastrojejunostomy (anastomotic ulcer).
- **Multiple ulcers:** In the duodenum, stomach, and/or jejunum in Zollinger-Ellison syndrome.
- **At metaplastic or heterotopic gastric mucosa,** e.g. Meckel diverticulum within an ileum having ectopic gastric mucosa.

Incidence: ~12% in males and 10% in females.

### *Etiology*

**Q. Write short essay/note on risk factors for peptic ulcer disease.**

#### **Normal process in the stomach**

Two opposing sets of forces keep stomach in a normal state: (1) damaging forces and (2) defensive forces.

1. **Damaging forces:** Capable of inducing mucosal injury are two gastric secretory products: (1) hydrochloric acid, and (2) pepsinogen.
2. **Defensive forces** is a three-level barrier composed of pre-epithelial, epithelial, and subepithelial elements. **Pre-epithelial barrier** is a mucus-bicarbonate layer of the stomach.

- **Surface mucus secretion:** Mucin is secreted by surface foveolar cells. Actions of mucus are: (1) Mucus layer promotes formation of an 'unstirred' protective layer of fluid on the mucosa. (2) Prevents the direct contact of large food particles with the epithelium. (3) Impedes the diffusion of ions and molecules such as pepsin.
- **Bicarbonate secretion into mucus** by surface epithelial cells → diffuse into the unstirred mucus → buffer the hydrogen ions entering from the luminal aspect → result in a pH gradient, ranging from 1 or 2 at the gastric luminal surface, and reaching to a neutrality of 6 to 7 along the epithelial cell surface.

**Epithelial barrier:** Consists of surface epithelial cells act through several factors, such as (1) production of mucus, (2) epithelial cell ionic transporters that maintain intracellular pH, and (3) bicarbonate production, and (4) intracellular tight junctions. Subepithelial barrier

- **Rich gastric mucosal blood flow:** Provides (1) bicarbonate ( $\text{HCO}_3^-$ ), which neutralizes the acid generated by parietal cell, (2) an adequate supply of nutrients and oxygen and (3) removes toxic metabolic by-products.

### ***Pathogenesis of Peptic Ulcer (Fig. 10.6)***

**Q. Write short essay/note on *Helicobacter pylori* and its role in pathogenesis (pathophysiology) of gastric ulcer.**

**The imbalances between mucosal defensive forces** (disruption of any of protective mechanisms) and damaging forces (direct mucosal injury) **cause chronic gastritis and also PUD.**

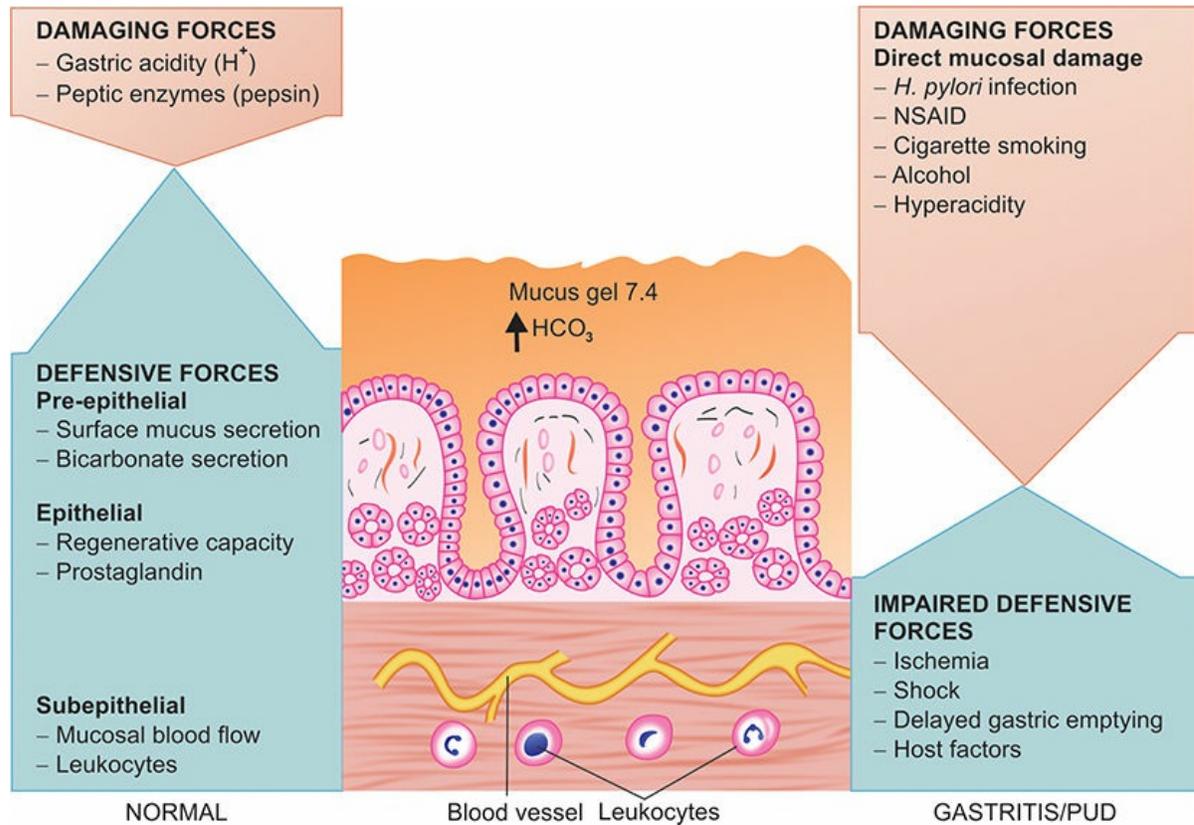

*Direct mucosal injury/increased damage*

Majority of PUD (both gastric and duodenal ulcers) can be attributed to NSAIDs and *H. pylori*.

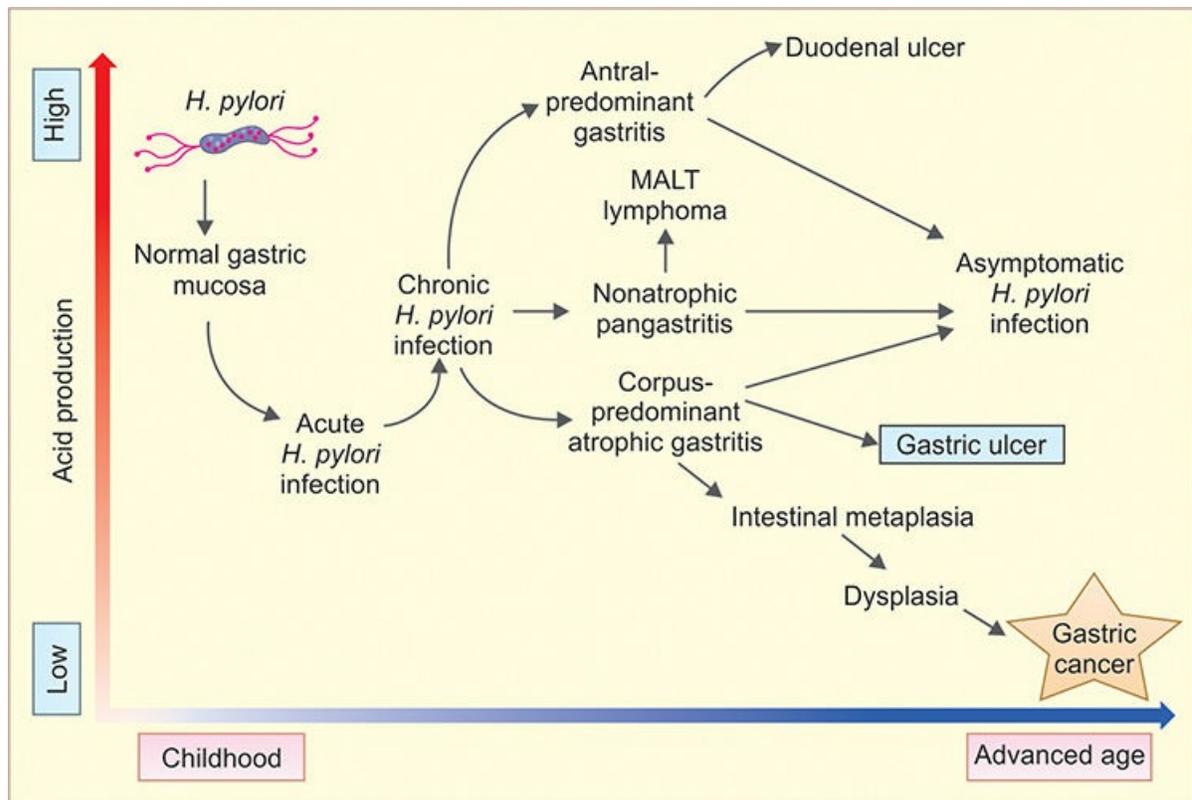

- *Helicobacter pylori* is a Gram-negative spiral bacteria with multiple unipolar flagella that allow them to move freely through the gastric mucous layer, where they remain protected from low gastric pH. It is one of the most important, common, primary causes of PUD. It is associated with ~85–90% of duodenal and ~65% of gastric ulcers. *Helicobacter pylori* infection remains one of the most common chronic bacterial infections in humans more than 50% of the world's population is infected

with the bacterium. *H. pylori* also play a role in the development of gastric and duodenal ulcer, gastritis, MALT (mucosal-associated lymphoid tissue) lymphoma, and gastric adenocarcinoma.

- **Mode of spread:** Oral-oral or feco-oral route either by kissing or ingestion of contaminated vomitus.

**Fig. 10.6:** Components involved in mucosal defense and repair in normal (left side) and in acute or chronic gastritis. Gastric mucus barrier consists of viscid mucus (which forms an unstirred layer between the epithelium and the gastric lumen) and bicarbonate.

**Fig. 10.7:** Natural history of *H. pylori* infection.

- **Lesions produced:** *H. pylori* may attach to gastric epithelium causing damage to the mucosa. Causes chronic antral gastritis with high acid production → may progress to pangastritis → resulting multifocal atrophic gastritis → increased risk of gastric adenocarcinoma. Natural history of *H. pylori* infection is shown in Figure 10.7.
- **Nongastric diseases and *H. pylori* infection:** Raynaud’s, scleroderma, idiopathic urticaria, acne rosacea, migraines, thyroiditis, and Guillain-Barré syndrome coronary artery disease, immune thrombocytopenic purpura.
- **Mechanism of action by *H. pylori*:**
  - ◆ **Flagella:** It makes them motile, allows them to burrow and live beneath the mucus layer above the epithelial surface.
  - ◆ **Urease:** It is produced by *H. pylori* → converts urea into ammonia (strong alkali) → raises the local gastric pH, acts on the antral G cells → release of gastrin → hypergastrinemia → result in hypersecretion of gastric acid.
  - ◆ **Adhesion molecule:** It helps it to bind to gastric epithelial (surface

foveolar) cells.

- ◆ **Enzymes:** These include proteases and phospholipases acts on the mucous gel → reduces the mucosal defense.
- ◆ **Cytotoxins:** Two genes namely cytotoxin-associated gene A (*CagA*) and vacuolating agent (*vacA*) gene cause gastritis, peptic ulceration and cancer.
- ◆ **Cytokine induces inflammatory response:** Normally *H. pylori* do not invade the cells/tissues. It causes increased production of pro-inflammatory cytokines {interleukin (IL)-1, IL-6, tumor necrosis factor (TNF) and IL-8} by the mucosal epithelial cells → activation of neutrophils and macrophages (inflammatory response to gastric mucosa) → release of lysosomal enzymes, leukotrienes and reactive oxygen species → impairs mucosal defense. The cytokines also stimulate gastrin release → increased acid production.
- **Nonsteroidal anti-inflammatory drugs (NSAID) and aspirin:** Causes (1) **direct chemical irritation of mucosa**, (2) **suppresses mucosal prostaglandin synthesis**, and (3) **reduces the bicarbonate secretion**.
- **Cigarette smoking** impairs blood flow to the mucosa and healing of mucosal damage.
- **Alcohol**, radiation therapy and chemotherapy: Direct injury to mucosal cells.
- **Ingestion of chemicals:** Such as acids or bases cause direct injury.
- **Gastric hyperacidity:** It is induced by *H. pylori* infection, parietal cell hyperplasia and Zollinger–Ellison syndrome.
- **Others:** High-dose corticosteroids that suppress prostaglandin synthesis and impair healing, other drugs (e.g. bisphosphonates, cocaine, amphetamines), hypercalcemia psychological stress, duodenal gastric reflux, Crohn's disease and systemic mastocytosis.

### ***Etiology of Acute and Stress Ulcers***

- **Stress ulcers:** They occur with shock, sepsis, or severe trauma.
- **Curling ulcers:** They develop in the proximal duodenum with severe burns or trauma.
- **Cushing ulcers:** They develop in the stomach, duodenum, and esophagus in patients with intracranial disease. Highly prone for perforation.

## ***Clinical Features***

**Recurrent episodes of abdominal pain:** It is the **most common presentation** and has three notable characteristics:

- **Localization to the epigastrium:** Pain is referred to epigastrium and the patient will be able to localize the site with one finger (pointing sign). The characteristics of pain are:
  - **Nature:** Usually burning in character or gnawing discomfort.
  - **Radiating pain:** May radiate to the back, thorax, other parts of abdomen.
  - **Nocturnal:** Pain in duodenal ulcer occurs 90 minutes to 3 hours after a meal. May occur at night (most specific) and wakes the patient from sleep between midnight and 3 AM), and is relieved by food, milk or antacids.
  - **Hunger pain:** Pain occurs on empty stomach (painful hunger) relieved by food or antacids.
- **Relationship to food**
  - Pain is usually **relieved by food, milk, antacids**, belching or vomiting in duodenal ulcer.
  - In contrast, in few patients with gastric ulcer food may precipitate the pain.
- **Periodicity (episodic pain)**
  - In untreated patients, pain tends to occur in episodes. Each episode consisting of daily pain **lasting 2 to 8 weeks**, separated by prolonged asymptomatic intervals.
  - Between episodes (periods of remission) patient may be perfectly well and may be able to eat even heavy or spicy meals without apparent discomfort.
  - During the initial stages, the episodes tend to be of short in duration and less frequent. Later, the episodes become longer in duration and more frequent. More symptomatic during winter and spring. Relapses are more common in smokers compared to non-smokers.

## ***Other symptoms***

Retrosternal burning (heartburn), water-brash (excessive salivation), loss of appetite, acidic regurgitation into the throat and vomiting. Persistent daily

vomiting suggests gastric outlet obstruction. Fullness, bloating, anorexia, nausea, and dyspepsia. Tarry stools or coffee-ground vomitus indicate bleeding. Rarely, with anemia due to chronic blood loss, abrupt hematemesis, acute perforation or gastric outlet obstruction.

Difference between gastric ulcer and duodenal ulcer (Table 10.34).

### Complications (Box 10.7)

**Q. Write short essay/note on complications of peptic ulcer disease.**

#### Box 10.7: Complications of peptic ulcer.

- Upper gastrointestinal bleeding (20%)
- Perforation of ulcer (6–7%)
- Gastric outlet obstruction 1–2% (with fluid and electrolyte imbalance), gastrocolic or duodenocolic fistulas
- Rarely malignant transformation
- Rarely pancreatitis due to posterior penetration of ulcer

**Table 10.34: Difference between gastric ulcer and duodenal ulcer.**

<b>Features</b>	<b>Gastric ulcer</b>	<b>Duodenal ulcer</b>
Commonest site	Along the lesser curvature	First part of duodenum
Incidence	Less common	More common
Age	Beyond 6th decade, M>F	Between 25 to 50 years, M>F
Association with H. pylori infection	Less common	Strong association
Acid level	Usually normal	High
<b>Clinical features</b>		
Relationship of pain to antacids	Relief of pain not consistent	Prompt relief of pain
Relationship of pain to food	Aggravates the pain	Relieves the pain
Night pain	Not observed	Common
Heartburn	Not common	Common
Hematemesis/melena	Hematemesis more common	Melena more common
Vomiting	Common	No vomiting
Weight loss	Present	Absent
Anorexia and nausea	More common	Less common
Duration of episodes of pain	Relatively longer in duration	Relatively shorter in duration
Course of the illness	Less remission	More remission

Complication

Rarely undergo malignant change

No malignant change

## **Investigations/Diagnosis**

**Q. Write short essay/note on diagnosis of peptic ulcer disease.**

**Anatomic diagnosis:** Documentation of a peptic ulcer needs either a radiographic (barium study) or an endoscopic examination.

- **Endoscopy (Fig. 10.8):** It is most sensitive and specific for the detection of ulcer disease of the upper GI tract. Typical location of peptic ulcer is duodenal bulb and lesser curvature of stomach. Advantages of endoscopy are: 1) direct visualization of mucosa (to determine if an ulcer is a source of blood loss) and the ulcer (even lesions too small to detect by radiographic examination), 2) useful for photographic documentation of a mucosal defect, and 3) biopsy can be taken to rule out malignancy (about 10% of gastric ulcers are malignant) or *H. pylori*.
- **Endoscopic ultrasound:** It may be useful in detecting an unsuspected submucosal component or enlarged lymph nodes (e.g. in gastric malignancies such as lymphoma and linitis plastica).
- **Etiologic diagnosis:** The cause of the ulcer must be established. The major risk factor for peptic ulcers is either *H. pylori* or NSAID.
- **Tests for *Helicobacter pylori*** (Table 10.35)

**Fig. 10.8:** Endoscopic picture of a benign gastric ulcer.

**Q.** Write short essay/note on investigation in *Helicobacter pylori* infection.

**Table 10.35:** Diagnostic tests for *Helicobacter pylori* (HP).

	<i>Advantages</i>	<i>Disadvantages</i>
<b>NONENDOSCOPIC TESTS</b>		
Serology (qualitative or quantitative immunoglobulin G [IgG])	Widely available, economical. Good NPV (negative predictive value)	Poor PPV (positive predictive value) if HP prevalence is low. Not useful after treatment
Urea breath test ( <sup>13</sup> C or <sup>14</sup> C)	Detects active infection. Accuracy (PPV, NPV) not affected by <i>H. pylori</i> prevalence. Useful both before and after treatment	Accuracy affected by PPI and antibiotic use, small radiation dose with <sup>14</sup> C test
Stool antigen test	Detects active infection. Accuracy (PPV, NPV) not affected by <i>H. pylori</i> prevalence. Useful both before and after treatment (monoclonal test)	Accuracy affected by PPI and antibiotic use
<b>ENDOSCOPIC TESTS</b>		

Microscopic examination	Excellent sensitivity and specificity, especially with special and immune stains; provides additional information about gastric mucosa	Expensive (endoscopy and histopathology costs), interobserver variability, accuracy affected by PPI and antibiotic use
Rapid urease test	Rapid results, accurate in patients not using PPIs or antibiotics, no added histopathology cost	Requires endoscopy, less accurate after treatment or in patients using PPIs
Culture	Specificity 100%, allows antibiotic sensitivity testing	Difficult and tedious to perform; not widely available; expensive
Polymerase chain reaction (PCR) assay	Excellent sensitivity and specificity, permits detection of antibiotic resistance	Not widely available; technique not standardized; expensive

- **Nonsteroidal anti-inflammatory drugs (NSAIDs):** Diagnosis is established based on history of drug use and symptoms of pain.
- **Hypersecretory syndromes:** Zollinger- Ellison syndrome should be considered in patients with multiple ulcers. Serum gastrin and gastric acid analysis should be performed in these patients.

### Box 10.8: General measures in peptic ulcer disease.

- **Avoid:** Cigarette **smoking**, **aspirin** and **NSAIDs**
- **Alcohol** to be avoided
- **No special dietary advice** is necessary

### Q. Write short essay/note on medical management of peptic ulcer disease and mention the new drugs used in its treatment.

#### Treatment/Management

Treatment may be divided into short-term management and long-term management (intermittent, maintenance and surgical treatment).

#### A. Short-term management

- **General measures (Box 10.8)**
- **Acid neutralizing/inhibitory drug**
  - a. **Antacids:** Neutralizes the secreted acid and rarely used at present.
    - Mainly used for symptomatic relief of dyspepsia.
    - Preparation: Tablet or liquid preparations
    - Dose: 15–30 mL liquid antacid 1 and 3 hours after food and at bed time for 4–6 weeks.
    - **Commonly used antacids:** Combination of aluminium hydroxide and magnesium hydroxide. Others include calcium carbonate and sodium bicarbonate.
    - **Side effects**

- ◆ Aluminium compounds causes constipation, phosphate depletion and interfere with the absorption of digoxin and tetracycline
- ◆ Magnesium compounds cause diarrhea, hypocalcemia and hypermagnesemia.
- ◆ Calcium carbonate causes milk-alkali syndrome and sodium bicarbonate produces systemic alkalosis.

**Q. Write short essay/note on H<sub>2</sub> receptor blockers.**

**b. Histamine H<sub>2</sub>- receptor antagonists:**

- **Drugs:** These include four agents namely cimetidine (400 mg BD or 800 mg at night), ranitidine (150 mg BD or 300 mg at night), famotidine (20 mg BD or 40 mg at night), and nizatidine (150 mg BD or 300 mg at night). All are equally effective.
- **Mechanism of action:** Inhibit acid and pepsin secretion by blocking H<sub>2</sub>-receptors.

**Duration of treatment:**

- **Duodenal ulcer:** Usually for 4 weeks. Smokers and patients with recent major complications (e.g. hematemesis, perforation), treatment is prolonged to 6–8 weeks.
- **Gastric ulcer:** For 6 weeks, followed by endoscopy and further treatment if necessary.

**Q. Write short essay/note on proton pump inhibitors with their dose.**

**c. Proton Pump (H<sup>+</sup>,K<sup>+</sup>-ATPase) Inhibitors (PPIs)**

- These agents are substituted benzimidazole derivatives that covalently bind and irreversibly inhibit H<sup>+</sup>, K<sup>+</sup>-ATPase.
- They include omeprazole (20 mg/d), esomeprazole (20–40 mg/d), lansoprazole (15–30 mg/d), rabeprazole (20 mg/d), and pantoprazole (40 mg/d). All have similar efficacy in the treatment of various acid-peptic disorders.
- **Mechanism of action**
  - PPIs are lipophilic compounds that cross the parietal cell membrane and enter the acidic parietal cell canaliculus.
  - Upon entering the acidic parietal cell, the PPIs are protonated, and trapped within the acid environment of the tubulovesicular and canalicular system. They become activated and bind covalently with the H<sup>+</sup>/K<sup>+</sup> ATPase enzyme and potently inhibit all phases of gastric acid secretion by the proton pump.
- **Side effects:** Headache, diarrhea, abdominal pain and nausea. The use of PPI may predispose to an increased risk of *Clostridium difficile* infection, community acquired pneumonia, hip fracture, and vitamin B<sub>12</sub> deficiency.
- **Advantages:** Superior healing rates, shorter healing time and faster relief of symptom compared to H<sub>2</sub>-blockers.
- **Indications (Box 10.9)**

**Box 10.9: Indications for proton pump inhibitors (PPIs).**

- GERD and reflux esophagitis
- Peptic ulcer not responding to other medical measures.
- As an adjunct to anti-H.pylori treatment.
- Zollinger-Ellison syndrome

#### d. Cytoprotective Agents

- **Sucralfate:** It is a complex sucrose salt insoluble in water and becomes a viscous paste within the stomach and duodenum. It binds to sites of active ulceration. Sucralfate acts as a protective barrier, over the ulcer and increases the mucosal defense and repair. Standard dose 1 g qid.
- **Bismuth-containing preparations:** Colloidal bismuth subcitrate (CBS) and bismuth subsalicylate are used to induce healing of peptic ulcers. Side effects include black stools, constipation, darkening of the tongue and neurotoxicity. They are commonly used as one of the agents in an anti-*H. pylori* regimen.
- **Prostaglandin analogues:** They enhance mucosal defense and repair and useful in preventing NSAID-induced mucosal injury. Dose (e.g. Misoprostol) is 200 µg qid.

**Q. Write short essay/note on management of *Helicobacter pylori* infection/*Helicobacter pylori* eradication regimens.**

#### e. Treatment for *H. pylori* infection (Tables 10.36 and 10.37)

- **Indications:** Consensus of opinion is that all patients with proven acute or chronic duodenal ulcer and those with gastric ulcers who are *H. pylori*-positive should be administered drugs against *H. pylori* (even without documenting the presence of bacteria).
- **Advantages:** It reduces the risk of recurrence of ulcer.
- **Type of therapy:** Triple or quadruple therapy (Refer Tables 10.36 and 10.37).

#### B. Long-term management

1. **Intermittent treatment:** When the symptoms relapses <4 times a year, 4 weeks course of one of the ulcer-healing agents are prescribed

**Table 10.36: First-line treatment of *Helicobacter pylori* infection.**

<b>Treatment regimen</b>	<b>Duration</b>
PPI (omeprazole/lansoprazole/pantaprazole/rabeprazole/esmoprazole), clarithromycin 500 mg, amoxicillin 1000 mg (each twice daily)	10–14 days
PPI, clarithromycin 500 mg, metronidazole 500 mg (each twice daily)	10–14 days
<b>Sequential therapy</b> PPI, amoxicillin 1000 mg (each twice daily) for 5 days <b>followed</b> by PPI, clarithromycin 500 mg, tinidazole 500 mg (each twice daily) for next 5 days.	10 days
Bismuth subsalicylate 525 mg, metronidazole 500 mg, tetracycline 500 mg (each four times daily) <b>plus</b> PPI or H <sub>2</sub> RA (Ranitidine twice daily)	10–14 days

(PPI: proton pump inhibitors; H<sub>2</sub>RA: histamine H<sub>2</sub>- receptor antagonists)

**Table 10.37:** Rescue treatment for persistent *Helicobacter pylori* infection.

<b>Regimen</b>	<b>Duration</b>	<b>Eradication rate</b>
<b>Quadruple therapy:</b> Bismuth subsalicylate 525 mg, metronidazole 500 mg, tetracycline 500 mg (each four times daily) plus PPI or H <sub>2</sub> RA (twice daily)	14 days	70%
PPI, amoxicillin 1000 mg, levofloxacin 250 mg (each twice daily)	10–14 days	57–91%
PPI amoxicillin 1000 mg, rifabutin 150 mg (each twice daily)	14 days	60–80%

## 2. Maintenance treatment

- Continuous maintenance treatment is not required after successful eradication of *H. pylori*.
- If symptoms relapses for more than four times per year or history of complications (e.g. repeated bleeding or perforation) require the lowest effective dose of PPI.
- Long-term maintenance is with H<sub>2</sub>-receptor antagonists (cimetidine 400 mg at night, ranitidine 150 mg at night, famotidine 20 mg at night or nizatidine 150 mg at night).

## New Treatments

- Cholecystokinin 2 receptor antagonists (CCK2): Itriglumide.
- Potassium competitive acid blockers (P-CABs): Revaprazan

## 3. Surgical treatment

- Most of peptic ulcers are cured by *H. pylori* eradication therapy and by acid-suppressing drugs. Elective surgery is reserved for the treatment of medically refractory disease (recurrence of ulcer following surgery, gastric outlet obstruction), or urgent/emergency surgery for the treatment of an ulcer-related complication (e.g. perforation and hemorrhage).
- **Indications for surgery**
  - **Chronic non-healing gastric ulcer:** Persistent ulceration despite adequate medical therapy. The procedure of choice is partial gastrectomy with a Billroth I anastomosis, in which the ulcer and the ulcer-bearing area of the stomach are resected.

- **Gastric outflow obstruction**
- **Recurrent ulcer following gastric surgery**
- **Duodenal ulcer:** Most commonly performed procedures are:
  - ◆ Vagotomy and drainage (by pyloroplasty, gastroduodenostomy, or gastrojejunostomy)
  - ◆ Highly selective vagotomy (which does not require a drainage procedure)
  - ◆ Vagotomy with antrectomy.
- As an emergency for complications namely **perforation and hemorrhage**

## Dumping Syndrome

### **Q. Write a short note on dumping syndrome.**

- It is a series of vasomotor and GI signs and symptoms that occurs when food reaches the small bowel too rapidly and usually develops in patients who have undergone vagotomy and drainage (especially Billroth procedures).

**Triggering factor:** It usually occurs after meals rich in simple carbohydrates (especially sucrose) and high osmolarity. Ingestion of large amounts of liquids may also contribute.

**Phases:** There are two phases of dumping namely early and late.

- **Early dumping:**
  - **Time of occurrence:** Occurs 15–30 minutes after meals.
  - **Signs and symptoms:** Consists of crampy abdominal discomfort, nausea, diarrhea, belching (bloating), borborygmi, tachycardia, palpitations, diaphoresis, light-headedness, and, rarely, syncope.
  - **Mechanism:** The signs and symptoms are due rapid emptying of hypertonic gastric contents into the small intestine that draws the fluid into lumen of the gut and leads to distension of small intestine. This leads to reduced volume of plasma and acute intestinal distention. Release of vasoactive GI hormones (vasoactive intestinal polypeptide, neurotensin, motilin) may also play a role.
- **Late phase of dumping:**
  - **Time of occurrence:** Occurs 90 minutes to 3 hours after meals.
  - **Signs and symptoms:** Consists of vasomotor symptoms such as light-headedness, diaphoresis/sweating, palpitations, tachycardia, and occasionally syncope.
  - **Mechanism:** Possibly secondary to hypoglycemia from excessive

insulin release.

### ***Provocative Test***

- After an overnight fast, a solution of 50–75 g glucose given orally.
- Measure blood glucose, hematocrit, pulse rate and blood pressure at 30 minutes intervals, immediately before and up to 180 minutes after ingestion of glucose.
- Positive test: Characterized by an early (30 minutes) increase in pulse rate (>10/minutes) or hematocrit >3% and late (120–180 minutes) hypoglycemia.

#### **Treatment**

- Patient should be asked have small, multiple (six) meals and avoid simple carbohydrates and liquids during meals.
- Antidiarrheals and anticholinergic drugs are complementary to diet.
- Guar and pectin: They increase the viscosity of intraluminal food contents, thereby slowing down gastric emptying.
- Acarbose: It is a  $\alpha$ -glucosidase inhibitor that delays digestion of ingested carbohydrates. It appears beneficial in the treatment of the late phases of dumping.
- Octreotide: It is a somatostatin analogue given subcutaneously (50 g tid), before the meal may be used in diet- refractory cases. A long-acting octreotide may be given once every 28 days.

## **Gastric Outlet Obstruction**

**Q. Write short note differential diagnosis of gastric outlet obstruction.**

**Types:** Obstruction may be prepyloric, pyloric or duodenal.

### ***Causes (Box 10.10)***

#### ***Consequences***

**Vomiting:** After gastric outlet obstruction the stomach, gastric juice and ingested fluid and food accumulate and produce vomiting. It is infrequent, projectile, large in volume, and the vomitus contains particles of previous meals. Severe or persistent vomiting may cause loss of acid from the stomach and result in metabolic alkalosis.

On examination of the abdomen there may be a succussion splash.

#### ***Diagnosis***

- **Clinical suspicion:** By the nature of the vomiting. Differential diagnosis is

psychogenic vomiting which is frequent, small volume and usually noisy.

- **Endoscopy**

**Treatment**

- **Vomiting is treated** by intravenous fluid, antiemetics, and electrolyte replacement, gastric drainage via a nasogastric tube and potent acid suppression therapy.
- **Endoscopic dilatation** of the pyloric region.
- **Treatment of the underlying cause**

**Box 10.10: Causes of gastric outlet obstruction.**

- Obstruction due to peptic ulcer disease
  - Active ulcer with surrounding edema
  - Healing of an ulcer has been followed by scarring
- Gastric malignancy
- Crohn's disease
- External compression from a pancreatic carcinoma
- Adult hypertrophic pyloric stenosis is very rare

# DISEASES OF THE INTESTINE

## Malabsorption Syndrome

**Q.** Discuss the classification, etiology, clinical features, investigations (diagnosis) and management of malabsorption syndrome.

**Q.** Write short essay/note on investigation of a case of steatorrhea.

**Definition:** Malabsorption is defined as defective/diminished intestinal absorption of one or more dietary nutrients.

### *Classification and Etiology (Fig. 10.9)*

**Q.** Write short essay/note on causes of malabsorption syndrome.

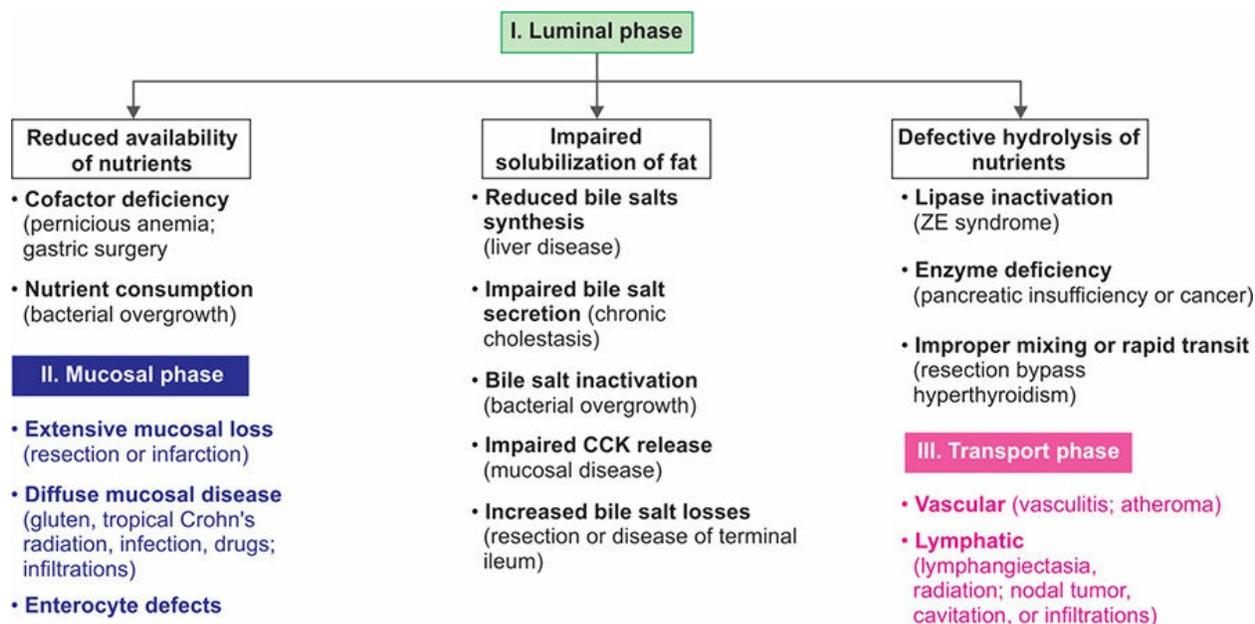

Drugs causing malabsorption and systemic diseases associated with malabsorption are presented in Table 10.38.

### *Clinical Features*

- Onset: Insidious and gradually progresses.
- General features: Diarrhea, abdominal pain, distension, loss of weight, anemia.
- Symptoms and signs and relevant pathophysiology are presented in Table 10.39 and Figure 10.10.

**Table 10.38:** Drugs causing malabsorption and systemic diseases associated with malabsorption.

<i>Drug</i>	<i>Systemic diseases</i>
Colchicine, neomycin, methotrexate, cholestyramine, laxatives	Addison's disease, thyrotoxicosis, hypothyroidism, diabetes mellitus, collagen vascular disease

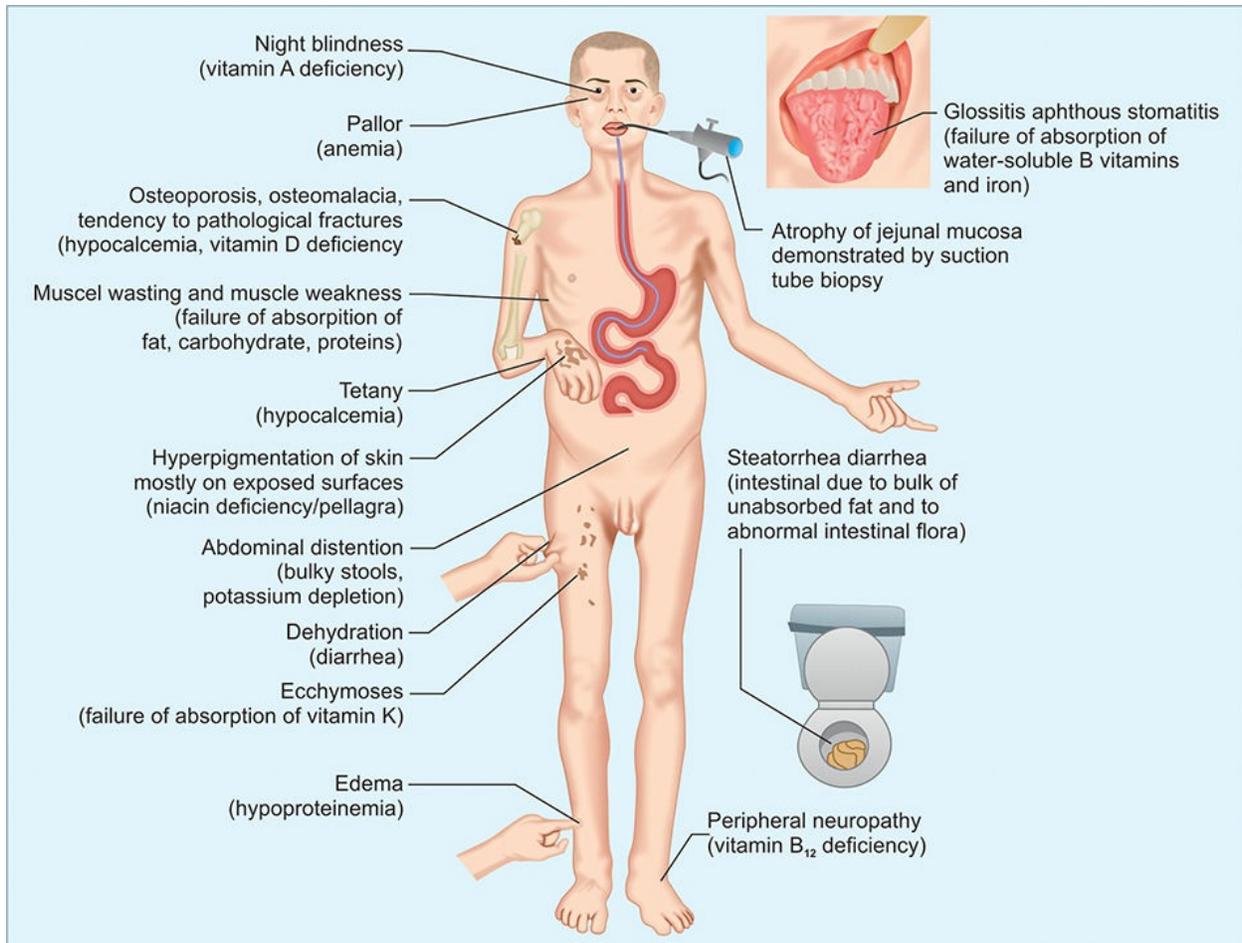

**Fig. 10.9:** Classification and causes of malabsorption

**Table 10.39:** Signs and symptoms of malabsorption and relevant pathophysiology.

<i>Symptom or sign</i>	<i>Pathophysiology</i>
<b>Gastrointestinal</b>	
Diarrhea	<ul style="list-style-type: none"> <li>• Osmotic activity of carbohydrates or short-chain fatty acids</li> <li>• Secretory effect of bile acids and fatty acids</li> <li>• Decreased absorptive surface</li> <li>• Intestinal loss of conjugated bile acids</li> </ul>
Abdominal distention, flatulence	Bacterial gas production from carbohydrates in colon, small intestinal bacterial overgrowth
Foul-smelling flatulence or stool	Malabsorption of proteins or intestinal protein loss
Pain	Gaseous distention of intestine
Ascites	Protein loss or malabsorption
<b>Musculoskeletal</b>	
Tetany, muscle weakness, paresthesias	Malabsorption of vitamin D, calcium, magnesium, and phosphate
Bone pain, osteomalacia, fractures	Protein, calcium, or vitamin D deficiency; secondary hyperparathyroidism
<b>Cutaneous and Mucosal</b>	
Easy bruisability, ecchymosis, petechiae	Vitamin K deficiency and vitamin C deficiency

Glossitis, cheilosis, stomatitis	Vitamin B complex, vitamin B <sub>12</sub> , folate, or iron deficiency
Edema	Protein loss or malabsorption
Ichthyosis, acrodermatitis, scaly dermatitis	Zinc and essential fatty acid deficiency
Follicular hyperkeratosis	Vitamin A deficiency
Hyperpigmented dermatitis	Niacin deficiency (pellagra)
Koilonychia	Iron deficiency
Perifollicular hemorrhage	Malabsorption of vitamin C
<b>Other</b>	
Weight loss, hyperphagia	Nutrient malabsorption
Growth and weight retardation, infantilism	Nutrient malabsorption in childhood and adolescence
Anemia	Iron, folate, or vitamin B <sub>12</sub> deficiency
Kidney stones	Increased colonic oxalate absorption
Amenorrhea, impotence, infertility	Multifactorial (including protein malabsorption, secondary hypopituitarism, anemia)
Night blindness, xerophthalmia	Vitamin A deficiency
Peripheral neuropathy	Vitamin B <sub>12</sub> or thiamine deficiency
Fatigue, weakness	Calorie depletion, iron and folate deficiency, anemia
Neurologic symptoms, ataxia	Vitamin B <sub>12</sub> , vitamin E, or folate deficiency

**Fig. 10.10:** Signs and symptoms of malabsorption.

Clinical features of specific malabsorption disorders is presented in Table 10.40

**Table 10.40: Clinical features of specific malabsorption disorders.**

<b>Disorder</b>	<b>Cardinal clinical features</b>
Adrenal insufficiency	Skin darkening, hyponatremia, hyperkalemia
Amyloidosis	Renal disease, nephrotic syndrome, cardiomyopathy, neuropathy, carpal tunnel syndrome, macroglossia, hepatosplenomegaly
Carcinoid syndrome	Flushing, cardiac murmur
Celiac disease	Variable symptoms: dermatitis herpetiformis, alopecia, aphthous mouth ulcers, arthropathy, neurologic symptoms, and (life-threatening) malnutrition; abnormal liver function test results, mild iron deficiency

Crohn's disease	Arthritis, aphthous mouth ulcers, episcleritis, uveitis, pyoderma gangrenosum, erythema nodosum, abdominal mass, fistulas, primary sclerosing cholangitis (PSC), laboratory signs of inflammation
Cystic fibrosis	Chronic sinopulmonary disease, meconium ileus, distal intestinal obstruction syndrome (DIOS), elevated sweat chloride
Diabetes mellitus	Long history of diabetes and diabetic complications
Glucagonoma	Migratory necrolytic erythema
Hyperthyroidism, hypothyroidism	Symptoms and signs of thyroid disease
Lymphoma	Enlarged mesenteric or retroperitoneal lymph nodes, abdominal mass, abdominal pain, fever
Pancreatic insufficiency	History of pancreatitis, abdominal pain; or alcoholism; large-volume fatty, oily stools
Parasitic infection	History of travel to endemic areas
Primary biliary cirrhosis	Jaundice, itching
Scleroderma	Dysphagia, Raynaud's phenomenon, skin tightening
Tropical sprue	History of travel to endemic area
Tuberculosis	Specific history of exposure, living in or travel to endemic area, immunosuppression, abdominal mass or intestinal obstruction, ascites
Whipple's disease	Lymphadenopathy, fever, arthritis, cerebral symptoms, heart murmur
Zollinger-Ellison syndrome	Peptic ulcers, diarrhea

### ***Investigations (Table 10.41 and Flowchart 10.6)***

**Table 10.41: Laboratory tests useful in patients with suspected malabsorption.**

<b><i>Test</i></b>	<b><i>Comment</i></b>
<b>Peripheral Blood Findings</b>	
Hematocrit, hemoglobin	Decreased in iron, vitamin B <sub>12</sub> , and folate malabsorption or with blood loss
Mean corpuscular hemoglobin or mean corpuscular volume	Decreased in iron malabsorption; increased in folate and vitamin B <sub>12</sub> malabsorption
White blood cells, differential	Decreased in vitamin B <sub>12</sub> and folate malabsorption

<b>Biochemical Tests (Serum)</b>	
Triglycerides	Decreased in severe fat malabsorption
Cholesterol	Decreased in bile acid malabsorption or severe fat malabsorption
Albumin	Decreased in severe malnutrition, protein-losing enteropathy
Alkaline phosphatase	Increased in calcium and vitamin D malabsorption (severe steatorrhea); decreased in zinc deficiency
Calcium, phosphorus, magnesium	Decreased in extensive small intestinal mucosal disease, after extensive intestinal resection, or in vitamin D deficiency
Zinc	Decreased in extensive small intestinal mucosal disease or intestinal resection
Iron, ferritin	Decreased in celiac disease, in other extensive small intestinal mucosal diseases, and with chronic blood loss
<b>Other Serum Tests</b>	
Prothrombin time	Prolonged in vitamin K malabsorption
Folic acid	Decreased in extensive small intestinal mucosal diseases, with anticonvulsant use, in pregnancy; may be increased in small intestinal bacterial overgrowth
Vitamin B <sub>12</sub>	Decreased after gastrectomy, in pernicious anemia, terminal ileal disease, and small intestinal bacterial overgrowth
<b>Endoscopy and biopsy</b>	
<b>Stool Tests</b>	
Fat	Qualitative or quantitative increase in fat malabsorption
Elastase, chymotrypsin	Decreased concentration and output in exocrine pancreatic insufficiency
pH	< 5.5 in carbohydrate

### *Tests for fat absorption*

#### *Quantitative test*

- 72-hour stool fat collection: Gold standard
- 6 g/day: Pathologic, patients with steatorrhea >20 g/day.

#### *Qualitative tests*

- Sudan III stain for fat globules in stool: Detect clinically significant steatorrhea in >90% of cases. Acid steatocrit: A gravimetric assay. Sensitivity – 100%, specificity – 95%, PPV – 90%
- NIRA (near infra reflectance analysis): Equally accurate with 72 hours stool fat test. Allows

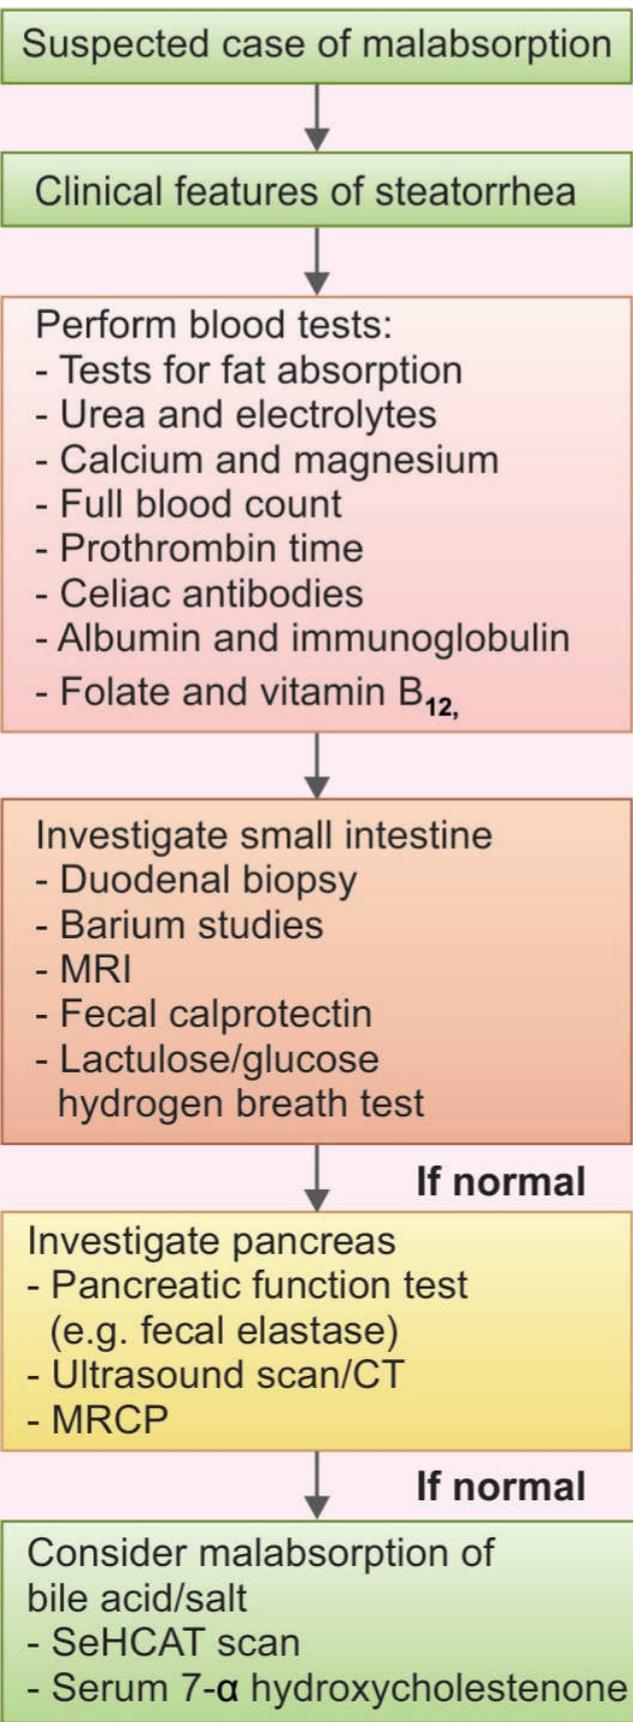

simultaneous measurement of fecal fat, nitrogen, CHO (carbohydrate)

- Measurement of blood levels of fat-soluble vitamins (A, D, E, K); prothrombin time.
- Plasma vitamin A level after 2–3 days of oral retinol: It will be lower than normal.

*Tests for carbohydrate absorption*

- **Glucose tolerance test:** It reveals absence of rise in blood glucose levels.
- **Blood sugar level:** Low
- **D-xylose absorption test:** D-xylose is a pentose monosaccharide absorbed exclusively at the proximal small intestine. This test is used to assess proximal small intestine mucosal function. The procedure is as follows:
  - After overnight fast, administer 25 g D-xylose perorally.
  - Urine collected for next 5 hours and urinary excretion of D-xylose is estimated.
  - Abnormal test: <4.5 g is abnormal and suggest intestinal malabsorption (duodenal/jejunal mucosal disorders) and excludes pancreatic cause.
- **Lactose tolerance test (LTT):**
  - Orally 50 g of lactose is given.
  - Blood glucose levels measured at 0, 60, 120 minutes.
  - Normally, blood glucose shows a rise of >20 mg/dL.
  - Blood glucose <20 mg/l + development of symptoms favor diagnosis.
- **Hydrogen breath test (refer page 752):** It is used for the diagnosis of lactase deficiency. 50 g lactose given orally and breath hydrogen measured every hour for 4 hours. Normal value is <10 ppm increase above baseline.

**Flowchart 10.6:** Step-wise investigation in a suspected case of malabsorption

### *Tests for protein absorption*

- **Serum albumin:** Low
- **Nitrogen in the 24-hour stool:** >2.5 g.
- **$\alpha_1$ -Antitrypsin content in stool:** Normally no antitrypsin in stool. A 3 days collection of stools is estimated for  $\alpha_1$ -antitrypsin content.

### *Test for bile acid malabsorption*

**Selenium-homocholic acid taurine (SeHCAT) test:** In this test Se-labeled bile acid is given orally. After 7 days, total body retention is measured with a gamma camera. Retention value of <10% is abnormal.

### *Tests for absorption of other substances*

- Serum B<sub>12</sub> level: Reduced
- **Schilling test for absorption of B<sub>12</sub>:** To determine the cause of cobalamine (B<sub>12</sub>) malabsorption (refer Fig. 8.18) (discussed on pages 568-9).

### *Test for bacterial overgrowth*

- Quantitative bacterial count from aspiration from small intestine. Normal count is <10 U/mL (jejunum), >10 U/mL (ileum).
- **Breath tests:** Cholyl-14 C-glycine, e.g. bacterial overgrowth. Lactose H<sub>2</sub> for lactose intolerance, e.g. in bacterial overgrowth.
- **Small intestinal biopsy (duodenal or jejunal):** Lesions seen can be classified into three:
  1. Diffuse and specific, e.g. Whipple's disease
  2. Patchy and specific, e.g. Crohn's disease, lymphoma, infectious causes.
  3. Diffuse and non-specific, e.g. celiac sprue, tropical sprue, autoimmune enteropathy.

**Barium studies:** Important information about the gross anatomy and morphology of small intestine.

### **Treatment of Malabsorption Syndrome**

- **General measures**
  - Dehydration and electrolyte deficiency is treated by intravenous infusion.
  - Replacement therapy for anemia, bone disease and coagulation defects. Vitamin D, B complex,

and calcium supplements

- **Specific therapy depending on the cause**

- Celiac disease: Gluten-free diet.
- Pancreatic insufficiency: Pancreatic supplements
- Bile acid deficiency/malabsorption: Low-fat diet and cholestyramine (bile acid binder).

## Celiac Disease

**Q. Write short essay/note on Celiac disease (non-tropical spure/gluten-induced enteropathy).**

### *Definition*

Celiac disease is characterized by small intestinal malabsorption of nutrients after the ingestion of wheat gluten or related proteins from rye and barley, villus atrophy of the small intestinal mucosa, prompt clinical and histologic improvement following strict adherence to a gluten-free diet, and clinical and histologic relapse when gluten is reintroduced.

### *Etiology*

Exact etiology is not known, but environmental, immunologic, and genetic factors play important role.

- **Environmental factor:** Gluten is the protein present in the cereals wheat, barley and rye. **Gliadin** is a component of gluten. There is a clear cut association of the celiac disease with gliadin. Gluten restriction results in morphologic changes within hours in patient with celiac disease.
- **Immunologic factor:** It involves both adaptive and innate immune responses. Presence of serum antibodies such as IgA antigliadin, IgA antiendomysial (90–95% sensitivity and specificity), and IgA anti-tTG antibodies in patients with celiac disease. It is not known whether they represent primary or secondary to the tissue damage.
- **Genetic factor(s):** Increased incidence of celiac disease is observed within families but the exact mode of inheritance is unknown. All patients express the HLA-DQ2 or HLA-DQ8 allele.

### *Pathology*

- **Site of lesion:** Biopsy from the second portion of the duodenum or proximal jejunum (which are exposed to the highest concentrations of

dietary gluten) is diagnostic.

- **Microscopic changes:** Characterized by increased numbers of intraepithelial CD8+ T lymphocytes (intraepithelial lymphocytosis), crypt hyperplasia and villous atrophy. Increased numbers of plasma cells, mast cells, and eosinophils within the upper part of the lamina propria.

### ***Clinical Features***

**Age and gender:** It can manifest at any age. Usually manifests early in childhood at about 2 years of age (after wheat is introduced into the diet), or later in the second to fourth decades of life with a female preponderance.

**Symptoms:** Many patients are asymptomatic (silent). The symptoms are very variable and often nonspecific.

- Symptoms due to malabsorption of multiple nutrients, with diarrhea, steatorrhea, weight loss, and the consequences of nutrient depletion (i.e. anemia and metabolic bone disease).
- Symptoms due to the depletion of a single nutrient (e.g. iron or folate deficiency or vitamin B<sub>12</sub> deficiency, osteomalacia, edema from protein loss, tetany).

*Associated diseases (Box 10.11)*

***Complications (Box 10.12)***

### ***Investigations and Diagnosis***

- Small-intestinal biopsy: Duodenal/jejunal biopsy is required and is considered as ‘gold standard’ to establish a diagnosis.
- Serologic tests (Box 10.13)
- Tests for malabsorption of proteins, carbohydrate, fat and vitamins.
- HLA typing. HLADQ2 is observed in 90–95% of patients and HLADQ8 in about 8%.

**Box 10.11:** Diseases associated with celiac disease.

- Insulin-dependent diabetes mellitus (2–8%)
- Thyroid disease (5%)
- Primary biliary cirrhosis (3%)
- Sjögren’s syndrome (3%)
- IgA deficiency (2%)
- Pernicious anemia

### Box 10.12: Complications of celiac disease.

- Gastrointestinal malignancies: An increased incidence of both gastrointestinal (e.g. Carcinoma of the esophagus) and nongastrointestinal neoplasms as well as enteropathy associated T cell lymphoma (EATCL)
- Development of intestinal ulceration independent of lymphoma (ulcerative jejunitis), refractory sprue and collagenous sprue
- Nonresponsive celiac disease: Few patients do not improve on a strict diet
- Refractory celiac disease (RCD)
- Pneumococcal infections
- Dermatitis herpetiformis
- Osteomalacia

### Box 10.13: Serologic tests in celiac disease.

#### Serologic tests

- IgA antiendomysial antibody
- IgA antitissue transglutaminase antibody (anti-tTG)
- IgA antigliadin antibody
- IgG antigliadin antibody

#### Treatment/Management of Celiac Disease

- **Diet:** Lifelong gluten-free diet. Avoid wheat, rye, and barley. Oats not contaminated with flour are tolerated by most patients. Rice, meat, dairy products, vegetables and fruits are safe. Completely avoid beer and whisky obtained from malt distillation procedures. Lactose-free diet is advisable because of secondary lactase deficiency associated with celiac disease.
- **Supplementation of** vitamins and minerals in cases patients with these deficiency, folic acid supplements for women of childbearing age.
- **Pneumococcal vaccinations** (because of splenic atrophy) once in every 5 years.
- **Corticosteroids:** They are rarely required. Used in critically ill patients who present with acute celiac crisis characterized by severe diarrhea, dehydration, weight loss, acidosis, hypocalcemia and hypoproteinemia. May be used in gliadin shock after a gluten challenge.

## Tropical Sprue

**Q. Write short essay on tropical sprue (idiopathic tropical malabsorption syndrome).**

**Definition:** Tropical sprue is a condition presenting with chronic diarrhea and malabsorption (of two or more substances) that occurs in residents or travelers to certain, but not all tropical areas (especially India and Southeast Asia) in the absence of other intestinal diseases or parasites.

## ***Etiology***

- Etiology and pathogenesis of tropical sprue is unknown.
- **Role of infectious agents:** Because tropical sprue responds to antibiotics, it is possible that it may be caused by one or more infectious agents (e.g. *Klebsiella pneumoniae*, *Enterobacter cloacae*, or *E. coli*) or a toxin produced by these agents.
- **Role of folic acid deficiency:** Folic acid is absorbed in the duodenum and proximal jejunum, and most patients with tropical sprue show evidence of folate malabsorption and depletion.

## ***Clinical Features***

- Clinical features vary in different parts of the world.
- **Intensity:** Vary and consist of diarrhea, anorexia, abdominal distension, fatigue and weight loss.
- **Onset:**
  - **Acute:** Sometimes acute with sudden severe diarrhea and accompanied by fever. It occurs either a few days or many years after being in the tropics.
  - **Chronic phase:** Onset may also be insidious, with chronic diarrhea and evidence of nutritional deficiency. Features of megaloblastic anemia (folic acid malabsorption) and other deficiencies, including ankle edema, glossitis and stomatitis, are common. Remissions and relapses may occur.

## ***Diagnosis and Investigations***

- **Abnormal jejunal mucosal biopsy:** It shows partial villous atrophy and mononuclear cell infiltrate in the lamina propria. The lesion is less severe than that of celiac disease.
- **Stool examination**
- **Demonstration of malabsorption**

### **Treatment of Tropical Sprue**

- **Broad-spectrum antibiotics:** Tetracycline or oxytetracycline 1 g daily in four divided doses for up to 6 months and produces improvement within 1–2 weeks.
- **Folic acid:** Dose of 5 mg daily along with tetracycline is most often curative. It induces a hematologic remission and improvement in appetite, weight gain, and also morphological changes in small intestinal biopsy.

- **Correction of deficiencies:** Severely ill patients require resuscitation with fluids and electrolytes for dehydration. Nutritional deficiencies should be corrected such as vitamin B (1000 µg).
- **Symptomatic treatment for diarrhea.**
- **Prognosis:** Excellent. Mortality is usually due to water and electrolyte depletion

## Lactose Intolerance

**Q. Write short note on lactose intolerance.**

### *Etiology*

- Lactose is the disaccharide present in milk and for it is digested to monosaccharides (glucose and galactose) by the brush border lactase.
- **Classification:** There are two types of lactase deficiency namely primary and secondary.
  - *Primary lactase deficiency:* It is due to genetic deficiency or absence of lactase and both intestinal absorption and brush border enzymes are normal.
  - *Secondary lactase deficiency:* It occurs in association with both structural and functional disorder of brush border enzymes and transport processes. Examples, celiac disease, tropical sprue and Crohn's disease.
- Lactose intolerance develops due to the deficiency of lactase and lactose present in the milk cannot be hydrolyzed. Hence, lactose gets fermented by bacteria causing gastrointestinal symptoms.

### *Clinical Features*

- Diarrhea, abdominal pain, cramps, and/or flatus develops after ingesting milk or milk products.
- Symptoms improve on withdrawal of milk or milk products.

### *Investigations*

- **Hydrogen breath test:** This is used as a screening test to measure transit time and detect bacterial overgrowth in the small intestine. Appearance of breath hydrogen peak after oral lactulose indicates that the undigested lactose is fermented by the colonic microflora and produces hydrogen which can be detected in expired air.
- Measurement of lactase activity in a jejunal biopsy.

### Treatment

- Lactose free diet. Avoid milk and dairy products. However, it may lead to nutritional deficiencies, particularly calcium deficiency.
- **Administration of exogenous  $\beta$ -galactosidase**
  - Enzyme replacement therapy with microbial exogenous lactase (obtained from yeasts or fungi).
  - Enzymes supplement to milk and dairy products.
  - Use of yogurt and probiotics (source of  $\beta$ -galactosidase).

## Whipple's Disease

**Q. Write short note on Whipple's disease and its important clinical features.**

Whipple's disease is a chronic, rare, multisystemic infectious bacterial disease caused by **Tropheryma whipplei** (gram-positive).

### *Clinical Features*

- Gender: More common in males than in females.
- Whipple's disease is a chronic multisystem disease associated with diarrhea, steatorrhea, weight loss, arthralgia, and central nervous system (CNS) and cardiac problems.
- Migratory arthralgias of the large joints
- Dementia and other central nervous system findings (such as supranuclear ophthalmoplegia, nystagmus, and myoclonus).
- Cardiac disease (dyspnea, pericarditis, culture-negative endocarditis)
- Pleuropulmonary (pleural effusion).

### *Investigations*

**Biospy:** Jejunal biopsy and biopsy of other involved tissues show numerous **PAS –positive macrophages with small bacilli**. In the small intestine, these macrophages produce lymphatic blockade in the lamina propria causing malabsorption.

**Treatment:** Trimethoprim-sulfamethoxazole (double strength tablet): Dose twice a day for 1 year. This should be preceded by a 2-week course of parenteral therapy with ceftriaxone (2 g daily) or by meropenem

## Giardiasis

**Q. Write short essay/note on clinical features, diagnosis and treatment of Giardiasis.**

- Giardiasis is an infection caused by flagellate *Giardia lamblia* (*Giardia intestinalis*).
- Giardiasis is found worldwide and is one of the most common parasitic diseases in both developed and developing countries, causing intestinal disease and diarrhea.
- It mainly affects children, tourists and immunosuppressed individuals (agammaglobulinemia).
- **Incubation period: 1–3 weeks**
- **Mode of infection:** By ingesting **contaminated water**. In cystic form, it is viable in water for up to 3 months.
- Malabsorption may develop due to loss of brush–border enzyme activities and few patients may show flattening of villi.

### ***Clinical Features***

- Range from asymptomatic carrier stage to fulminant diarrhea and malabsorption.
- After ingestion of flagellar trophozoite form, it attaches to the mucosa of duodenum and jejunum and causes inflammation. It produces disease of small intestine.
- **Acute giardiasis:** Starts as **diarrhea, abdominal pain**, nausea, vomiting, anorexia, belching, flatus, weakness and abdominal pain. Fever and blood in stool are rare. The duration is usually >1 week.
- **Chronic giardiasis:** May present with or without having experienced antecedent acute episode. Diarrhea may not be a prominent symptom and they may have increased flatus, and loose stools. It may produce steatorrhea; malabsorption if illness is prolonged may result in marked weight loss. Symptoms may be continuous or episodic and can persist for years. Chronic giardiasis in children from developing countries may develop retardation of growth.
- **Severe disease:** Giardiasis may be severe in patients with hypogammaglobulinemia, resulting in malabsorption, weight loss, growth retardation, and dehydration.
- Physical examination may reveal abdominal distension and tenderness.

- **Extra-intestinal manifestations:** These include urticaria, anterior uveitis, and arthritis.

### ***Investigations/Diagnosis***

- **Stool examination:** Demonstration of protozoal parasite.
- **Duodenal or jejunal aspiration** by endoscopy or with a luminal capsule gives a higher diagnostic yield.
- **String test:** In this one end of a piece of string is passed into the duodenum by swallowing and retrieved after an overnight fast. The fluid is expressed from this and examined for the presence of *G. lamblia* trophozoites.
- **Biopsy:** Biopsy and histological examination of jejunal mucosa may show *G. lamblia* on the epithelial surface.
- **Stool antigen detection tests: Detection of parasite antigens in the feces** is sensitive and specific and easier to perform.
- **Other tests:** Chronic cases may show steatorrhea, malabsorption of xylose and vitamin B<sub>12</sub> and lactose intolerance.

### **Treatment/Management**

- **Tinidazole** 40 mg/kg (2 g/day) once by mouth and repeated after 1 week.
- **Metronidazole** 2 g daily for 3 days or metronidazole 200 mg thrice daily for 5 to 7 days is usually curative in >90% of cases.
- **Nitrazoxanide** 500 mg twice a day for 3 days. Other drugs include mepacrine and albendazole.
- **Paromomycin** is an oral aminoglycoside and is not well absorbed. It can be given to symptomatic pregnant patients.
- **Refractory cases:** Prolonged therapy with metronidazole 800 mg thrice daily for 3 weeks

## **Carcinoid Tumors (Neuroendocrine Tumors)**

**Q. Write short note on carcinoid tumors (neuroendocrine tumors) and carcinoid syndrome.**

- Neuroendocrine cells are amine- and acid-producing cells located throughout the body.
- Neuroendocrine tumors (NETs) are tumors derived from the diffuse neuroendocrine system of the GI tract.
- Location of carcinoid tumors: Appendix (25%), small intestine (25%), and

rectum (15%). Stomach (5%) and lung (15% of all carcinoid tumors).

### ***Classification of Carcinoid Tumors***

According to their anatomic area of origin

- Foregut (lungs, bronchi, stomach)
- Midgut (small intestine, appendix, proximal large bowel)
- Hindgut (distal large bowel, rectum).

Ultrastructurally, they possess electron-dense neurosecretory **granules which may contain various substances. These include: 5-hydroxytryptamine (serotonin), histamine, tachykinins, motilin, prostaglandins, bradykinins, adrenocorticotrophic hormone, corticotrophin releasing factor.**

### ***Carcinoid Syndrome***

It is symptom complex in which systemic symptoms are produced when the vasoactive substances are secreted by carcinoid tumors into the systemic circulation. Carcinoid syndrome occurs in only 8–10% of patients.

- **Midgut carcinoids** (usually ileal carcinoid) with hepatic metastasis can produce carcinoid syndrome. Because, normally liver is able to metabolize these secretory products into inactive forms and with hepatic metastasis the product can reach systemic circulation.
- **Foregut (bronchial and extraintestinal) carcinoids** can present with carcinoid syndrome without hepatic metastases. This is because bioactive products can bypass liver and can be released directly into systemic circulation.
- **Hindgut carcinoids** seldom produce syndrome since they do not secrete these products.
- Intestinal carcinoids have an increased tendency for liver metastasis.

### ***Clinical Features (Table 10.42)***

Characterized by cutaneous flushing, involving head and neck (blush area) associated with lacrimation, sweating, bronchospasm, colicky abdominal pain, diarrhea, and right-sided cardiac valvular fibrosis.

### ***Diagnosis***

Diagnosed by measuring urinary or plasma serotonin or its metabolites in the urine.

- **Measurement of 5-hydroxyindoleacetic acid (5-HIAA):** Increased (>9 mg) urinary excretion in 24-hour sample collection.
- **Serum chromogranin A levels** are elevated in 56–100% of patients.
- Serotonin level in blood and platelets is high, because it is overproduced in 92% of patients.
- Plasma neuron-specific enolase levels are increased but are less sensitive than chromogranin A.
- **Others:** CT, MRI, and somatostatin receptor scintigraphy, PET (positron emission tomography) with radiolabeled 5-hydroxytryptophan may be helpful.

**Table 10.42: Clinical features of carcinoid tumors.**

• Intestinal obstruction by tumor	• Intestinal ischemia due to either mesenteric infiltration or vasospasm
• Hepatic metastases may produce pain and jaundice	• Features of carcinoid syndrome: Flushing wheezing, diarrhea, etc.
• Cardiac involvement (e.g. tricuspid regurgitation, pulmonary stenosis) leading to heart failure	• Facial telangiectasia

#### Treatment

- Avoid conditions and diets that precipitate flushing and diarrhea.
- Supplementation of diet with nicotinamide.
- Wheezing is treated with oral bronchodilators.
- Treatment of heart failure with diuretics.
- Control of the diarrhea with antidiarrheal agents (e.g. loperamide and diphenoxylate). If not controlled advise serotonin receptor antagonists (cyproheptadine, methysergide, ondansetron) to control diarrhea.
- Analogues of somatostatin (e.g. octreotide, lanreotide) to control flushing.
- Surgical resection of the carcinoid tumor.
- Excision of liver metastases or hepatic artery embolization with or without chemotherapy.

## Ischemic Colitis

**Q. Write short note on ischemic colitis.**

### *Etiology*

- **Transient nonocclusive hypoperfusion of a segment of the colon**, e.g. systemic hypoperfusion.
- **Occlusion of the inferior mesenteric artery or its branches**, e.g. atherosclerotic or thrombotic occlusion.
- **Less common causes**, e.g. hypercoagulable states (in young persons), iatrogenic ligation of the inferior mesenteric artery (e.g. with aortic surgery), embolism, vasculitis, and colonic obstruction (e.g. colonic cancer).
- **Drugs and chemicals**: Medications, illicit drugs, and chemicals may also produce chemical picture identical or similar to ischemic colitis (e.g. digitalis, vasopressin, pseudoephedrine, amphetamines, cocaine, estrogens, ergot alose tron, etc).

### ***Clinical Features***

- **Age**: Occur in persons older than 60 years without any apparent cause.
- **Onset**: Many cases are acute and self-limited.
- **Symptoms**: Colicky lower abdominal pain (mostly left lower quadrant), diarrhea, and passage of bright red blood per rectum, nausea and vomiting. Though the blood loss is not usually enough to require transfusion, some patients may progress to shock because of loss of blood and fluid.
- **Physical examination**: Abdominal tenderness and guarding over the affected portion of the colon (especially left iliac fossa), and abdominal distention fever, tachycardia.

### ***Laboratory Findings/Investigation***

- Nonspecific findings such as leukocytosis and hemoconcentration.
- Plain radiographs of the abdomen: It may show 'thumbprinting' at splenic flexure and descending colon or may be normal.
- CT scanning of abdomen: Useful to exclude other disorders.
- Double contrast barium enema demonstrates involvement of splenic flexure and descending colon. Mucosal abnormalities are **thumbprinting** and ulceration.
- Colonoscopy has replaced barium studies as it is more sensitive. Sigmoidoscopy shows normal rectal mucosa and bleeding descending from above.

- Arteriography confirms the diagnosis in patients with obstructive lesions.

#### Treatment

- **For right-sided ischemic colitis:** It requires visceral angiography which is needed for both diagnosis and intra-arterial administration of vasodilators (e.g. papaverine as a 60-mg intravenous bolus followed by an infusion of 30 to 60 mg/hour). Some patients may need urgent surgery.
- **Left-sided acute ischemic colitis:** It accounts for most cases and most cases resolve within hours to a few days with supportive therapy. Therapy includes volume replacement, correction of any low-flow state, broad-spectrum antibiotics (similar to those recommended earlier for patients with small bowel ischemia), avoidance of vasoconstrictive medications, and rarely, blood transfusion. Surgery is required only in patients with signs and symptoms of transmural necrosis, perforation, or massive bleeding.
- **Conservative management:** Intravenous fluids, hemodynamic stabilization, discontinuation or avoidance of vasoconstrictive agents, bowel rest and empiric antibiotics.
- **Surgical treatment:** Peritonitis and strictures.

## Pseudomembranous Colitis

**Q. Write short note on pseudomembranous colitis (antibiotic-associated colitis).**

Pseudomembranous colitis also referred to as antibiotic-associated colitis or antibiotic-associated diarrhea, generally caused due to toxin produced by *Clostridium difficile*, when the normal bacterial flora is altered or suppressed by antibiotics.

- Antibiotic-associated diarrhea may (Table 10.43) also be caused by other organisms such as *Salmonella*, *C. perfringens* type A, or *Staphylococcus aureus* but only *C. difficile* causes pseudomembranous colitis.
- In the colon, the vegetative form of *C. difficile* multiplies and produces **two major toxins** namely toxin A (an enterotoxin) and toxin B (a cytotoxin).

### Clinical Features

- **Age:** Pseudomembranous colitis usually develops in adults and about 80% of cases occur in people over 65 years of age.
- Patient is on antibiotics or has received antibiotics within last 8 weeks. Clinical symptoms range from asymptomatic to severe and sometimes life-threatening fulminant pseudomembranous colitis.
- **Diarrhea:** It is the most common manifestation.
  - Stool: Soft and unformed to watery or mucoid in consistency and has a

characteristic odor. Stools are almost never grossly bloody.

- Frequency: Patients may have as many as 20 bowel movements/day.
- Profuse watery diarrhea with abdominal cramps.
- Substantial fluid and protein losses combined with fever, cramps, hypoalbuminemia, leukocytosis, and hypotension.
- **Laboratory findings:** Leukocytosis is common (observed in up to 50% of patients) and is a marker of severe disease. Leukocytosis often >15,000/mm<sup>3</sup> white blood cells (WBCs)/L. Extremely high level (>50,000/mm<sup>3</sup> indicates fulminant and potentially fatal illness).
- **Complications:** Dehydration, electrolyte disturbances, hypoalbuminemia, toxic megacolon, bowel perforation, hypotension, renal failure, hypotension, lactic acidosis sepsis and death.

**Table 10.43:** Antimicrobial agents that predispose to *Clostridium difficile*-associated diarrhea and colitis.

Most frequently	Less frequently
<ul style="list-style-type: none"><li>• Ampicillin and amoxicillin</li><li>• Cephalosporins</li><li>• Clindamycin</li><li>• Fluoroquinolones</li></ul>	<ul style="list-style-type: none"><li>• Macrolides (including erythromycin)</li><li>• Other penicillins</li><li>• Sulfonamides</li><li>• Trimethoprim/ sulfamethoxazole</li></ul>

### ***Investigations and Diagnosis***

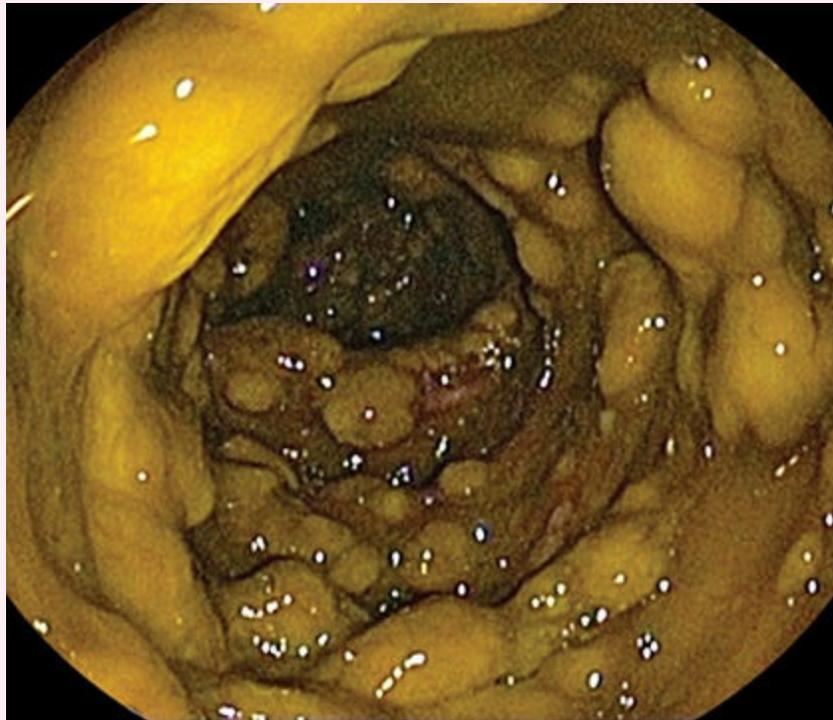

- Enzyme immunoassay for *C. difficile* glutamate dehydrogenase
- Enzyme immunoassay for *C. difficile* toxins A and B
- Real-time PCR tests detect the critical gene is tcdB.
- Stool culture for *C. difficile*
- **Sigmoidoscopy or colonoscopy:** Endoscopy is a rapid diagnostic tool in seriously ill patients and characteristically shows erythema, white plaques or an adherent pseudomembrane (Fig. 10.11). Biopsy can be done.

### **Treatment/Management**

Treatment consists of (1) discontinuation of the implicated antibiotic, (2) supportive care, and (3) avoidance of antiperistaltic agents and opiates.

- **Withdraw/discontinue** the precipitating antibiotic/antimicrobial drug and isolate the patient.
- **Supportive care:** Oral or intravenous rehydration
  - **Mild to moderate cases:** Oral metronidazole 500 mg thrice daily for 10–14 days. Rifaximin can be added.

- **Severe cases:** Oral vancomycin 125 mg 6 hourly for 14 days.
- **Severe complicated or fulminant cases:** Vancomycin (500 mg orally or via nasogastric tube) plus intravenous metronidazole (500 mg q8h) plus consider rectal instillation of vancomycin (500 mg in 100 mL of normal saline as a retention enema q6–8h). Intravenous vancomycin not effective. Newer drug fidaxomicin (200 mg twice daily) is as efficacious as vancomycin. If ileus develops vancomycin administered by enema.
  - ◆ **Oral probiotic therapy:** Use of live non-pathogenic bacteria to re-establish the gut flora often used in resistant or relapsed cases. Probiotics use organisms resistant to gastric acid. However, its clinical benefits are not proved.
- **Avoidance of antiperistaltic agents and opiates:** Antiperistaltic drugs such as loperamide or diphenoxylate should not be administered because they can precipitate toxic megacolon.
- Colectomy may be necessary in severely ill and refractory cases.
- Newer treatment modalities: **Fecal microbiota transplantation** (fecal enemas or infusion of donor feces through a nasoduodenal tube)

**Fig. 10.11:** Endoscopic appearance of pseudomembranous colitis

## Psychosomatic Disorders of the Gastrointestinal Tract

### *Classification (Table 10.44)*

### Irritable Bowel Syndrome (IBS)

**Q.** Write short essay/note on irritable bowel syndrome, its clinical features and management.

## Definition

- Irritable bowel syndrome (IBS) is a functional disorder of the gastrointestinal tract characterized by abdominal pain or discomfort and altered bowel habits in the absence of detectable structural, infective or biochemical abnormalities.
- IBS is benign, chronic symptom complex of altered bowel habits and abdominal pain.

**Table 10.44:** Classification of the functional disorders of gastrointestinal tract.

<ul style="list-style-type: none"><li>• Bad taste (cacogeusia)</li><li>• Foul smell of breath (halitosis)</li><li>• Functional heartburn</li><li>• Non-cardiac chest pain due to esophageal dysmotility</li><li>• Functional dyspepsia</li><li>• Functional bloating</li><li>• Aerophagia</li></ul>	<ul style="list-style-type: none"><li>• Globus hystericus</li><li>• Unspecified excessive belching</li><li>• Functional or psychogenic vomiting and cyclic vomiting syndrome</li><li>• Irritable bowel syndrome</li><li>• Functional diarrhea and functional constipation</li></ul>
---	---

## Pathophysiology

Exact cause not known and pathogenesis of IBS is poorly understood. However, the following factors have been proposed.

**Gastrointestinal motor abnormalities:** GI motility is quantitatively different in 25–75% of IBS patients compared with healthy controls.

- Patients with diarrhea as a predominant symptom exhibit rapid jejunal contraction waves, rapid intestinal transit, an increased number of colonic contractions (colonic transit is accelerated) and rectosigmoid motor activity.
- Patients with predominant constipation have decreased orocecal transit and a reduced number of colonic contraction waves.

**Visceral hypersensitivity:** IBS is associated with increased sensory responses to visceral stimulation induced by intestinal distension. The mechanism for visceral hypersensitivity is not known. This is more common in females and in diarrhea-predominant IBS.

**Central neural dysregulation:** There is a clinical association of emotional

disorders and stress with symptom exacerbation in IBS. MRI has shown that in response to distal colonic stimulation, the mid-cingulate cortex (brain region concerned with attention processes and response selection) shows greater activation in IBS patients. This cerebral dysfunction may lead to the increased perception of visceral pain.

**Abnormal psychological features:** Abnormal psychiatric features are found in up to 80% of IBS patients. These include anxiety, tension, depression, excessive worry, somatization and neurosis.

**Altered intestinal flora:** Bacterial overgrowth (shown by positive lactulose hydrogen breath test) in the small bowel has been observed in IBS patients and may contribute to symptoms.

**Abnormal serotonin pathways:** Serotonin is a neurotransmitter that plays an important role in the regulation of GI motility and visceral perception.

**Post-infectious IBS:** IBS may be induced by initial GI infection by *Campylobacter*, *Salmonella*, and *Shigella*.

**Immune activation and mucosal inflammation:** Certain diet/foods may precipitate an attack.

### ***Clinical Features***

- **Age:** IBS affects all ages. Most patients present before age 45 (20 to 40 years).
- **Gender:** More common in women compared to men (3:1).
- **Abdominal pain or abdominal discomfort** is the most common key symptom (prerequisite clinical feature) for the diagnosis of IBS. Characteristics of pain:
  - **Location:** Pain is most typically referred to the lower abdomen (left or right iliac fossa) or hypogastrium.
  - **Aggravation:** Pain and discomfort may be aggravated by emotional stress or poor sleep, and intake of food.
  - **Relief:** Abdominal symptoms are relieved by defecation or passage of flatus, but this relief may be temporary.
- **Altered bowel habits:** Most consistent clinical feature in IBS. Bowel pattern subtypes/variants are:
  - **IBS-constipation predominant (IBS-C):** These patients have spastic

colitis, and present with chronic abdominal pain and constipation.

- **IBS-diarrhea predominant (IBS-D):** They present with chronic intermittent watery diarrhea, often without abdominal pain.
- **Mixed IBS:** They have features of alternating diarrhea and constipation.

Most common alteration in the bowel habit is constipation alternating with diarrhea.

- **Diarrhea:** Frequent defecation, often painless, but produce low-volume stools and rare/never at night. Diarrhea usually consists of small volumes of loose stools. Sense of incomplete evacuation, leading to repeated attempts at defecation in a short time span.
- **Constipation:** Pass infrequent pellet-like (ribbon-like or pencil-like) stools usually in association with abdominal pain or proctalgia.
- **Stools:** Usually hard with narrowed caliber. May be accompanied by passage of large amounts of mucus.
- **Gas and flatulence:** Abdominal distention and increased belching or flatulence more common among female patients. Post-prandial tenesmus is common and is due to an exaggerated gastrocolic reflex.
- **Other symptoms:** Dyspepsia, heartburn, nausea, and vomiting.
- **Extraintestinal symptoms:** Headache, back pain, fatigue myalgia, dyspareunia and urinary frequency are often observed.
- **Physical examination:** Usually unremarkable, except for abdominal tenderness (most often in the left lower quadrant) or a tender, palpable sigmoid colon. In IBS-C, rectal examination may show paradoxical contraction of the puborectalis muscle or decreased descent of the pelvic floor when simulating a bowel movement.

## ***Investigations***

Aim of investigations is to exclude organic gastrointestinal diseases.

- **Full blood count**
- **Stool examination:** For parasites, ova, leukocytes, occult blood
- **Sigmoidoscopy:** Usually normal. There may be difficulty in negotiating rectosigmoid curve due to spasm. There may be marked motor activity of bowel and may show abundant mucus.

- **Colonoscopy:** Should be performed to exclude colorectal cancer, in older patients and those with history of rectal bleeding.
- **Barium enema:** Usually normal but may show spasticity of sigmoid, exaggerated haustral markings and a tubular appearance of the descending colon.
- In diarrhea-predominant patients investigations to exclude microscopic colitis, lactose intolerance, bile acid malabsorption, celiac disease, and thyrotoxicosis.

### ***Diagnostic Criteria***

Rome III Diagnostic criteria for irritable bowel syndrome are presented in Table 10.45.

**Table 10.45:** Rome III diagnostic criteria for irritable bowel syndrome.

Recurrent abdominal pain or discomfort at least 3 days per month in the last 3 months (with symptom onset at least 6 months prior to diagnosis) associated with two or more of the following:

1. Improvement with defecation
  2. Onset associated with a change in frequency of stool
  3. Onset associated with a change in form (appearance) of stool
- Symptoms that support the diagnosis of irritable bowel syndrome

- Abnormal stool frequency:  $\leq 3$  bowel movements per week or  $>3$  bowel movements per day
- Abnormal stool form: Lumpy/hard stool or loose/watery stool
- Defecation straining
- Urgency
- Feeling of incomplete bowel movement
- Passing mucus
- Bloating or feeling of abdominal distention

Red flag signs of IBS are presented in Table 10.46.

**Table 10.46:** Red flag signs of IBS.

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• More than minimal rectal bleeding</li> <li>• Weight loss</li> <li>• Unexplained iron deficiency anemia</li> <li>• Nocturnal symptoms</li> </ul> | <ul style="list-style-type: none"> <li>• Family history of selected organic diseases including colorectal cancer, inflammatory bowel disease (IBD), or celiac sprue</li> <li>• Fever</li> </ul> |
|--|---|

### **Treatment (Flowchart 10.7)**

#### ***Patient counseling and dietary alterations***

- **Reassurance** and thorough careful explanation of the functional nature and benign prognosis of the disorder.
- **Dietary modification:** Avoid obvious foods that precipitate symptoms. The role of probiotics is not well established.
  - Many IBS patients have non-specific intolerance to foods.
  - The dietary restriction of fermentable carbohydrates popularly termed the low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet.
  - Exclusion of gas-producing foods/foods that increase flatulence (e.g. beans, onions, celery, carrots, raisins, bananas, apricots, prunes, brussels sprouts, wheat germ, pretzels, and bagels), alcohol, and caffeine.
  - IBS patients should avoid foods that trigger an onset of their symptoms, consume a minimum of high fat foods and take part in regular physical activity.

### ***Constipations-predominant IBS***

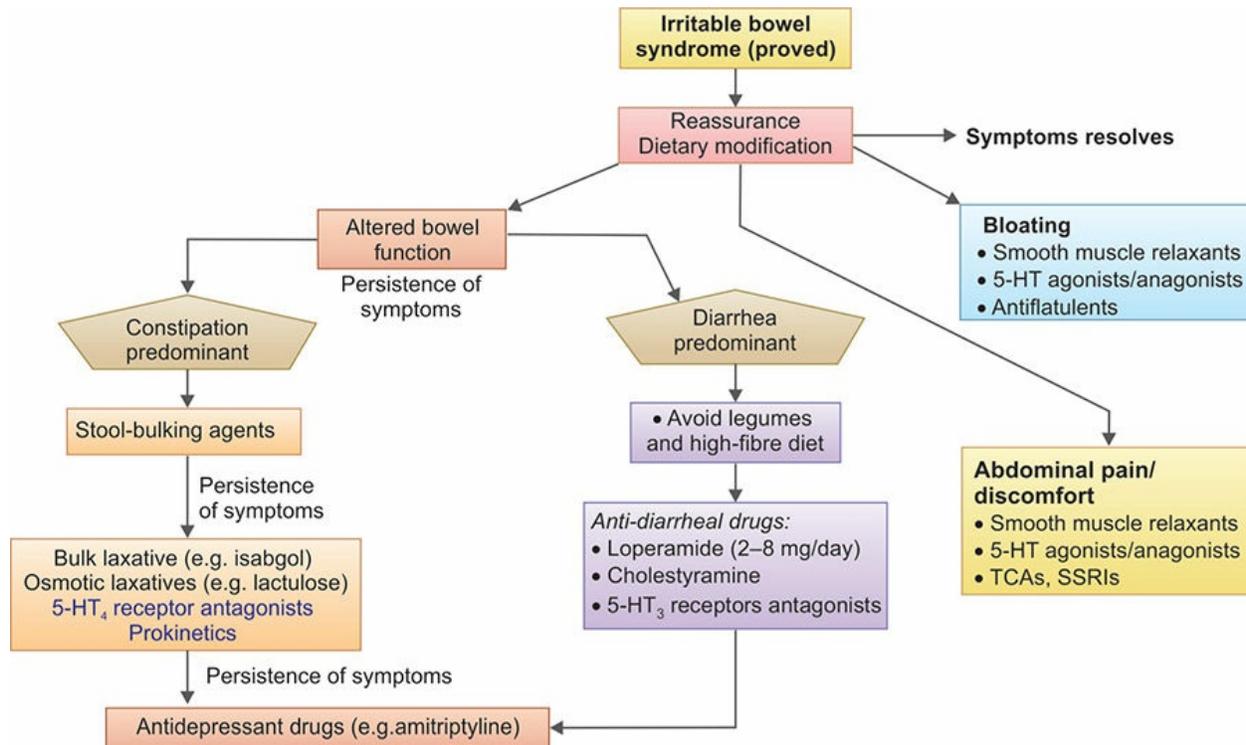

- **Stool-bulking agents:** High-fiber diets and bulking agents (e.g. bran or hydrophilic colloid) increase the roughage content of the diet (increases the fecal output of bacteria) and delay colonic transit. If symptoms persist add a bulk laxative (methylcellulose, isabgol husk, psyllium fiber supplement, corn fiber). Osmotic laxatives (e.g. polyethylene glycol, lactulose and milk of magnesia) or secretory stimulators (e.g. lubiprostone) may be tried, if high-fiber supplementation fails.
- **Prokinetic agents**
  - Tegaserod is a 5-HT<sub>4</sub> receptor agonist and a prokinetic drug, stimulates intestinal peristalsis. However, tegaserod has been withdrawn from the market; because of serious cardiovascular events.
  - Cisapride and mosapride are not useful in most patients.
- **Antispasmodics:** If abdominal pain is not adequately relieved, synthetic anticholinergic agent (dicyclomine 10 mg TID) or an antispasmodic (mebeverine 135 mg TID) may be given.
- **Antidepressant drugs:** Patients with intractable symptoms may be benefited from tricyclic antidepressant drugs such as amitriptyline (10–25 mg orally at bedtime) or desipramine (10–25 mg orally at bedtime).
- **Antiflatulence therapy:** Advised to eat slowly and avoid chew gum or carbonated beverage drinks. Antibiotic rifaximin (400, three times a day) may also help in relieving bloating.
- **Chloride-channel activators:** Lubiprostone activates chloride channels in the intestinal epithelial cells. This in-turn induces passive movement of sodium and water into the lumen of the intestine and improves bowel function.

### ***Diarrhea-predominant IBS***

- Advised to avoid legumes and high-fiber diet.
- **Anti-diarrheal drugs**
  - Loperamide (2-4 mg up to four times a day maximum of 12 g/day).
  - Cholestyramine resin is a bile acid-binding agent used as a second-line agent (4 g four to six times a day).
- **Serotonin receptor antagonists:** Serotonin acts on 5-HT<sub>3</sub> receptors and increases the sensitivity of afferent neurons of the gut. Alosetron (others drugs include ondansetron, granisetron, alosetron and cilansetron) is a 5-HT<sub>3</sub> receptor antagonist reduces abdominal visceral pain, induces rectal relaxation, increases rectal compliance, and delays colonic transit. But it is of little use because of danger of producing ischemic colitis.
- **Antispasmodics:** For the control of pain.

- **Antibiotics:** Nonabsorbable antibiotics such as rifaximin 400 mg BID for 5–6 weeks has been tried.
- **Probiotics use:** The Bifidobacteria, Saccharomyces boulardii and other combinations of probiotics demonstrate some efficacy in IBS.
- **Asimadoline:** Kappa-opioid receptor agonist has been in trials for IBS.

**Flowchart 10.7:** Management of irritable bowel syndrome.

(5-HT: 5-hydroxytryptamine; TCAs: tricyclic antidepressants; SSRIs: Selective serotonin reuptake inhibitors)

## Abdominal Tuberculosis

**Q. Describe the etiology, pathology, clinical features, complications, differential diagnosis, investigations and treatment of abdominal tuberculosis.**

It includes gastrointestinal tuberculosis, peritoneum, and abdominal lymph nodes, either individually or in combinations.

### Gastrointestinal Tuberculosis

- **Intestinal tuberculosis** commonly involves ileocecal region (about 70% of cases) probably because this region has: (1) increased rate of absorption of fluid and electrolyte; (2) increased physiological stasis; (3) prominent

lymphoid tissue; and (4) minimal digestive activity.

- **Other rare regions:** These include ascending colon, jejunum, sigmoid colon, rectum, duodenum, stomach and esophagus.

### *Etiology*

- **Causative agent:** *Mycobacterium tuberculosis* human or bovine strain.
- **Routes of spread of intestinal tuberculosis**
  - **Hematogenous spread:** Primary or secondary tuberculosis of lung may spread through blood into the intestine.
  - **Ingestion:** Mycobacteria in sputum from active pulmonary focus may be ingested and cause intestinal tuberculosis.
  - **Direct spread:** From nearby or adjacent organs.
  - **Through lymphatics:** From infected lymph nodes
- **Routes of spread of peritoneal tuberculosis:** Infection may spread to peritoneum from lymph nodes or intestinal lesions or tuberculous salpingitis (fallopian tube) in females.

### *Pathology*

#### **Intestinal tuberculosis: Three types:**

1. **Ulcerative (60%):** More often observed in malnourished adults.
  - **Gross:** Characteristics of tuberculous ulcers are: (1) multiple superficial ulcers mainly found in the ileocecal region; (2) long axis of ulcers is perpendicular to the long axis of the intestine (in typhoid fever, long axis of ulcers lies parallel to the long axis of the intestine).
  - **Consequences:** Fibrosis occurring during healing of ulcers produces strictures. Rarely, endarteritis may lead to massive bleeding.
2. **Hypertrophic (10%):** This is a variant of secondary tuberculosis observed in ileocecal region. More often found in relatively well-nourished adults.
  - **Gross:** The lesions are seen mainly in cecum and/or ascending colon. These regions become thick-walled due to scarring, fibrosis and local hypertrophy) and show mucosal ulceration.
  - Clinically, the lesion present as a palpable and may be mistaken for carcinoma.
3. **Ulcerohypertrophic (30%):**

- It represents combination of both ulcerative and hypertrophic types.
- Right iliac fossa mass due to hypertrophic ileocecal region, and involved mesenteric fat and lymph nodes.

### ***Peritoneal Tuberculosis***

- **Gross appearance of peritoneum:** Shows multiple yellow-white tubercles. Peritoneum is thick and hyperemic with a loss of its shiny appearance. Omentum also thickened.
- **Forms:**
  1. *Wet type:* It presents with ascites.
  2. *Encysted (loculated) type:* It presents with a localized abdominal swelling.
  3. *Fibrotic type:* It presents with abdominal masses. They consist of thickening of mesentery and omentum with matted bowel loops. Adhesions may produce intestinal obstruction.

A combination of above types is also can be seen.

### ***Solid Organ Tuberculosis***

These include: (1) Spleen, (2) liver, (3) adrenal tuberculosis, and (4) genitourinary tuberculosis.

### ***Tuberculosis of Mesenteric Lymph Nodes***

Usually observed in young adults. Involves mesenteric lymph nodes and these nodes may become palpable as rounded mass (tabes mesenterica). May be confused with lymphoma.

#### ***Clinical features***

- Usually found in young adults.
  - It may present as acute, chronic or acute on chronic condition.
  - *Common symptoms:* Fever, abdominal pain, anorexia, malaise, weight loss, diarrhea, constipation, alternating constipation and diarrhea and gastrointestinal bleeding or obstruction.
  - Abdominal pain may be either colicky (due to luminal compromise) or dull and continuous when there is involvement of mesenteric lymph nodes.
- *Physical examination of the abdomen:* It is described as ‘**doughy**’ because

matted loops of bowel may be palpable. A well-defined, firm, mobile mass may be found in the right lower quadrant of the abdomen. Mesenteric lymphadenitis produces mass. Abdominal distention due to ascites.

### **Complications (Box 10.14)**

### **Differential Diagnosis (Table 10.47)**

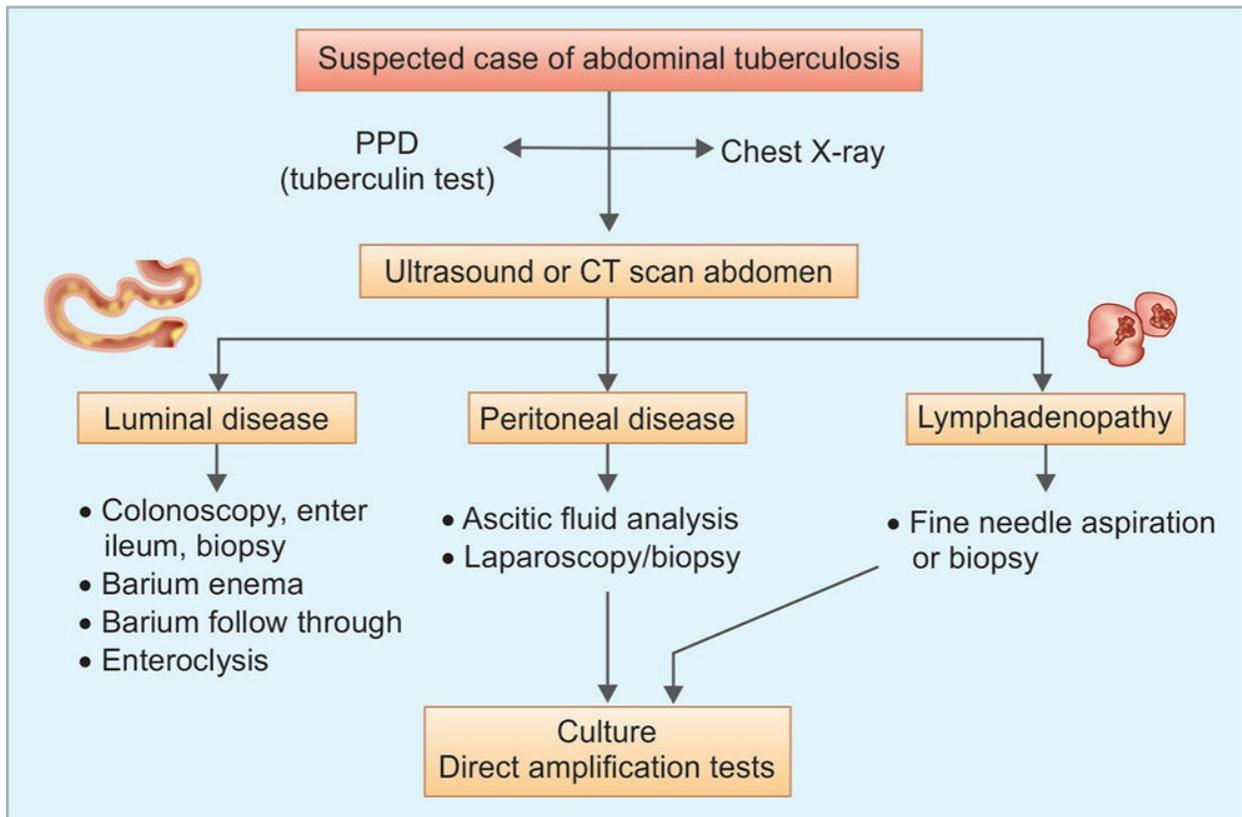

**Box 10.14:** Complications of intestinal tuberculosis.

- Intestinal hemorrhage
- Subacute intestinal obstruction
- Fistula formation (between skin and intestine or between loops of intestines).
- Intestinal perforation
- *Malabsorption*: Ileocecal tuberculosis is the common cause of malabsorption in India.

**Table 10.47:** Causes of vitamin A deficiency.

• Tropical sprue	• Amebiasis
• Intestinal worm infestations	• Crohn's disease
• Lymphoma	• Malignancy of colon

**Flowchart 10.8:** Diagnostic algorithm for abdominal tuberculosis.

### ***Investigations (Flowchart 10.8)***

**Hematological investigations:** ESR is raised, anemia and hypoalbuminemia

#### **Radiological investigations**

- Chest X-ray: May show evidence of active or old tuberculosis.
- Plain X-ray of abdomen: It may reveal:

#### **Calcified mesenteric lymph nodes**

**If there is intestinal obstruction:** Dilated bowel loops with multiple air-fluid levels may be seen.

**If intestinal perforation:** Air under diaphragm and dilated loops.

- **Barium meal**

May show hypermotility (accelerated intestinal transit)

Hypersegmentation of the barium column ('chicken intestine')

Precipitation, flocculation and dilution of the barium.

Luminal stenosis with smooth but stiff contours ('hour-glass stenosis')

Multiple strictures with segmental dilatation of bowel loops:

**Stierlin sign:** A defect characterized by failure of the diseased segment to

retain barium that is otherwise normally retained by adjacent uninvolved segments. Appears as a narrowing ileum with rapid emptying into a shortened cecum.

**String sign:** A thin stream of barium seen in the terminal ileum.

Note: Both Stierlin and string sign can also be seen in Crohn's disease, and hence, are not specific for tuberculosis.

- **Barium enema.**

Wide gaping of ileocecal valve with narrowing of the terminal ileum ('Fleischner' or 'inverted umbrella sign').

Fold thickening and contour irregularity or terminal ileum shrunken in size ('conical cecum').

Pulled up cecum due to contraction and fibrosis of the mesocolon.

Loss of normal ileocecal angle and dilated terminal ileum, appearing suspended from a retracted, fibrosed cecum.

Localized stenosis opposite the ileocecal valve with a rounded off smooth cecum and a retracted fibrosed cecum.

- **Abdominal ultrasound**

Intra-abdominal fluid (free or loculated; with or without debris and septae)

Localized fluid between rapidly oriented bowel loops due to local exudation from the inflamed bowel (interloop ascites; 'club sandwich' or 'sliced bread' sign).

Lymphadenopathy, discrete or matted with heterogeneous echotexture due to caseation.

Uniform and concentric bowel wall thickening in the ileocecal region (versus eccentric thickening at the mesenteric border found in Crohn's disease and variegated appearance of malignancy).

- **Contrast-enhanced CT scan**

Symmetric circumferential thickening of cecum and terminal ileum. Ulceration or nodularity within the terminal ileum, along with narrowing and proximal dilatation.

*Regional lymph nodes:* Caseating lymph nodes with hypodense centers and peripheral rim enhancement. Retroperitoneal nodes (periaortic and pericaaval) almost never seen in isolation, unlike lymphoma.

*Mesenteric thickening:* Omental thickening seen as an omental cake

appearance. Thickened peritoneum and enhancing peritoneal nodules.

Ascitic fluid of high-attenuation value.

- **Ascitic fluid examination lymphocytic ascites with serum-ascites albumin gradient (SAAG) (1.1 g/dL and elevated ascites ADA level).**
- **Biopsy of peritoneum: Punch or laparoscopic biopsy**
- **Colonoscopy:** It may show mucosal nodules and ulcers in colon and is used for taking biopsy from the edge of ulcers.
- **Biopsy from other organs involved:** Liver, lymph node

#### Treatment

- Antitubercular treatment similar to treatment of pulmonary tuberculosis.
- Surgery
- Strictureplasty for strictures that reduce the lumen by 50% or more and that cause proximal dilation.
- Resection of segment having multiple strictures.

## Ulcers in Intestine

**Q. Write short note on ulcers in intestine.**

Conditions causing ulcers in intestine are presented in Table 10.48.

**Table 10.48:** Conditions causing ulcers in intestine.

<i>Predominantly small intestine</i>	<i>Predominantly large intestine</i>	<i>Both small and large intestine</i>
<ul style="list-style-type: none"><li>• Enteric/typhoid fever</li><li>• Tuberculosis</li><li>• Zollinger-Ellison syndrome</li><li>• Mesenteric artery occlusion</li></ul>	<ul style="list-style-type: none"><li>• Amebiasis</li><li>• Ulcerative colitis</li><li>• Gram-negative bacillary dysentery</li><li>• Ischemic colitis</li></ul>	<ul style="list-style-type: none"><li>• Crohn's disease</li><li>• Malignant ulcers</li></ul>

## INFLAMMATORY BOWEL DISEASE (IBD)

**Q. Describe the etiology, pathology, clinical features, investigations and management of inflammatory bowel diseases (ulcerative colitis and Crohn disease).**

Inflammatory bowel disease (IBD) is an immune-mediated chronic intestinal condition. It results from inappropriate mucosal immune activation.

These include several conditions:

1. Ulcerative colitis (UC)
  2. Crohn disease (CD)
- } Most important
3. *Others (uncommon) non-specific inflammatory bowel disease:*  
Indeterminate colitis (15% patients with IBD) microscopic ulcerative, microscopic lymphocytic and microscopic collagenous colitis.

## Etiology and Pathogenesis of IBD

### *Genetic Factors*

**Genetic predisposition/susceptibility contributes to IBD.**

#### 1. **Familial:**

- **Crohn disease:** Genetic factors **play a prominent role**. The concordance rate for monozygotic twins is about 50%.
- **Ulcerative colitis:** Genetic factors are less prominent than in Crohn disease. The concordance of monozygotic twins is only 16%. Concordance for dizygotic twins for both Crohn disease and ulcerative colitis is less than 10%.

#### 2. **Susceptibility Genes:**

- **Genes associated with innate immunity and autophagy (e.g. *NOD2/CARD15*, *ATG16L1*, and *IRGM*):** Actions of NOD2/CARD15 protein are: (1) **prevents the entry of microbes** into the wall of the intestine; (2) **regulates innate immune responses**; and (3) prevents excessive immune response by luminal microbes.

### *Environmental Factors*

Include both the local microenvironment (intestinal microflora) and the nutritional environment.

#### 1. Intestinal microflora/microbiota:

- **Hygiene hypothesis:** The **gut lumen** contains **abundant commensal** bacteria and its composition within individuals remains stable for several years. This intestinal microflora can **be modified by diet and disease**. **IBD is associated with an alteration in the bacterial flora.**
- **Improved food storage conditions and decreased food**

**contamination: It has reduced frequency of enteric infections**, with 'clean' environment in the intestinal lumen → the **immune system may not be exposed to microorganisms** (pathogenic or non-pathogenic) → **inadequate development of regulatory processes** to limit mucosal immune responses.

## 2. Smoking

CD patients are more likely to be smokers, and smoking exacerbates CD. In contrast, an increased risk of UC is observed in non- or ex-smokers.

### *Host Factors*

These include epithelial defects, impaired mucosal barrier, abnormal intestinal defensins, and immune dysregulation.

### *Psychosocial Factors*

It can contribute to worsening of symptoms in IBD. Major life events (e.g. illness or death in the family, divorce or separation) are associated with an increase in symptoms such as pain, bowel dysfunction, and bleeding.

## Ulcerative Colitis

### *Definition*

Ulcerative colitis is a severe-ulcerating inflammatory disease. It is limited to large intestine (the **colon and rectum**). It is characterized clinically by recurrent attacks (exacerbations and remissions) of bloody diarrhea. Pathologically, the inflammatory response is found only in the **mucosa and submucosa** of the intestinal wall and shows chronic destruction of crypts.

### *Pathology*

**Site (Fig. 10.12):** Ulcerative colitis primarily involves the colonic mucosa. Usually **involves the rectum** (involved in 95% of cases) **and extends proximally** for a variable distance in a continuous fashion to involve part or the entire colon. Skip lesions are not seen in UC.

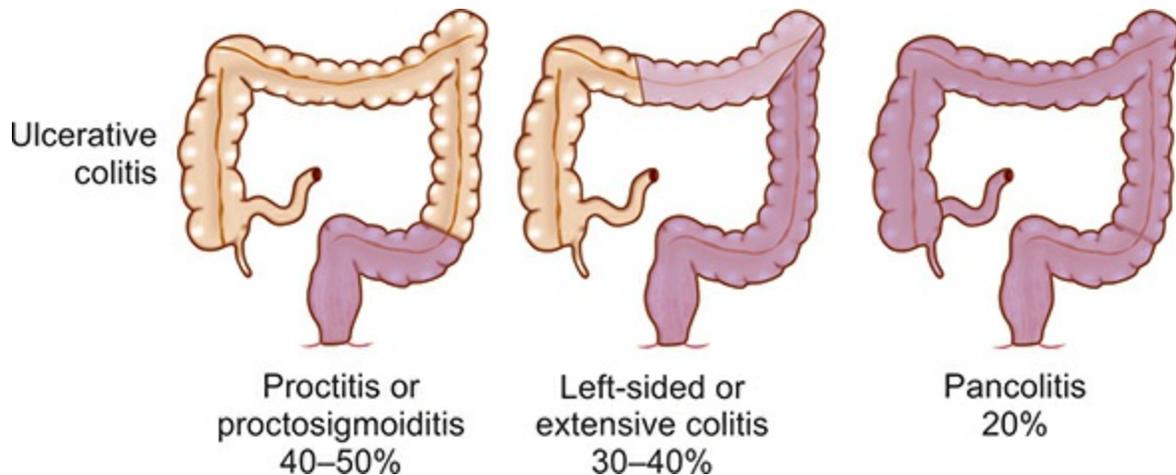

- **Pancolitis:** If entire colon is involved by the disease, then it is termed **pancolitis**.
- **Left-sided colitis:** When disease involves only the left-side of colon.
- **Extensive colitis:** When disease involves colon up to the hepatic flexure.
- **Proctitis/proctosigmoiditis:** When the disease is limited to the rectum

alone, then it is known as **ulcerative proctitis**. When the process involves rectum and sigmoid colon, then it is termed **ulcerative proctosigmoiditis**.

- **Backwash ileitis:** The small intestine is normal. However, in severe cases of pancolitis mild mucosal inflammation of the distal ileum may be present and is termed as **backwash ileitis**.

### **Microscopy**

- **Chronic inflammatory infiltrates: Lymphocytes, plasma cells, and macrophages in the lamina propria.** The density of plasma cells is more in the basilar region of the lamina propria (basal plasmacytosis) and extends into the muscularis mucosae.
- **Changes in the crypt:** These include **cryptitis, crypt abscesses, destruction of crypts and distortion of crypt architecture.** Chronic UC may show epithelial dysplasia.
- **Toxic megacolon:** In severe cases (fulminant disease-toxic megacolon), inflammation may damage the muscularis propria and disturb neuromuscular function and leads to **colonic dilation** and **toxic megacolon** that can undergo perforation. The colon is dilated, walls are thin, and with denuded mucosa and colon may rupture.

**Fig. 10.12:** Patterns of distribution in ulcerative colitis.

### **Clinical Features of UC**

**Q. Write short essay/note on clinical features of ulcerative colitis.**

**Major symptoms of UC:** The first attack is usually the most severe and the disease is later characterized by relapses and remissions.

- **Diarrhea:** Colonic motility is altered due to inflammation. When the disease is severe, patients develop diarrhea and pass liquid stool containing blood, mucus, pus, and fecal matter. Diarrhea is often nocturnal and/or postprandial.
- **Rectal bleeding:** Patients with proctitis usually pass fresh blood. When the disease extends beyond the rectum, blood is usually mixed with stool or grossly bloody diarrhea may be noted.
- **Tenesmus** or urgency with a feeling of incomplete evacuation.
- **Passage of mucus**
- **Crampy abdominal pain:** Severe pain is not a prominent symptom, but some patients with active disease may present with vague lower abdominal discomfort or mild central abdominal cramping. Severe cramping and abdominal pain can develop when the attack is severe.
- **Others:** These include anorexia, nausea, vomiting, malaise, fever, and weight loss. There may be symptoms and signs of dehydration and anemia. In severe cases, the patient is toxic with fever, tachycardia and signs of peritoneal inflammation.

**Severity of symptoms:** It reflects the extent of disease and the intensity of inflammation.

**Duration of symptoms:** Although UC can present acutely, symptoms are usually present for weeks to months.

**Exacerbations and remissions:** They are characteristic features. Relapses are provoked by emotional stress, intercurrent infection, gastroenteritis, antibiotics or NSAID therapy.

**Q. Write short note/essay on extraintestinal manifestations of ulcerative colitis.**

**Extraintestinal manifestations** (Refer Table 10.57 and Fig. 10.14.)

**Risk of carcinoma colon:** The incidence is high, especially in patients with total colitis, disease of more than 10 years duration and early age of onset.

**Signs:**

- Tenderness on palpation directly over the colon, especially in the left iliac fossa.
- Signs of proctitis include tender anal canal and blood on rectal

examination.

- *Signs of toxic megacolon:* It is a serious complication and its signs include severe pain and bleeding, and signs of peritonitis, if there is associated perforation.

## **Investigations**

### **Q. Write short essay/note on investigation of ulcerative colitis.**

They are required for confirmation of the diagnosis, know the distribution and activity, and identify complications.

#### *Laboratory findings*

- **Anemia:** Decrease in hemoglobin may be due to blood loss or malabsorption (nutritional deficiencies) of iron, folic acid or vitamin B<sub>12</sub>. It may be associated with raised platelet count.
- Raised erythrocyte sedimentation rate (**ESR**) and **acute-phase reactants** [C-reactive protein (CRP)], are nonspecific serum inflammatory markers and are observed during exacerbations. They are sometimes used to monitor the activity of disease.
- **Total WBC count:** Moderate leukocytosis is observed in active disease, but a marked leukocytosis suggests an abscess or another suppurative complication.
- **Hypoalbuminemia:** Reduced serum albumin concentration may be due to protein-losing enteropathy, inflammatory disease or malnutrition (poor nutrition).
- **Stool examination**
  - *Stool microscopy and culture:* To exclude infective pathology and *C. difficile* toxin.
- Blood cultures in patients with septicemia.
- **Serological tests:** These are supportive and not used independently as markers for diagnose IBD.
  - ***Antisaccharomyces cerevisiae* antibodies (ASCA):** These are antibodies to yeast. They are observed in 40–70% of patients with Crohn disease and in less than 15% of patients with ulcerative colitis. Presence of raised ASCA immunoglobulin A (IgA) and IgG titers is highly specific for Crohn's disease.

- **Perinuclear antineutrophil cytoplasmic antibodies (pANCA):** They are detected in 10–20% of colon-predominant Crohn disease, and in 55–70% of patients with ulcerative colitis.
- **Anti-goblet cell autoantibodies:** Found in 30–40% cases of ulcerative colitis and Crohn disease.
- **Other Tests:**
  - **Fecal lactoferrin:** It is a very sensitive and specific marker for detecting intestinal inflammation.
  - **Fecal calprotectin:** Its levels correlate with inflammation and helpful in predicting relapses.

### *Endoscopy*

**Endoscopy with mucosal biopsy is the gold standard investigation for ulcerative colitis.**

**Colonoscopy:** For mild-to-moderate disease and patient not having an acute flare, colonoscopy is preferable to flexible sigmoidoscopy because it can assess the disease extent and activity. Colonoscopy helps in assessing the extent and activity of ulcerative colitis.

### **Sigmoidoscopy:**

- **During early phase of the mild disease:** (1) Uniform continuous involvement of the mucosa; (2) diffuse mucosal erythema/hyperemia, (3) loss of the normal mucosal vascular pattern, granularity, and edema, and (4) exudate of mucus, pus and blood on the mucosa.
- **As the disease becomes severe:** Mucosa becomes more friable, bleeds easily on touch, and may ulcerate. Pseudo-polyps represent epithelial regeneration and may develop after recurrent attacks in patients with long-standing disease.

### *Biopsy*

Histological changes develop more slowly than clinical features. Biopsies help in diagnosis and to know the disease extent. Rectal biopsy shows mucosal inflammation and histological abnormalities are most severe in the distal colon and rectum.

**Chromoendoscopy:** Used for diagnosis of dysplasia in patients with long-standing UC.

### *Radiological features*

- **Plain abdominal X-ray: Useful to exclude toxic dilatation of colon.**
- **Barium enema in ulcerative colitis:**
  - Earliest change in UC: Fine mucosal granularity
  - Later, the mucosa shows thickening and superficial ulcers. Deep ulcers appear as ‘collar-button’ ulcers, which indicate that the ulcer has penetrated the mucosa.
  - Haustral folds may be normal in initial phase of the disease, but later become edematous and thickened.
  - Long-standing disease may show loss of haustration, pseudopolyps, narrowing and shortening of the colon.
- **CT scan:** It is not so helpful when compared to endoscopy and barium enema in UC. CT scanning shows: mild mural thickening (<1.5 cm), inhomogeneous wall density, no thickening of small bowel, increased perirectal and presacral fat and target appearance of the rectum.

### *Biochemical abnormalities*

- Electrolyte abnormalities
- Abnormal liver function tests

## **Q. Write short essay/note on management of ulcerative colitis.**

### **Treatment (Flowchart 10.9) of Ulcerative Colitis**

Whenever possible, IBD should be approached by a multidisciplinary team consisting of physicians, surgeons, radiologists, and dietitians. IBDs are life-long conditions and have psychosocial implications. Truelove and Witts’ severity index of ulcerative colitis is presented in Table 10.49.

### **Medical Management of UC**

- Aims of medical therapy (Box 10.15)
- **5-Aminosalicylate (5-ASA) agents (Table 10.49):**
  - Acts as a topical anti-inflammatory within the lumen of the intestine.
  - Controls acute exacerbation, maintains remission and prevent relapses in UC. Maintenance therapy may decrease the risk of colorectal cancer.
  - Available as oral tablets or topical (enema/suppository) preparation (for rectal and sigmoid disease).
  - These agents include 5-aminosalicylic acid (5-ASA) or mesalazine alone, or combination of 5-ASA with a carrier which releases 5-ASA after splitting by bacteria in colon (sulfasalazine, olsalazine, balsalazide).
  - **Sulfasalazine** is the most frequently used agent **for mild-to-moderate ulcerative colitis**. Sulfasalazine is the combination of a sulfapyridine (acting as a ‘carrier’ that allows 5-ASA to be delivered into the colon) with 5-ASA (active agent). Side effects include: nausea, dyspepsia,

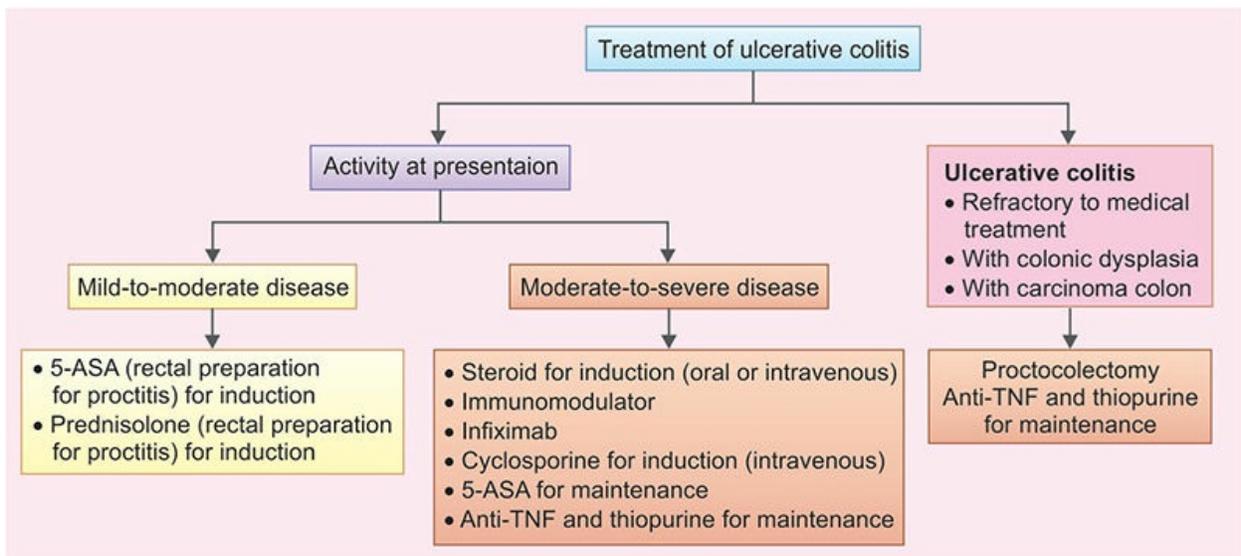

hair loss, headache, worsening diarrhea, and hypersensitivity reactions.

- Sulfa-free aminosalicylate preparations (Table 10.50): They deliver higher amounts of the active ingredient of sulfasalazine (5-ASA, mesalamine) to the site of active disease in the bowel and have limited systemic toxicity

**Box 10.15:** Aims of medical therapy in ulcerative colitis.

- Treat acute attacks and reduce inflammation.
- Prevent relapses and maintain clinical remission.
- Detect carcinoma at an early stage.
- Select patients for surgery.

**Flowchart 10.9:** Algorithm for treatment of ulcerative colitis.

(5-ASA: 5-aminosalicylate agents; TNF: tumor necrosis factor)

**Corticosteroids**

- Oral or parenteral corticosteroids are beneficial in inducing remission in moderate-to-severe ulcerative colitis.
- They have no role in maintaining remissions. During clinical remission, steroids should be tapered according to the clinical activity.

**Table 10.49:** Various oral 5-ASA (5-Aminosalicylate agents) preparations used in ulcerative colitis.

<b>Preparation</b>	<b>Dosage</b>
<b>Azo-bond</b>	
Sulfasalazine	3–6 g (acute) 2–4 g (maintenance)

Olsalazine	1–3 g
Balsalazide	6.75–9 g
<b>Delayed-release</b>	
Mesalamine	2.4–4.8 g (acute) 1.6–4.8 g (maintenance)
<b>Controlled-release</b>	
Mesalamine	2–4 g (acute)1.5–4 g (maintenance)
<b>Delayed and Extended-release</b>	
Mesalamine	1.5 g (maintenance)

**Table 10.50:** Truelove and Witts' severity index of ulcerative colitis.

<i>Features</i>	<i>Mild</i>	<i>Moderate</i>	<i>Severe</i>
Bowel movements (number per day)	Fewer than 4	4–6	6 or more plus at least one of the features of systemic upset (marked with * below)
Blood in stools	No more than small amounts of blood	Between mild and severe	Visible blood
Pyrexia (temperature greater than 37.8°C) *	No	No	Yes
Pulse rate greater than 90 bpm *	No	No	Yes

Anemia *	No	No	Yes
Erythrocyte sedimentation rate (mm/hour) *	30 or below	30 or below	Above 30

#### Local Treatment

- Topical applications of steroid are also beneficial for distal colitis and as an adjunct in patients with involvement of rectal involvement associated with involvement of proximal colon.
- Hydrocortisone or prednisolone enemas, suppositories or foam may control active disease. Budesonide-MMX uses colonic release technology to extend the application of budesonide throughout the colon.
- **Duration of treatment:** 3–6 weeks.

#### Systemic Treatment

- **Oral:** Active UC that is unresponsive to 5-ASA therapy is treated with oral prednisone at doses of 40–60 mg/day for 3–6 weeks.
- **Parenteral:**
  - **Intravenous:** Hydrocortisone 300 mg/day or methylprednisolone, 40–60 mg/day are given as a constant infusion in severe cases.
  - **Intramuscular or subcutaneous injection:** Long-acting corticotrophin is used in the treatment of relapses.
- **Tapering of dose:** Steroids once started are gradually tapered and withdrawn, normally at a rate of no more than 5 mg/week.

#### Antibiotics

No role in the treatment of active or quiescent UC.

#### Immune Modulators

##### Indications:

- Patients who remain symptomatic despite 5-ASA therapy.
- Patients who have moderate-to-severe ulcerative colitis.

##### Drugs

#### 1. Azathioprine and 6-mercaptopurine (6-MP):

- *Usefulness are as follows:*
  - Patients who require two or more corticosteroid courses within a year.
  - Relapse of disease as the dose of prednisolone is reduced below 15 mg.
  - Relapse within 6 weeks of stopping corticosteroid.
- *Dosage:* Azathioprine 2 to 3 mg/kg/day and 6-mercaptopurine 1.5 mg/kg/day

**Table 10.51:** Indications for surgery in ulcerative colitis.

Intractable/extensive colitis	Toxic megacolon	Colonic perforation
Severe colonic hemorrhage	Colon cancer prophylaxis	Colon dysplasia/cancer

Frequent relapses

Chronic damage to  
bowel-strictures

- *Disadvantage*: Slow clinical response and may not be evident for as long as 12 weeks.
  - *Side effects*: These include allergic reactions, pancreatitis, myelosuppression, infections, hepatotoxicity, and malignancy (lymphoma).
2. **Methotrexate**: It is a folic acid antagonist useful in patients who do not respond to azathioprine.
  3. **Cyclosporine (CSA)**: It inhibits both the cellular and humoral immune systems. CSA blocks the production of IL-2 by T-helper cells. CSA prevents activation of T cells by inhibiting calcineurin and indirectly inhibits B cell function by blocking helper T cells.
  4. **Tacrolimus**: It is a macrolide antibiotic with immunomodulatory properties similar to CSA.
  5. **Infiximab**: anti-tumor necrosis factor (anti-TNF) therapy can prevent or reduce rates of colectomy.

#### **General supportive measures**

- Parenteral nutrition: It is necessary in seriously ill patients and parenteral broad-spectrum antibiotics may be required in septicemia.
- Correction of dehydration and electrolyte imbalance.
- Antispasmodic medications and antidiarrheal (loperamide) for mild diarrhea (to be avoided in severe colitis).

#### **Surgical management (Table 10.51)**

- Surgery involves removal of the entire colon (colectomy) and rectum and is a curative procedure. It is indicated if UC does not respond adequately to medical therapy. Emergency colectomy may be necessary for toxic megacolon.
- Elective surgical procedure is either panproctocolectomy with ileostomy, or proctocolectomy with ileal-anal pouch anastomosis.

#### **Follow-up**

- Extensive colitis of more than 10 years duration; Colonoscopy with multiple biopsies is recommended every three years to assess for dysplasia or malignant changes.
- UC for more than 20 years: Colonoscopy is recommended every 2 years. Biopsies from entire colon and samples from suspicious areas. If the biopsy shows high-grade dysplasia, total colectomy is performed

## Crohn's Disease

**Q. Discuss the etiology, pathology, clinical features, investigations and management of Crohn's disease.**

**Q. Write short note on Crohn's disease.**

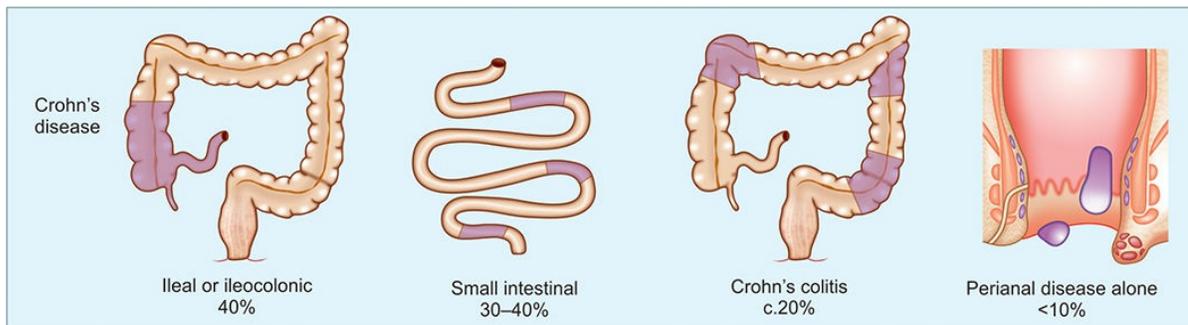

### ***Etiology and Pathogenesis***

Refer etiology and pathogenesis of IBD (pages 762-3).

### ***Pathology***

## Gross

- **Site (Fig. 10.13):** It can involve any area of the gastrointestinal (GI) tract from mouth to anus. Unlike UC, rectum is spared in CD. Most commonly involved sites are:
  - Terminal ileum and right side of colon (40–55%)
  - *Small intestine/bowel disease alone (30–40%):* Terminal ileum alone or ileum and jejunum.
  - Colon alone (15–25%)

**Fig. 10.13:** Patterns of distribution in Crohn's disease.

- **Number of lesions:** Usually, the lesions are **multiple**.
- **Skip lesions:** The intestinal involvement is **discontinuous in which inflamed segments of intestine are sharply demarcated/separated by apparently normal** intervening bowel/intestine in between.
- **Intestinal wall:** The involved intestinal wall shows **fibrotic thickening and is rubbery** and appears like a hosepipe and produces a characteristic radiological sign known as the '**string sign**'.
- **Transmural inflammation:** Inflammation involves all layers of the bowel wall.
- **Mucosal lesions :** The earliest lesion is the **aphthous ulcer** which becomes deeper, transmural, and discrete. Multiple lesions may coalesce longitudinally to form linear or **serpentine** (snake-like) ulcers and produces characteristic '**cobblestone**' appearance. Later the ulcer becomes deeper and form linear clefts or **fissures**. Similar to UC, pseudopolyps may also form in CD.
- **External surface:** The fat may encircle around the antimesenteric serosal surface producing a pattern known as **creeping fat**.
- **Adhesion and fistulae:** Involved loops of bowel are often adherent to each other. Fissures frequently develop between mucosal folds. They may

extend deeply to become fistula tracts or sites of perforation. These fistulas may also penetrate from the bowel into other organs, including the bladder, uterus, vagina, and skin.

### *Microscopic features*

- **Chronic inflammation by lymphocytes, plasma cells, and macrophages.**
- **Mucosal ulcerations:** Which are small, superficial (aphthous ulcers).
- **Crypt abscesses:** Clusters of neutrophils within a crypt and are often associated with crypt destruction.
- **Noncaseating granulomas.**

### *Clinical Features of Crohn's Disease*

Symptoms due to involvement of small intestine or ileum and right colon (ileocolitis). CD present with one of two patterns of disease: (1) penetrating fistulous pattern or (2) fibrostenotic obstructing pattern. The clinical manifestations depend on the site of disease.

- Crohn's disease is a chronic disease with exacerbations and remissions.
- Major symptoms include abdominal pain (typically in the right lower quadrant), diarrhea and weight loss (due to malabsorption and patients avoid food because eating provokes pain).
- Ileal Crohn's disease may cause subacute or acute intestinal obstruction and patients present with recurrent episodes of colicky abdominal pain, abdominal distention, nausea, vomiting and excessive borborygmi.
- Sparing of rectum and the presence of perianal disease is observed in about 30% of patients in the form of fistulas, abscesses, fissures, and skin tags. It presents with pain, discharge and fever (if there is an abscess).

### *Physical examination*

- Signs depend on the location and severity of the disease process.
- Abdominal tenderness in the right lower quadrant (classical), accompanied by fullness, guarding or a mass depending on the severity of inflammation.
- Palpable mass per abdomen and rectally reflects adherent loops of intestine and abscess.
- Features of malabsorption such as weight loss and anemia (iron, folic acid and vitamin B<sub>12</sub> malabsorption).

- Sodium, potassium, water, magnesium and zinc deficiency may develop due to chronic diarrhea.
- Stool usually does not show frank blood, mucus or pus unless colon is involved.
- Oral ulcers

### ***Investigations***

- **Anemia:** Anemia may result from chronic disease, blood loss or nutritional deficiencies of iron, folate, or vitamin B<sub>12</sub>. It may be normochromic normocytic or macrocytic or hypochromic anemia depending on the deficiency/cause.
- **Leukocytosis:** Modestly raised leukocyte count indicates active disease, but a marked leukocytosis suggests an abscess or other suppurative complication.
- **Raised ESR (erythrocyte sedimentation rate) and C-reactive protein:** They are nonspecific serum inflammatory markers and may be used to monitor the activity of disease.
- Abnormal liver function tests.
- **Hypoproteinemia/hypoalbuminemia:** Indication of malnutrition.
- **Malabsorption:** Ileal disease results in malabsorption of vitamin B<sub>12</sub> (reduced serum vitamin B<sub>12</sub> level) and Schilling test is done to determine the malabsorption of vitamin B<sub>12</sub>.
- **Serologic markers:** They are supportive but may not independently used for the diagnose IBD.
  - **Anti-*Saccharomyces cerevisiae* antibodies (ASCA):** These are antibodies to yeast, are present in 40–70% of patients with Crohn's disease (positive in only 10–15% cases of ulcerative colitis).
  - **Perinuclear antineutrophil cytoplasmic antibodies (pANCA):** They are present in 20% of patients with CD (colon-predominant disease), and in 55% of patients with ulcerative colitis.
  - Antigoblet cell autoantibodies in 30–40% cases of Crohn's disease.
  - Antiglycan antibodies in about 40–50% cases (e.g. antilaminaribioside, antimannobioside antibodies).
- **Stool examination:** Stool microscopy and culture to exclude infectious

causes of diarrhea.

- **Sigmoidoscopy and colonoscopy in Crohn disease:**

- Segmental inflammation with normal mucosa between (skip lesions).
- Discrete, aphthous or deep ulcers and occasionally connected to one another, forming longitudinal stellate, serpiginous, and linear ulcers.
- Perianal disease (fissures, fistulas and skin tags) or sparing of the rectum.
- Strictures are common.
- Biopsy of involved region (e.g. colonic mucosa, ileal mucosa, anal skin tags and perianal inflammatory lesions) shows typical non-caseating granulomatous inflammation (tuberculosis must be excluded) and infiltration by lymphocytes and plasma cell.
- Wireless capsule endoscopy (WCE) allows direct visualization and identification of inflammation in the entire small bowel mucosa. However, it should be avoided in the presence of small bowel strictures.

### *Radiological Findings in Crohn's disease*

#### *Barium meal follow through and barium enema*

- *Early radiographic findings in the small bowel:*

- Thickened folds and aphthous ulcerations.
- Cobblestone appearance of mucosa resulting from longitudinal and transverse ulcerations.

- *More advanced disease:*

- Transmural inflammation leads to decreased luminal diameter and limited distensibility.
- Rigidity of involved segments and multiple strictures.
- As ulcers progress deeper, they can lead to fistula formation. Radiographic 'string sign' is due to long areas of transmural inflammation and fibrosis, producing narrowing of lumen of involved small intestine.
- *Segmental nature of CD:* It results in wide gaps of normal or dilated bowel between involved segments (skip lesions).
- Inflammatory masses and abscesses may be found.

- Fistulous tracts

### High-resolution ultrasound and spiral CT scanning

- It helps in defining thickness of the bowel wall and intra-abdominal abscesses.

### Radionuclide scan

- Using gallium-labeled polymorphs or indium-labeled leukocytes identify intestinal and colonic disease and localize extraintestinal abscesses.

### Treatment (Flowchart 10.10)

#### Medical Management of Crohn's Disease

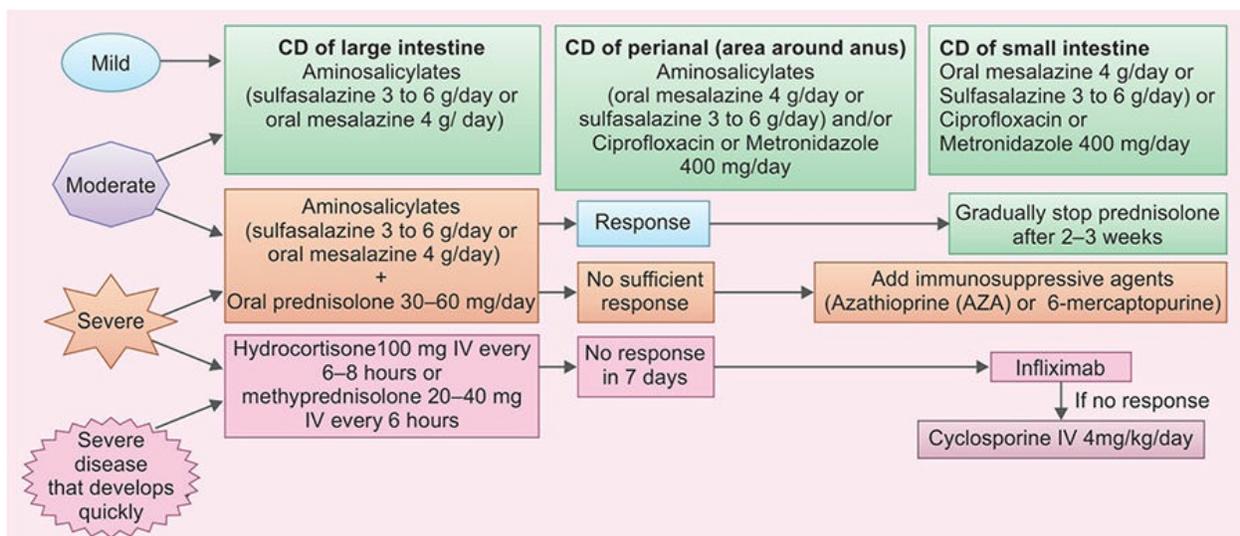

##### General Considerations

- Stop cigarette smoking.
- Diarrhea can be controlled with loperamide, codeine phosphate or co-phenotrope.
- Long-standing diarrhea may be due to bile acid malabsorption and is treated with bile salt sequestrants (e.g. cholestyramine).
- Anemia: Due to vitamin B<sub>12</sub>, folic acid or iron deficiency, should be treated accordingly.

##### Induction and Maintenance of Remission

- **Glucocorticosteroids:** Used to induce remission in moderate and severe Crohn's disease. Oral prednisolone 30–60 mg/day, which is gradually tapered and withdrawn. Mild-to-moderate ileocecal, CD should be treated by controlled-release steroids such as budesonide (9 mg by mouth once a day).

**Flowchart 10.10:** Treatment approach to Crohn's disease.

- **Aminosalicylates:** 5-ASA (e.g. mesalazine 4 g/day or sulfasalazine 3 to 6 g/day) as maintenance in mild-to-moderate ileocolonic disease. However, they are not effective for maintaining remission.

- **Antibiotics:** Ciprofloxacin and metronidazole 400 mg are used in abscess and perineal Crohn's disease.
- **Nutritional therapy:** Dietary antigens may stimulate the immune response in the intestinal mucosa. Bowel rest and total parenteral nutrition (TPN) are effective in inducing remission but are not effective as maintenance therapy. Enteral diets with a low fat and a low linoleic acid content (not palatable) may induce remission are similar to steroids.
- **Immunosuppressive agents:** Azathioprine (AZA) and its metabolite 6-mercaptopurine (6MP) and newer drugs (e.g. mycophenolate mofetil) suppresses the proliferation of T- and B-lymphocytes. They are effective in inducing and maintaining remission and have steroid-sparing properties.
- **Biologic therapy:** Anti-TNF therapy is reserved for moderate-to-severe Crohn disease that failed to respond to other therapies (infliximab, adalimumab) and in CD with refractory perianal and enterocutaneous fistulas.

*Maintenance of Remission*

- Aminosalicylates
- Azathioprine, 6MP, mycophenolate mofetil

**Surgical Management (Table 10.52)**

**Table 10.52: Indications for surgery in CD.**

<i>Small intestine</i>	<i>Colon and rectum</i>
<ul style="list-style-type: none"> <li>• Stricture and obstruction not responding to medical therapy</li> <li>• Severe hemorrhage</li> <li>• Refractory fistula</li> <li>• Abscess</li> </ul>	<ul style="list-style-type: none"> <li>• Intractable/fulminant disease</li> <li>• Perianal disease not responding to medical therapy</li> <li>• Refractory fistula</li> <li>• Colonic obstruction/perforation</li> <li>• Colon dysplasia/cancer</li> </ul>

- **Small intestine:** Strictures can be widened (stricturoplasty)/minimal resection and anastomosis.
- **Colorectal:**
  - Subtotal colectomy and ileorectal anastomosis, if rectum is spared.
  - Pancolectomy with ileostomy, if whole colon and rectum are involved

Assessment of severity of Crohn's disease is presented in Table 10.5

**Table 10.53: Severity of Crohn's disease.**

<i>Mild–moderate</i>	<i>Moderate–severe</i>	<i>Severe/fulminant</i>
<b>CDAI 150–220</b>	<b>CDAI 220–450</b>	<b>CDAI &gt;450</b>
Ambulatory Able to tolerate oral alimentation without manifestations of	Failed to respond to treatment for mild–moderate disease or Has more	Persistent symptoms despite treatment with corticosteroids/biologics as outpatients or Has high fevers,

dehydration Systemic toxicity (high fevers, rigors, and prostration) Abdominal tenderness Painful mass Intestinal obstruction, or >10% weight loss	prominent symptoms of fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstructive findings), or significant anemia	persistent vomiting, intestinal obstruction, significant peritoneal signs, cachexia, or abscess
--	---	---

(CDAI: Crohn' disease activity index)

## Toxic Megacolon

**Q. Give a brief account of toxic dilatation of colon (toxic megacolon).**

**Definition:** Toxic megacolon is defined as a transverse or right colon with a diameter of greater than 6 cm, with loss of haustration.

### Causes

- **Ulcerative colitis:** One of the most significant complications of UC. It can be triggered by electrolyte abnormalities, narcotics, antidiarrheal (diphenoxylate, loperamide) antispasmodics medications (reduce gastrointestinal motility) and barium enema.
- **Other rare causes:** (1) Diarrheas are due to *Clostridium difficile*, (2) *Campylobacter jejuni* gastroenteritis, (3) Shigellosis, (4) Chagas' megacolon and (5) amebic colitis.

### Clinical Features

- Features of severe colitis.
- High fever, tachycardia, dehydration, electrolyte imbalance and leukocytosis.
- **Physical examination:** Patient is toxic and ill, postural hypotension, colonic dilatation, abdominal tenderness over the involved colon, and absent or hypoactive bowel sounds.
- **Plain radiograph of abdomen:** Shows colonic dilatation with transverse colonic diameter greater than 6 cm. Air may be observed in the wall of the colon.

### Treatment

- **Medical therapy:** About 50% of cases will resolve with medical therapy alone.
  - Nil mouth, and nasogastric suction

- Intravenous fluids to replace water and electrolyte abnormalities
- Broad-spectrum antibiotics (e.g. ampicillin-sulbactam) plus metronidazole.
- Urgent colectomy may be necessary when there is no improvement with medical therapy

## Complications

Perforation is the most dangerous of the local complications.

## Complications of Inflammatory Bowel Disease

**Q. Write short note on the complications of inflammatory bowel disease.**

It may be local and systemic (extraintestinal).

### Local Complications (Tables 10.54 and 10.55)

#### Table 10.54: Local complications of Crohn's disease.

- **Fistula formation:** It may develop between loops of intestine and surrounding structures such as urinary bladder, vagina, and abdominal or perianal skin. Perforations and peritoneal abscesses are common.
- **Stricture formation:** May produce intestinal obstruction.
- **Iron-deficiency anemia** with colonic disease.
- **Malabsorption:** Extensive involvement of the small intestine may result in loss of **protein and hypoalbuminemia, generalized nutrient malabsorption, or malabsorption of vitamin B<sub>12</sub> and bile salts.**
- **Fibrosing strictures** in the terminal ileum are common.
- **Acute complications:** Perforation abscesses and hemorrhage.
- **Development of carcinoma** is rare. Risk of carcinoma colon is increased in patients with long-standing colonic disease.
- Gallstones and **urinary oxalate stones.**
- **Systemic secondary amyloidosis** rare.

#### Table 10.55: Local complications of UC

- **Toxic megacolon:** In fulminant cases, the inflammation and inflammatory mediators can damage the muscularis propria and disturb neuromuscular function. This may lead to colonic dilation and toxic megacolon, which may lead to perforation.
- **Colorectal Cancer:** Long-standing ulcerative colitis may develop colorectal cancer than the general population.

- Hemorrhage leading to blood loss.
- Electrolyte disturbances due to diarrhea.

**Table 10.56:** Conditions that mimic inflammatory bowel disease (ulcerative or Crohn’s colitis).

**Infective**

- **Bacterial:** Salmonella, *Shigella*, pseudomembranous colitis, *Campylobacter jejuni*, gonococcal proctitis, *Chlamydia proctitis* *E. coli* O157
- **Viral:** Herpes simplex proctitis, cytomegalovirus
- **Protozoal:** Amoebiasis

**Noninfective**

Ischemic colitis, collagenous colitis, radiation proctitis, Behçet’s disease, diverticulitis, carcinoma colon, NSAIDs

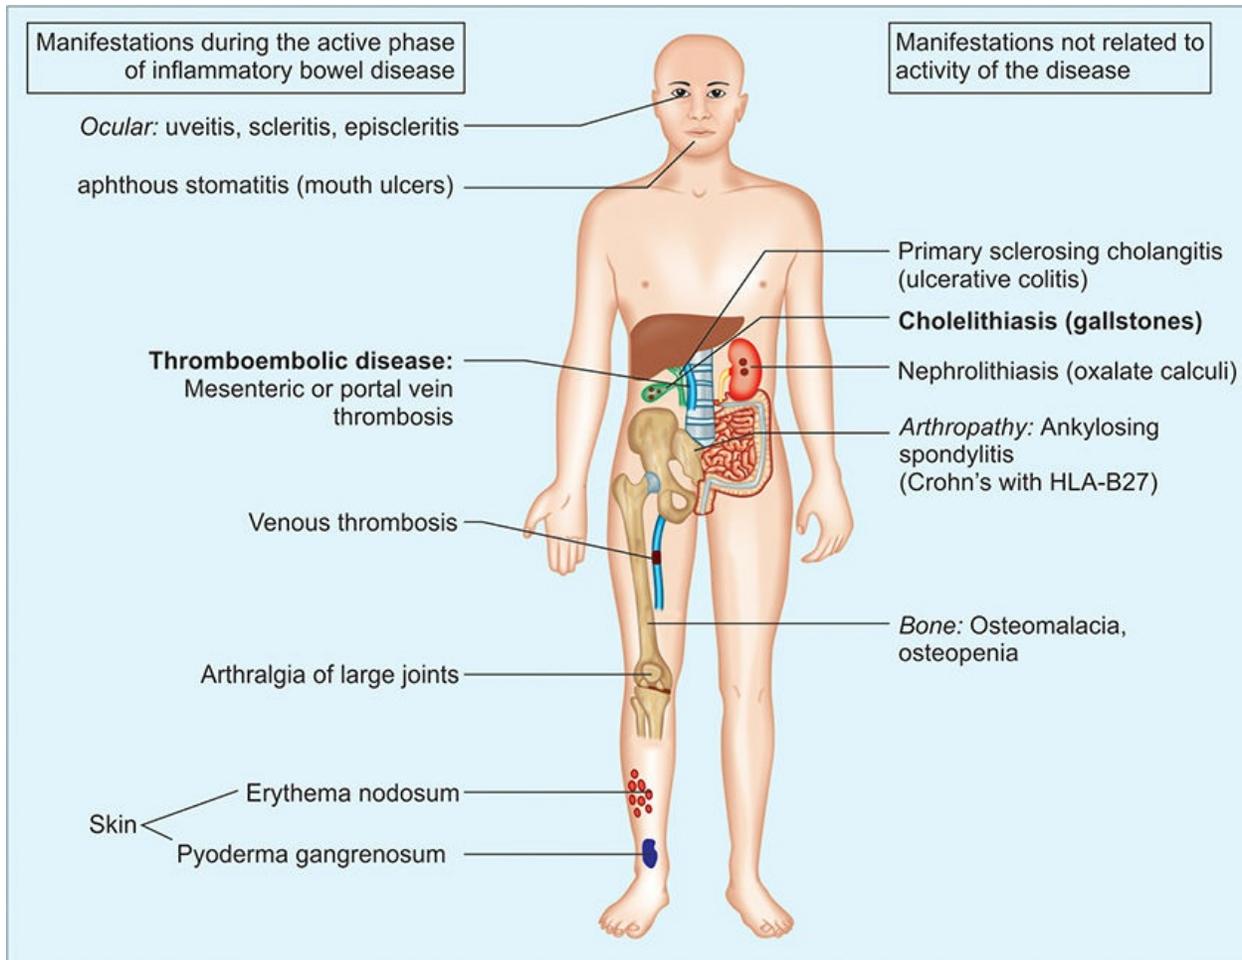

Conditions that mimic inflammatory bowel disease (ulcerative or Crohn’s colitis) are presented in Table 10.56.

**Extraintestinal Manifestations (Table 10.57 and Fig. 10.14)**

**Q. Write short note/essay on extraintestinal manifestations of inflammatory bowel disease.**

**Table 10.57:** Extraintestinal manifestations of IBD.

<b>Complication</b>	<b>Crohn’s disease</b>	<b>Ulcerative colitis</b>
Ocular: Uveitis, scleritis, episcleritis	+	+
Arthropathy: Pauciarticular, polyarticular, ankylosing spondylitis	+	+
Skin: Erythema nodosum, pyoderma gangrenosum	+	+
Primary sclerosing cholangitis	+	+
Thromboembolic disease	+	+
Renal: Nephrolithiasis	+	+
Bone: Osteomalacia, osteoporosis	+	–
Oral ulcers	+	–
Vitamin B <sub>12</sub> deficiency	+	–

**Fig. 10.14:** Systemic complications of inflammatory bowel disease.

## Differences between Ulcerative Colitis and Crohn's Disease of the Colon (Table 10.58)

**Q.** Write short note on the differences between ulcerative colitis and Crohn's disease of the colon.

**Table 10.58:** Differences between ulcerative colitis and Crohn's disease of the colon.

<i>Characteristics</i>	<i>Ulcerative colitis</i>	<i>Crohn's disease</i>
<b>Pathological features</b>		
Involvement of bowel	Continuous involvement	Segmental involvement (skip lesions)
Inflammation	Restricted to mucosa and submucosa	Transmural
Non-caseating granulomas	Absent	Common

Crypt abscess	Common	Uncommon
Goblet cell depletion	Seen	Absent
Strictures, fissures and fistulae	Uncommon	Common
Mesenteric and lymph nodal involvement	Absent	Common
<b>Clinical features</b>		
Rectal bleeding	Common	Uncommon
Abdominal pain	Less common	More common
Abdominal masses	May be palpable	Not usually palpable
Fistulae, fissures and perianal skin tags	Uncommon	Common and characteristic
Small bowel involvement	Uncommon	Common
Rectal and colonic involvement	Common	Rare
Recurrence after surgery	Not common	Common
Toxic dilatation	Relatively common	Uncommon

## PROBIOTICS AND PREBIOTICS

**Q. Discuss briefly about probiotics and prebiotics.**

### Probiotics

**Definition:** Probiotics are defined as live microorganisms which are beneficial to its host. Throughout their journey in the digestive tract, they need to be intact, so they can reach the intestines where they act to give their beneficial effects to the body.

### *Nature*

- **Bacteria:** Probiotics are usually bacterial components of the normal intestinal flora of human beings (e.g. *lactobacilli* and *Bifidobacterium infantis*). They produce lactate and short-chain fatty acids (e.g. acetate and butyrate) as end products of metabolism.
- **Yeast:** *Saccaromyces boulardii* is yeast.

### *Preparation*

- **Yogurt:** It is commonly used probiotic in which is milk fermented by bacteria that convert lactose into lactic acid.

- **Freeze-dried bacteria:** Probiotics are also available as freeze-dried bacteria (in capsule, tablet or powder form). Their composition varies and most of them contain *Lactobacillus acidophilus* often with bifidobacteria. Other strains include *Bacillus coagulans*, *L. Paracasei*, *L. johnsonii*.

**Limitations:** Problems with quality control and formulation restrict the clinical availability of some probiotics.

## Uses

- **Malnutrition:** Helps in normalizing the nutritional status of malnourished children. WHO suggested the use of yogurt in nutritional recovery.
- **Lactose intolerance:** Yogurt is preferred.
- **Prevention and treatment of antibiotic-associated diarrhea:** Probiotics containing *Saccharomyces boulardii* yeast) may be useful to some extent.
- Irritable bowel syndrome (IBS) and colitis
- Improve immune function/immunity
- Necrotizing enterocolitis in neonates
- Speed treatment of certain intestinal infections
- Prevent and treat eczema in children
- Prevent or reduce the severity of colds and flu
- Prevent and treat vaginal yeast infections and urinary tract infections
- *Reduce bladder cancer recurrence:* Probably reduces the development of carcinoma of colon.

## Prebiotics

### Definition

Prebiotics are referred to as a dietary fiber or carbohydrates that act as the food of probiotics. This is why it triggers bacterial growth and activity in the intestinal microflora. Therefore, it promotes good health of the host.

- Chemical substances (usually oligosaccharides) which beneficially nourishes and acts as a fertilizer to promote growth of the host's intrinsic probiotic bacteria. They encourage their growth.
- Prebiotics are special form of dietary fiber.
- Prebiotics are not digested (non-digestible) by the small intestine and non metabolized by non-probiotic gut flora such as *Bacteroides* spp and *Escherichia coli* present in the host.

- Synthetic prebiotics are oligosaccharides containing fructose or galactose, known as fructose oligosaccharides (FOS) and galactose oligosaccharides (GOS), respectively. Lactulose is also a prebiotic.
- These oligosaccharides are enriched with the combination of inulin.
- They may be added to foods, or combined with a probiotic.

### **Box 10.16: Potential uses of prebiotics.**

- Relief of constipation
- Reduce intestinal pH.
- Restore intestinal bacterial balance
- Increase in the absorption of calcium and magnesium
- Effect on blood cholesterol level
- Reduction of fasting glucose level in type 2 diabetes patients
- Reduce risk on colorectal cancer
- Effects on the immune system
- Better intestinal flora in infants
  - Lactulose: Useful in hepatic encephalopathy.
  - Prevention of osteoporosis: Prebiotics may increase calcium absorption.
  - Chronic constipation.

### ***Potential Uses of Prebiotics (Box 10.16)***

#### **Synbiotics**

- Synbiotics refer to the combination of the prebiotics and probiotics within a single product.
- Prebiotics are targeted to act on the large intestines while the probiotics are most effective in doing its role in the small intestine.
- The two agents have been said to act synergistically. So, the term synbiotics is used.

## **MISCELLANEOUS**

**Q. Write short note on Gardner's syndrome.**

### **Gardner's Syndrome**

- Condition in which familial adenomatous polyposis (FAP) is associated with predominant extraintestinal manifestations.
- Autosomal dominant disorder

- *Adenomatous polyps*: Numerous in colon and few in the stomach and duodenum.
- *Extraintestinal lesions*: These include:
  - **Osteomas of mandible, skull, and long bones**
  - **Epidermal cysts, desmoid tumors, thyroid tumors, etc.**

**Treatment:** Prophylactic total colectomy.

## Peutz-Jeghers Syndrome

**Q. Write short note on Peutz-Jeghers syndrome.**

- It is a rare autosomal dominant syndrome.
- Median age of presentation is 11 years
- It is characterized by:
  - **Multiple GI hamartomatous polyps**: Involves the entire GIT but are most common in the small intestine. Usually, present in the dozens.
  - **Mucocutaneous hyperpigmentation**: The melanotic pigmentation is seen in the mouth, buccal mucosa and genitalia region.
- Peutz-Jeghers syndrome is associated with an **increased risk of several malignancies**. These include cancers of the colon, pancreas, breast, lung, ovaries, uterus, and testicles.
- **Genetics**: Inactivation (loss-of-function mutations) of the *STK11/LKB1* gene (tumor suppressor gene) detected in about 70% of affected families. **The hamartomas are not preneoplastic precursor lesions.**
- **Clinical presentation**: Abdominal pain, rectal bleeding, anemia, intestinal obstruction, intussusception.
- **Diagnosis and treatment**: Intraoperative enteroscopy (IOE) and remove all small intestinal polyps by double balloon enteroscopy (DBE).

## Indications, Contraindications and Complications of Upper Gastrointestinal Endoscopy (Table 10.59)

**Q. Write short note on indications, contraindications and complications of upper gastrointestinal endoscopy.**

**Table 10.59:** Indications, contraindications and complications of upper

## gastrointestinal endoscopy.

### Diagnostic indications

- Upper gastrointestinal bleeding: Past or present; acute or chronic
- Patients with splenomegaly or suspected chronic liver disease: For presence and grading of esophagogastric varices
- Upper abdominal distress that persists despite an appropriate trial of therapy
- Dysphagia or odynophagia
- Esophageal reflux symptoms that are persistent or recurrent despite appropriate therapy
- Persistent nausea and vomiting of unknown cause
- Surveillance for malignancy, abnormal CT scan or barium meal
- Gastric or esophageal ulcers
- Familial adenomatous polyposis
- Adenomatous gastric polyps
- Barrett's esophagus
- Occult gastrointestinal bleeding
- After caustic ingestion to assess for acute injury
- Dyspepsia over 55 years of age or with alarm symptoms
- Atypical chest pain
- Weight loss
- Duodenal biopsies in the investigation of malabsorption and to confirm a diagnosis of celiac disease prior to commencement of gluten-free diet

### Therapeutic indications

- Treatment of bleeding lesions
- Sclerotherapy or banding of varices
- Removal of foreign bodies
- Removal of selected polypoid lesions or superficial neoplasms
- Placement of feeding or drainage tubes
- Dilation of stenotic lesions
- Palliative treatment of stenosing neoplasms
- Drainage of pancreatic pseudocysts

### Contraindications

#### • Absolute contraindications

- Severe shock
- Possible visceral perforation

#### • Relative contraindications (can be performed by experienced hands)

- Recent myocardial infarction, unstable angina, cardiac arrhythmia
- Severe respiratory disease
- Atlantoaxial subluxation

### Complications

- Cardiorespiratory depression due to sedation
- Aspiration pneumonia
- Perforation

## Indications for Colonoscopy (Table 10.60)

**Q. Write short note on indications for colonoscopy.**

## Protein-losing Enteropathy

**Q. Write short note on protein-losing enteropathy.**

It is characterized by excessive loss of protein into the gut lumen, sufficient to cause hypoproteinemia.

**Causes (Table 10.61):** Most common in diseases with mucosal ulceration.

**Clinical features:** Peripheral edema and hypoproteinemia.

**Table 10.60:** Indications for colonoscopy.

Diagnostic	Therapeutic
<ul style="list-style-type: none"><li>• Unexplained rectal bleeding</li><li>• Unexplained lower gastrointestinal symptoms and signs, such as recent onset constipation or feeling of incomplete evacuation, especially in the elderly</li><li>• Polyp and cancer screening or follow-up</li><li>• Inflammatory bowel disease</li><li>• Stricture or colonic narrowing (with and without inflammatory bowel disease)</li><li>• Diverticular disease</li><li>• Infectious colitis</li><li>• Radiation colitis</li><li>• Ischemic colitis</li><li>• Endometriosis</li><li>• Pneumatosis cystoides intestinalis</li></ul>	<ul style="list-style-type: none"><li>• Polypectomy</li><li>• Foreign body removal</li><li>• Dilation of strictures in colon or terminal ileum</li><li>• Therapeutic: Hemostasis</li><li>• Tumor resection (palliative)</li><li>• Colonic decompression (volvulus and pseudo-obstruction)</li></ul>

**Investigations:** Liver function tests are normal liver function and no proteinuria. Diagnosis can be confirmed by measuring fecal clearance of  $\alpha_1$ -antitrypsin or 51 Cr-labeled albumin after intravenous injection. Other investigations depend on the underlying cause.

**Treatment** of the underlying disorder, with nutritional support and measures to control peripheral edema.

## Causes of Generalized Abdominal Distension (Box 10.17)

**Q.** Write short note on causes of abdominal distension.

**Box 10.17:** Causes of abdominal distension (7Fs).

Fat, Fluid (ascites), Flatus (obstruction/ileus), Fetus (pregnancy), Feces (constipation), Full bladder, Fatal neoplasm (organomegaly)

## Causes of Oral Ulceration

**Q.** Write short note on causes of oral ulceration and aphthous ulcer.

### *Aphthous Ulceration*

Aphthous ulcers are superficial and painful ulcers which can develop in any part of the mouth. Recurrent ulcers are common in women prior to menstruation. The cause is unknown. Other causes of oral ulceration are presented in Table 10.62.

**Table 10.61: Causes of protein-losing enteropathy.**

- **With erosions or ulceration of mucosa:** Crohn’s disease, ulcerative colitis, cancer of esophagus, stomach or colon, radiation damage, lymphoma
- **Without erosions or ulceration of mucosa:** Ménétrier’s disease, Celiac disease, bacterial overgrowth, eosinophilic gastroenteritis, systemic lupus erythematosus, tropical sprue
- **With obstruction of lymphatics:** Intestinal lymphangiectasia, lymphoma, Whipple’s disease, constrictive pericarditis

**Table 10.62: Causes of oral ulcers.**

• <b>Aphthous:</b> Idiopathic Infection, premenstrual	• <b>Gastrointestinal diseases:</b> Crohn’s disease, Celiac disease
• <b>Infection:</b> Fungal (candidiasis), viral (herpes simplex, HIV), bacterial (e.g. syphilis, tuberculosis)	• <b>Dermatological conditions:</b> Lichen planus, dermatitis herpetiformis
• <b>Drugs:</b> Nicorandil, NSAIDs (non-steroidal anti-inflammatory drugs), methotrexate, cytotoxic drugs, Stevens–Johnson syndrome	• <b>Systemic diseases:</b> Systemic lupus erythematosus, Behçet’s syndrome, vitamin deficiencies
• <b>Neoplasia:</b> Carcinoma, leukemia, Kaposi’s sarcoma	• Traumatic ulcers

# Hepatobiliary System

# CHAPTER 11

## FUNCTIONS OF LIVER

**Q. Enumerate important functions of liver.**

Important functions of liver are listed in Box 11.1.

**Box 11.1:** Important functions of liver.

- Protein metabolism and urea formation
- Carbohydrate metabolism: Including gluconeogenesis, glycogenolysis and glycogenesis
- Lipid metabolism
- Bilirubin formation from hemoglobin degradation
- Metabolism of vitamin and mineral
- Hormone metabolism
- Drug and alcohol metabolism
- Cholesterol metabolism
- Bile acid formation and bile secretion
- Synthesis of plasma proteins including coagulation factors
- Immunological function: Removal of gut endotoxins and foreign antigens
- Maintaining core body temperature
- Maintain pH balance and correction of lactic acidosis

## LIVER FUNCTION TESTS

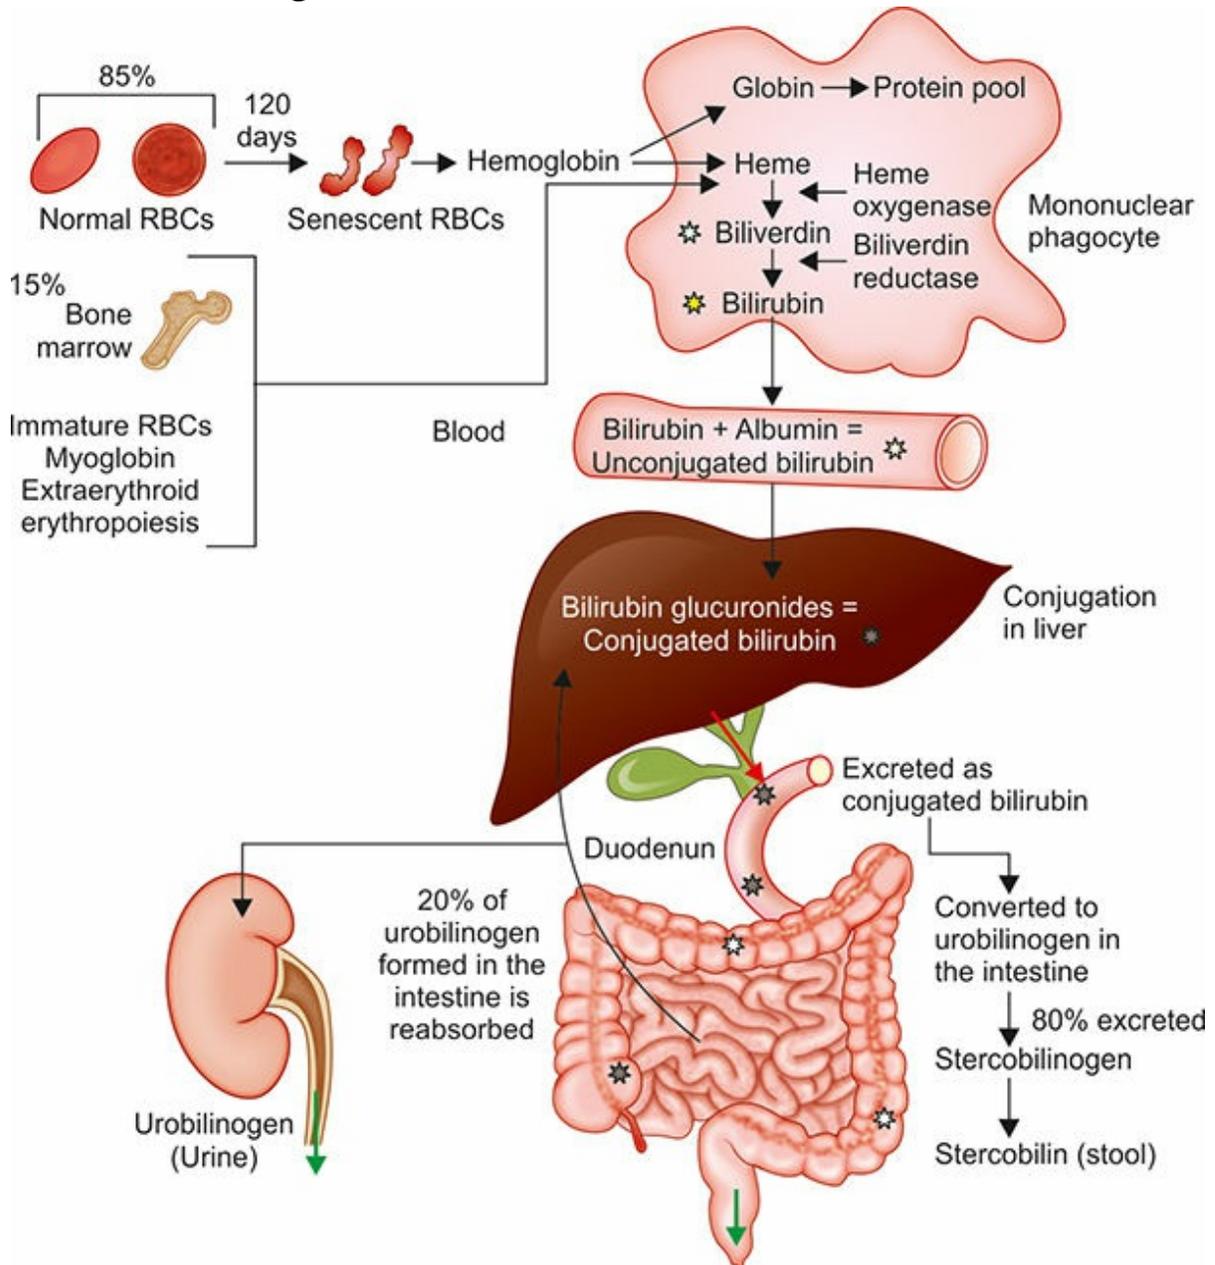

**Q. Write short essay on liver function tests and their significance in jaundice.**

### Liver Biochemistry

*No single test alone can be used to assess liver function.*

### ***Serum Bilirubin***

- Normal values of total serum bilirubin are between 0.3 and 1.3 mg/dL, with 95% of a normal population falling between 0.2 and 0.9 mg/dL (almost all unconjugated). Bilirubin is a degradation product of hemoglobin and hem-containing proteins. Bilirubin metabolism is summarized in Figure 11.1.

**Fig. 11.1:** Bilirubin metabolism

- Total serum bilirubin = Conjugated (direct) + unconjugated (indirect) bilirubin.

- **Unconjugated hyperbilirubinemia:** It is characterized by a **serum bilirubin level less than 6 mg/dL and absence of bilirubinuria**. The other liver function tests are normal, e.g. hemolytic anemia, ineffective erythropoiesis and Gilbert's syndrome.
- **Conjugated hyperbilirubinemia:** It is characterized by **higher levels of bilirubin and bilirubinuria**. The other liver function tests are often abnormal, e.g. parenchymal liver diseases and biliary tract obstructions.

The presence of conjunctival icterus suggests a total serum bilirubin level of at least 3.0 mg/dL level below which is called **anicteric jaundice**, but does not allow differentiation between conjugated and unconjugated hyperbilirubinemia. Tea or cola-colored urine may indicate the presence of bilirubinuria and thus conjugated hyperbilirubinemia. Fluctuating hyperbilirubinemia is observed in gallstones, carcinoma of ampulla of Vater, chronic hepatitis, hemolytic anemias and Gilbert's syndrome.

## ***Serum Enzymes***

*Enzymes that reflect damage to hepatocytes-aminotransferases (transaminases)*

- These enzymes are present in hepatocytes and leak into the blood with liver cell damage. These include two enzymes namely (1) aspartate aminotransferase (AST/SGOT) and (2) alanine aminotransferase (ALT/SGPT).
- **Normal value of serum transaminases ranges from 10–40 U/L.**
- Elevation of these serum enzymes **reflects damage to hepatocytes** and is useful for differentiating hepatocellular jaundice from obstructive jaundice.

***Aspartate aminotransferase (AST, formerly called SGOT)***

- It exists as two different isoenzymes: Mitochondrial (80%) and cytoplasmic (20%) form.
- AST is found in high concentration also in heart, muscle, kidney and brain.
- **Causes of raised levels: Hepatic necrosis, myocardial infarction, muscle injury and congestive cardiac failure.** Raised mitochondrial AST is seen in extensive tissue necrosis during myocardial infarction and

acute and chronic liver diseases.

### ***Alanine aminotransferase (ALT, formerly called SGPT)***

- It is a cytosol enzyme found in higher concentration in the liver than in other tissues (e.g. kidney, heart muscle).
- ALT is a **more specific indicator of liver injury**.
- Various causes of elevated serum aminotransferases are listed in Table 11.1.

### ***AST: ALT ratio***

- Most acute hepatocellular disorders are associated with ALT is higher than or equal to the AST.
- **AST to ALT ratio >2:1 is suggestive, while a ratio >3:1 is highly suggestive of alcoholic liver disease.** A low level of ALT in the serum in alcoholic patients is due to an alcohol-induced deficiency of pyridoxal phosphate (coenzyme required for synthesis of ALT).
- AST to ALT ratio is typically less than 1 in patients with chronic viral hepatitis and nonalcoholic fatty liver disease (NAFLD).

## **Table 11.1: Causes of elevated serum aminotransferases.**

### **Chronic, Mild Elevations, ALT > AST (<150 U/L)**

#### *Hepatic Causes*

- $\alpha$ 1-antitrypsin deficiency
- Autoimmune hepatitis
- Chronic viral hepatitis (B, C, and D)
- Hemochromatosis
- Medications and toxins
- Steatosis and steatohepatitis
- Wilson disease

#### *Nonhepatic Causes*

- Celiac disease
- Hyperthyroidism

### **Severe, Acute Elevations, ALT > AST (>1000 U/L)**

#### *Hepatic Causes*

- Acute bile duct obstruction
- Acute Budd-Chiari syndrome
- Acute viral hepatitis
- Autoimmune hepatitis

- Hepatic artery ligation
- Ischemic hepatitis (prolonged hypotension or acute heart failure)
- Medications/toxins (e.g. Amanita phalloides) or drug (e.g. paracetamol) induced liver injury
- Wilson disease

**Severe, Acute Elevations, AST > ALT (>1000 U/L or >20–25 times normal)**

*Hepatic Cause*

- Medications or toxins in a patient with underlying alcoholic liver injury

*Nonhepatic Cause*

- Acute rhabdomyolysis

**Chronic, Mild Elevations, AST > ALT (<150 U/L, <5 times normal)**

*Hepatic Causes*

- Alcohol-related liver injury (AST : ALT > 2 : 1)
- Cirrhosis

*Nonhepatic Causes*

- Hypothyroidism
- Myopathy
- Strenuous exercise

(ALT: alanine aminotransferase; AST: aspartate aminotransferase)

*Enzymes that reflect cholestasis*

These include three enzymes: (1) alkaline phosphatase, (2) 5'-nucleotidase, and (3)  $\gamma$ -glutamyl transpeptidase (GGT).

**Q. Write short answer on causes/diseases with elevated/very high serum alkaline phosphatase.**

**Alkaline phosphatase (ALP)**

- **Sources:** ALP is present in liver (canalicular and sinusoidal membranes of the liver) and many other tissues (e.g. bone, kidney, intestine, leukocytes and placenta).
  - *Simultaneous elevation of other liver enzymes such as  $\gamma$ -glutamyl transpeptidase (GGT) or 5'-nucleotidase assist in establishing the origin of ALP from liver.*
- **Normal serum level:** 3–13 KA units (80–240 IU/L).
- **Significance (Box 11.2):**
  - **Raised** levels of liver-derived alkaline phosphatase are **not totally specific for cholestasis.**
  - A **low** serum alkaline phosphatase level may occur in patients with

**Wilson disease**, especially those presenting with fulminant hepatitis and hemolysis, possibly because of reduced activity of the enzyme owing to displacement of the co-factor zinc by copper.

**Box 11.2:** Significance of raised serum ALP levels.

**Less than 2 ½ folds:** Hepatocellular jaundice

**Markedly raised** (more than 4 times)

- Obstructive (cholestatic) jaundice: Both in intrahepatic or extrahepatic obstruction
- Infiltrative liver diseases, e.g. cancer, metastases, amyloidosis tuberculosis, lymphoma, sarcoidosis
- Bone lesions with rapid bone turnover, e.g. Paget's disease
- Intrahepatic cholestasis, e.g. primary biliary cholangitis, primary sclerosing cholangitis, drug-induced cholestasis.

***γ-glutamyl transpeptidase (GGT)***

- GGT is a microsomal enzyme present in liver and other tissues (renal tubules, pancreas and intestine).
- **Significance:**
  - The primary use of serum GGT levels is to identify the source of an isolated elevation in the serum alkaline phosphatase level; GGT is **not elevated in bone disease**.
  - **Screening test for alcoholism** : If the ALP is normal, a raised serum GGT is a good guide to alcohol intake of more than 60 g alcohol/day.
- Causes of elevated GGT levels (Box 11.3).

**Box 11.3:** Causes of elevated GGT levels.

- Biliary obstruction
- Alcoholism
- Liver parenchymal damage
- Nonalcoholic fatty liver
- Drugs: Phenytoin, barbiturates, and some drugs used in highly active antiretroviral therapy, including non-nucleoside reverse transcriptase inhibitors and the protease inhibitor abacavir.
- Others: Chronic obstructive lung disease, diabetes mellitus, hyperthyroidism, obesity and renal failure.

***5-nucleotidase***

It is another microsomal enzyme similar significance as that of GGT.

The 5'NT level is not increased in bone disease and is primarily increased in hepatobiliary disease.

### ***Lactic dehydrogenase (LDH)***

It is **not useful in diagnosis of liver diseases**; because of it has other sources in body tissues. Moderate elevations are seen in ischemic hepatitis and hepatic metastasis. ALT/LDH ratio  $>1.5$  suggests ischemic hepatitis while ratio  $<1.5$  is seen with paracetamol toxicity.

*Tests that measure synthetic function of the liver*

### ***Plasma proteins***

#### **Serum albumin**

- It is **synthesized exclusively in liver** and used as a marker of synthetic function.
- **Normal serum albumin level:** 4–5.5 g/100 mL and albumin has a half life of around 20 days.

#### *Significance*

- **Low levels:** Serum albumin is an **excellent marker of hepatic synthetic function**. Hypoalbuminemia is observed in chronic liver diseases such as cirrhosis and chronic hepatitis and usually reflects severe liver damage and decreased albumin synthesis. A **falling serum albumin level in liver disease is a bad prognostic sign**.
- Apart from chronic liver disease, it may be observed in chronic inflammation, sepsis, expanded plasma volume and renal or gastrointestinal loss.

#### ***Serum globulins***

- They constitute a group of proteins made up of  $\gamma$ -globulins (immunoglobulins) synthesized by B lymphocytes and  $\alpha$  and  $\beta$  globulins synthesized primarily by hepatocytes.
  - **Normal serum globulin level:** 1.5–3.5 g/100 mL.
  - **Significance:**  $\gamma$ -globulins are **increased in chronic liver disease** (e.g. chronic hepatitis and cirrhosis). Increase in the concentration of specific isotypes of  $\gamma$ -globulins (immunoglobulins) are helpful in the recognition of certain chronic liver diseases (Table 11.2).
  - **Cirrhosis:** Plasma protein shows decrease in albumin and increase in  $\gamma$ -globulin.
- 

**Table 11.2:** Specific types of elevated immunoglobulin and its associated conditions.

<i>Specific type of immunoglobulin</i>	<i>Condition in which it is raised</i>
IgG	Chronic hepatitis, autoimmune hepatitis (AIH) and cryptogenic cirrhosis
IgA	Alcoholic liver disease
IgM	Primary biliary cholangitis

### **Coagulation factors**

- **Liver produces all the coagulation factors except factor VIII.**
- Vitamin K is required for the activation of coagulation **factors II, VII, IX, and X.**
- The coagulation factors have short half-life time. Thus, measurement of the clotting factors is the **single best measure of hepatic synthetic function** and useful in both the diagnosis and assessing the prognosis of acute parenchymal liver disease.
- **Prothrombin time:**
  - Prothrombin time depends on factors I, II, V, VII and X.
  - Normal value is 11–12.5 seconds.
  - Prothrombin time collectively measures factors II, V, VII, and X.
  - Causes of prolonged prothrombin time is listed in Box 11.4.
- *Unlike the serum albumin, the prothrombin time allows an assessment of current hepatic synthetic function; factor VII has the shortest serum half-life (six hours) of all the clotting factors.*

### **Box 11.4:** Causes of prolonged prothrombin time.

- **Severe liver damage:** Acute hepatitis (e.g. Viral hepatitis), cirrhosis
- **Deficiency of vitamin K**
  - Obstructive jaundice that reduces vitamin K absorption
  - Fat malabsorption
  - Poor intake
  - Antibiotic therapy which produces destruction of vitamin K-producing commensals.
- **Disseminated intravascular coagulation.**
- **Drugs and toxins:** Warfarin, rivaroxaban, apixaban, edoxaban, dabigatran, viper envenomation, anticoagulant rodenticide poisoning.

### **Ceruloplasmin**

- It is an **acute phase reactant** synthesized by the liver.
- In the blood, it binds to copper and acts as a major carrier for copper.
- **Normal plasma level:** 20–60 mg/dL
- **Causes of elevated levels:** Infections, liver diseases, obstructive jaundice, rheumatoid arthritis and pregnancy.
- **Causes of decreased levels:** Wilson’s disease (due to decreased rate of synthesis), neonates, Menke’s disease, kwashiorkor, marasmus, protein-losing enteropathy and copper deficiency.

### ***Cholesterol***

- It is synthesized in the liver. Advanced liver disease may be associated with very low cholesterol. However, primary biliary cholangitis may be associated with markedly raised cholesterol. Similarly a low urea level also indicates severe liver dysfunction.

Liver functions tests and their significance are summarized in Table 11.3.

### ***Serum autoantibodies***

- ***Antimitochondrial antibody (AMA):*** Antinuclear, smooth muscle (actin), liver/kidney microsomal antibodies, antinuclear cytoplasmic antibodies (ANCA).

## **Urine Tests**

### ***Bilirubin in the Urine***

- Normally, bilirubin cannot be detected in urine.
- In unconjugated hyperbilirubinemia, urine does not contain bilirubin (**acholuric jaundice**). Thus, **absence of bilirubin in the urine in a jaundiced patient suggests unconjugated hyperbilirubinemia.**
- In conjugated hyperbilirubinemia, urine contains bilirubin. Thus, **bilirubinuria in a jaundiced patient points to conjugated hyperbilirubinemia** (hepatobiliary disease).
- Urinary bilirubin is detected by Fouchet’s test.

### ***Urine Urobilinogen***

- Urobilinogen is **normally present in urine in trace amounts** (1–2 mg/dL) and is insufficient to cause a significant positive reaction.

**Table 11.3: Summary of main liver function tests and its significance.**

<i>Test</i>	<i>Function determined/assessed</i>
Serum bilirubin	<ul style="list-style-type: none"> <li>• Transport</li> </ul>
Serum enzymes <ul style="list-style-type: none"> <li>• Serum aminotransferases (ALT and AST)</li> <li>• Serum alkaline phosphatase (ALP)</li> <li>• <math>\gamma</math>-glutamyl transpeptidase (GGT)</li> </ul>	<ul style="list-style-type: none"> <li>• Hepatocellular damage</li> <li>• Biliary tract obstruction</li> <li>• Enzyme induction</li> </ul>
Plasma proteins	<ul style="list-style-type: none"> <li>• Synthesis</li> </ul>
Prothrombin time	<ul style="list-style-type: none"> <li>• Synthesis</li> </ul>

• **Causes of increased urobilinogen in urine (Box 11.5)**

**Box 11.5:** Causes of increased urobilinogen in urine.

- **Hemolytic anemias** (without bilirubin in urine)
  - Thalassemia
  - Sickle-cell anemia
  - Hereditary spherocytosis
- **Liver diseases** (bilirubinuria present)
  - Pre-icteric phase of infective hepatitis
  - Drugs or toxic hepatitis
  - Cirrhosis

- **Cause of absent urobilinogen:** In **obstructive jaundice** (bilirubinuria present), bilirubin does not reach the intestine and so is not converted into urobilinogen.
- Urinary urobilinogen is detected by Ehrlich’s aldehyde test.

***$\alpha$ -Fetoprotein (AFP)***

**Q.** Write a short note on  *$\alpha$ -fetoprotein* (discussed in detail in Chapter 17).

- $\alpha$ -fetoprotein is normally produced by fetal liver cells and its levels falls to low levels after birth
- **Causes of elevated levels** of  $\alpha$ -fetoprotein are:
  - **Hepatocellular carcinoma (HCC)**
  - **Carcinomas of stomach, pancreas, gallbladder, bile ducts and**

- lungs
- Teratomas

## DIAGNOSTIC PROCEDURES

### Endoscopic Retrograde Cholangiopancreatography (ERCP)

**Q. Write short note on endoscopic retrograde cholangiopancreatography (ERCP).**

ERCP is a technique used to **outline the biliary and pancreatic ducts**.

#### *Procedure*

An endoscope is passed into the second part of the duodenum and cannulation of the ampulla. Contrast is injected into the biliary tree and the patient is screened radiologically. Figure 11.2 shows ERCP with stone in the common bile duct.

**Fig. 11.2:** ERCP shows stone in the common bile duct (CBD).

#### *Uses of ERCP (Table 11.4)*

**Table 11.4: Uses of ERCP.**

<i>Diagnostic procedure</i>	<i>Therapeutic procedure</i>
<ul style="list-style-type: none"><li>• Evaluation of acute/chronic pancreatitis</li></ul>	<ul style="list-style-type: none"><li>• Removal of common bile duct stones</li></ul>
<ul style="list-style-type: none"><li>• Evaluation of patient with obstructive jaundice</li></ul>	<ul style="list-style-type: none"><li>• Sphincterotomy</li></ul>
<ul style="list-style-type: none"><li>• Cholangitis</li></ul>	<ul style="list-style-type: none"><li>• Dilatation of benign strictures</li></ul>
<ul style="list-style-type: none"><li>• Biopsy for periampullary carcinoma</li></ul>	<ul style="list-style-type: none"><li>• Placement of nasobiliary catheters and biliary stents</li></ul>
	<ul style="list-style-type: none"><li>• Brachytherapy for cholangiocarcinoma</li></ul>

### **Complications**

The complication rate in diagnostic ERCP is 2–3%. Complications include pancreatitis, cholangitis, bleeding and duodenal perforation.

### **Magnetic Resonance Cholangiopancreatography (MRCP)**

**Q. Write short note on magnetic resonance cholangiopancreatography (MRCP).**

MRCP is a noninvasive technique largely replacing diagnostic (but not therapeutic) ERCP.

### **Technique**

A heavily T2-weighted sequence enhances visualization of the water-filled biliary (intrahepatic ducts) and pancreatic ducts (extrahepatic ducts). It produces high-quality images of ductal anatomy.

### **Advantages of MRCP over ERCP (Box 11.6)**

#### **Indications**

- Diagnosis of bile duct obstruction and pancreatic duct abnormalities, e.g. choledocholithiasis, malignant obstruction of bile and pancreatic ducts, congenital anomalies and chronic pancreatitis.
- Unsuccessful ERCP or a contraindication to ERCP (as in patients with cardiorespiratory compromise, renal failure).

#### **Box 11.6: Advantages of MRCP over ERCP.**

- No need for contrast media or ionizing radiation
- Images can be acquired faster
- Less operator dependent

- No risk of pancreatitis.

## Endoscopic Ultrasound (EUS)

**Q. Write a short note on endoscopic ultrasound (EUS).**

### *Procedure*

In EUS, a small high-frequency ultrasound probe is placed on the tip of an endoscope and placed by direct vision into the duodenum.

### *Advantages*

Gradually replacing diagnostic ERCP

- Close proximity of the ultrasound probe to the pancreas and biliary tree allows high-resolution ultrasound imaging.
- Accurate staging of small, potentially operable, pancreatic tumors (e.g. neuroendocrine tumors) can be done.
- Less-invasive method for bile duct imaging.

### *Uses*

#### *Diagnostic*

- Imaging pancreatic and biliary diseases, e.g. choledocholithiasis, pancreatic and biliary cancers, and cystic lesions of the pancreas.
- Ampullary carcinoma: To know the local extension of tumor and regional lymph node metastasis that cannot be evaluated by ERCP.
- Performing fine needle aspiration under EUS guidance from suspicious lesions for confirmation of malignancy.

#### *Therapeutic*

- Increasingly used for guided interventions:
  - To reduce pain in patients with unresectable pancreatic carcinoma, for injecting bupivacaine and alcohol into the celiac ganglia.
  - Endoscopic management of pancreatic pseudocysts.

### *Disadvantages*

- Cost is high
- High degree of training required.

# LIVER BIOPSY

**Q. Write short note on the indications, significance and complications of liver biopsy.**

Percutaneous liver biopsy is an invasive procedure that can be performed with or without radiographic guidance.

## Indications for Liver Biopsy (Table 11.5)

**Table 11.5: Indications for liver biopsy.**

- Liver disease
  - Cirrhosis of liver: Assess the type, etiology and activity of the disease process
  - Tumors: Primary (HCC) or secondary
  - Chronic hepatitis: Assess the severity and stage of liver damage, and evaluation of the course
  - Unexplained hepatomegaly, splenomegaly, jaundice
  - Some cases of jaundice
  - Hepatocellular disease of uncertain cause
  - Occasionally in acute hepatitis
  - Diagnosis of granulomatous diseases like tuberculosis, leprosy and sarcoidosis
  - Storage and metabolic disorders, e.g. amyloidosis, glycogen storage disorders, hemochromatosis and Wilson's disease.
  - After liver transplantation: To assess for rejection and the presence and intensity of disease recurrence
- Pyrexia of unknown origin (when associated with hepatomegaly).
  - Miliary tuberculosis      – Brucellosis
  - Cholangitis                – Malignancy
- Staging of lymphoma

## Contraindications of Liver Biopsy (Box 11.7)

**Q. Write short note on contraindications of liver biopsy.**

## Complications of Liver Biopsy (Box 11.8)

**Q. Write short note on complications of liver biopsy.**

# JAUNDICE

**Q. List the causes of jaundice. How will you arrive at the etiology of jaundice? Give the points of differentiation in clinical features and investigations.**

## Definition

Jaundice (icterus) is defined as **yellowish pigmentation of skin, mucus membranes and sclera** due to **increased levels of bilirubin** in the blood. The scleral involvement is because of its rich elastic tissue that has special affinity for bilirubin.

- **Normal serum bilirubin level:** In normal adult ranges from 0.3 to 1.2 mg/dL.
- **Jaundice** is clinically detected when the **serum bilirubin level is above 2.0 to 2.5 mg/dL**. With severe disease, the levels may be as high as 30 to 40 mg/dL.
- **Latent jaundice** is the term used when serum bilirubin is more than 1.2 mg/dL but less than 2.5 mg/dL.
- *Carotenemia is characterized by yellowish pigmentation of skin by carotene but not of sclera. Quinacrine consumption also causes yellowish discoloration of skin and mucous membranes.*

## Box 11.7: Contraindications of liver biopsy.

- Congenital coagulation disorders, e.g. hemophilia A and B
  - Prolonged prothrombin time: More than 3 seconds over control (In such cases transjugular biopsy can be tried)
  - Obstructive jaundice with evidence of dilatation of intra- hepatic biliary radicles. Liver biopsy may cause leakage of bile from liver into the peritoneum causing severe and fatal biliary peritonitis
  - Severe jaundice
  - Massive ascites
  - Hepatobiliary infections
  - Patients with severe cough where diaphragm movements cannot be controlled
  - Uncooperative patients
  - Hydatid cyst liver
  - Hemangioma liver
- } These are relative contradictions

## Box 11.8: Complications of liver biopsy.

- Pleurisy, perihepatitis
- Hemorrhage
- Intrahepatic hematoma

- Biliary peritonitis
- Hemobilia
- Arteriovenous fistula
- Infection
- Other organ perforation
- Carcinoid crisis

## Classification of Jaundice

**Q. Write short note on causes of indirect/unconjugated hyperbilirubinemia.**

Jaundice can be classified in two ways:

1. **Based on the underlying cause (Box 11.9):**
  - Predominantly unconjugated hyperbilirubinemia
  - Predominantly conjugated hyperbilirubinemia.
2. **Based on pathological mechanism (Table 11.6):**
  - Hemolytic (prehepatic) jaundice
  - Hepatocellular jaundice (hepatic)
  - Obstructive jaundice (posthepatic).

### *Hemolytic Jaundice*

**Q. Write short note on prehepatic jaundice.**

- **Increased destruction of red blood cells or their precursors** causes increased production of bilirubin.
- **Unconjugated bilirubin** accumulates in the plasma and results in jaundice.
- **Jaundice is usually mild (Fig. 11.3)**, because normal liver can easily handle the increased bilirubin production.

**Fig. 11.3:** Conjunctiva showing mild jaundice in hemolytic anemia.

### **Box 11.9:** Classification of jaundice.

#### ***Predominantly Unconjugated Hyperbilirubinemia***

1. Increased production of bilirubin
  - Hemolytic anemias
  - Resorption of blood from internal hemorrhage (e.g. GI bleeding, hematomas)
  - Ineffective erythropoiesis (e.g. pernicious anemia, thalassemia)
2. Reduced hepatic uptake
  - Drug that interference with membrane carrier systems
  - Diffuse liver disease (hepatitis, cirrhosis)
  - Some cases of Gilbert syndrome
3. Impaired bilirubin conjugation
  - Physiologic jaundice of the newborn
  - Crigler-Najjar syndrome types I and II
  - Gilbert syndrome
  - Diffuse liver disease (e.g. hepatitis, cirrhosis)

#### ***Predominantly Conjugated Hyperbilirubinemia***

1. Decreased hepatocellular excretion
  - Deficiency of canalicular membrane transporters
    - Dubin-Johnson syndrome
    - Rotor syndrome
  - Liver damage or toxicity (e.g. hepatitis)
2. Impaired intra/extrahepatic bile flow
  - Inflammatory destruction of bile ducts (e.g. primary biliary cholangitis)
  - Gallstones
  - Carcinoma: Carcinoma head of pancreas, periampullary carcinoma, carcinoma of bile duct

**Q.** How do you clinically differentiate hemolytic jaundice,

## hepatocellular jaundice and obstructive (cholestatic) jaundice?

**Table 11.6:** Classification of jaundice based on the pathological mechanism.

<b><i>Hemolytic jaundice</i></b>	
<p>Intracorpuseular defects</p> <ul style="list-style-type: none"> <li>• Hereditary: Spherocytosis, sickle cell disease, thalassemia, G6PD deficiency</li> <li>• Acquired: Vitamin B<sub>12</sub> and folate deficiency</li> </ul>	<p>Extracorpuseular defects</p> <ul style="list-style-type: none"> <li>• Autoimmune and alloimmune hemolytic anemias</li> <li>• Fragmentation syndromes, e.g. prosthetic heart valves</li> <li>• Drugs, e.g. sulfasalazine and dapsons</li> <li>• Infections of RBCs, e.g. malaria</li> </ul>
<b><i>Hepatocellular jaundice</i></b>

### *Clinical features*

Depends on the cause of anemia.

- **Pallor** due to anemia
- **Mild jaundice** without any signs of liver disease.
- **Hepatosplenomegaly** due to increased activity of reticuloendothelial system.
- Gallstones and leg ulcers may be seen depending on the cause of anemia.
- **Dark stools** due to increased stercobilinogen in stool.

- **Urine turns dark yellow** on standing. This is due to increased urobilinogen being converted to urobilin in urine.

### *Investigations*

Show features of hemolysis

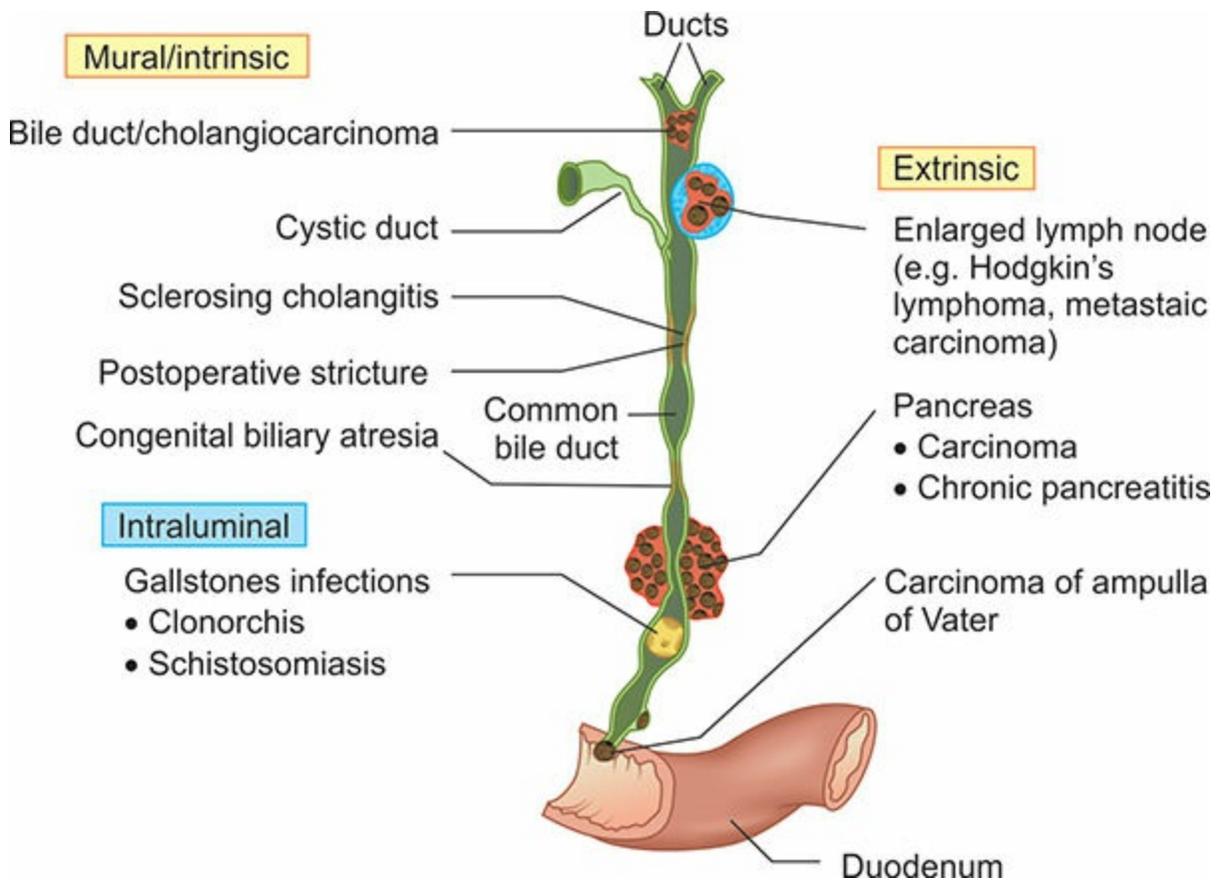

- **Predominantly unconjugated hyperbilirubinemia.** Serum bilirubin is raised (less than 6 mg %).
- **No bilirubin in urine**, because the unconjugated bilirubin is not water-soluble and cannot pass into the urine; hence the term '**acholuric jaundice**'.
- **Urinary urobilinogen is increased** (more than 4 mg/24 hours).
- Other liver function tests (e.g. serum ALP, transferases and albumin) are normal however LDH is increased.

### ***Hepatocellular Jaundice***

- Hepatocellular jaundice occurs as a **consequence of parenchymal liver disease** which leads to an inability of the liver to transport bilirubin across the hepatocyte into the bile.
- Defect in bilirubin transport across the hepatocyte may occur at any point between the uptake of unconjugated bilirubin into the hepatocyte and transport of conjugated bilirubin into biliary canaliculi.
- In hepatocellular jaundice (Fig. 11.4), **both unconjugated and conjugated bilirubin level rises** in the blood.

**Fig. 11.4:** Deep jaundice in viral hepatitis.

**Fig. 11.5:** Causes of obstructive jaundice.

### Investigations

- **Raised transaminases (AST, ALT):** Acute jaundice with AST >1000 U/L is highly suggestive of an **infectious cause** (e.g. hepatitis A, B), **drugs** (e.g. paracetamol) or **hepatic ischemia**.
- Imaging
- Liver biopsy

### Cholestatic (Obstructive/Surgical) Jaundice

**Q. Write short note on causes and features of obstructive jaundice.**

- **Cholestasis means failure of bile flow.** Its cause may be anywhere between hepatocyte and duodenum (Fig. 11.5).
- Cholestatic jaundice is usually a **'surgical jaundice'** meaning a cause that requires surgical intervention.
- Cholestasis can be intrahepatic or extrahepatic.

- **Consequences of cholestasis:**
  - **Retention of bile acids and bilirubin** in the liver and blood.
  - **Deficiency of bile acids in the intestine.**

*Clinical features (Boxes 11.10 and 11.11)*

*Investigations*

**Serum findings**

- **Serum bilirubin markedly raised** and is predominantly conjugated hyperbilirubinemia.
- **Serum ALP markedly raised** (3–4 times that of normal).
- Minimal biochemical changes of liver parenchymal damage.
- Antimitochondrial antibody (in primary biliary cholangitis).

**Box 11.10:** Symptoms of cholestasis.

- **Jaundice** (gradually progressive or fluctuating)
- **Pruritus** (as **bile salts saponify the fat surrounding the free nerve endings**)
- **Pale or clay-colored stools**
- **Dark urine** (increased conjugated bilirubin)
- **Bradycardia**
- Other symptoms depending on the cause
  - Fever with chills and rigors (cholangitis)
  - Weight loss (malabsorption)
  - Bleeding tendency (vitamin K deficiency)
  - Bone pains (calcium and vitamin D deficiency)
  - Abdominal pain (gallstones).

**Box 11.11:** Signs of cholestasis.

- **Deep jaundice** with a greenish hue
- **Scratch marks**
- **Xanthelasma**s on eyelids and xanthomas over tendons due to lipid deposit
- Other signs depending on the cause
  - Palpable gallbladder observed in carcinoma head of pancreas
  - Large hard irregular liver (malignancy)
  - Late features: Secondary biliary cirrhosis and signs of liver cell failure

**Urine findings**

- Bilirubin present.
- Urobilinogen absent.

Clinical features useful in differentiating different types of jaundice are listed in Table 11.7.

**Table 11.7:** Clinical features useful in differentiating different types of jaundice.

<i>Feature</i>	<i>Hemolytic (prehepatic)</i>	<i>Hepatocellular (intrahepatic)</i>	<i>Obstructive (posthepatic)</i>
Jaundice • Color • Depth	Lemon yellow Mild	Orange yellow Variable	Greenish yellow Deep
Pruritus	-	Variable	+
Bleeding tendency	-	+	+ (late)
Anemia	+	-	-
Splenomegaly	+	Variable	Absent (may develop later when cirrhosis develops)
Palpable gallbladder	-	-	May be present
Features of hepatocellular failure	-	+ (early)	+ (late)
Conjugated bilirubin	Absent	Raised	Raised
AST or ALT	Normal	Increased	Normal
ALP	Normal	Normal	Raised
Urine bilirubin	Absent	Present	Present
Urine urobilinogen	Present	Present	Absent

## CONGENITAL NONHEMOLYTIC HYPERBILIRUBINEMIAS

**Q. Write short note/essay on congenital nonhemolytic hyperbilirubinemias.**

**Q. List the causes of congenital hyperbilirubinemias.**

**Q. Write short note on causes of congenital hyperbilirubinemia.**

Various congenital nonhemolytic hyperbilirubinemias are listed in Table 11.8.

**Table 11.8: Congenital nonhemolytic hyperbilirubinemias.**

<i>Hereditary disorder</i>	<i>Mode of inheritance</i>	<i>Defects in bilirubin metabolism</i>	<i>Characteristics</i>
<b>Unconjugated Hyperbilirubinemia</b>			
Crigler-Najjar syndrome type I	Autosomal recessive	Absent UGT1A1 activity	Fatal
Crigler-Najjar syndrome type II	Autosomal dominant with variable penetrance	Decreased UGT1A1 activity	Usually mild
Gilbert syndrome	Autosomal dominant	Decreased UGT1A1 activity	Harmless
<b>Conjugated Hyperbilirubinemia</b>			
Dubin-Johnson syndrome	Autosomal recessive	Impaired biliary excretion of bilirubin glucuronides	Liver with pigmented granules in cytoplasm. Harmless
Rotor syndrome	Autosomal recessive	Decreased hepatic uptake Decreased biliary excretion	Harmless

(UGT: uridine diphosphate-glucuronyltransferase)

## Gilbert Syndrome

Relatively **common, harmless**, inherited hyperbilirubinemia with no clinical consequences has also been called “constitutional hepatic dysfunction” and “familial nonhemolytic jaundice”.

### *Etiology*

- Caused by **mutations in the UGT1 gene** that leads to inadequate synthesis of the UGT1A1 enzyme (activity is about 30% of normal) resulting in unconjugated hyperbilirubinemia.
- Autosomal **dominant** mode of inheritance.

### *Clinical Features*

- More common in males.
- Usually asymptomatic and jaundice is incidentally detected on a routine check.
- **Mild, chronic unconjugated fluctuating hyperbilirubinemia** not associated with other liver functional derangements.
- Characterized by recurrent episodes of jaundice and may be triggered by,

among other things, dehydration, fasting, inter-current disease, menstruation, and overexertion.

- Physical examination is normal, except for mild jaundice.

### ***Investigation***

- **Unconjugated hyperbilirubinemia** (less than 6 mg%). A raised bilirubin level during fasting is the most common diagnostic tool.
- **Urine:** Urobilinogen is increased and bilirubinuria is absent.
- Peripheral smear, reticulocyte count and serum haptoglobin: Normal.

**Treatment:** Usually no treatment is required.

Glucuronosyl-transferase activity may be increased by administering phenobarbital 60 mg BD.

## **Crigler-Najjar Syndrome**

### ***Crigler-Najjar Syndrome Type I***

Rare, **autosomal recessive** disorder.

#### *Etiology*

Due to **complete absence of hepatic UGT1A1** (uridine diphosphate-glucuronosyl-transferase).

#### *Features*

- Characterized by chronic, severe, **unconjugated hyperbilirubinemia** that produce severe jaundice, icterus and **death** secondary to kernicterus **within 18 months** of birth.

#### **Treatment**

- **Phenobarbital** (which induces microsomal enzymes including UGT), has no **effect**.
- Treatment includes daily phototherapy and liver transplantation. Plasmapheresis, calcium phosphate, tin-protoporphyrin and orlistat have been tried. Hepatocyte transplantation and gene therapy are being tried.

### ***Crigler-Najjar Syndrome Type II (Arias Syndrome)***

- **Less severe, nonfatal disorder** and also known as Arias syndrome.
- Autosomal recessive inheritance in most cases.
- **Partial deficiency of UGT1A1** enzyme (<10% of normal).
- Jaundice is milder than type I (serum bilirubin <20 mg/dL) and does not

develop kernicterus.

**Treatment:** Treatment includes ultraviolet light therapy and liver transplantation. Phenobarbital treatment can improve bilirubin glucuronidation by inducing hypertrophy of the hepatocellular endoplasmic reticulum.

## Dubin-Johnson Syndrome

### *Etiology*

- **Benign autosomal recessive** disorder.
- Due to the **complete absence of this multidrug resistance protein 2 (MRP2)** which is required for secretion of conjugated bilirubin from the hepatocytes into canaliculi. This leads to defect in hepatocellular excretion of bilirubin glucuronides across the biliary canalicular membrane.

### *Clinical Features*

- **Chronic or recurrent conjugated hyperbilirubinemia**, generally after puberty.
- Degree of hyperbilirubinemia may be increased by intercurrent illness, oral contraceptives and pregnancy.

### *Investigations*

- **Conjugated hyperbilirubinemia** (usually 2–5 mg/dL).
- Bromosulphthalein (BSP) clearance test shows impaired clearance with reflux into blood at 90 minutes.
- **Bilirubinuria**
- Gallbladder is usually not visualized on oral cholecystography.
- Liver biopsy shows **dark pigment** in centrilobular hepatocytes. This is due to **coarse melanin-like pigmented granules** within the enlarged lysosomes present in the cytoplasm of hepatocytes. Pigment are composed of polymers of epinephrine metabolites.

No treatment is required in most cases. Patients have a normal life expectancy.

## Rotor Syndrome

- Rare form of **asymptomatic conjugated hyperbilirubinemia**.
- Inherited as an **autosomal recessive** trait.

- Due to many defects such as hepatocellular uptake, intracellular binding and excretion of bilirubin pigments.
- Clinical presentation is with **mild jaundice**.

### ***Investigations***

- **Conjugated hyperbilirubinemia**
- **Bilirubinuria.**
- BSP clearance test shows impaired clearance but there is no reflux back into blood.
- Gallbladder is visualized on oral cholecystography.
- Liver is morphologically normal.

### **Charcot's Triad**

**Q. Write short note on Charcot's triad.**

It consists of following in the presence of stones in bile ducts:

- Pain in the right hypochondrium.
- Intermittent or persistent jaundice.
- Fever with chills and rigors due to acute cholangitis.

### **Courvoisier's Law**

**Q. Describe Courvoisier's law.**

In obstruction of common bile duct due to a stone, the gallbladder as a rule is impalpable (no distension). This is because; the gallbladder is usually already shriveled, fibrotic, and nondistensible and hence will not be palpable.

In obstruction from other causes (e.g. carcinoma head of pancreas) distension of the gallbladder is common and hence gallbladder may be palpable.

Exceptions of Courvoisier's law

- Double impaction: Stones, simultaneously occluding the cystic duct and the distal common bile duct (CBD).
- Pancreatic calculus obstructing the ampulla of Vater
- Oriental cholangiohepatitis
- Periampullary carcinoma in patients with cholecystectomy
- Mirizzi syndrome.

# VIRAL HEPATITIS

- Q. Describe the etiology, epidemiology, pathogenesis, clinical features and treatment of viral hepatitis.**
- Q. Write short note on the diagnosis, prevention and management of acute viral hepatitis.**
- Q. Briefly describe anicteric hepatitis.**
- Q. How do you approach to a case of fever with jaundice in a young male? Mention the management.**

## *Etiology*

- Q. List the viruses causing acute hepatitis.**

Various causes of acute hepatitis and types and causes of viral hepatitis are listed in Box 11.12 and Table 11.9 respectively.

### **Box 11.12:** Causes of acute hepatitis.

- Viral hepatitis (Table 11.9)
- Other infections: Leptospirosis, malaria, dengue, brucellosis
- Alcohol
- Drugs: Paracetamol, isoniazid (INH), rifampicin, halothane
- Ischemic hepatitis
- Toxins: Amanita, carbon tetrachloride, yellow phosphorous
- Pregnancy
- Systemic lupus erythematosus (SLE)
- Wilson's disease

**Table 11.9:** Types of viral hepatitis.

<i>Hepatitis caused by common (hepatotropic) viruses</i>	<i>Hepatitis caused by other viruses (nonhepatotropic)</i>
<b>Type of hepatitis</b>	<b>Causative agent</b>
Hepatitis A	• Cytomegalovirus
Hepatitis B	• Epstein-Barr virus
Hepatitis C	• Herpes simplex virus
Delta hepatitis	• Yellow fever virus

## Hepatitis A

**Q. Discuss the clinical features, investigations and management of hepatitis A infection.**

### *Etiology*

- Caused by hepatitis A virus (HAV) which is a nonenveloped, 27 nm, **RNA virus** belonging to the picornavirus group.
- Hepatitis A is the **most common type of viral hepatitis** often occurs in epidemics.
- Most commonly affects children and young adults.
- **Overcrowding and poor sanitation** facilitates the spread.

### *Source of Infection*

Only source of infection is **acutely infected person**.

- Virus replicates in the liver, excreted in bile and then excreted in stool/feces of infected persons for about 2 weeks before the onset of symptoms and then for a further 2 weeks or so.

### *Mode of Spread*

**Fecal-oral route** (either via person-to-person contact or consumption of contaminated food or water). In outbreaks it spreads through water, milk and shell fish.

### *Incubation Period*

**15–45 days** (average 28 days).

There is no carrier state.

Clinical features are discussed together on page 752 of Chapter 11.

### *Extrahepatic Manifestations*

Less frequent in acute HAV infection than in acute HBV infection. Most commonly quickly fading rash (14%) and arthralgias (11%) and uncommonly myocarditis, thrombocytopenia, aplastic anemia, red cell aplasia, leukocytoclastic vasculitis, glomerulonephritis, and arthritis, in which

immune-complex disease is believed to play a pathogenic role.

### ***Prevention and Prophylaxis***

- Maintaining good hygiene and improving social conditions. HAV is resistant to chlorination but is killed by boiling water for 10 minutes.
- **Active immunization:** A formaldehyde-inactivated **HAV vaccine** (contains the single HAV antigen) for active immunization and can be used in individuals above the age of 2 years. It probably provides lifelong immunity.
- **Passive immunization:** Normal human immunoglobulin (0.02 mL/kg IM) made from pooled human plasma is used if exposure to HAV is <2 weeks and can protect from HAV infection for 3 months. HAV vaccine should also be administered.

## **Hepatitis B**

**Q. What are the common causes of viral hepatitis? Discuss the clinical features, complications and management of hepatitis B infection.**

### ***Etiology***

Caused by hepatitis B virus (HBV) which is a **hepatotropic DNA virus** belonging to the family Hepadnaviridae.

#### *Structure and genome of HBV*

- Complete infective virion (HBV virion) is called as Dane particle. It is spherical 42 nm particle and **double-layered** comprising an inner core or nucleocapsid (27 nm) surrounded by an outer envelope of surface protein (HBsAg).
- **Viral genome:** It consists of partially double-stranded circular DNA and has four genes.
  - **HBsAg (S gene):** HBsAg, **hepatitis B surface antigen** is a product of S gene which is secreted into the blood in large amounts. HBsAg is immunogenic.
  - **HBcAg (C gene):** The C gene produces two antigenically different products:
    - ◆ **Hepatitis B core antigen (HBcAg):** Remains intracellular within the hepatocytes and do not circulate in the serum. Hence, not

detectable in the serum of patients.

- ◆ **Hepatitis B e antigen (HBeAg):** Is secreted into serum and is a **surrogate (substitute) marker for high levels of viral replication**. It is essential for the establishment of persistent infection.
- **HBV polymerase (P gene):** A **polymerase (Pol)** is a product of P gene and DNA polymerase enzyme is needed for virus replication.
- **HBxAg (X gene):** **HBx protein** is necessary for virus infectivity and has been **implicated in the pathogenesis of liver cancer** in HBV infection.

**Source of infection:** **Human suffering from hepatitis (acute/chronic) or carriers** is the only source of infection. HBV is 100 times as infectious as human immunodeficiency virus (HIV) and 10 times as infectious as hepatitis C virus (HCV).

### ***Mode of Transmission***

**Q. Write short note on mode of transmission of hepatitis B (serum hepatitis).**

1. **Vertical/congenital transmission:** From mother [who is carrier for HBV (90% HbeAg +ve, 30% HbeAg –ve)] to child may occur in utero, during parturition or soon after birth. It not transmitted by breastfeeding.
2. **Horizontal transmission:** Is the **dominant mode** of transmission.
  - **Parenteral:** It is the major route of transmission but occasionally non-parenteral.
    - By **percutaneous and mucous membrane** exposure to infectious body fluids, through minor cuts/abrasions in the skin or mucous membranes. In children it can be transmitted through minor abrasions or close contact with other children. HBV can survive for long periods on household articles, e.g. toys, toothbrushes and may transmit the infection.
    - **Intravenous route:** Through transfusion of unscreened infected blood or blood products. This mode of spread is rare now, because of routine screening of all blood donors for HBV and HCV. Intravenous drug abuse with sharing of needles and syringes, tattooing and acupuncture are other ways of developing infection.

- **Close personal contact:** Nonparenteral route of transmission include spread through body fluids (virus can be found in these fluids) like saliva, urine, semen and vaginal secretions. However, this requires close personal contact, unprotected **heterosexual or homosexual intercourse**.

**Incubation period: 30–180 days** (mean, 8–12 weeks)

**Chronic carrier state** can develop with HBV infection (1–20%).

### ***Prevention and Prophylaxis***

#### **Q. Write short on prevention and prophylaxis of HBV.**

- **Avoiding risk factors:**
  - Not to share needles
  - Having safe sex
  - Transfuse safe blood and blood products
  - Enforced strict standard safety precautions in laboratories and hospitals to avoid accidental needle punctures and contact with infected body fluids.
- **Active immunization:** By using recombinant vaccines (containing HBsAg). It is advised in following individuals:
  - **Children:** In India, non-percutaneous routes of transmission are quite prevalent and active immunization using vaccine is recommended in all children.
  - **High-risk groups:** For example, health care personnel, hemodialysis patients, injection drug users, hemophiliacs and sexual contacts of HBsAg carriers.
- **Dosage regimen:** Three injections are given into the deltoid muscle at 0, 1 and 6 months. Dose is 10 ug for children under 10 years and 20 ug in children above 10 years. More frequent and larger doses are required in individuals over 50 years of age or clinically ill and/or immunocompromised (including HIV infection or AIDS). Side-effects are very few.
- **Combined prophylaxis:** This consists of vaccination and immunoglobulin. It should be given to individuals with:
  - Accidental needle-stick injury, gross personal contamination with

infected blood and exposure to infected blood in the presence of cuts and grazes.

- All newborn babies of HBsAg-positive mothers.
- Regular sexual partners of HBsAg-positive patients, who have been found to be HBV-negative.
- Dosage: For adults a dose 0.05–0.07 mL/kg body weight hepatitis B immunoglobulin (HBIG) (200 IU to newborns) and the vaccine (IM) given at another site.

**Treatment:** Pegylated interferon alpha, lamivudine, adefovir, entecavir, telbivudine, or tenofovir may be used as initial therapy but lamivudine and telbivudine are not preferred because of high rates of resistance.

## Hepatitis C

**Q. Write short note on hepatitis C.**

### *Etiology*

- Previously called blood-borne non-A, non-B hepatitis.
- It is a small, **enveloped, single-stranded RNA virus** belonging to the family Flaviviridae.
- A characteristic feature is emergence of an endogenous, newly mutated strain. Because of this **genomic instability and antigenic variability, producing an effective HCV vaccine is difficult.**
- HCV has six genotypes and in India, most prevalent is **HCV 3.**
- **Mode of spread:** HCV is not transmitted by breastfeeding.
  - Mainly by the **parenteral route (transfusion** of blood and blood products, and in drug addicts) as a blood-borne infection.
  - Sexual contact (low chances of transmission)
  - Perinatal/vertical transmission
- **Incubation period: 15–160 days** (mean, 7 weeks)
- Nearly 80% infected individuals develop chronic hepatitis.

## Hepatitis D (Delta Hepatitis)

**Q. Write short note/essay on etiology and epidemiology of delta hepatitis.**

## ***Etiology***

- Caused by hepatitis D virus (HDV or delta virus), which is a **defective/incomplete RNA virus** and belongs to the Deltaviridae family. The RNA genome is covered by an outer coat/shell of HBsAg.
- It has no independent existence and requires HBV for its replication and expression.
- Because HDV is dependent on HBV, the duration of HDV infection is determined by the duration of HBV infection. It causes **delta hepatitis** with two clinical patterns.
  - **Acute coinfection:** It develops when individual is exposed simultaneously to serum containing both HDV and HBV. The HBV infection first becomes established and the HBsAg is necessary for development of complete HDV virions.
  - **Superinfection:** It occurs when an individual is already infected with HBV (chronic carrier of HBV) is exposed to a new dose HDV.
- **Mode of spread:** Parenteral route and sexual contact.
- Fulminant hepatitis can follow both patterns of infection but is more common after co-infection.

## **Hepatitis E**

**Q. Write short note/essay on transmission, clinical features and management of hepatitis E infection.**

It was previously called epidemic or enterically transmitted non-A, non-B hepatitis.

## ***Etiology***

- HEV is an unenveloped, single-stranded RNA virus in the Hepevirus genus.
- Viral particles are 32 to 34 nm in diameter.
- Hepatitis E occurs primarily in young to middle-aged adults.
- **Source of infection:** HEV is a **zoonotic disease with animal reservoirs**, such as monkeys, cats, pigs, rodents and dogs. Virions are shed in stool during the acute illness.
- **Mode of transmission:** An **enterically transmitted, water-borne** infection. Common after contamination of water supplies as after monsoon

flooding.

- **Incubation period:** 14–60 days (mean, 5–6 weeks).

### ***Outcome of Infection***

- HEV infection is responsible for more than 30–60% of cases of sporadic acute hepatitis (clinically very similar to hepatitis A) in India. It **produces self-limiting acute hepatitis**.
- It **does not cause chronic liver disease**.
- **High mortality** rate (about 20%) among **pregnant women**.

### ***Prevention and Control***

- Good sanitation and hygiene similar to hepatitis A.
- Vaccine has been developed and used successfully in China.

## **Clinical Feature of Viral Hepatitis**

**Q. Write short note/essay on clinical features of acute hepatitis/hepatitis A /hepatitis B.**

Acute viral hepatitis is the sudden onset of significant aminotransferase elevation due to diffuse necroinflammatory liver injury.

**Acute viral hepatitis** can be caused by any one of four hepatotropic viruses. Its clinical features can be divided into four phases:

### ***Incubation Period***

Acute viral hepatitis develops after an incubation period that varies according to the type of virus (Table 11.10).

### ***Symptomatic Preicteric Phase***

- Usually **last for a 1–2 weeks** before the onset of jaundice.
- **Prodromal symptoms** of acute viral hepatitis are systemic and variable. **Constitutional symptoms are nonspecific** and include anorexia, nausea and vomiting, poor appetite, fatigue, malaise, headache, distaste for cigarettes, etc. A low-grade, fever is more often present in hepatitis A and E than in hepatitis B or C. Hepatitis B may occasionally present with a serum sickness–like immunological syndrome consisting of rashes (e.g. urticaria or a maculopapular rash) and polyarthritis affecting small joints.

- **Upper vague abdominal pain** due to stretching of liver capsule.
- **Dark urine** (conjugated hyperbilirubinemia) and clay-colored stools (due to cholestasis) may be noticed by the patient.

### ***Symptomatic Icteric Phase***

- With the onset of clinical jaundice, the constitutional prodromal symptoms usually diminish.
- Liver becomes enlarged and tender. Pruritis may develop due to bile salt retention.
- Splenomegaly and cervical lymphadenopathy may be observed in about 10–20% of patients.
- Dark urine and pale stool.

### ***Recovery (Convalescence) Phase***

- Constitutional symptoms disappear and appetite improves, jaundice decreases, stools and urine become normal, and liver size decreases.
- Duration of this phase is variable, ranging 2–12 weeks. Usually more prolonged in acute hepatitis B and C.
- Complete clinical and biochemical recovery is observed within 1–2 months after the onset in hepatitis A and E and 3–4 months after the onset in hepatitis B and C.

### **Fulminant Hepatitis**

It can develop in hepatitis B, D and E. It is uncommon with hepatitis C and rare in hepatitis A. With hepatitis E, fulminant hepatitis occurs in nearly 20% cases in pregnant females.

Summary of various hepatotropic viruses are presented in Table 11.10.

**Table 11.10:** Summary of various hepatotropic viruses.

<b>Feature</b>	<b>HAV</b>	<b>HBV</b>	<b>HCV</b>	<b>HDV</b>	<b>HEV</b>
Incubation period in days (range)	30 (15–45)	90 (30–180)	50 (15–160)	90 (30–180)	40 (14–60)
Onset	Acute	Insidious or acute	Insidious	Insidious or acute	Acute
Age group affected	Children, young adults	Young adults, babies, toddlers	Adults, but any age	Any age (similar to HBV)	Young adults

Mode of transmission	Fecal-oral	Parenteral, sexual contact, perinatal	Parenteral, sexual contact, perinatal	Parenteral	Fecal-oral
<b>Clinical</b>					
Severity	Mild	Occasionally severe	Moderate	Occasionally severe	Mild
	Never	10%	80%	5% with coinfection; ≤70% for superinfection	Never
Carrier state	None	1–30%	1.5–3.2%	Variable	None
Progression to cancer	None	+ (Neonatal infection)	+	±	None
Prognosis	Good	Worse	Moderate	Good in acute and poor in chronic	Good
Prophylaxis	Immunoglobulin Inactivated vaccine	Hepatitis B immunoglobulin, recombinant vaccine	None	HBV vaccine (none for HBV carriers)	Vaccine

## Investigations

- **Urine**
  - **Bilirubinuria** (in early stages), and **increased urinary urobilinogen** slight microscopic hematuria and mild proteinuria.
- **Hematological tests**
  - **Leukopenia with a relative lymphocytosis.**
  - Prothrombin time (PT) is prolonged in severe cases signifies extensive hepatocellular damage. This is one of the best indices of prognosis.
  - **Erythrocyte sedimentation rate (ESR) is raised.**
- **Biochemical investigations:**
  - **Aminotransferases (AST, ALT): Raised** and maximum levels are observed during the prodromal phase (400–4000 IU/L). They progressively decline during icteric and recovery phase.
  - **Bilirubin:** Both conjugated and unconjugated bilirubin levels are equally **raised**.
  - **Alkaline phosphatase:** It may be **raised** but usually less than two times the normal.
  - Serum protein: Normal

- Blood glucose: It may be low.
- **Serological tests:** During prodromal phase, low titers of antismooth muscle antibody, rheumatoid factor, antinuclear antibody and heterophil antibody may be observed.

### ***Serological Markers for Viral Hepatitis***

**Q. Write short note on investigations in hepatitis A.**

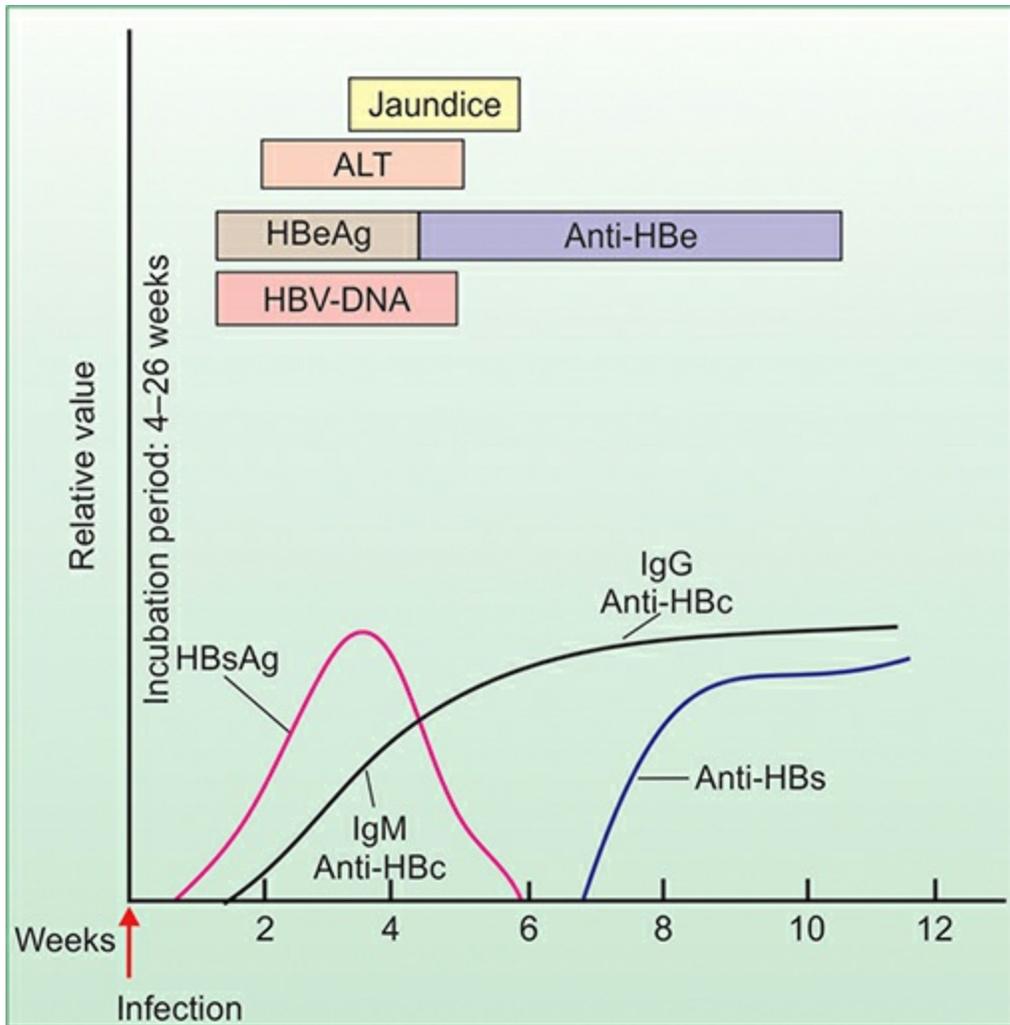

*Hepatitis A*

**Q. Write short note/essay on the laboratory findings in hepatitis A.**

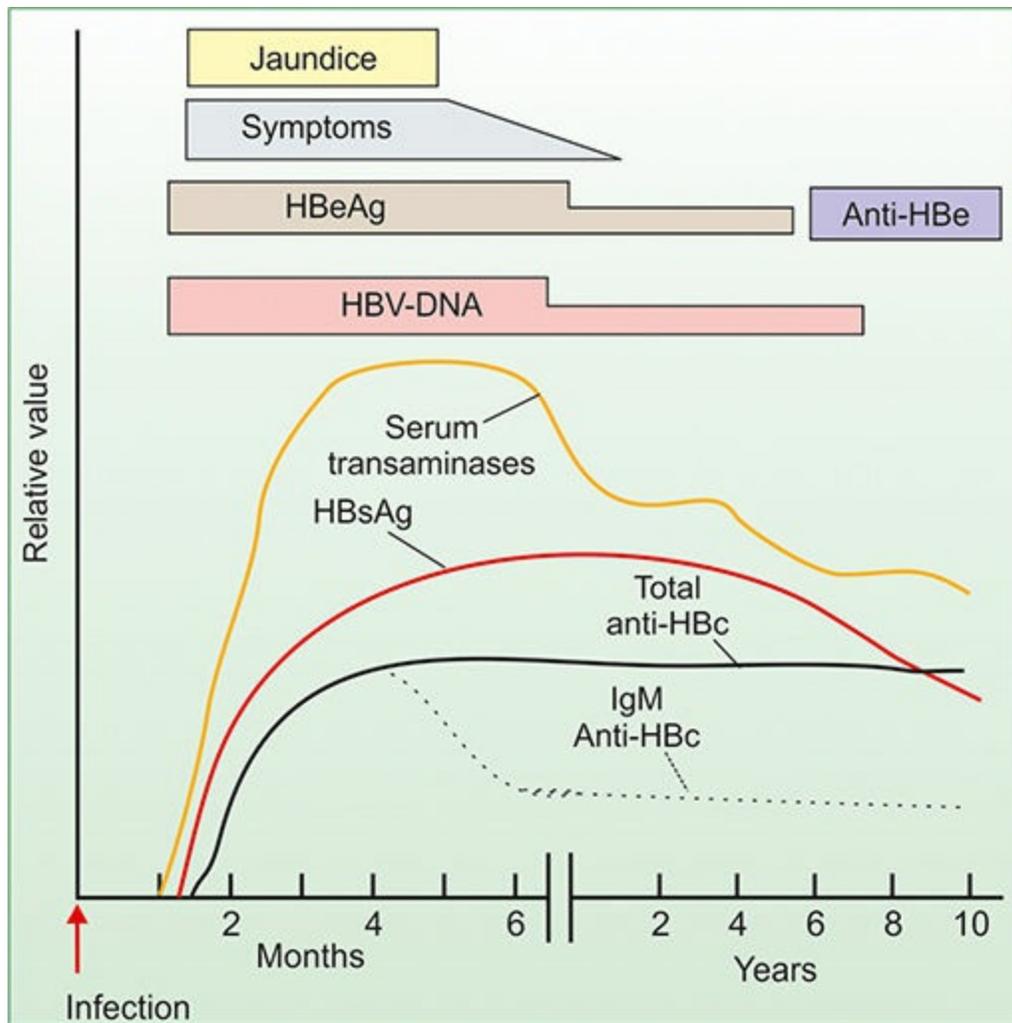

- **IgM anti-HAV (IgM antibody against HAV):** Appears in blood at the onset of symptoms and is a **reliable marker of acute infection**.
- **IgG anti-HAV:** IgM anti-HAV is followed by the appearance of IgG anti-HAV. It represents recovery phase and immunity phase. It persists for years and **provides a lifelong immunity** against reinfection by HAV.
- **Aminotransferase: Raised** ranging from 10 to 100 times the upper limit of the reference range.

*Hepatitis B (Figs. 11.6 and 11.7)*

**Q. Write short note on HBsAg/Australia antigen/hepatitis B surface antigen.**

**Fig. 11.6:** Sequence of serologic markers in acute hepatitis with resolution caused by HBV.

**Fig. 11.7:** Sequence of serologic markers in chronic hepatitis caused by HBV.

### ***Hepatitis B surface antigen (HBsAg)***

- **HBsAg:** It is the **first** virologic marker which appears in serum before the onset of symptoms (late in the incubation period or prodromal phase of hepatitis B). It is a reliable marker of infection. It peaks during the disease and becomes undetectable within 3–6 months.
- **HBsAg, hepatitis B surface antigen** is a product of S gene which is secreted into the blood in large amounts.
- HBsAg is immunogenic. It is located in the capsular material of the virus. HBsAg is also named **Australia antigen**, because of its first detection in Australian aborigine.
- **Significance:**
  - Present in the serum in both acute and chronic hepatitis B; **indicates an**

**infectious state.** Loss of HBsAg plus the development of anti-HBs denotes recovery.

- Persistence of HBsAg beyond 6 months suggests a chronic hepatitis B infection. In such cases anti-HBc remains positive while anti-HBs is negative.
- A negative test for HBsAg indicates HBV infection very unlikely, but does not exclude it.

- Identified by hemagglutination and radioimmunoassay methods.

### ***Anti-HBs***

It is antibody to HBsAg and appears after the disappearance of HBsAg.

**Significance:** Anti-HBs is a **protective antibody and may persist for life providing protection.**

### ***Anti-HBc***

HBcAg is not found in the serum. But its antibody, IgM anti-HBc appears in serum a week or two after the appearance of HBsAg. After about 6 months, the IgM anti-HBc antibody is replaced by IgG anti-HBc. Its significance are:

- **IgM anti-HBc** is the **earliest antibody marker** and **indicates recent infection** (first six months).
- **IgG anti-HBc** indicates **remote infection** (beyond 6 months). Its presence **indicates previous infection with HBV** even when all the other viral markers are not detectable.

### ***HBeAg***

It is detected transiently, early in the course.

- **Their persistence** 6 weeks after the onset of symptoms **indicates infectivity and probable development of chronic hepatitis B.**
- Their absence is a favorable serologic finding.

***Anti-HBe*** is present in the serum in the recovery phase.

***HBV-DNA, and DNA polymerase:*** These appear in serum soon after HBsAg.

- **Significance:** Usually not helpful in the diagnosis of hepatitis B, but may be valuable in assessing prognosis. They indicate active viral replication.

Interpretations of serological findings and its significance in HBV are

summarized in Table 11.11.

HBV viral DNA (HBV DNA): Most accurate marker of virus replication.

**Table 11.11:** Interpretation of serological findings and its significance in HBV.

<i>Antigens</i>		<i>Antibodies</i>			<i>Interpretation</i>
HBsAg	HBeAg	Anti-HBc	Anti-HBs	Anti-HBe	
–	–	–	–	–	Susceptible
–	–	–	+	–	Immunity to HBV caused by previous exposure or vaccination
+	+	IgM +ve and IgG –ve	–	–	<b>Acute hepatitis B</b> , highly infectious High titer in acute hepatitis B and low titer in chronic hepatitis B
–	–	IgM –ve and IgG +ve	+	+	<b>Resolved acute hepatitis B, seroconversion, low infectivity</b>
+	+	IgM –ve and IgG +ve	–	–	<b>Chronic infection</b> or carrier state, <b>high infectivity</b>
+	–	IgG +ve	–	+/-	<b>Chronic infection</b> or carrier state, <b>low infectivity</b>
–	–	–	+	–	<b>HBV vaccination</b>
–	–	+	–	–	<b>Interpretation unclear*</b>

HBV DNA: (i) indicative of active viral replication, (ii) detected in both serum and liver and (iii) its levels indicate response to treatment

\*May be most commonly resolved infection, resolving acute infection, false +ve anti-HBc (thus susceptible) or chronic infection (low level).

## Complications of Acute Viral Hepatitis (Table 11.12)

**Q. Write short note on complications of acute viral hepatitis.**

### Hepatitis C

- **Anti-HCV:** Appears after infection; disappears after recovery; persists in chronic hepatitis C.
- **HCV-RNA:** Appears after exposure.
- Anti-HCV (antibodies against HCV) does not confer immunity.

### Hepatitis D (delta hepatitis)

- **HDV RNA:** Detectable in the blood and liver before and in the early days of acute disease.

- **Anti-HDV:** IgM anti-HDV-most reliable indicator of recent HDV exposure.

### *Hepatitis E*

- Before the onset of clinical illness, HEV RNA and HEV virions can be detected in stool and serum.
- After the onset of clinical illness, serum aminotransferases rises and elevated **IgM anti-HEV** titers also occur simultaneously. After recovery the IgM is replaced with a persistent IgG anti-HEV titre.

**Table 11.12:** Complications of acute viral hepatitis.

<i>Hepatic complications</i>	<i>Extrahepatic complications</i>
Fulminant hepatic failure	Aplastic anemia
Cholestatic viral hepatitis	Renal failure
Relapsing hepatitis	Polyarteritis nodosa
Posthepatitis syndrome	Henoch-Schonlein purpura
Chronic hepatitis	Myocarditis
Cirrhosis	Transverse myelitis
Hepatocellular carcinoma	Peripheral neuropathy

**Table 11.13:** Poor prognostic features of viral hepatitis.

<i>Laboratory findings</i>	<i>Other features</i>
Marked increase in AST and ALT level	Liver not enlarged
Serum bilirubin >20 mg/dL	Renal failure
Prolongation prothrombin time by more than 5 seconds than control	Recurring attacks of hypoglycemia
Low serum albumin	HBV, HCV or HDV infection

Poor prognostic features of viral hepatitis are listed in Table 11.13.

### **Treatment**

#### **General Measures**

- Avoid drugs which are metabolized in the liver, e.g. sedatives and narcotics.
- **Avoid alcohol** during the acute illness.
- No specific dietary modifications are required.
- Elective surgery should be avoided during acute viral hepatitis, as there is a risk of postoperative liver failure.
- Liver transplantation performed for complications of cirrhosis resulting from chronic hepatitis B and C infection.

#### **Hepatitis A**

**Q. Write short note on treatment of hepatitis A infection.**

- **No specific treatment.**
- Rest and dietary measures are not helpful.
- Supportive symptomatic treatment.
- Corticosteroids do not have benefit.

### **Hepatitis B**

**Q. Write short note on treatment of hepatitis B infection.**

#### **Therapeutic goal**

Prevent the progression to end stage liver disease, HCC and death with improvement in quality of life.

- Clearance of HBV DNA.
- Absence of HBeAg and HBsAg and appearance of antibody.
- Normalization of liver enzymes and histology.

#### **Acute Hepatitis B**

In previously healthy adults, recovery occurs in ~99%; therefore, antiviral therapy is not required.

- Mainly symptomatic.
- Monitor HBV markers.
- Entecavir (ETV) or tenofovir (TDF) to be given when HbeAg persists beyond 12 weeks, and in patients who are very ill.

**Box 11.13:** Indications for therapy in chronic hepatitis B.

- Patients with moderate to severe active necroinflammation and/or fibrosis in the liver biopsy
- Presence of cirrhosis
- Immunotolerant patients

#### **Chronic Hepatitis B**

- Indications for therapy (Box 11.13)
- Antiviral agents:
  - First line: Most commonly used include **interferon, entecavir and tenofovir.**
  - Second line: **Telbivudine, adefovir and lamivudine.**

**Postexposure Prophylaxis to Prevent Hepatitis B Virus Infection (Described in detail in Chapter 5).**

#### **Hepatitis C**

- **Goals of treatment of HCV:** (1) Eradication of virus, (2) reduce progression of disease, (3) histological improvement and (4) decrease frequency of HCC.
- **Interferon- $\alpha$**  is used in acute hepatitis C to prevent chronic disease.
- **HCV:** Progression of fibrosis determines the prognosis and liver biopsy is the gold standard to assess fibrosis.

#### **Hepatitis D**

Active liver disease (raised ALT levels and/or inflammation on biopsy) is treated with peginterferon  $\alpha$ -2a and adefovir for 12 months.

## ***Transfusion Associated Hepatitis (TAH)***

**Q. Write short essay on transfusion associated hepatitis.**

These include HCV and/or HBV (discussed above).

## **CHRONIC HEPATITIS**

**Q. Discuss the classification, etiology, pathology, clinical features, complications, prevention and management of chronic hepatitis/chronic hepatitis B infection.**

**Q. Write short essay on chronic active hepatitis.**

### **Definition**

Chronic hepatitis is defined as **symptomatic, biochemical, or serologic evidence of hepatic disease for more than 6 months**. Microscopically, there should be inflammation and necrosis in the liver.

### **Classification**

**Older classification:** Previously chronic hepatitis was classified

- Milder forms: (i) Chronic persistent hepatitis (CPH) and (ii) Chronic lobular hepatitis (CLH)
- Severe forms: Chronic active hepatitis (CAH).

However, this classification is not very helpful in determining the prognosis.

**Present classification:** In order to assess response to therapy and prognosis, present classification is based on combination of three factors (Box 11.14).

**Box 11.14:** Basis of present classification of chronic hepatitis.

- **Etiology:** Cause of hepatitis
- **Grade:** Histologic activity
- **Stage:** Degree of progression

## ***Classification Based on the Causes of Chronic Hepatitis (Table 11.14)***

**Table 11.14:** Classification based on the causes of chronic hepatitis.

A. Chronic viral hepatitis <ul style="list-style-type: none"> <li>• Chronic hepatitis B</li> <li>• Chronic hepatitis B + hepatitis D</li> <li>• Chronic hepatitis C</li> </ul>	B. Drug-induced chronic hepatitis <ul style="list-style-type: none"> <li>• Methyldopa</li> <li>• Isoniazid</li> <li>• Ketoconazole</li> <li>• Nitrofurantoin</li> </ul>
C. Autoimmune hepatitis	D. Hereditary: Wilson's disease
E. Unknown cause, or cryptogenic chronic hepatitis	F. Others: Inflammatory bowel disease (ulcerative colitis) and rarely alcohol

### ***Classification Based on the Grade of Chronic Hepatitis***

Grade is a histological assessment of inflammation and necrosis observed on the liver biopsy. It indicates severity of liver disease. The histological features assessed are interface hepatitis, bridging necrosis, interlobular necrosis, degree of portal inflammation and fibrosis.

This is also known as **histologic activity index (HAI) or Knodell-Ishak score**. Other staging systems include Scheuer score and Metavir score.

### ***Classification Based on Stage of Chronic Hepatitis***

- Indicates level of progression of disease.
- Based on the degree or extent of fibrosis (Box 11.15).

### **Autoimmune Hepatitis (AIH)**

**Q. Write short note on clinical features and treatment of autoimmune hepatitis.**

Autoimmune hepatitis is a **chronic and progressive (unresolving) hepatitis** of unknown cause. No features are absolutely diagnostic and is associated with **circulating autoantibodies and hypergammaglobulinemia**.

**Box 11.15:** Staging of chronic hepatitis based on degree of fibrosis.

<b><i>Degree of fibrosis</i></b>	<b><i>Stage</i></b>
No fibrosis	0
Mild portal fibrosis in some areas	1
Moderate portal fibrosis in most areas	2
Bridging fibrosis—few (portal to portal)	3
Bridging fibrosis—many (portal to portal and portal to central)	4
Incomplete cirrhosis	5

## ***Clinical Features***

- **May be asymptomatic or** present with **fatigue** (most common), **anorexia, jaundice, myalgia and diarrhea.**
- **Acute hepatitis:** In about 30% of cases, it may present as acute hepatitis similar to viral hepatitis, which do not resolve with time.
- **Fulminant hepatic failure (FHF) or asymptomatic elevation of serum ALT.**
- **Cirrhosis:** In about 25% patients.
- **Jaundice** may be mild to moderate and is found in 69% of patients.

**Box 11.16:** Classification of autoimmune hepatitis based on immunological markers.

Based on the differences in immunological markers AIH is divided into:

- **Type 1 AIH** is characterized by **anti-smooth muscle antibodies (SMAs)** and **antinuclear antibodies (ANA)**, or both. Most commonly seen in females and associated with extra- hepatic immunologic diseases like autoimmune thyroiditis, Graves' disease, ulcerative colitis, rheumatoid arthritis, Coombs-positive hemolytic anemia, etc.
- **Type 2 AIH** is characterized by **antibodies to liver/kidney microsome type 1 (anti-LKM1)**. Most affected persons are children.
- **Type 3 AIH: Presence of antibodies to** soluble liver antigen/liver pancreas (anti-SLP/LP).

## ***Investigations***

### *Biochemical findings*

- **Serum aminotransferases:** High and more than 10 times during relapses.
- **Serum bilirubin:** Mildly raised usually less than 6 mg/dL.
- **Serum alkaline phosphatase:** Mildly raised.
- **Serum  $\gamma$ -globulins:** High. Hypergammaglobulinemia is polyclonal; the IgG fraction predominates.
- **Serum albumin:** Low.
- Serum  $\alpha$  1-antitrypsin, serum ceruloplasmin, iron and ferritin levels: Normal.

### *Autoantibodies*

Classification of autoimmune hepatitis based on immunological markers and

autoantibodies is presented in Box 11.16.

### Other tests

- HBsAg and other viral markers: Negative.
- Prothrombin time: Prolonged.

### Liver biopsy

#### Treatment

- Initially, **prednisolone 30 mg given orally daily for 2 weeks**, followed by gradually tapering the dose as the liver function improves and then a maintenance dose of 10–15 mg daily. Maintenance dose to be given for at least 2 years after LFT has become normal.
- **Azathioprine** in the dose of 1–2 mg/kg daily to be added as a steroid-sparing agent and in some patients as sole long-term maintenance therapy or if maintenance dose of prednisolone is more than 10 mg/day.
- **Other immunosuppressive agents:** Mycophenolate, cyclosporine and tacrolimus are used in resistant cases when there is no response to above treatment.
- **Duration of treatment:** Lifelong in most cases.
- **Liver transplantation:** It is performed if treatment fails.

## Chronic Hepatitis B

### Q. Write short note on complications of HBV infection.

- Chronic hepatitis B virus (HBV) infection occurs following an acute HBV infection (may be subclinical) and occurs **in about 1–10%** of patients.
- HBV infection is considered as chronic when the HBsAg (hepatitis B surface antigen) persists for more than 6 months.
- **May progress to cirrhosis and hepatocellular carcinoma.**
- **Risk of chronic hepatitis:** Depends on:
  - **Age at which the contact of acute infection:** Chronic hepatitis occurs **more commonly with neonatal (90%) or childhood (20–50% below the age of 5 years) infection** rather than in adult life (<10%).
  - **Immune status:** In immunocompetent adults, the incidence of acute hepatitis is high while chronic infection is rare (1–2% of cases).

Other conditions where incidence of chronic hepatitis B infection is high are given in Table 11.15.

**Table 11.15:** Conditions associated with chronic hepatitis B state.

• Down syndrome

• Polyarteritis nodosa

- |                       |                                    |
|-----------------------|------------------------------------|
| • Lepromatous leprosy | • Patients on chronic hemodialysis |
| • Leukemias           | • Needle using drug addicts        |
| • Hodgkin lymphoma    | • HIV infection                    |

## ***Phases of Chronic HBV Infection***

Chronic HBV infection is a dynamic process and occurs in three major phases: (1) immune tolerant, (2) immune-active and (3) inactive carrier phases.

1. **Immune-tolerant phase:** Characteristic features are:
  - **Asymptomatic** and frequent **in children**. Infection during birth or in early childhood develop prolonged immune-tolerant phase, and disease progresses even after the disappearance of HBeAg in some of these patients.
  - **Active viral replication** in liver but **little or no evidence of disease activity**.
  - **HBsAg and HBeAg positive** and **very high levels of serum HBV DNA**.
  - Normal liver function tests.
  - Liver biopsy shows no inflammation or fibrosis.
  - May **lasts for decades**. Therefore, lifelong monitoring is necessary.
2. Immune-active phase (chronic hepatitis): Most patients with immune-tolerant phase progress to the immune-active phase.
  - **Vigorous immune response**.

**Criteria for chronic HBV active hepatitis** are:

  - Liver biopsy shows **chronic hepatitis** with moderate or severe necroinflammation and fibrosis.
  - **Evidence of active HBV replication: High levels of HBV DNA and HBeAg**.
  - Persistent or intermittent **elevation of serum aminotransferases (ALT/AST)**.
3. **Carrier phase with low replication:** Incidence varies. Most patients with chronic HBV infection will eventually enter inactive carrier phase.
  - **Criteria for carrier phase:**
    - **Serological findings:**
      - ♦ **HBsAg positive** in the serum >6 months.
      - ♦ **HBeAg negative** and **HBe antibody positive** (seroconversion from HBeAg to HBeAb).
      - ♦ **Undetectable or low levels** (below 400 iu/L) **of HBV DNA** in the serum.
      - ♦ **Normal aminotransferase (ALT)** levels.
    - **Liver biopsy** does not show any significant hepatitis.
  - **Low risk for hepatocellular carcinoma**.
  - Liver abnormalities generally do not progress to more severe disease.
  - Disease may be re-activated by severe immunosuppression (e.g. during chemotherapy for cancer or with bone marrow transplantation).
  - Individuals **infected during adults or adolescents** usually **become inactive carriers** after they clear HBeAg.
4. **Chronic HBeAg negative state:**
  - Patients harbor HBV variants with mutations that prevent production or have low HBeAg.

- HBV DNA levels high, liver enzymes are raised and presence of active histological activity.
- Late phase in the natural history of chronic HBV and often seen in older patients with advanced disease.

HBV genotype C infection (prevalent in India) have an increased of developing cirrhosis and hepatocellular carcinoma.

### ***Clinical Features***

- Asymptomatic or may develop severe end-stage liver disease.
- **Symptoms: Fatigue, malaise and anorexia**, persistent or intermittent jaundice.
- **During end-stage liver disease:** Symptoms due to complications of cirrhosis occur.
- **Extrahepatic manifestations:** Arthralgias, arthritis, vasculitis, glomerulonephritis and polyarthritis nodosa.
- Mild hepatomegaly
- Long-standing cases **may develop hepatocellular carcinoma.**

### ***Investigations***

*Biochemical investigations:*

- **Serum aminotransferase: Mildly elevated** but may be as high as 1000 units. ALT (SGPT) tends to be more raised than compared to AST (SGOT). Once cirrhosis develops AST levels exceeds ALT.
- **Serum bilirubin:** May be normal or raised up to 10 mg/dL.
- **Serum proteins: Hypoalbuminemia** in severe cases and hyperglobulinemia.

**Prothrombin time:** Prolonged

*Serological markers (Box 11.17)*

**Box 11.17:** Serological markers of chronic hepatitis B.

- **Positive HBsAg**
- **Positive IgG anti-HBc, negative IgM anti-HBc**
- **Positive HBe antigen or rarely, positive anti-HBe**
- **Positive HBV-DNA**

**Treatment for Chronic Hepatitis B (Flowchart 11.1)**

**Criteria:** Three criteria are used namely (1) serum levels of HBV DNA, (2) serum levels of ALT and (3) histological grade and stage.

- Serum HBV-DNA above 2000 iu/mL (about >10,000 copies/mL).
- Serum ALT level greater than two times normal.
- Moderate to severe active necroinflammation and/or fibrosis in the liver biopsy

**Box 11.18:** Aim of treatment of chronic hepatitis B.

- Seroconversion of HBeAg when present to anti-HBe. When HBeAg disappears, remission is usually attained for several years.
- Reduction of HBV DNA to 400 iu/L or less.
- Achieve normal levels of serum ALT.
- Histological improvement in inflammation and fibrosis in the liver biopsy.
- Patients usually remain HBsAg positive, but loss of serum HBsAg indicates a good response.

In **presence of cirrhosis** (compensated or decompensated) **oral antiviral agents** are recommended, but liver transplantation may be necessary. Immunotolerant patients, usually young with normal ALT and high HBV DNA levels, without evidence of liver disease do not need therapy, but be regularly followed-up.

**Aim of treatment (Box 11.18)**

**Box 11.19:** Drugs used for chronic hepatitis B.

- Peginterferon in combination with other agents:
  - Lamivudine plus peginterferon
  - Entecavir plus peginterferon
  - Tenofovir plus peginterferon
  - Adefovir plus peginterferon
  - Telbivudine plus peginterferon
- Lamivudine plus adefovir dipivoxil
- Tenofovir disoproxil plus entecavir
- Tenofovir disoproxil plus emtricitabine

**Antiviral agents:** Most commonly used drugs (Box 11.19) are:

- **Pegylated  $\alpha$ -2a interferon**
  - Response (defined as loss of HBeAg and HBV-DNA) occurs in 25–40% of cases.
  - **Dose:** 180  $\mu$ g once a week subcutaneously and produces response after 48 weeks of treatment.
  - **Side effects:** Acute flu-like symptoms, malaise, headache, depression, reversible hair loss, bone marrow depression, thrombocytopenia and infection.
  - Patients with HIV respond poorly and it should not be given to patient with cirrhosis.
- **Entecavir:** A cyclopentyl guanosine analog that is a very effective and quickly reduces HBV DNA by 48 weeks.
- **Tenofovir:** It is a cytosine nucleoside analog which is also very effective and has a similar potency to entecavir. It is used for HIV patients with HBV infection.
- **Lamivudine:** It is well tolerated. However, rate of development of viral resistance (80%) is high and itself may cause hepatitis. Hence, lamivudine monotherapy is no longer recommended.

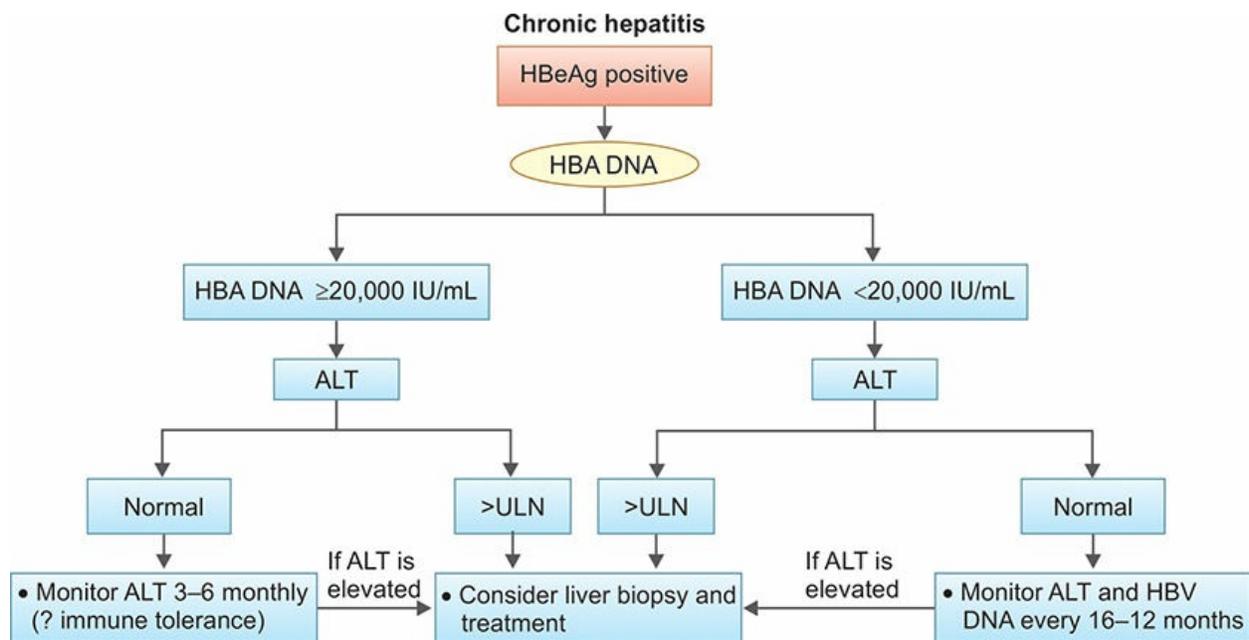

Dosage is 100 mg/day given orally once a day until HBeAg becomes negative.

- **Adefovir dipivoxil:** A nucleotide reverse transcriptase inhibitor. It may be used in patients who develop resistance to lamivudine.
- **Telbivudine:** An L-nucleoside that may cause elevation of CPK.

## Prognosis

- Development of chronic hepatitis depends on the age at which infection is acquired.
- Development of cirrhosis is associated with a poor prognosis.
- Hepatocellular carcinoma is one of the most common carcinomas in HBV-endemic areas.

**Flowchart 11.1:** Treatment algorithm for HBeAg positive chronic hepatitis B.

(HBeAg: hepatitis B 'e' antigen; HBV DNA: hepatitis B DNA; ALT: alanine transaminase; ULN: upper limit normal)

## Chronic Hepatitis C

### **Q. Write short note on complications of HCV.**

- **Chronic hepatitis occurs in the majority (70–85%) of individuals infected by HCV** and is the hallmark of HCV infection.
- **Cirrhosis develops over 5–20 years in 20–30% of patients**, while hepatocellular carcinoma also develops in several patients especially with cirrhosis.

- **Factors that accelerate progression** to advanced liver disease includes: **Alcohol consumption, coinfection with HIV or HBV, and older age** at the time of acquiring the infection.

### *Clinical Features*

- **Usually asymptomatic.** Detected following a routine biochemical test when mild elevations in the aminotransferases (usually ALT) are detected.
- Clinical features **when present** are **similar to chronic hepatitis B.** Most common being fatigue and jaundice being rare.
- Extrahepatic features (Table 11.16).

### *Investigations*

- **HCV antibody** in the serum detected in more than 95% cases.
- **HCV RNA** detectable in all patient.
- **Liver biopsy** is performed if active treatment is being considered. The histological changes are highly variable. Most commonly shows features of chronic hepatitis, often with **lymphoid follicles in the portal tracts, and fatty change.**
- Other laboratory features are similar to those seen in chronic hepatitis B.

### **Extrahepatic Manifestations of Hepatitis B and Hepatitis C Virus Infection (Table 11.16)**

**Table 11.16:** Extrahepatic manifestations of B and hepatitis C virus infection.

<b><i>Hepatitis B virus infection</i></b>	
Polyarteritis nodosa	Glomerulonephritis
Cryoglobulinemia	Serum sickness-like symptoms
Papular acrodermatitis (in children)	Aplastic anemia
<b><i>Hepatitis C virus infection</i></b>	
<i>Proven Associations</i>	<i>Possible Associations</i>
<ul style="list-style-type: none"> <li>• Autoimmune thyroiditis</li> <li>• B-cell non-Hodgkin’s lymphoma</li> <li>• Diabetes mellitus</li> <li>• Lichen planus</li> <li>• Mixed cryoglobulinemia</li> <li>• Monoclonal gammopathies</li> <li>• Porphyria cutanea tarda</li> </ul>	<ul style="list-style-type: none"> <li>• Chronic polyarthritis</li> <li>• Idiopathic pulmonary fibrosis</li> <li>• Non-cryoglobulinemic nephropathies</li> <li>• Sicca syndrome</li> <li>• Carcinoma of thyroid</li> <li>• Renal cell carcinoma</li> <li>• Vitiligo</li> </ul>

- Glomerulonephritis

- Cutaneous necrotizing vasculitis

### Treatment of Chronic Hepatitis C (Tables 11.17 and 11.18)

- **Indications for treatment:**

- **Chronic hepatitis** on liver histology with **HCV-RNA in the serum** and raised serum aminotransferases for more than 6 months.
- Chronic hepatitis with persistently normal aminotransferases.
- **Cirrhosis, fibrosis** or **moderate inflammation** on liver biopsy (biopsy not mandatory).

- **Aim of treatment:** To eliminate the HCV RNA from the serum in order to **prevent:**

- **Progression** of active liver disease.
- Development of hepatocellular carcinoma.

- **Liver transplant:** For patients with decompensated cirrhosis

**Table 11.17: Drugs for the treatment of chronic hepatitis C.**

## ACUTE LIVER FAILURE

**Q. Define fulminant hepatic failure. Discuss the causes, pathology,**

## clinical features, investigations, complications and management of fulminate hepatic failure.

**Q. Enumerate the precipitating causes of hepatic coma in a case of chronic liver disease. Discuss the diagnosis and treatment of hepatic coma.**

### Definition

Acute liver failure is defined as the rapid progressive deterioration in liver function, specifically coagulopathy and mental status changes (encephalopathy) in a patient without known prior liver disease.

### Classification of Acute Liver Failure

Acute liver failure is subclassified into hyperacute, acute and subacute, depending on the interval between onset of jaundice and encephalopathy.

1. **Hyperacute hepatic failure:** If encephalopathy develops within 7 days, it is called **hyperacute hepatic failure** and has better prognosis than acute hepatic failure.
2. **Fulminant hepatic failure:** In this, encephalopathy develops within 4 weeks (8–28 days) from onset of symptoms in a patient with a previously normal liver.
3. **Subacute hepatic failure:** If hepatic failure develops at a slower pace (4–12 weeks), it is called **subacute or subfulminant hepatic failure**.

### Fulminant Hepatic Failure (FHF)

It is defined as severe hepatic failure (insufficiency) in which encephalopathy develops within 4 weeks (8–28 days) from onset of symptoms in a patient with a previously normal liver.

**Etiology:** FHF is a rare but often life-threatening condition the various causes are listed in Table 11.19.

**Table 11.19:** Important causes of fulminant hepatic failure.

A. Viruses: HAV and HAB. Occasionally, HCV and others

B. Non-infectious causes

1. Drugs: Important examples include:
  - Analgesics (e.g. paracetamol)
  - Monoamine oxidase inhibitors

- Antituberculosis (e.g. isoniazid)
- Antiepileptic (e.g. valproate)
- Halogenated anesthetics
- 'Social' drugs (e.g. 'Ecstasy')

2. Toxins: Amanita phalloides (mushroom) poisoning

3. Miscellaneous

- Wilson's disease
- HELLP syndrome
- Eclampsia, preeclampsia
- Acute fatty liver of pregnancy
- Reye's syndrome
- Autoimmune hepatitis
- Budd-Chiari syndrome
- Shock, ischemic hepatitis

4. Unknown

## ***Clinical Features***

1. **General features:**

- Jaundice, weakness, nausea and vomiting.
- Pain in the right hypochondrium.
- Small liver and liver dullness absent on percussion.
- Ascites and edema develop later.

2. **Features of hepatic encephalopathy:**

- **Mental state:** It varies from mild drowsiness, confusion and disorientation (grades I and II) to unresponsive coma (grade IV) with convulsions (refer Table 11.33).
- **Fetor hepaticus and flapping tremor** (asterixis) is common.
- Ascites and splenomegaly are rare.
- Fever, vomiting, hypotension and hypoglycemia may be observed.
- Spasticity and extension of the arms and legs and plantar responses remain flexor until late.

3. **Features of cerebral edema:** Cerebral edema develops in ~80% of patients.

- Bradycardia, intracranial hypertension and irregular respiration (Cushing's triad).
- Pupils: Unequal or abnormally reacting or fixed pupils.

- Hyperventilation and hyperreflexia.
- Consequences: Intracranial hypertension and brain herniation are the most common causes of death.

## ***Investigations***

Investigations to determine the cause of acute liver failure.

- **Serum findings:**
  - **Hyperbilirubinemia:** Serum bilirubin is raised.
  - **Serum aminotransferases: Raised**, but are not useful indicators of the course of the disease as they tend to fall with progressive liver damage.
  - **Coagulation factors: Decreased** including prothrombin and factor V. Prothrombin time is prolonged.
  - Serum proteins: **Hypoalbuminemia**
  - **Plasma and urine amino acids are increased.**
  - **Blood ammonia levels: Raised.**
- **Urine:** Shows protein, bilirubin and urobilinogen.
- **Peripheral blood:** Leukocytosis and thrombocytopenia.
- **EEG:** It may be help in grading the encephalopathy.
- **Ultrasound:** To detect liver size and for any evidence of underlying liver pathology.
- **CSF:** Intracranial pressure is raised, but CSF is normal.

**Complications of fulminant hepatic failure** are listed in Table 11.20.

**Table 11.20:** Complications of fulminant hepatic failure.

• Encephalopathy	• Bacterial and fungal infections
• Cerebral edema	• Gastrointestinal bleeding, hypotension
• Respiratory failure	• Hypoglycemia, hypokalemia
• Renal failure	• Hypothermia
• Pancreatitis	• Acid-base imbalance
• Hypocalcemia, hypomagnesemia	

**Management:** There is no specific treatment. Pathogenesis and management of major complications of acute liver failure are summarized in Table 11.21.

- General measures:

- **Monitor vital signs, urine output, renal functions, central venous pressure, and electrolytes.**
- **Maintain fluid and electrolyte balance.** Hypokalemia, hypomagnesemia, hypophosphatemia, hypocalcemia and hypoglycemia should be corrected.
- **Supply of adequate calories:** Glucose (300 g/day) orally or by nasogastric tube or by infusion into a central vein.

**Table 11.21: Pathogenesis and management of major complications of acute liver failure.**

<b>Complication</b>	<b>Pathogenesis</b>	<b>Management</b>
Hypoglycemia	Diminished hepatic glucose synthesis	Blood glucose monitoring
		Intravenous glucose supplementation (10 or 20% dextrose)
Encephalopathy	Cerebral edema	(refer pages 822-3)
Infections	Reduced immune function	Aseptic medical, nursing care
	Invasive procedures	Daily surveillance cultures of blood, urine, and sputum
		High index of suspicion for bacterial and fungal infection
		Presumptive antibiotics for gram-negative organisms, anaerobes, and skin flora
		Consider antifungal therapy if patient worsens despite antibacterial coverage
Gastrointestinal hemorrhage	Stress ulceration	Nasogastric tube placement. Intravenous H <sub>2</sub> receptor antagonist or proton pump inhibitor
Coagulopathy	Reduced clotting factor synthesis	Parenteral vitamin K
	Thrombocytopenia	Platelet infusions for bleeding and before procedures
	Fibrinolysis	Plasma infusions for bleeding and before procedures
		Cryoprecipitate for bleeding with hypofibrinogenemia
		Recombinant factor VIIa
Hypotension	Hypovolemia	Hemodynamic monitoring of central venous pressures
	Decreased vascular resistance	Volume repletion with blood or colloid
		α-Adrenergic agents
Respiratory failure	Acute respiratory distress syndrome (ARDS)	Hemodynamic monitoring of central venous pressures
		Mechanical ventilation

Pancreatitis	Hypoxia	Supportive care, including supplemental oxygen if needed
		Abdominal CT to exclude necrotizing pancreatitis
Renal failure	Hypovolemia	Hemodynamic monitoring of central venous pressures
	Hepatorenal syndrome	Volume repletion with blood or colloid
	Acute tubular necrosis	Avoidance of nephrotoxic agents (e.g. aminoglycosides, nonsteroidal anti-inflammatory drugs, contrast dye)
		Oral N-acetylcysteine prior to intravenous contrast agent
		Hemofiltration, dialysis

**Prognosis:** The mortality is ~80% without liver transplantation, and ~35% with transplantation.

## Reye's Syndrome

### Q. Describe Reye's syndrome.

- Reye/Reye's syndrome is a rapidly progressive encephalopathy with hepatic dysfunction, which begins several days after apparent recovery from a viral illness, especially varicella or influenza A or B. History of aspirin intake may be present.
- **Liver shows severe fatty change.**
- **Raised ammonia levels and liver enzymes.**
- Usually no jaundice.

## FATTY LIVER

### Q. Discuss fatty liver and its causes.

Fatty liver (steatosis) is **abnormal accumulations of triglycerides within cytosol of the parenchymal cells.**

### Causes of fatty liver (Table 11.22)

**Table 11.22:** Various causes of fatty liver.

<i>Alcohol</i>	<i>Non-alcoholic fatty liver disease (NAFLD)</i>
<b>Drugs</b>	<b>Nutritional</b>
<ul style="list-style-type: none"> <li>• Glucocorticoids, amiodarone, tetracycline,</li> </ul>	<ul style="list-style-type: none"> <li>• Protein-calorie malnutrition</li> </ul>

aspirin, methotrexate, didanosine, zidovudine, tamoxifene, amiodarone	<ul style="list-style-type: none"> <li>• Total parenteral nutrition</li> <li>• Rapid weight loss/obesity</li> </ul>
<b>Metabolic</b>	<b>Miscellaneous</b>
<ul style="list-style-type: none"> <li>• Diabetes</li> <li>• Lipodystrophy</li> <li>• Pregnancy (acute fatty liver)</li> </ul>	<ul style="list-style-type: none"> <li>• Inflammatory bowel disease</li> <li>• HIV infection</li> <li>• Chronic hepatitis C</li> <li>• Toxic mushrooms (<i>Amanita phalloides</i>)</li> <li>• Reye's syndrome</li> <li>• Obstructive sleep apnea</li> <li>• Indian childhood cirrhosis</li> </ul>

## Non-alcoholic Fatty Liver Disease (NAFLD), Non-alcoholic Steatosis and Non-alcoholic Steatohepatitis (NASH)

**Q. Write short note on non-alcoholic fatty liver disease (NAFLD); non-alcoholic steatohepatitis (NASH).**

Non-alcoholic fatty liver disease (NAFLD) is a disease of affluent societies. Its prevalence increases in proportion to the rise in obesity. Its progression accounts for the majority of cryptogenic cirrhosis.

It is increasingly recognized condition and is the most common cause of chronic liver disease after hepatitis B, hepatitis C and alcohol.

### ***Classification***

- **Simple fatty liver disease** with favorable prognosis.
- **Non-alcoholic steatohepatitis (NASH)** associated with fibrosis and progression to cirrhosis and sometimes to hepatocellular carcinoma.

### ***Risk Factors for NAFLD***

Increased prevalence in those with the metabolic syndrome.

- **Obesity, hypertension, type 2 diabetes mellitus, hyperlipidemia and insulin resistance.**
- **Rare causes:** Tamoxifen, amiodarone and exposure to certain petrochemicals.
- **Pathogenesis:** NASH is induced by two consecutive steps: Excess fat accumulation and subsequent necroinflammation in the liver (Fig. 11.8).

### ***Clinical Features***

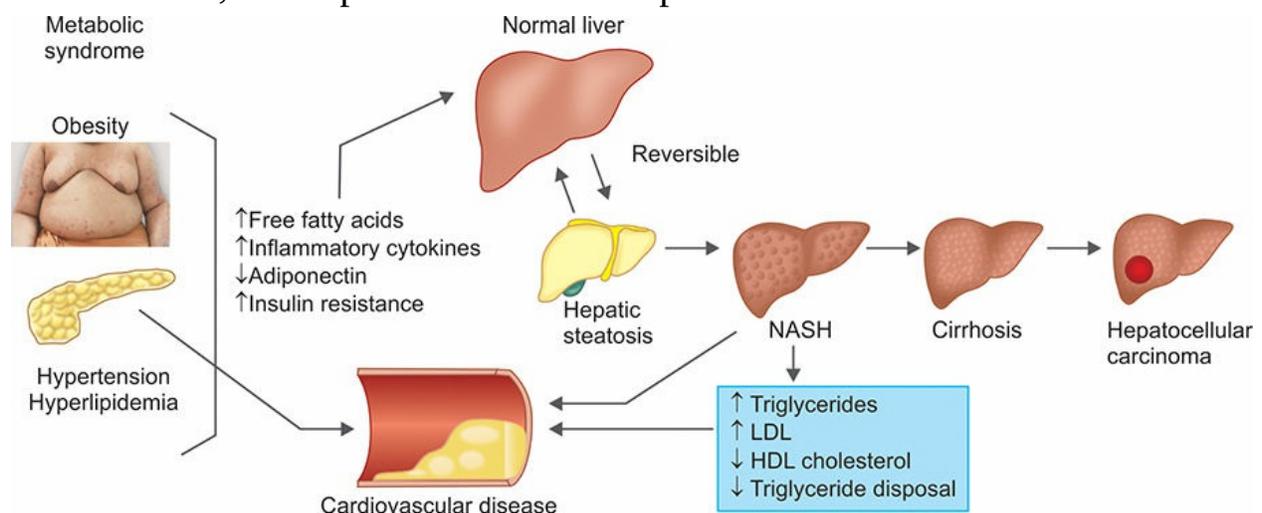

- Most are **asymptomatic** at the time of diagnosis and many patients are **obese**.
- Some have fatigue, malaise and a sensation of fullness in the upper abdomen.
- **Hepatomegaly** is the only sign in most patients.

## Diagnosis of NAFLD

Patient with mild to moderately elevated serum transaminases, no history of alcohol abuse and a negative chronic liver disease screen.

## Investigations

- **Mild elevation of serum aminotransferases** are frequently the sole abnormality with AST: ALT <1. This ratio increases as fibrosis advances. May be only isolated elevation of the GGT. Elevated ALP in about 30% of patients.
- **Ferritin levels are increased** in 20–50% of patients.
- **Autoantibodies in about 25%** patients with more advanced fibrosis.
- Ultrasound and CT features: Similar to those in alcoholic fatty liver.
- **Liver biopsy:**
  - **Best diagnostic tool for confirmation and staging the disease.**
  - Microscopic changes are **similar to those of alcohol-induced** hepatic injury and range from simple fatty change to fat and inflammation (steatohepatitis) and fibrosis. NASH is characterized by fat, Mallory bodies, neutrophil infiltration and pericellular fibrosis.

**Fig. 11.8:** Pathogenesis of non-alcoholic fatty liver disease (NAFLD).

(NASH: non-alcoholic steatohepatitis; LDL: low-density lipoprotein; HDL: high density lipoprotein)

#### Management/Treatment

- Weight loss, control of diabetes and hyperlipidemia in the early stages.
- Some drugs like metformin, thiazolidinediones (e.g. pioglitazone), liraglutide, ursodeoxycholic acid (UDCA), vitamin E, Orlistat, Obeticholic acid, Aramchol, Betaine, Losartan pentoxipylline and atorvastatin have shown some promise.
- Liver transplantation for end-stage cirrhosis. Unfortunately, it may recur in the graft.
- Regular follow-up, particularly for steatohepatitis.

**Table 11.23:** Amount of alcohol consumption and its associated risk of alcoholic liver disease in male.

<i>Amount of ingestion per day</i>	<i>Degree of risk</i>
160 g ethanol (20 single drinks)	High
80 g ethanol (10 single drinks)	Medium
40 g ethanol (five single drinks)	Low

## ALCOHOLIC LIVER DISEASE

### **Q.** Write short essay/note on alcoholic liver disease.

Chronic and excessive consumption of alcohol can produce a wide spectrum of liver disease which can be divided mainly into four major lesions:

1. Fatty liver
2. Alcoholic hepatitis
3. Alcoholic cirrhosis (refer later)
4. Hepatocellular carcinoma

Threshold for alcohol and risk of alcoholic liver disease: Generally, the effects of alcohol are worse in women compared to men and amount of alcohol with degree of risk in male are presented in Table 11.23.

For women, the above figures should be reduced by 50%. Alcohol by volume (ABV) of various alcoholic beverages is shown in Box 11.20.

### **Box 11.20:** Alcohol percentage content.

- Vodka | ABV: 40–95%
- Gin | ABV: 36–50%

- Rum | ABV: 36–50%
- Whiskey | ABV: 36–50%
- Tequila | ABV: 50–51%
- Liqueurs | ABV: 15%
- Fortified Wine | ABV: 16–24%
- Unfortified Wine | ABV: 14–16%
- Beer | ABV: 4–8%
- Malt Beverage | ABV: 5–15%

*Note:* ABV: alcohol by volume. ABV-millilitres (mL) of pure ethanol present in 100 mL of solution at 20°C.

## Alcoholic Fatty Liver (Alcoholic Steatosis)

**Q. Write short note on alcoholic fatty liver or alcoholic steatosis.**

### *Clinical Features*

- Asymptomatic
- Occasionally, may present with discomfort in right upper quadrant, nausea and jaundice.
- Most common feature is **hepatomegaly** with or without tenderness.
- Progression to cirrhosis not common with its associated complications.

### *Investigations*

- **Biochemical findings:**
  - Moderately **raised ALT and aspartate aminotransferase (AST) with AST: ALT > 1.**
  - $\gamma$ -GT level is a sensitive test to determine whether the individual is taking alcohol.
- Ultrasound: Diffuse increase in echogenicity.
- CT scan: Fatty infiltration produces a low-density liver.
- **Liver biopsy: It shows accumulation of fat in perivenular hepatocytes and later in entire hepatic lobule.**

**Treatment:** Complete cessation of alcohol consumption and nutritional support results in normalization of biochemical findings and histological changes.

## Alcoholic Hepatitis

## ***Clinical Features***

- It may be **asymptomatic or present with fever, rapid onset of jaundice, abdominal discomfort** and proximal muscle wasting.
- Portal hypertension, spider nevi, ascites and bleeding due to esophageal varices can occur without cirrhosis
- Hepatomegaly (tender), splenomegaly.

## ***Investigations***

- Biochemical findings
  - **Serum aminotransferase (AST and ALT) raised** to 2–7 times of normal (usually <400 IU).
  - **AST: ALT ratio is >1 (generally >2).**
  - Raised bilirubin
  - Mildly elevated serum alkaline phosphatase
  - Decreased albumin
- Hematological findings: Prolonged prothrombin time and leukocytosis.
- **Liver biopsy: Ballooning degeneration** of hepatocytes with **leukocyte infiltration. Mallory bodies** often seen.

Potentially reversible but many progress to cirrhosis.

## ***Prognosis***

- **Variable** and despite abstinence, the liver disease progresses in many patients. Conversely, a few patients continue to drink heavily without developing cirrhosis.
- Mortality high in patient's with severe alcoholic hepatitis.
- Poor prognostic factors (Box 11.21).

**Box 11.21:** Poor prognostic factors of alcoholic hepatitis.

- Prothrombin time >5 seconds of control
- Anemia
- Albumin <2.5 g/dL
- Serum bilirubin >8 mg/dL
- Progressive encephalopathy
- Renal failure
- Presence of ascites
- Maddrey discriminant function >32.

---

**Maddrey discriminant function (DF)** = (4.6 x [prothrombin time (sec) – control prothrombin time (sec)]) + (serum bilirubin)

### Treatment

- Advised to stop alcohol consumption for life, because this is a precirrhotic condition.
- Severe hepatitis needs bed rest.
- Nutrition: Feeding—via a fine-bore nasogastric tube or sometimes intravenously (>3000 kcal/day; multivitamins mainly vitamins B and C).
- Treatment for encephalopathy and ascites.
- Corticosteroids (prednisolone) may be tried in severe cases (discriminant function >32) in the absence of any infection.
- Antibiotics (pentoxifylline) in severe cases (discriminant function >32) and antifungal prophylaxis.

## CIRRHOSIS

**Q. Mention the causes of cirrhosis. Discuss the pathology, pathogenesis, classification, clinical features, investigations, complications and treatment/management of cirrhosis.**

**Q. Describe Laennec's cirrhosis and alcoholic cirrhosis.**

### Definition

Cirrhosis is an **end stage** of any chronic liver disease. It is a **diffuse process** (entire liver is involved) characterized by **fibrosis** and conversion of normal architecture to structurally **abnormal regenerating nodules** of liver cells. The three main morphologic characteristics of cirrhosis are: (1) **fibrosis**, (2) **regenerating nodules** and (3) **loss of architecture** of the **entire liver**.

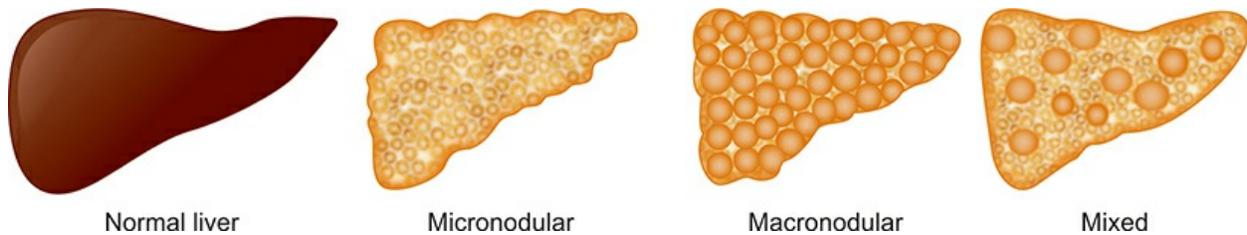

### Classification

Morphological classification (Box 11.22 and Fig. 11.9).

**Box 11.22:** Morphological classification of cirrhosis.

- Micronodular cirrhosis (Laennec's cirrhosis)
  - Regular and small regenerating nodules of less than 3 mm in diameter
  - Uniform thin regular fibrous connective tissue septa
  - Involvement of every lobule of whole liver
  - Most common cause is alcoholic cirrhosis
- Macronodular cirrhosis

- Regenerating, more irregular, coarse nodules of variable size and usually larger than 3 mm in diameter
- Fibrous connective tissue septa are broad and vary in thickness
- Liver surface is grossly distorted
- Most common cause is chronic viral hepatitis
- Increased risk of developing carcinoma of liver
- Mixed cirrhosis: Shows features of both micronodular and macronodular cirrhosis

**Fig. 11.9:** Morphological classification of cirrhosis.

## ***Etiological Classification***

Main causes of cirrhosis are listed in Box 11.23.

## **Pathology and Pathogenesis of Cirrhosis**

- Chronic injury to the liver results in inflammation and **widespread necrosis of liver cells** and, eventually, **fibrosis**. Fibrosis is due to **activation of the stellate cells (in the space of Disse) by many cytokines** and their receptors, reactive oxygen intermediates and other paracrine and autocrine signals. TGF- $\beta$  is the most potent fibrogenic mediator.
- Cirrhotic changes affect the **whole liver**, but not necessarily every lobule.
- **Extensive fibrosis** that distorts and results in loss of liver architecture.
- **Regenerating nodules** are produced due to hyperplasia of the remaining surviving liver cells.
- **Destruction and distortion of hepatic vasculature** by fibrosis lead to obstruction of blood flow. Vascular reorganization leads to portal hypertension and its sequelae (gastroesophageal varices and splenomegaly).
- **Ascites and hepatic encephalopathy** develop due to hepatocellular insufficiency and portal hypertension.
- Hepatocellular damage produces jaundice, edema, coagulopathy and a various metabolic abnormalities.

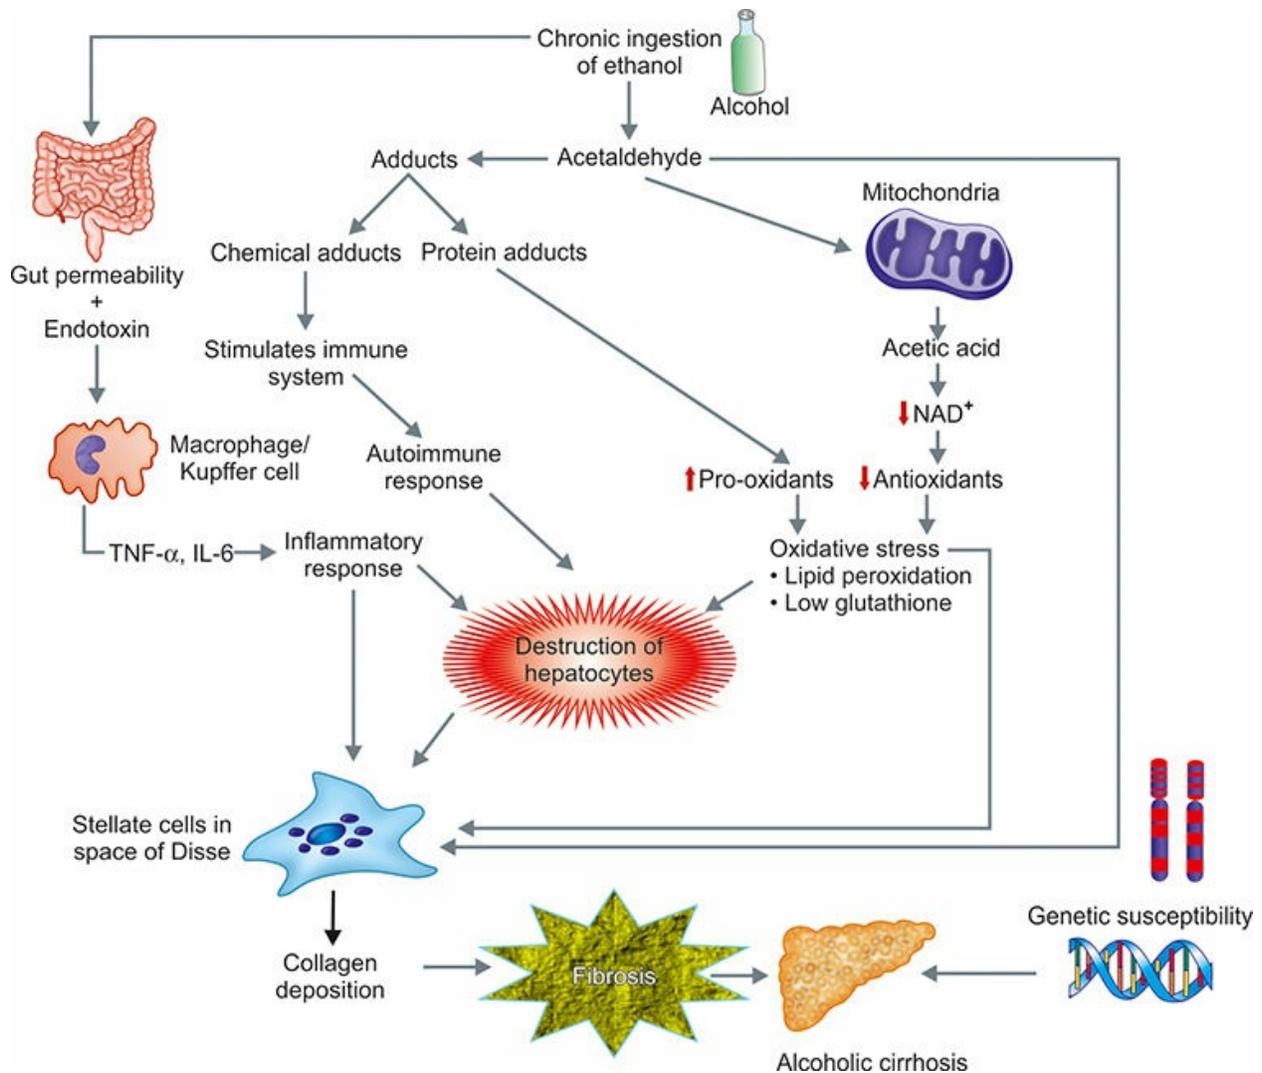

**Box 11.23:** Main causes of cirrhosis.

- Alcohol (one of the commonest causes)
- Chronic viral hepatitis (most common cause)
  - Hepatitis B
  - Hepatitis C
  - Delta hepatitis (hepatitis D) + hepatitis B
- Non-alcoholic steatohepatitis (NASH) or non-alcoholic fatty liver disease (NAFLD) (earlier was considered as cryptogenic cirrhosis)
- Biliary cirrhosis
  - Primary biliary cholangitis
  - Secondary biliary cirrhosis
  - Primary sclerosing cholangitis
  - Autoimmune cholangiopathy, IgG4 cholangiopathy
- Autoimmune hepatitis
- Budd-Chiari syndrome
- Intrahepatic or extrahepatic biliary obstruction: Recurrent biliary obstruction (e.g. gallstones)
- Inherited metabolic liver disease
  - Hemochromatosis
  - Wilson's disease
  - $\alpha_1$  antitrypsin deficiency
  - Cystic fibrosis
  - Glycogen storage disease
- Drug-induced cirrhosis: For example, methotrexate, methyl dopa, isoniazid, phenylbutazone, sulfonamides
- Others: Indian childhood cirrhosis, cardiac cirrhosis, chronic venous outflow obstruction, celiac disease. Hereditary hemotelangiectasia, infection [e.g. brucellosis, syphilis, echinococcosis, porphyria, idiopathic adulthood ductopenia (Caroli disease)]

---

## Alcoholic Cirrhosis

- Safe limits of alcohol are 200 g (20–40 g per day) in males and 140 g (16–30 g per day) in females of alcohol per week. Intake of 180 g of alcohol/day for 25 years increases the risk of cirrhosis by 25 times.
- Development of cirrhosis is six fold when alcohol consumption is double the safety limit.
- Hepatitis C infection is an important contributory factor for progression to cirrhosis.
- Pathogenesis of alcoholic cirrhosis (Fig. 11.10).

**Fig. 11.10:** Pathogenesis of alcoholic liver disease.

## Clinical Features

**Q. Write the clinical features and treatment of alcoholic cirrhosis.**

### Symptoms

- **Highly variable** and in some patients it may be completely asymptomatic and are incidentally diagnosed at ultrasound or at surgery.
- **Nonspecific symptoms:** Weakness, fatigue, muscle cramps, weight loss, anorexia, nausea, vomiting, upper abdominal discomfort.
- **Symptoms of hepatic insufficiency** (refer page 802).
- **Symptoms of portal hypertension and its sequelae** (refer pages 814-5).
- **Symptoms due to endocrine changes:**

- Loss of libido, hair loss
- Females: Irregular menses, amenorrhea and atrophy of breast
- Males: Gynecomastia, testicular atrophy, and impotence.
- **Hemorrhagic tendencies:** Due to decreased production of coagulation factors by the liver and thrombocytopenia resulting from hypersplenism. These include easy bruising, purpura, epistaxis, menorrhagia and gastrointestinal bleeding.

**Box 11.24:** Summary of signs of cirrhosis of liver.

- Ascites
- Circulatory changes
  - Spider naevi
  - Palmar erythema
- Endocrine changes
  - Loss of libido, diminished body hair and hair loss
  - Male: Gynecomastia, testicular atrophy, impotence
  - Female: Irregular menses, amenorrhea and atrophy of breast
- Hemorrhagic tendency: Bruises, purpura, epistaxis
- Features due to portal hypertension: Splenomegaly, development of portosystemic collateral vessels, variceal bleeding
- Flapping tremors and fetor hepaticus
- Other features
  - Pigmentation
  - Clubbing and cyanosis
  - White nails (Terry nails)
- Parotid enlargement and Dupuytren's contracture (signs of alcoholism)

### *Signs*

Summary of signs of cirrhosis of liver (Box 11.24).

### ***Jaundice***

- Jaundice is not a common feature of cirrhosis, its more common with acute diseases.
- Mechanisms of jaundice in cirrhosis:
  - Failure to excrete bilirubin (mainly)
  - Intrahepatic cholestasis (superadded hepatitis/tumor)
  - Hemolysis due to hypersplenism (not a major contributor).

### ***Hepatomegaly***

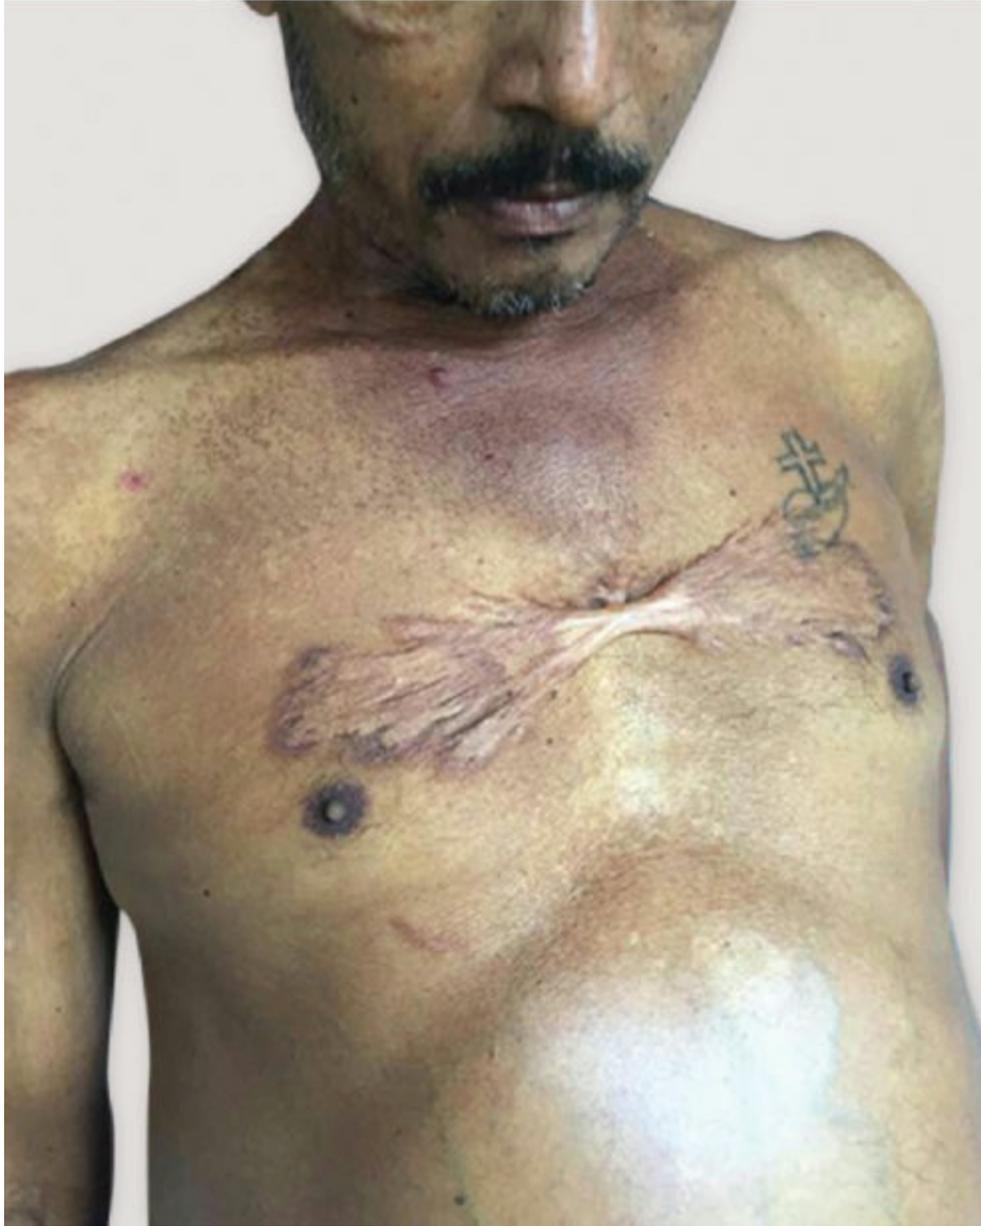

- **Early stages: Liver is enlarged**, firm to hard, irregular and nontender. Hepatomegaly is not common in cirrhosis but common when the cirrhosis is due to alcoholic liver disease, NASH and hemochromatosis. Hepatomegaly may indicate transformation into HCC.
- **Late stages: Liver decreases in size** and non-palpable due to progressive destruction of liver cells and accompanying fibrosis.

### *Ascites*

**Ascites** due to liver failure and portal hypertension (refer ascites, pages 825-7), and signifies advanced disease.

### *Circulatory changes*

1. Spider naevi (Fig. 11.11)
  - (Spider telangiectasia; vascular spiders; spider angiomas; arterial spiders).

**Fig. 11.11:** Cirrhosis of liver with ascites and spider nevi. Patient in addition has tattoo and keloid—which may suggest viral hepatitis as the cause of cirrhosis.

- **Appearance:** Consists of a central arteriole from which numerous small vessels radiate peripherally-resembling spider's legs. Whole spider disappears when central arteriole is compressed with a pinhead. When compression is released filling occurs from center to periphery.
- **Cause:** Due to arteriolar changes induced by hyperestrogenism.
- **Sites affected:** Usually found only in the necklace area, i.e. above

the nipples, territory drained by the superior vena cava such as: head and neck, upper limbs, front and back of upper chest.

- **Size:** Vary from pinhead to 0.5 mm in diameter.
- **Significance:** They are a strong indicator of liver disease but can be found in other conditions (Table 11.24).

Florid spider telangiectasia, gynecomastia and parotid enlargement are most common in alcoholic hepatitis.

Florid spiders and new onset clubbing in a patient with cirrhosis indicates hepato-pulmonary syndrome.

**Table 11.24: Conditions associated with spider nevi.**

<i>Liver disorders</i>	<i>Others</i>
<ul style="list-style-type: none"> <li>• Viral hepatitis</li> <li>• Alcoholic hepatitis               <ul style="list-style-type: none"> <li>– Hepatocellular carcinoma</li> <li>– Treatment with Sorafenib</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• 2% of healthy individuals</li> <li>• Third trimester of pregnancy</li> <li>• Rheumatoid arthritis</li> <li>• Thyrotoxicosis</li> </ul>

Differential diagnosis for spider naevi includes *venous star*, *Campbell de Morgan spots*, *petechiae* and *hereditary hemorrhagic telangiectasias*.

## 2. Palmar erythema (liver palm) (Fig. 11.12A)

- Can be seen early but is of limited diagnostic value, as it occurs in many conditions associated with a hyperdynamic circulation (e.g. normal pregnancy).
- **Cause:** Develops due to increased peripheral blood flow. In cirrhosis, circulatory changes results in increased peripheral blood flow and decreased visceral blood flow (especially to the kidneys).
- **Sites involved:** Prominent in the thenar and hypothenar eminences of palm. May be seen on the sole.

### *Endocrine changes*

- **Diminished body hair and loss of hair (Fig. 11.12B)**
  - Seen mainly in males with loss of male hair distribution.
  - Alopecia affects usually the face, axilla and chest and is due to hyperestrogenism
  - Causes of hyperestrogenism: Due to increased peripheral formation of

estrogen resulting from diminished hepatic clearance of the precursor, androstenedione.

- Effects of hyperestrogenism: Alopecia, gynecomastia and testicular atrophy.
- **Hyperglycemia:** 80% of cirrhotics have impaired glucose tolerance, 20% develop diabetes.

## Males

**Q.** Write short note on gynecomastia and enumerate its causes.

- **Gynecomastia (Fig. 11.12C)**
  - Found in males (atrophy of breasts in females).
  - Cause: Due to increased estradiol/free testosterone ratio. Causes of gynecomastia are listed in Table 11.25.
  - Appear as palpable nodule (4 cm, subareolar). Microscopy: Proliferation of glandular tissue of breast. *Pseudogynecomastia* is accumulation of subareolar fat tissue without palpable nodule.
- **Testicular atrophy:** Due to hyperestrogenic state, it is characterized by a small size compared with Prader's orchidometer (Fig. 11.13C)—soft testes with loss of testicular sensation (sickening sensation in epigastrium on squeezing the testes). The dimensions of the average adult testicle is  $4.5 \times 3.5 \times 2.5$  cm and the volume is 15–25 mL.

**Table 11.25:** Cause of gynecomastia.

• Cirrhosis of liver	
• Drugs: <ul style="list-style-type: none"><li>– Spironolactone</li><li>– Cimetidine</li><li>– Digoxin</li><li>– Ketoconazole</li><li>– Estrogens</li><li>– Isoniazid</li></ul>	<ul style="list-style-type: none"><li>• Physiological (puberty/ageing)</li><li>• Klinefelter's syndrome</li><li>• Hypogonadism</li><li>• Tumor<ul style="list-style-type: none"><li>– Testes</li><li>– Lung</li></ul></li></ul>

## Female

- Irregular menses, amenorrhea and atrophy of breast.

**Flapping tremors (Fig. 11.13A):** Observed in hepatic pre-coma (refer

hepatic encephalopathy on pages 820-3).

### **Other features**

- **Generalized skin hyperpigmentation:** Due to increased melanin deposition.
- **Dupuytren's contracture (Fig. 11.12A)—sign of alcoholism**

**Figs. 11.12A to C:** Features of cirrhosis. (A) Palmar erythema with Dupuytren's contracture; (B) Diminished facial hair with parotid enlargement; (C) Gynecomastia.

- **Cause:** Fibrosis of palmar aponeurosis probably caused by local microvessel ischemia. Platelet and fibroblast-derived growth factors promote fibrosis.
- **Sites involved:** Flexion contracture of the fingers (especially ring and little fingers).
- **Other causes** of Dupuytren's contracture: Diabetes mellitus, rheumatoid arthritis, and manual labor (workers exposed to repetitive handling tasks or vibration).
- **Clubbing and central cyanosis:** Due to development of pulmonary arteriovenous shunts that leading to hypoxemia.
- **Nail changes**
  - White (Terry's) chalky (Fig. 11.13B) and brittle nails.
  - Muehrcke's nails: Characterized by transverse white lines that disappear on applying pressure and these lines do not move with growth of nail.
  - Clubbing is present in primary biliary cholangitis or hepatoma.
- **Parotid and lacrimal gland enlargement:** Observed commonly in alcoholic cirrhosis due to associated autonomic dysfunction.
- **Anemia:** Due to various causes (Box 11.25).

**Box 11.25:** Causes of anemia in cirrhosis.

---

- Acute and chronic blood loss from varices
- Nutritional deficiency of vitamin B<sub>12</sub> and folate
- Hypersplenism
- Bone marrow suppression by alcohol
- Hemolysis.
- Zeives syndrome: Alcohol induced hemolytic anemia with hypercholestroemia

## Symptoms and Signs due to Complications

**Q. Write short essay on complications/life-threatening complications of cirrhosis of liver.**

Three major complications of cirrhosis (Table 11.26) are:

1. **Portal hypertension** (refer pages 813-6): Splenomegaly and collateral vessel formation are features of portal hypertension develops in advanced disease.
2. **Hepatic encephalopathy** (refer pages 820-3)
3. **Renal failure** (refer page 824).

**Table 11.26: Complications of cirrhosis.**

• Portal hypertension and its sequelae	• Hepatic encephalopathy	• Hepatocellular carcinoma
• Ascites	• Portal gastropathy	• Bleeding manifestations and coagulopathy
• Spontaneous bacterial peritonitis	• Hepatorenal syndrome	• Cirrhotic cardiomyopathy
• Portopulmonary hypertension	• Hepatopulmonary syndrome	• Hepatic hydrothorax
• Coagulopathy, thrombocytopenia, hyponatremia	• Endocrine dysfunction—adrenal insufficiency, gonadal dysfunction, thyroid dysfunction.	• Cirrhotic osteodystrophy

### Extrahepatic manifestations

1. **Pleural effusion (hepatic hydrothorax):**
  - It is transudate. Often associated with ascites. Most often seen on right side.
  - **Mechanisms:**

- ◆ Hypoalbuminemia causes decreased colloid osmotic pressure.
- ◆ Leakage of ascitic fluid may occur through diaphragmatic defects.
- ◆ Transdiaphragmatic migration of fluid via lymphatic channels.

**Figs. 11.13A to C:** (A) Flapping tremor; (B) White nails; (C) Prader's orchidometer.

– **Treatment:** It

Tincludes control of ascites (refer pages 829-30), transjugular intrahepatic portosystemic shunt, video-assisted thoracoscopy with pleurodesis, video-assisted thoracoscopy with repair of defects in the diaphragm and liver transplantation.

## 2. Hepatopulmonary syndrome

- **Definition:** Hypoxemia occurring in patients with advanced liver disease.
  - **Cause:** Hypoxemia is due to intrapulmonary vascular vasodilation without any evidence of primary pulmonary disease.
  - Patients show features of cirrhosis with **spider nevi, clubbing and cyanosis.**
  - **Symptoms:** Most patients have no respiratory symptoms but with more severe disease complain of insidious onset of breathlessness on standing (**orthodeoxia-platypnea**).
  - **Investigations:**
    - ◆ Chest X-ray: May show a bibasilar interstitial pattern that reflects the predominantly basal vascular dilatations.
    - ◆ Transthoracic ECHO: Shows intrapulmonary shunting.
    - ◆ Arterial blood gases: Confirm the arterial oxygen desaturation.
- Diagnosis by contrast-enhanced (microbubble) echocardiography,

perfusion lung scan and pulmonary angiography.

- **Treatment:** Oxygen inhalation and coil embolization (in localized shunts). Liver transplantation.

3. **Portopulmonary hypertension:** It is characterized by a raised mean pulmonary artery pressure, increased pulmonary vascular resistance and normal wedge pressure developing in portal hypertension. Dyspnea on exertion is the most common symptom, and can lead to right heart failure.
4. **Cirrhotic cardiomyopathy:** Characterized by systolic and diastolic dysfunction, electrophysiological changes, and gross and microscopic structural changes.
5. **Hepatic osteodystrophy:** Osteoporosis and osteomalacia.

Table 11.27 shows noninvasive direct and indirect markers of hepatic fibrosis.

**Table 11.27:** Noninvasive direct and indirect markers of hepatic fibrosis.

<b>Direct markers</b>	
Procollagen type I carboxy terminal peptide (PICP), Procollagen type III amino-terminal peptide (PIIINP)	Metalloproteinases (MMPs), tissue inhibitors of matrix metalloproteinases (TIMPs), hyaluronic acid
<b>Indirect Serum Markers of Liver Fibrosis</b>	
<b>Indices</b>	<b>Individual components</b>
AST/ALT ratio	Aspartate aminotransferase, alanine aminotransferase
PGA	Prothrombin index, GGT, apolipoprotein A1
APRI	AST/platelet count
FibroSpect II	HA, TIMP-1, $\alpha$ 2-macroglobulin
FibroTest/FibroSure	$\gamma$ 2 macroglobulin, $\gamma$ 2 globulin, $\gamma$ globulin, apolipoprotein A1, GGT, total bilirubin
FibroIndex	Platelet count, AST, GGT
FibroMeter	Platelet count, $\gamma$ 2 macroglobulin, AST, age, prothrombin index, HA, blood urea nitrogen
Hepascore	Age, gender, bilirubin, GGT, HA, $\gamma$ 2-macroglobulin
FIB-4	Platelet count, ALT, AST, platelet count, age

## Prognostic Classifications

**Q.** Write short note on Child-Pugh score or Child-Turcotte-Pugh score.

The Child-Pugh (CP) scoring classification was originally used to risk-stratify patients undergoing shunt surgery. Modifications of Child's-Pugh grading (A, B and C)/Child-Turcotte-Pugh score is shown in Table 11.28 and is useful to grade the **severity of liver disease and prognosticate** patients with established cirrhosis. Other scoring system used is **The Model for End-stage Liver Disease (MELD)** which bilirubin, creatinine, and INR for prothrombin time to predict three-month survival.

Characteristics of end stage of cirrhosis (Box 11.26).

**Box 11.26:** Characteristics of end stage of cirrhosis.

- Jaundice
- Progressive, refractory ascites
- Worsening of signs of portal hypertension
- Progressive renal dysfunction Hepatic encephalopathy

**Table 11.28:** Modified Child's-Pugh classification or Child-Turcotte-Pugh (CTP) score.

Parameter	Score		
	1	2	3
• Encephalopathy	None	Mild	Marked
• Ascites	None	Mild or controlled with diuretics	Moderate/severe
• Prolongation of prothrombin time (seconds over normal)	<4	4–6	>6
• Serum albumin (mg/dL)	>3.5	2.8–3.5	<2.8
• Serum bilirubin (mg/dL)	<2	2–3	>3

CTP class A: Points 5–6; CP class B: 7–9; CP class C: > 9 (range 5–15) One-year survival rates for patients with Child-Pugh class A, B, and C cirrhosis are approximately 100, 80, and 45 percent, respectively.

**Poor Prognostic Factors in Cirrhosis (Table 11.29)**

**Table 11.29:** Poor prognostic factors in cirrhosis.

Laboratory findings	Clinical findings
• Low serum albumin of less than 2.5 g/dL	• Persistent jaundice (serum bilirubin more than 20 mg/dL)

• Low serum sodium of less than 120 mmol/L	• Ascites responding poorly to therapy
• Rising serum creatinine	• Encephalopathy not associated with an extensive collateral circulation
• Prolongation of prothrombin time more than 1.5 times of control (>6 seconds above normal)	• Hemorrhage from varices with poor liver function
	• Neuropsychiatric complications
	• Persistent hypotension
	• Small liver
	• Etiology (e.g. hepatitis C, alcoholic cirrhosis, if the patient continues drinking)

## Investigations

Investigations are helpful for assessing the severity and type of liver disease.

### *Liver Function Tests*

- **Hyperbilirubinemia:** Due to raise in both conjugated and unconjugated bilirubin. Not very common with cirrhosis. could suggest superadded hepatitis, hepatocellular carcinoma, congestive or obstructive etiology.
- **Serum proteins: Show reversal of A:G ratio.**
  - **Serum albumin is decreased** (hypoalbuminemia) and is due to reduced synthesis by liver.
  - **Serum globulin is increased** (hyperglobulinemia) due to stimulation of reticuloendothelial system.
- **Serum transaminases**
  - **AST (SGOT) is raised**
  - **ALT (SGPT) is raised** and usually less than 300 units/dL.
  - **AST:ALT ratio**
    - ◆ **More than 2 in alcoholic cirrhosis.**
    - ◆ **Less than 2 in cirrhosis complicating viral hepatitis.**
- **Alkaline phosphatase:** It may be slightly elevated.
- **Prothrombin time: Prolonged** due to reduced synthesis of clotting (especially vitamin K-dependent) factors.

### *Hematological Tests*

### *Peripheral blood picture*

- **Anemia and acanthocytosis** (spur-like projections on RBC)
- **Leukopenia and thrombocytopenia** (due to hypersplenism and bone marrow suppression by alcohol).

**Serological markers:** For hepatitis B and C.

### ***Other Biochemical Markers***

- Serum electrolytes:
  - Low sodium (hyponatremia) indicates severe liver disease and is due to either defect in free water clearance or to excess diuretic therapy.
  - Hypokalemia, hypomagnesemia, hypophosphatemia.
- **Blood ammonia** estimation: It is a reliable investigation when hepatic encephalopathy is suspected. Raised blood ammonia is due to:
  - Decreased clearance by liver
  - Shunting of portal venous blood to systemic circulation.
- Respiratory alkalosis: It may develop due to central hyperventilation.
- Glucose intolerance.

### **Box 11.27:** Ultrasound examination in cirrhosis.

- Changes in size and shape of the liver
- Fatty change and fibrosis produce a diffuse increased echogenicity
- Nodularity of the liver surface
- Distortion of the arterial vascular architecture
- Patency and size of the portal and hepatic veins and their diameters
- Detect hepatocellular carcinoma
- Enlargement of spleen
- Ascites.

### ***Imaging***

- **Ultrasound examination** can demonstrate features listed in Box 11.27.
- **CT scan:** To detect hepatosplenomegaly and dilated collaterals. Arterial phase-contrast-enhanced scans to detect hepatocellular carcinoma. Other noninvasive markers to detect hepatic fibrosis are Hepascore, FIB-4 index, Fibroindex, AST to platelet ratio, etc. (refer Table 11.29).

**Endoscopy** for detecting and treating varices and portal hypertensive

gastropathy. Barium swallow may also be useful for demonstration of varices.

- **Hepatic Elastography**

**Q. Write short note on hepatic elastography.**

- Hepatic fibrosis represents an early stage of chronic liver disease and cirrhosis.
- Conventional liver tests and imaging studies are not sensitive for detecting hepatic fibrosis.
- Hepatic elastography is a noninvasive method **for measurement of hepatic fibrosis.**

Methods used are ultrasound and MRI [acoustic radiation force impulse imaging (ARFI), real-time shear wave elastography (SWE)].

### ***Liver Biopsy (Box 11.28)***

**Special investigations** depending on the etiology

- Chemical measurement of iron (serum transferrin saturation level, serum ferritin) and copper (ceruloplasmin) are required to confirm diagnosis of iron overload or Wilson's disease.
- Others: Serum  $\alpha$ -foetoprotein,  $\alpha_1$ -antitrypsin, antinuclear antibodies and anti-smooth muscle antibodies, etc. depending on the etiology.

**Box 11.28:** Usefulness of liver biopsy in cirrhosis.

- **To confirm the diagnosis** of cirrhosis
- **Assesses the severity and type** of liver disease
- Special stains: It may be necessary for iron and copper
- Immunocytochemical stains: It can identify viruses

### ***Ascitic Fluid Examination (Discussed Later)***

Investigations for the etiology of cirrhosis: Even in a patient with chronic consumption of alcohol with cirrhosis rule out other causes (viral serology, etc.) as only 15–18% of alcoholics develop cirrhosis.

#### **Management (Treatment)**

- There is **no treatment available to arrest or reverse the cirrhotic changes** in liver. **Liver transplantation** is the specific treatment.

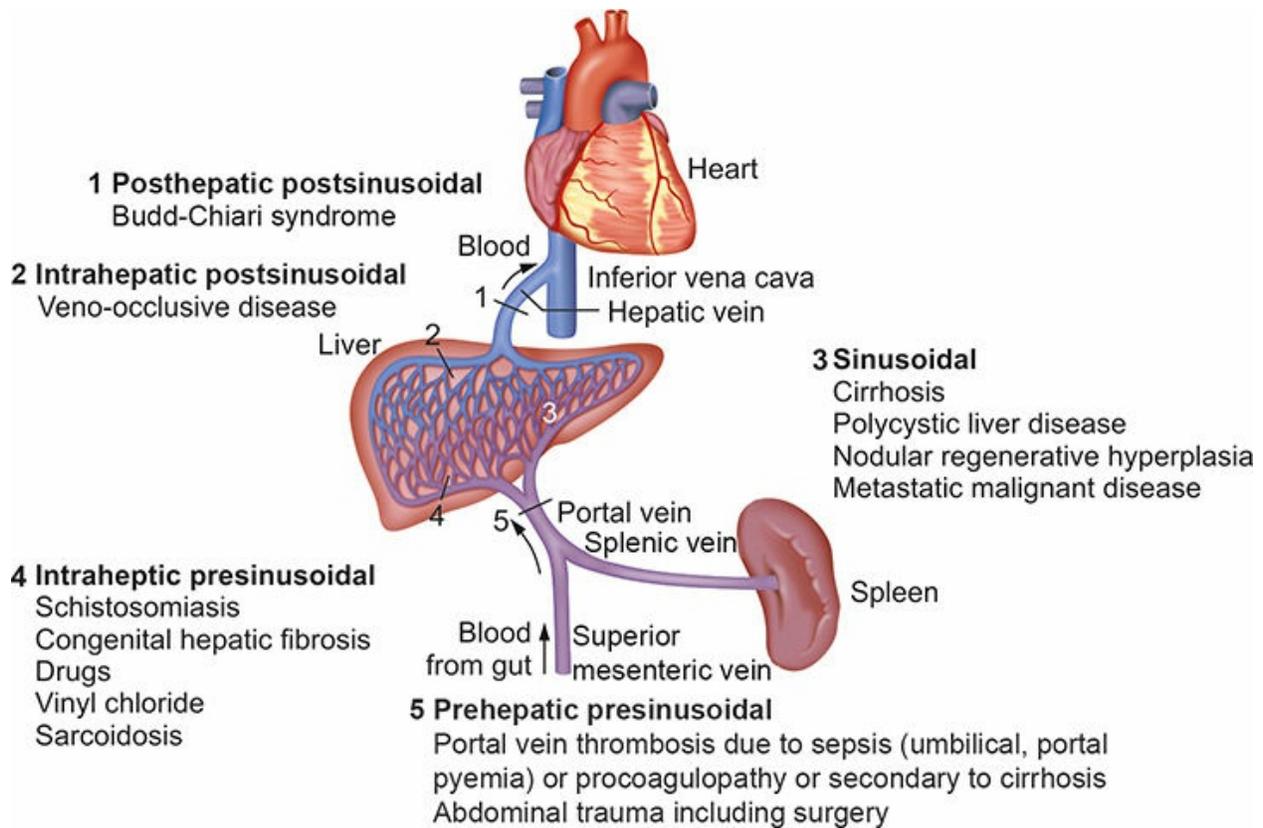

- Progression may be halted by correcting the underlying cause, removal of causative agents like drugs, alcohol, etc.
- **Diet:**
  - High-protein diet-minimum 1 g/kg/day; 2000–3000 kcal/day.
  - Diets with branched-chain amino acids in patients predisposed to hepatic encephalopathy.
  - Multivitamin supplements.
  - Reduce salt intake.
- Avoidance of aspirin, NSAIDs and other hepatotoxic drugs.
- **Management of the complications:** Specific treatment of complications, e.g. variceal bleeding, hepatic encephalopathy and ascites (discussed separately).
- **Follow-up:** With 6-monthly ultrasound and serum  $\alpha$ -fetoprotein measurements for early detection of development of a hepatocellular carcinoma.

## PORTAL HYPERTENSION

Portal vein is formed by the union of the superior mesenteric and splenic veins. Normally, the pressure within portal vein is 5–8mm Hg (or 10–15 cm saline).

### Definition

- Portal hypertension is defined as **prolonged elevation of portal venous pressure** (more than 30 cm saline).
- It is better defined as elevation of **hepatic venous pressure gradient** (HVPG-difference in pressure between portal vein and hepatic vein) more than 7 mm Hg. HVPG more than 10 mm Hg defines significant portal hypertension.

**Fig. 11.14:** Classification of portal hypertension according to site of vascular obstruction.

## Classification of Portal Hypertension (Fig. 11.14)

### **Q. Define and classify portal hypertension.**

Portal hypertension can be classified according to the site of obstruction into **prehepatic, intrahepatic, and posthepatic**.

- **Prehepatic causes:** Obstruction/blockage of the portal vein before it ramifies within the liver, e.g. portal vein thrombosis, splenic vein thrombosis and massive splenomegaly (Banti's syndrome).
- **Intrahepatic causes:** Due to distortion of the liver architecture and may be further divided into:
  - **Presinusoidal** (e.g. in schistosomiasis)
  - **Sinusoidal** (e.g. in cirrhosis)
  - **Postsinusoidal** (e.g. hepatic sinusoidal obstruction—veno-occlusive syndrome).
- **Posthepatic causes:** Due to venous blockage outside the liver and are rare, e.g. severe right-sided heart failure, Budd-Chiari syndrome,

constrictive pericarditis, and hepatic vein outflow obstruction.

## Pathogenesis of Portal Hypertension (Fig. 11.15)

**Q. Discuss the etiology, pathogenesis, clinical features, investigations, complications and management of portal hypertension.**

Portal hypertension in cirrhosis results from:

- **Increased intrahepatic resistance** to blood flow through the liver and leads to:
  - As portal pressure rises above 10–12 mm Hg, the portal venous system dilates, reduces the portal blood to the liver and collaterals occur within the systemic venous system. Development of collateral vessels allowing portal blood to bypass the liver and enter systemic circulation.
  - Initially, collateral vessel formation diverts most of the portal blood and later almost all of the entire portal blood directly to the systemic circulation, bypassing the liver.
- **Increase in portal venous inflow (flow)** resulting from the hyperdynamic circulation.

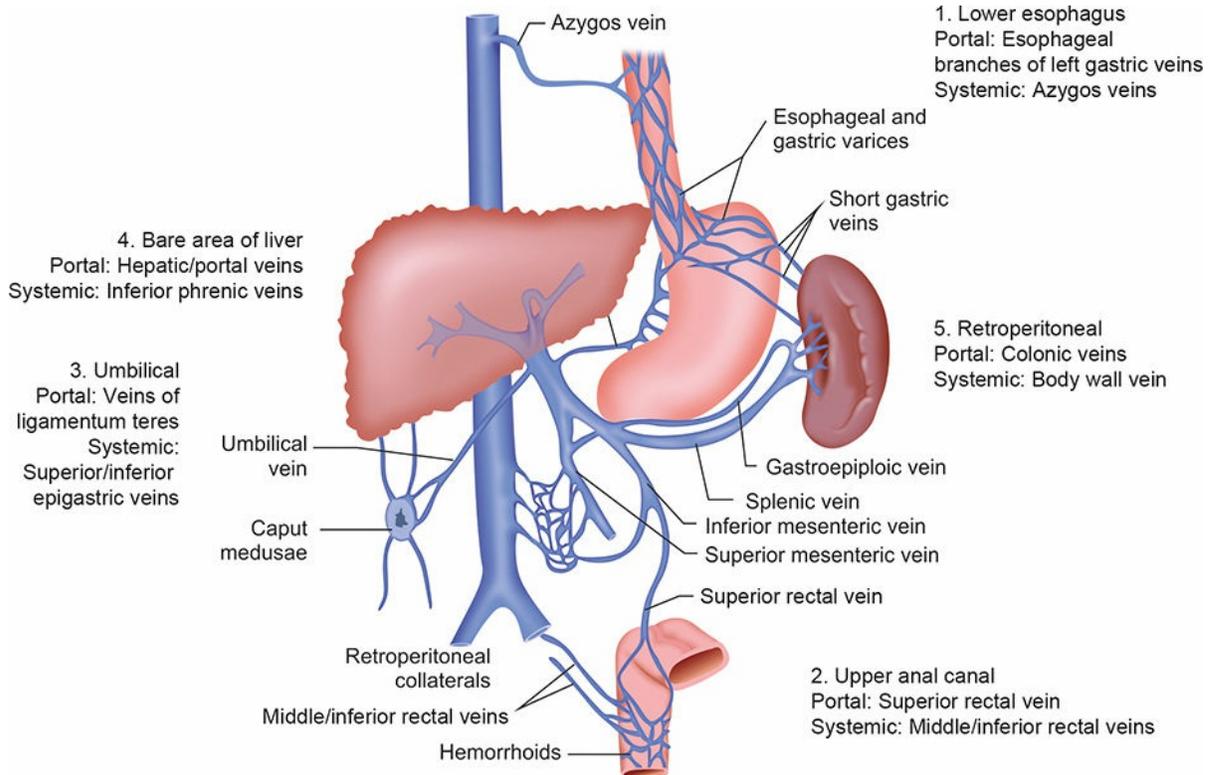

## Clinical Features

**Q. Write short note on clinical features and diagnosis of portal hypertension.**

- Patients with portal hypertension are often asymptomatic.
- History, e.g. alcoholism, past history of hepatitis. Triad of portal hypertension consists of **ascites, splenomegaly and dilated tortuous abdominal wall veins (Fig. 11.16)**.
- **Bleeding from esophageal varices** or portal hypertensive gastropathy causes hematemesis and melena.
- **Splenomegaly:** It may be only clinical evidence and single most important diagnostic feature of portal hypertension.
  - A diagnosis of portal hypertension should not be made if there is no documentation of splenomegaly either clinically, radiographically or ultrasonography.
  - Usually spleen is palpable less than 5 cm below costal margin.

However, marked splenomegaly can be found in younger patients, those with macronodular cirrhosis and in extrahepatic portal hypertension.

- Hypersplenism manifests as thrombocytopenia and leukopenia. Splenomegaly may disappear after massive GI bleed or shunt surgery.

**Fig. 11.15:** Consequences of portal hypertension with sites of portosystemic anastomosis in cirrhosis.

- **Features due to liver cell failure/hepatic encephalopathy.**
- **Fetor hepaticus:** It is a musty odor of breath due to shunting of blood from portal system to systemic circulation that allows mercaptans to pass directly to the lungs, bypassing the liver.
- **Caput medusae,** suggestive of an intrahepatic cause of portal hypertension, are present around the umbilicus; the flow of blood is away from the umbilicus.
  - In Budd-Chiari syndrome, by contrast, veins are dilated in the flanks and back, and blood flows in a cephalic direction.

**Fig. 11.16:** Dilated veins over the anterior abdominal wall and ascites in cirrhosis.

- A bruit may be heard in the left or the right upper quadrant in a patient with a splanchnic arteriovenous fistula.
- **Cruveilhier-Baumgarten syndrome:** A venous hum may be heard in the epigastrium of a patient with portal hypertension and represents collateral flow in the patent umbilical vein in the falciform ligament. A patent umbilical vein excludes an extrahepatic cause of portal hypertension because the umbilical vein arises from the intrahepatic portion of the left portal vein.
- **Rectal varices** may be confused with internal hemorrhoids because of their location. However, hemorrhoids result from a displacement of the anal cushions and hyperperfusion of the arteriovenous plexus vascular cushions without direct communication with any of the major branches of the portal venous system.
- **Liver:** It may be enlarged or shrunken.
  - **Small, contracted, fibrotic** liver is found when the portal venous pressure is very high.
  - Soft liver usually suggestive of extrahepatic portal vein obstruction.
  - Firm liver suggestive of cirrhosis and hence intrahepatic portal

hypertension.

- **Ascites:** It develops partly due to portal hypertension but mainly due to liver cell failure.

## Investigations

The diagnosis of portal hypertension can be made on clinical grounds.

- **Barium swallow:** It shows varices as filling defects in the lower-third of esophagus ('**bag of worms appearance**').
- **Upper gastrointestinal scopy**
  - Most reliable method of investigation.
  - Esophageal varices appear as blue rounded projections (red spots and red stripes) under submucosa.
  - '**Cherry red spots**' indicate impending rupture of varices.

### Box 11.29: Complications of portal hypertension.

- Variceal bleeding: Mainly esophageal and gastric
- Hepatic encephalopathy
- Ascites, SBP
- Hepatorenal, hepatopulmonary syndrome
- Congestive gastropathy
- Hypersplenism
- Iron deficiency anemia

- **Ultrasonography** (refer Box 11.27).
- **Portal venography** (splenoportal venogram) rarely done nowadays.
- **Measurement of portal venous pressure:** By either wedged hepatic venous pressure (WHVP) or transhepatic venous pressure. It is useful for (1) confirmation of portal hypertension, and (2) differentiating sinusoidal from presinusoidal portal hypertension.
- **Proctoscopy and barium enema:** Useful for demonstrating varices in the rectum and colon.
- **Liver function tests:** To confirm the liver diseases.

### Box 11.30: Drugs used in the treatment of portal hypertension.

Drugs that decrease portal blood flow

- Nonselective  $\beta$ -adrenergic blocking agents (propranolol, nadolol, carvedilol)
- Somatostatin and its analogs

- Vasopressin

Drugs that decrease intrahepatic resistance

- $\alpha$ 1-adrenergic blocking agents (e.g. prazosin)
- Angiotensin receptor blocking agents
- Nitrates

## Complications of Portal Hypertension (Box 11.29)

**Q. Name the drugs that are used in the reduction of portal venous pressure.**

### Treatment of Portal Hypertension

- Treatment of underlying disease
- Drugs used in the treatment of portal hypertension (Box 11.30)
- Non-selective  $\beta$ -blockers (propranolol, nadolol) produce vasodilatation of both splanchnic arterial bed and portal venous system. Also reduce recurrence of variceal bleed. The usual starting dose of long-acting propranolol is 40 mg once daily and that of nadolol is 20 mg once daily
- Nitrates (nitroglycerine and isosorbide dinitrate) along with  $\beta$ -blockers reduce the risk of variceal bleed and are used for primary prophylaxis of variceal bleed.

## Esophageal Varices

**Q. Discuss the diagnosis and management of esophageal variceal bleeding.**

- About 90% of patients with cirrhosis will develop gastroesophageal varices, but only one-third of these will bleed from them.
- Commonest site of bleeding is esophageal varices within 3–5 cm of the esophagogastric junction.
- Factors that predispose to rupture of varices are listed in Box 11.31.

**Box 11.31:** Factors predisposing varices rupture.

- Large varices
- ‘Red sign’ on varices (diagnosed at endoscopy) suggest imminent rupture
- Associated with severe liver disease
- High portal venous pressure
- Salicylates and other nonsteroidal anti-inflammatory drugs

## Clinical Features

- **Painless, mild to massive hematemesis**, with or without associated melena.

## *Signs*

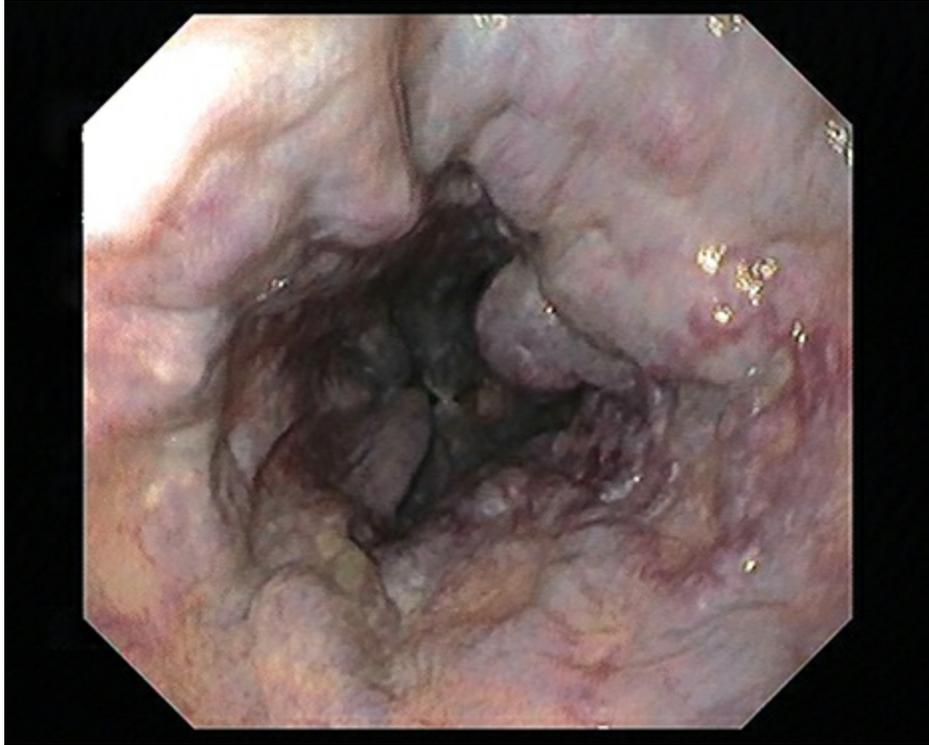

- **Depending on the amount of blood loss**, it may vary from mild postural tachycardia to shock.
- **Features of liver cell failure, ascites and portal hypertension.**

### **Box 11.32:** Descriptors of esophageal varices.

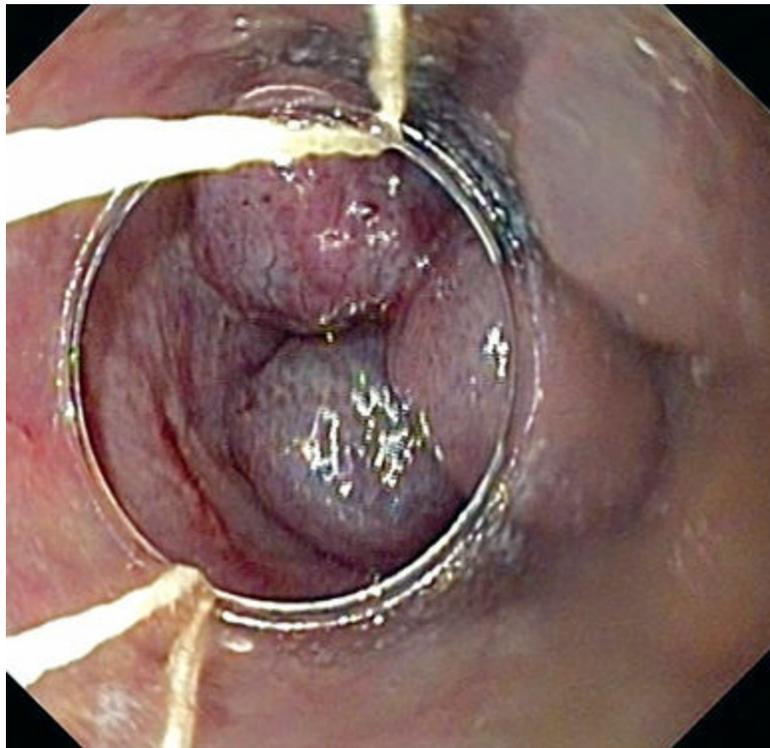

- Red color signs (ominous signs) include:
  - Red “wale” markings, which are longitudinal whip-like marks on the varix
  - Cherry-red spots, which usually are 2–3 mm or less in diameter
  - Hematocystic spots, which are blood-filled blisters 4 mm in diameter
- Color of the varix can be white or blue
- Form (size) of the varix at endoscopy:
  - Grade I: Esophageal varices may be small and straight
  - Grade II: Tortuous and occupying less than one-third of the esophageal lumen
  - Grade III: Large and occupying more than one-third of the esophageal lumen.

## *Diagnosis*

- **Fiberoptic endoscopy:** Performed within 8 hours of bleeding reveals the bleeding site and the presence of varices (Fig. 11.17). This helps in excluding the other causes of bleeding. The descriptors are presented in Box 11.32.
- **Ultrasonography:** Useful to confirm the patency of portal vein.

**Fig. 11.17:** Endoscopy view of esophageal varices.

**Fig. 11.18:** Banding of esophageal varices.

**Q. Describe the management of acute variceal bleeding. Describe the**

## medical management of bleeding of esophageal varices.

### Management

Management goal (Box 11.33)

**Box 11.33:** Management goal in esophageal varices.

- Management of the active bleeding episode
- Prevention of rebleeding
- Prophylactic measures to prevent the first hemorrhage.

### *Management of acute variceal bleeding (Flowchart 11.2)*

#### *General measures—resuscitation*

- **Immediate hospitalization and nursing:** Patients require intensive-care nursing. Nil by mouth until bleeding stops.
- Assess the general condition of the patient pulse and blood pressure and maintain fluid (intake and output) and electrolyte balance.
- Obtain blood for grouping and cross matching, hemoglobin, prothrombin time, blood urea, electrolytes, creatinine, liver function tests and blood cultures.
- Grade cirrhosis according to Child-Pugh score (refer Table 11.28).
- Immediately restore blood volume with blood transfusion and avoid saline infusions as far as possible. Prompt correction of hypovolemia is needed.
- Correction of coagulation factor deficiency by fresh blood or fresh frozen plasma.
- Platelet transfusions to raise platelet count above 50,000/cumm.
- Vitamin K is administered intramuscularly or intravenously.
- To prevent stress ulcers give H<sub>2</sub> receptor antagonists (e.g. cimetidine, ranitidine or famotidine) or proton-pump inhibitors (e.g. pantoprazole or omeprazole).
- **Prophylactic antibiotics:** Reduce infection and mortality and prevent spontaneous bacterial peritonitis. Usually oral and intravenous quinolones are used (e.g. ciprofloxacin 500 mg twice daily).
- **Measures to prevent hepatic encephalopathy:** Portosystemic encephalopathy (PSE) may be precipitated when the amount of bleeding is large because blood contains protein (refer pages 820-3).
- Treatment of ascites by ascitic tap (paracentesis) or by administration of spironolactone or amiloride.
- Monitor for alcohol withdrawal (in case of alcoholic cirrhosis) and give thiamine.

#### *Urgent endoscopy*

- Urgent endoscopy to confirm the diagnosis of gastroesophageal varices. Varices may or may not be present and it helps to exclude bleeding from other sites (e.g. gastric ulceration).
- **Portal hypertensive (or congestive) gastropathy** is defined as chronic gastric congestion, punctate erythema and gastric erosions. It can also cause bleeding.
- To reduce esophageal ulceration following endoscopic therapy, sucralfate is given in the dose of 1 g four times daily.

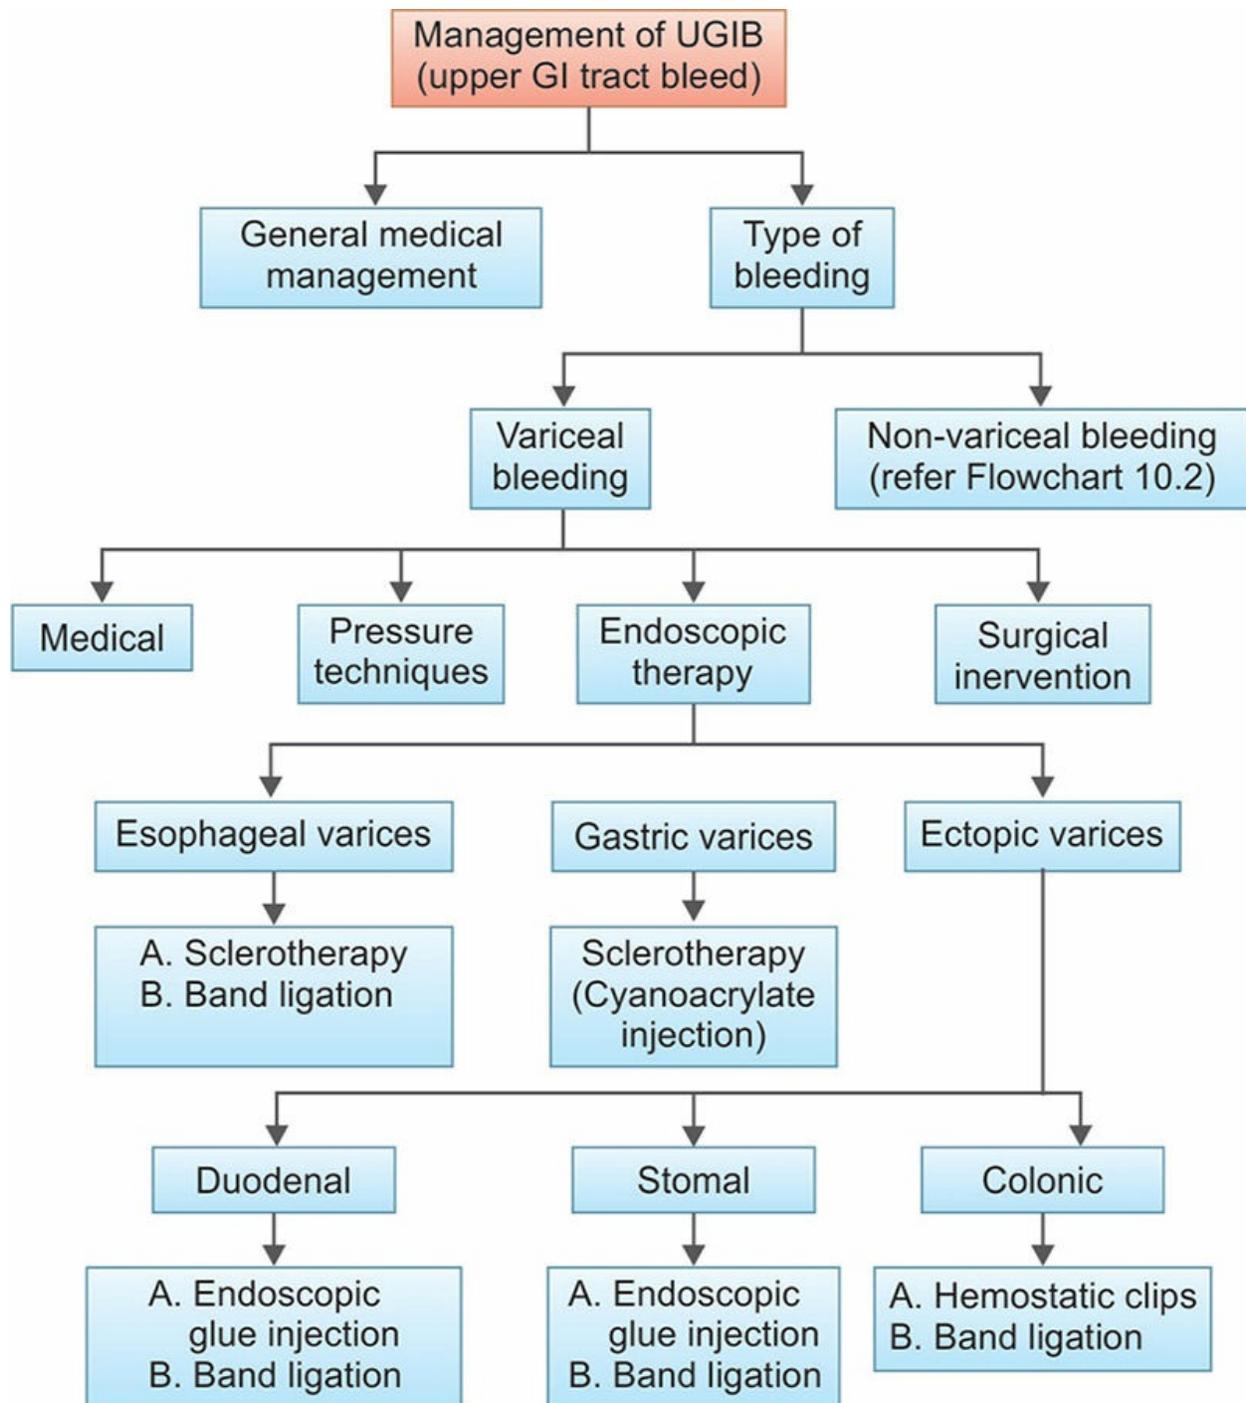

#### *Local measures*

### **Injection sclerotherapy or variceal banding**

Acute variceal bleeding may be treated by endoscopic procedure with (1) sclerotherapy and (2) endoscopic variceal banding (endoscopic variceal band ligation (EVBL). They arrest bleeding in 80% of cases and reduce early rebleeding.

- **Sclerotherapy:** Injection of sclerosing agent into the varices may arrest bleeding by producing thrombosis of vessel. Commonly used sclerosants are listed in Box 11.34 and complications of sclerotherapy are mentioned in Table 11.30.
- **Banding (Fig. 11.18):** Varices are banded by mounting a band on the tip of the endoscope, sucking the varix just into the end of the scope and dislodging the band over the varix.

**Flowchart 11.2:** Algorithm for the treatment of bleeding from acute esophageal varices.

**Table 11.30: Complications of sclerotherapy.**

Esophageal complications

- Re-appearance of varices
- Esophageal ulceration and perforation
- Esophageal reflux
- Stricture formation

Pulmonary complications

- Chest pain, pleural effusion, mediastinitis and aspiration pneumonia
- Acute respiratory failure

Abdominal pain, fever and dysphagia

Spinal cord paralysis due to anterior spinal artery occlusion

Mortality: 1%

### Box 11.34: Commonly used sclerosants in esophageal varices.

- Ethanolamine oleate
- Sodium morrhuate
- Absolute alcohol
- Sodium tetradecyl sulfonate

#### **Vasoconstrictor Therapy**

- **Uses:** This therapy is mainly used for (1) emergency control of bleeding while waiting for endoscopy and (2) in combination with endoscopic techniques.

**Aim:** To reduce the portal inflow of blood and portal pressure constricting the splanchnic arterioles.

#### **Drugs used**

- **Terlipressin**
  - **Action:** Terlipressin produces vasoconstriction by releasing vasopressin from it.
  - **Dose:** 2 mg IV 6-hourly till bleeding stops, and then reduced to 1 mg 4-hourly after 48 hours if a prolonged dosage regimen is used.
  - **Contraindication:** Patients with ischemic heart disease.
  - **Side effects:** Abdominal colic, evacuation of bowels and facial pallor due to the generalized vasoconstriction.
- **Somatostatin and octreotide**
  - Somatostatin and its synthetic analog octreotide stops bleeding from varices in more than 80% patients.
  - Its effects are equivalent to vasopressin and endoscopic therapy.
  - **Side-effects:** Very few.
  - **Dose:**
    - ◆ Somatostatin: Infusion of 250–500 µg/h followed by 250 µg/h for 2–5 days.
    - ◆ Octreotide: 50 µg as bolus followed by 50 µg/h for 2–5 days.
  - **Indication:** When there are contraindications to terlipressin.
- **Vasopressin (0.1 0.5 units/minute for 4 to 12 hrs (up to 48 hrs):** It was used in the past but is not commonly used now.

#### **Balloon Tamponade**

- **Indications:** To control variceal bleeding.
  - If endoscopic therapy or vasoconstrictor therapy fails or contraindicated.
  - If there is exsanguinating hemorrhage.
- **Instrument:** (1) Sengstaken-Blakemore tube with four lumens and (2) Minnesota tube with four lumens. These tubes have two balloons namely esophageal and gastric balloons.
- **Use:** It is very useful in the initial few hours of bleeding in about 90% of cases.
- **Complications:** (1) aspiration pneumonia, (2) esophageal rupture and (3) necrosis and ulcerations of esophageal mucosa and (4) obstruction to pharynx.

Algorithm for the treatment of bleeding from acute esophageal varices (Flowchart 11.2)

### **Management of an acute Rebleed**

- About 30% of patients develop rebleed within 5 days after a single therapeutic endoscopy.
- Source of the rebleed should be established by endoscopy. Sometimes it is due to an ulcer developed due to previous sclerotherapy and it is difficult to manage.
- Management: **Repeat endoscopic therapy** once only to control rebleeding and further sclerotherapy or banding should not be done.

### ***Transjugular Intrahepatic Portocaval Shunt (TIPS)***

- **Indication:** When the bleeding does not stop after two sessions of endoscopic therapy within 5 days.
- **Technique:** A guidewire is passed from the jugular vein into the liver. An expandable metal shunt is forced over it into the liver substance (intrahepatic) to form a portacaval shunt (between the systemic and portal venous systems).
- **Advantages:** It reduces the hepatic sinusoidal and portal vein pressure without the risks of general anesthesia and major surgery.
- **Disadvantages:** It is useful only for the short-term.
- If the patient does not respond, transjugular intrahepatic portosystemic shunt (TIPSS) is useful in most patients.

### ***Emergency Surgery***

**Indications:** (1) When other measures fail, (2) if TIPS is not available (3) continued or recurrent hemorrhage and (4) if the bleeding is from gastric fundal varices.

**Techniques:** Esophageal transection and ligation of the feeding vessels to the bleeding varices. Infrequently acute portosystemic shunt surgery and esophageal staple transaction.

### **Prevention of Recurrent Variceal Bleeding (Secondary Prophylaxis)**

Bleeding recurs in about 60–80% of patients within 2 year after initial bleed.

### ***Long-term Measures***

- **Medical therapy by non-selective beta-blockade:**
  - It is the treatment of choice.
  - Dose: Oral propranolol in a dose 80–160 mg/day decreases the portal pressure.
  - It decreases the frequency of rebleeding, and is as effective as sclerotherapy and ligation. It also prevents bleeding from portal hypertensive gastropathy.
- **Endoscopic treatment:** It consists of injection sclerotherapy or variceal banding (refer page 817). Repeated courses of banding done every 2 weeks until the varices are obliterated. It is superior to sclerotherapy.
- **Transjugular portosystemic stent shunts:** They reduce rebleeding rates compared to endoscopic techniques but are associated with increased rate of encephalopathy. They are used if endoscopic or medical therapy fails.

### ***Surgical Procedures***

#### ***Surgical portosystemic shunting***

- Reserved when medical therapy, EVBL and sclerotherapy are not successful.
- Performed in patients with good liver function (Child-Pugh A and B).
- Very low risk of rebleeding.

#### ***Types of portal systemic shunts***

- Non-selective shunt: With end-to-side portocaval anastomosis that decompress the entire portal venous system. It produces significant postoperative hepatic encephalopathy.
- Selective distal splenorenal shunt (Warren shunt): Decompress only the varices while maintaining blood flow to liver via the superior mesenteric vein. It produces less encephalopathy.

#### *Complications of portosystemic shunts*

- Mortality of 5%
- Shunt closure
- Hepatic encephalopathy following surgery due to: Reduction in portal pressure and hepatic blood flow leads to deterioration of liver function. Normally, encephalopathy-inducing toxic substances carried by the portal system are metabolized by the liver. Following shunt, these substances bypass the liver, enter systemic circulation and reach the brain.
- Postoperative jaundice because of deterioration of liver function.
- **Devascularization procedures** include esophageal transection and do not produce encephalopathy.
- **Liver transplantation:** It is the treatment of choice when there liver function is poor.

#### **Primary Prevention of Variceal Bleeding (Prophylactic Measures)**

Patients with cirrhosis and varices, who have not bled following prophylactic measures are useful.

- Non-selective beta-blockers (e.g. propranolol or nadolol) reduce the chances of upper GI bleeding and are cost-effective. The efficacy of  $\beta$ -blockers is similar to that of prophylactic banding.
- Variceal banding is done if there are contraindications or intolerance to non-selective beta-blockers.

# HEPATIC ENCEPHALOPATHY

**Q. Define hepatic (portosystemic) encephalopathy.**

## Definition

Hepatic encephalopathy or portosystemic encephalopathy is defined as a **neuropsychiatric syndrome** (alteration in mental status and cognitive function) occurring **secondary to chronic liver disease**.

- Encephalopathy may be **acute** and potentially reversible, **or chronic** and progressive.

## Etiology

**Q. Discuss the etiology, pathogenesis, clinical features, precipitating factors, investigations and treatment/management of hepatic encephalopathy.**

**Q. Write short essay on alcoholic cirrhosis with acute hepatic encephalopathy.**

- More common in patients with chronic liver disease such as **cirrhosis**. In patients with portal hypertension it develops due to spontaneous 'shunting' or in patients following a **portosystemic shunt procedure**, e.g. TIPS (transjugular intrahepatic portocaval shunt).
- Acute encephalopathy can occur in **acute fulminant hepatic failure**.

## Pathogenesis

- **Mechanism is unknown** but many factors play a role. Six pathogenic mechanisms have been proposed
  1. Gut derived neurotoxins that are normally metabolized by the liver
  2. Brain water homeostasis
  3. Oxidative/nitrosative stress
  4. Astrocyte dysregulation
  5. Neurotransmitter dysfunction (decreased glutamine, increased GABA, serotonin)
  6. Infection and inflammation
- Hepatic encephalopathy develops **due to disturbance of brain function**

**resulting from various toxic substances reaching the brain.** Normally, these toxic substances are derived from the intestine (gut-derived neurotoxins) and carried by portal circulation to the liver, where they are detoxified. Hence, they neither enter the systemic circulation nor reach brain.

- In hepatic encephalopathy, these toxic substances are not removed by the liver and reach brain. **Three factors are responsible** for this are:
  1. **Vascular shunting/bypassing the liver:** The portal blood bypasses the liver via the collaterals into systemic circulation and the ‘toxic’ metabolites pass directly to the brain.
  2. **Decreased liver mass:** It results in severe hepatocellular dysfunction leading to defective detoxification of the toxic substances.
  3. **Increased permeability of the blood-brain barrier:** Allows the toxins to enter the brain.
- **Toxic substances:** Involved in hepatic encephalopathy is listed in Table 11.31. **Ammonia plays a major role** and is produced by the breakdown of protein by intestinal bacteria.

**Table 11.31:** Toxic substances involved in hepatic encephalopathy.

• Ammonia plays major role	• Aromatic amino acids (tyrosine and phenylalanine)
• Free fatty acids	• Reduced branched-chain amino acids (valine, leucine and isoleucine)
• Mercaptans derived from methionine	• Phenol, Indole (oxindole)
• $\gamma$ -aminobutyric acid (GABA)	• False neurotransmitters (octopamine)

*Precipitating Factors for Portosystemic/Hepatic Encephalopathy (Table 11.32)*

**Q. List the precipitating causes of hepatic encephalopathy.**

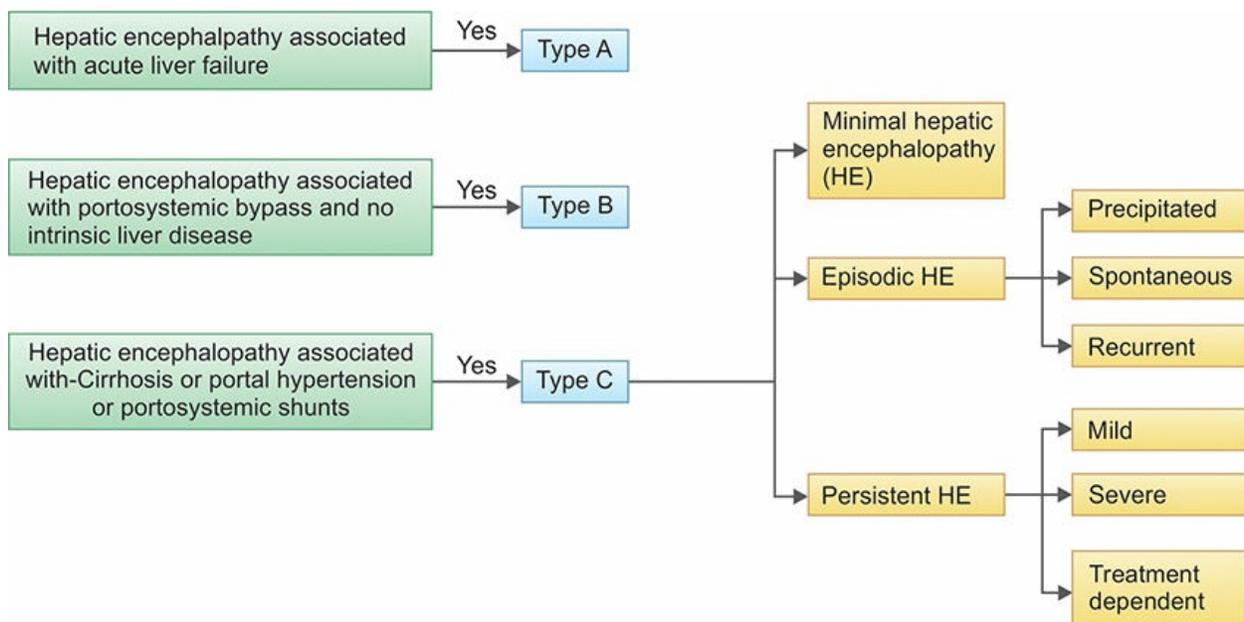

**Table 11.32:** Precipitating factors for hepatic/portosystemic encephalopathy.

• Increased protein load	• Acute infections including spontaneous bacterial peritonitis
– Dietary protein	• Drugs, e.g. sedatives, antidepressants,

	narcotics, alcohol
– Gastrointestinal bleeding	• Viral/alcoholic hepatitis
• Fluid and electrolyte disturbance such as hypokalemia, hyponatremia, metabolic alkalosis due to:	• Surgical procedure: Portosystemic shunt operations
– Large volume paracentesis	• Development of hepatocellular carcinoma, hepatic or portal vein thrombosis
– Overzealous use of diuretics	• Uremia
– Vomiting and diarrhea	• Constipation

## Types of Hepatic Encephalopathy (Flowchart 11.3)

Flowchart 11.3: Types of hepatic encephalopathy.

## Clinical Features

- **Acute hepatic (portosystemic) encephalopathy** often has a precipitating factor (Table 11.32) and the patient becomes drowsy and comatose within weeks to months. Brain edema may occur with severe encephalopathy and may lead to cerebral herniation.
- **Chronic hepatic (portosystemic) encephalopathy.**
- **Disturbances in consciousness and behavior:** Which may fluctuate. Hypersomnia is the earliest feature and may progress to **reversion of sleep rhythm (day time somnolence)**. Patient may become quite violent and difficult to manage or may be very sleepy and difficult to rouse.

Patients are **irritable, confused, disoriented** with slow slurred speech. Later may become drowsy and eventually progress to coma.

Clinical grade of hepatic encephalopathy are presented in Table 11.33.

**Table 11.33:** West Haven criteria clinical grade of hepatic encephalopathy.

<i>Clinical grade</i>	<i>Clinical signs</i>
Grade 0/ Minimal HE	Lack of detectable changes in personality or behavior. No asterixis
Grade 1	Trivial lack of awareness, euphoria or anxiety, shortened attention span, impaired performance of addition, asterixis may be present
Grade 2	Lethargy or apathy, minimal disorientation for time or place, subtle personality change, inappropriate behavior, slurred speech, impaired performance of subtraction. Asterixis is present
Grade 3	Somnolence to semi-stupor, but responsive to verbal stimuli, confusion, gross disorientation. Asterixis is usually absent
Grade 4	Coma (unresponsive to verbal or noxious stimuli)

(HE: hepatic encephalopathy)

- **Change in personality mood and intellect.**
- General features: Nausea, vomiting and weakness.

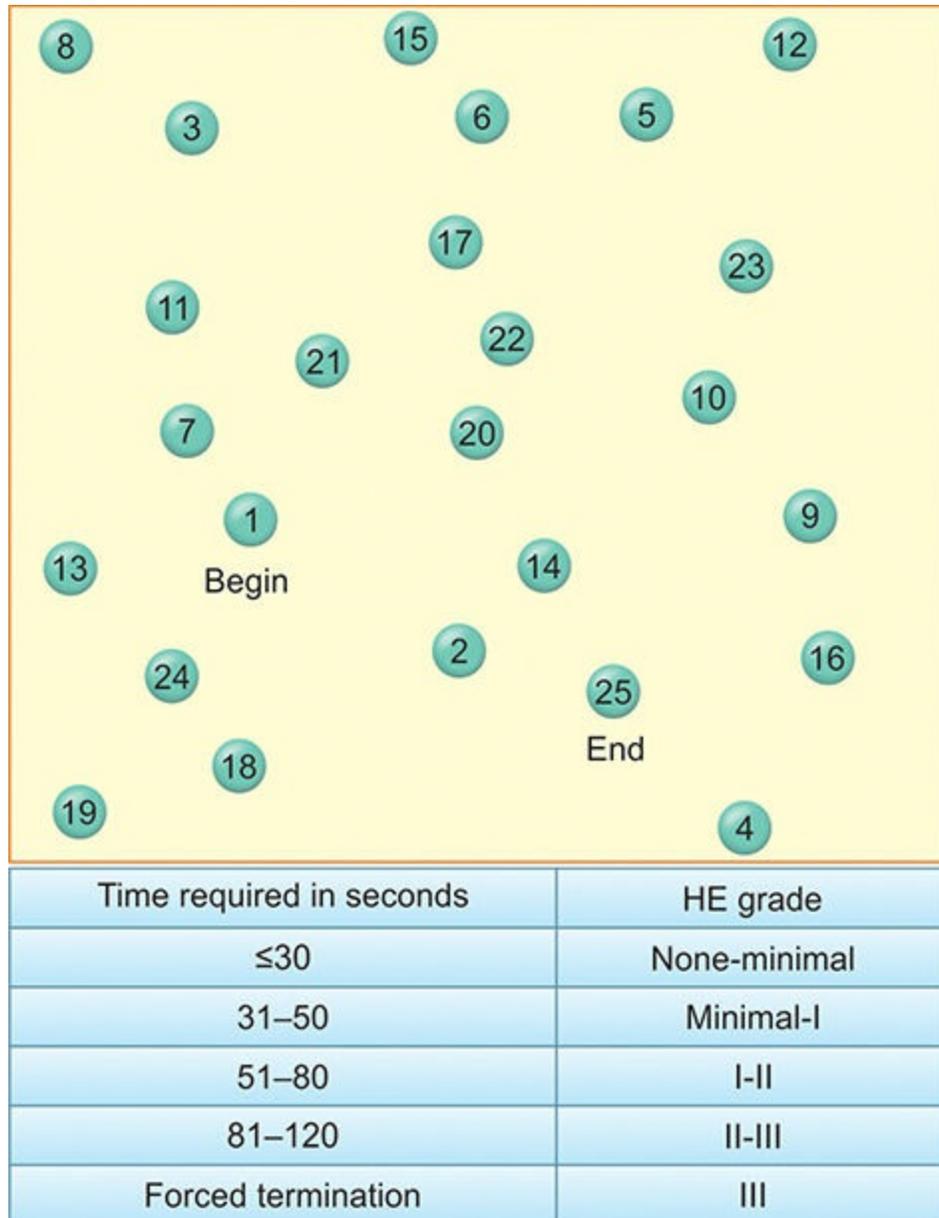

## Signs

- **Fetor hepaticus** (a sweet smell to the breath).
- **Asterixis** (flapping tremors) (refer Fig. 11.13A) is a motor disturbance marked by intermittent lapses of an assumed posture, as a result of intermittency of sustained contraction of groups of muscles. Usually manifests as a bilateral flapping tremor at the wrist, metacarpophalangeal, and hip joints. It may also be seen in tongue, foot, and any skeletal muscle.
  - **Mechanism:** Probably due to interruption of the posture pathway in the rostral reticular formation and abnormal joint proprioception.
  - The lapse of posture has been termed '**negative myoclonus**' because, during tonic muscle contraction (i.e. posture), a short EMG silent period precedes the tremor.
  - **Causes:** Hepatic encephalopathy, renal failure, metabolic encephalopathy, CO<sub>2</sub> toxicity, Wilson's disease, electrolyte abnormalities (hypoglycemia, hypokalemia and hypomagnesemia, drug intoxications (e.g. barbiturate intoxication, alcoholism, phenytoin intoxication ('phenytoin flap') and primidone intoxication) and psychotropic drugs (clozapine, sodium valproate, and risperidone). Lesions in the genu and anterior portion of the internal capsule or ventrolateral thalamus may cause unilateral asterixis.

- Fluctuating neurological signs.

- Constructional apraxia with the patient being unable to write or draw
- Hypertonia—later hypotonia
- Hyperreflexia and extensor plantar, later loss of reflexes
- Decreased mental function.

**Diagnosis:** It is based on clinical features. Diagnosis of minimal hepatic encephalopathy is currently based on neuropsychometric tests, including the number connection test, digit symbol test, and the block design test.

**Fig. 11.19:** Number connection test.

## Reitan's Number Connection Test (Fig. 11.19)

There are 25 numbered circles which can normally be joined together within 30 seconds.

### Investigations

- **Blood ammonia levels: Raised** (upper limit of normal is 0.8–1 ug/mL) and can be used for the differential diagnosis of coma and to follow a patient with PSE.
- **Electroencephalography (EEG): A decrease in the frequency of the normal  $\alpha$ -waves (8–13 Hz) to  $\alpha$ -waves of 1.5–3 Hz** is seen before coma develops.
- **Cerebrospinal fluid: Glutamine increased**, proteins normal and cell count is normal.
- Visual evoked potential abnormalities may be present during subclinical encephalopathy.
- Routine liver function tests only confirm the presence of liver disease and not the presence of encephalopathy. Imaging to rule out other causes.

### **Q. Write short note on treatment of hepatic encephalopathy.**

#### **Treatment of Hepatic Encephalopathy**

Treatment is multifactorial. Restriction of protein intake is reserved for resistant cases.

#### **General measures:**

- Management or removal of the precipitating factors is the most important aspect in the treatment.
- Maintain nutrition with adequate calories 35–40 kcal/kg/day.
- Maintain hydration and correct the electrolyte imbalance.
- **Protein restriction** in the diet. Administer 1.0–1.2 g/kg of proteins daily, preferably vegetable protein.
- Zinc supplementation may be helpful and is relatively harmless.
- Stop or reduce diuretic therapy.
- Treat any infection with **suitable antibiotics** (e.g. ampicillin, rifaximin, metronidazole or neomycin).
- Stop alcohol. **Avoid sedatives.** For restlessness and excitement small dose of diazepam or midazolam may be given intravenously.

#### **Evacuation of the bowels and sterilizing the bowel:**

Give purgation and enemas to empty the bowels of nitrogenous substances.

#### **Lactulose therapy: To reduce plasma ammonia level.**

- **Actions:** Lactulose (beta-galactosidofructose) is a nonabsorbable disaccharide acts as an osmotic purgative. In the colon, lactulose and lactitol are catabolized by the bacterial flora to lactic acid

and acetic acid. It lowers the colonic pH and favors the formation of the nonabsorbable  $\text{NH}_4^+$  from  $\text{NH}_3$ , trapping  $\text{NH}_4^+$  in the colon and thus reducing plasma ammonia concentrations. Other mechanism of action include (1) increased incorporation of ammonia by bacteria for synthesis of nitrogenous compounds, (2) modification of colonic flora, resulting in displacement of urease-producing bacteria with non-urease-producing bacteria and cathartic effects that improves gastrointestinal transit, allowing less time for ammonia absorption, (3) increased fecal nitrogen excretion due to the increase in stool volume and (4) reduced formation of toxic short-chain fatty acids (e.g. propionate, butyrate, valerate).

- **Dose: 15–30 mL three times orally per day.** Dose is increased gradually till there are 2–3 loose stools per day.

**Lactitol** ( $\beta$ -galactoside sorbitol 30 g daily): It has a similar action, more palatable and better than lactulose.

*Poorly absorbed antibiotics:* They are often used as adjunctive to sterilize the gut in patients who have difficulty with lactulose. They reduce the intestinal ammonia production by bacteria.

- **Alternating administration of neomycin and metronidazole** to reduce the individual side effects of each: neomycin for nephrotoxicity and ototoxicity and metronidazole for peripheral neuropathy.
- **Rifaximin** semisynthetic, gut-selective, and nonabsorbable oral antibiotic, derived from rifamycin and a structural analog of rifampin in the dose of 550 mg twice daily or 400 mg thrice daily is very effective and without any side effects of neomycin or metronidazole. It has only 0.4% systemic absorption.

**When there is gastrointestinal bleeding, Ryles tube aspiration and bowel washes** are performed to remove the blood and blood products. It reduces the production of nitrogen in the gut.

Other drugs tried are:

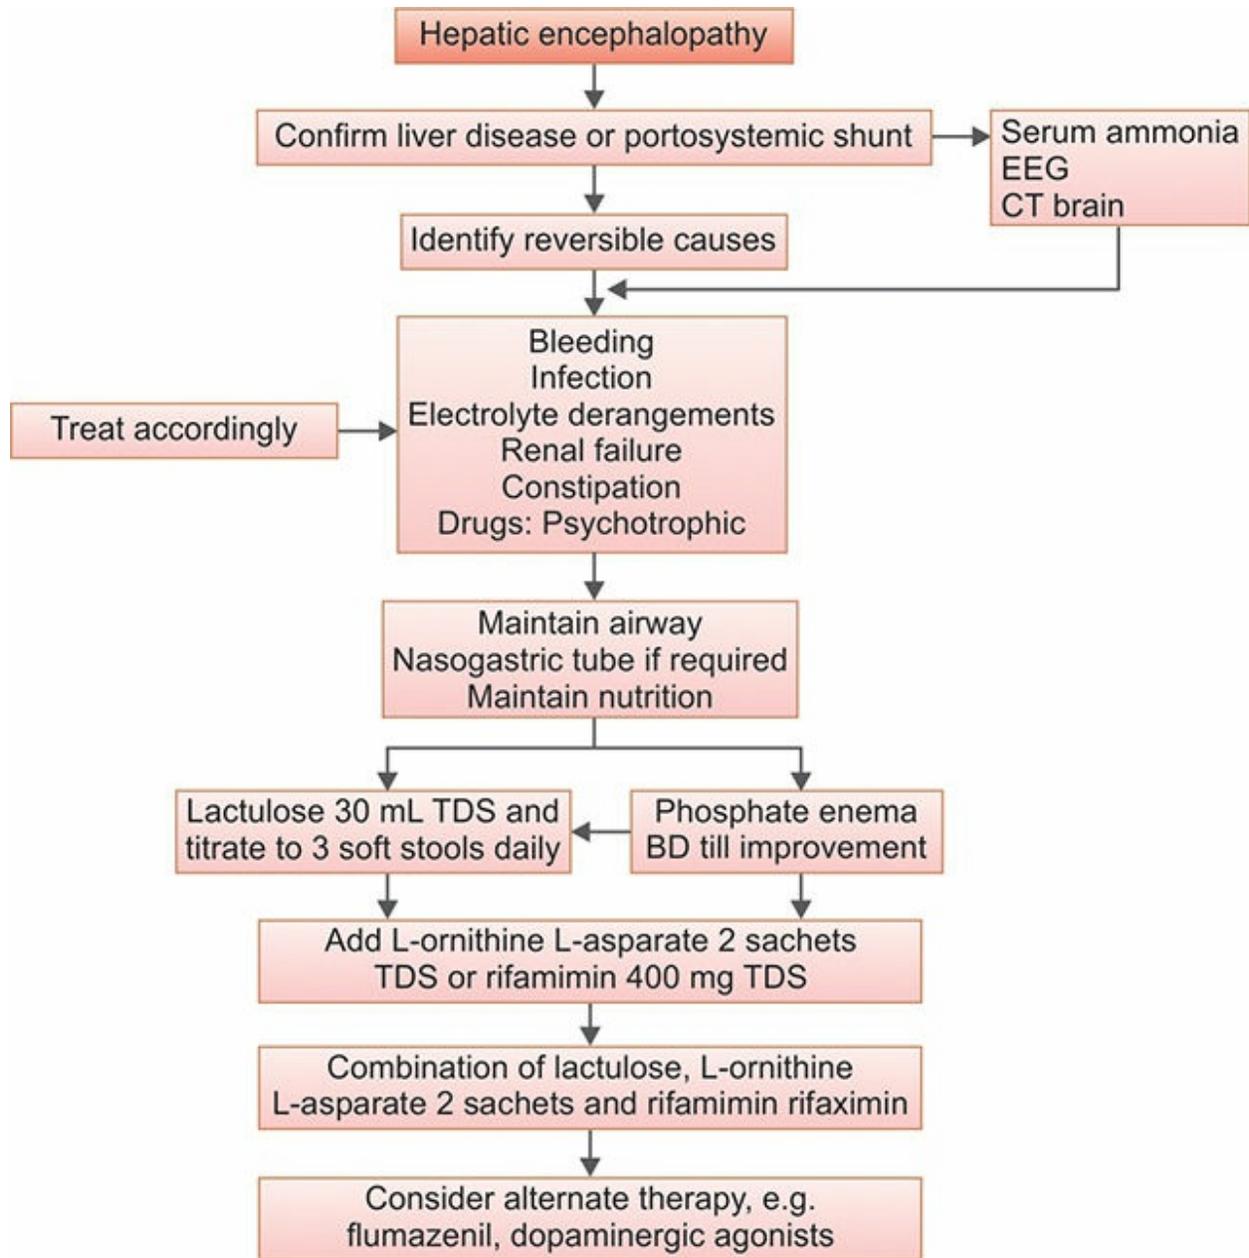

- |                 |     |                   |    |                  |
|-----------------|-----|-------------------|----|------------------|
| • Bromocriptine |     | • L-ornithine     | L- | • Branched chain |
| • Probiotics    | and | aspartate (LOLA)  |    | amino acids      |
| prebiotics      |     | • Sodium benzoate |    | • Zinc,          |
| • Flumazenil    |     | • Melatonin       |    | polyethylene     |
|                 |     |                   |    | glycol, acarbose |

Novel treatment strategies include use of L carnitine, rivastigmine, endocannabinoids, mGluR1 antagonists.

- In acute liver failure, mannitol and judicious use of intravenous fluids to reduce the spontaneous cerebral edema (controversial).
- Liver transplantation.
- **MARS—Molecular Adsorption reversibility System**—purifies the blood by removal of albumin bound as well as water soluble substrates.

Management of hepatic encephalopathy is summarized in Flowchart. 11.4.

**Flowchart 11.4:** Management of hepatic encephalopathy.

## Hepatorenal Syndrome

**Q. Write a short note on hepatorenal syndrome.**

- Hepatorenal syndrome (HRS) is a form of **functional azotemia without renal pathology in patients with advanced cirrhosis or acute liver failure.**
- The urine output is low, tubular function is normal and kidneys are histologically normal.
- This occurs in 10% of patients with advanced cirrhosis with jaundice and

ascites.

## ***Pathogenesis***

- **Initially, severe peripheral vasodilatation** (probably due to nitric oxide), leads to severe **reduction in the effective blood volume and hypotension**.
- This **activates** the homeostatic mechanisms and **rennin-angiotensin-aldosterone system leading to vasoconstriction of the renal vessels**.
- Increased preglomerular vascular resistance directs the flow of blood away from the renal cortex. This leads to a **reduced glomerular filtration rate**.
- **Eicosanoids** is another mediator involved in pathogenesis of HRS.

## ***Precipitating Factors for HRS (Box 11.35)***

**Box 11.35:** Precipitating factors for hepatorenal syndrome (HRS).

- Gastrointestinal bleeding
- Aggressive paracentesis
- Diuretic therapy
- Sepsis including spontaneous bacterial peritonitis
- Diarrhea.

## ***Clinical Types***

### **Type 1 hepatorenal syndrome**

- It is characterized by **progressive oliguria, a rapid rise of the serum creatinine** to above 2.5 mg/dL and has a **very poor prognosis**.
- **Usually precipitated by spontaneous bacterial peritonitis**.
- Without treatment, median survival is less than 1 month and almost all patients die within 10 weeks after the onset of renal failure.

### **Type 2 hepatorenal syndrome**

- It is characterized by a reduction in glomerular filtration, **moderate and stable increase in serum creatinine** (>1.5 mg/dL), but it is fairly stable and has a **better prognosis** than Type 1 HRS.
- **Usually occurs in patients with refractory ascites** (resistant to diuretics).
- Median survival is 3–6 months.

## ***Clinical Features***

- Develops in advanced cirrhosis, almost always with ascites.
- Anorexia, weakness, fatigue, oliguria, nausea, vomiting and thirst.

- Terminally coma deepens and hypotension develops.

## ***Investigations***

- **Urea and creatinine levels: High.**
- Serum sodium: less than 130 mEq/L.
- Urine sodium excretion: Less than 10 mEq/day
- Urinalysis: Normal
- Urine: Plasma osmolality ratio is more than 1.5.

**Table 11.34:** All of the following must be present for the diagnosis of hepatorenal syndrome (HRS).

- Cirrhosis with ascites
- Serum creatinine >1.5 mg/dL
- No improvement of serum creatinine (decrease to a level of 1.5 mg/dL or less) after at least 2 days of diuretic withdrawal and volume expansion with albumin
- Absence of shock
- No current or recent treatment with nephrotoxic drugs
- Absence of parenchymal kidney disease as indicated by proteinuria >500 mg/day, microhematuria (>50 red blood cells per high power field), and/or abnormal renal ultrasonography

## ***Diagnosis***

Usually made in the presence of a large amount of ascites in patients who have a stepwise progressive increase in creatinine.

Diagnostic criteria hepatorenal syndrome (Table 11.34).

### **Treatment**

- **Prevention:**
  - Avoid over vigorous diuretic therapy.
  - Slow treatment of ascites.
  - Early recognition of electrolyte imbalance, hemorrhage or infection.
- **Stop diuretic therapy**
- **Correct hypovolemia** by intravenous plasma protein solution or salt-poor albumin.
- Screen and **treat infection** including SBP (spontaneous bacterial peritonitis).
- An **albumin infusion** (1 g/kg body weight/day up to a maximum of 100 g/day) in combination with **terlipressin** (vasopressin analogues) is effective short-term medical therapy.
- Currently, **midodrine** ( $\alpha$ -agonist) along with octreotide and intravenous albumin is also used.
- TIPSS if vasoconstrictors fail.

**Liver transplantation** is the treatment of choice.

## ASCITES

**Q. Discuss the pathogenesis and management of ascites and refractory ascites in cirrhosis.**

**Q. Discuss the definition, mechanism, causes, clinical features and differential diagnosis of ascites.**

**Q. What is Puddle sign?**

Ascites is defined as the **accumulation of excess fluid within the peritoneal cavity**.

The **most common** (85% of cases) **cause** of ascites is **portal hypertension** caused by **cirrhosis**; however, malignant or infectious causes can also produce ascites.

### Pathogenesis/Mechanisms

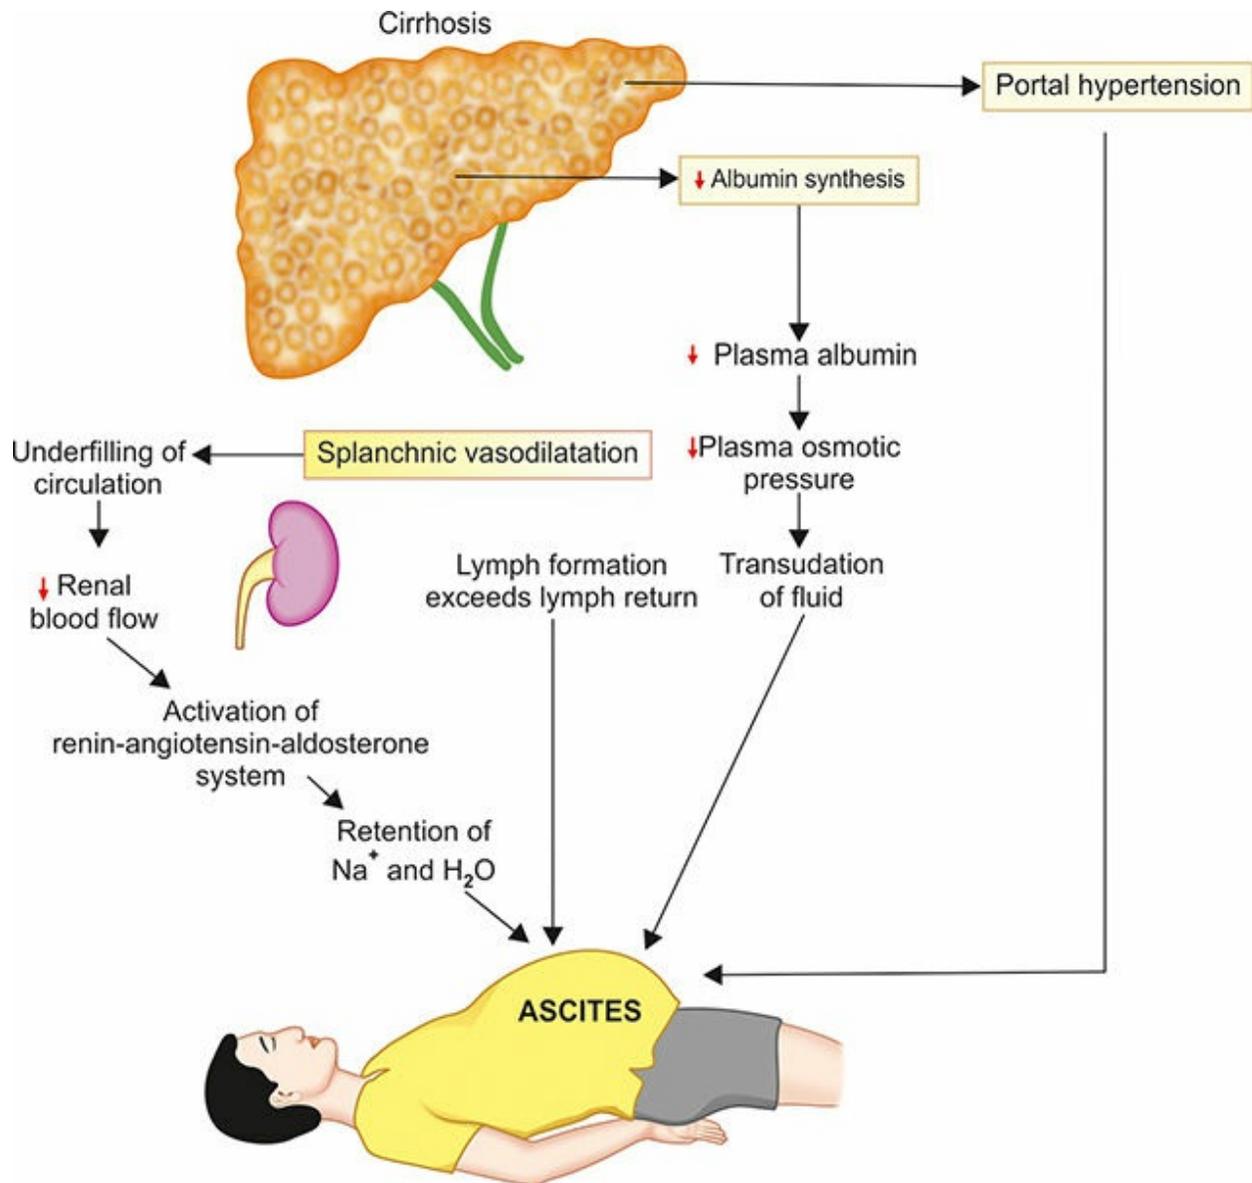

#### *Pathogenesis of Ascites in Cirrhosis (Fig. 11.20)*

It is complex, involving the following mechanisms.

- **Portal hypertension:** Increase in portal vein hydrostatic pressure and results in extravasation of fluid from plasma into the peritoneal cavity.
- **Hypoalbuminemia:** Due to decreased synthetic function in a cirrhotic liver reduces the plasma oncotic pressure. This results in an extravasation of fluid (ascites and edema).
- **Splanchnic vasodilation and hyperdynamic circulation.** It reduces systemic arterial blood pressure, activates **renin-angiotensin-aldosterone system** with the development of **secondary hyperaldosteronism**. Failure of liver to metabolize aldosterone intensifies secondary hyperaldosteronism. It leads to **sodium retention** and **fluid accumulation** and expansion of the extracellular fluid volume.

The combination of portal hypertension, splanchnic arterial vasodilation, and sodium and water retention increases the hydrostatic pressure as well as permeability of interstitial capillaries. It causes extravasation of fluid into the peritoneal cavity.

- **Percolation of hepatic lymph into the peritoneal cavity:** In cirrhosis, hepatic lymphatic flow exceeds thoracic duct capacity. The excess lymph oozes freely from the surface of cirrhotic liver into the peritoneal cavity and cause ascites.

**Fig. 11.20:** Pathogenesis of ascites in cirrhosis.

- **Theories of ascites:** According to the **underfill theory**, transudation from the liver leads to reduction of the blood volume, thereby stimulating sodium (Na) retention by the kidney.
  - According to the **overflow theory**, increased portal pressure stimulates renal Na retention through incompletely defined mechanisms.
  - The **vasodilation theory** suggests that portal hypertension leads to vasodilation and relative arterial hypotension.

## ***Pathogenesis in the Absence of Cirrhosis***

- **Ascites due to inflammation of peritoneum:** Inflammation of the peritoneum (peritonitis) by bacteria or mycobacteria (tuberculous peritonitis) causes increased vascular permeability and exudation of fluid into the peritoneal cavity.
- **Ascites due to venous obstruction:** Such as inferior vena cava (IVC) obstruction increases the hydrostatic pressure and leads to transudation of fluid into peritoneal cavity.
- **Ascites due to lymphatic obstruction:** Obstruction of lymphatic flow due to involvement of mesenteric lymph nodes, thoracic duct and abdominal lymphatic ducts can cause leakage of chyle into peritoneal cavity and can lead to chylous ascites.
- **Ascites following rupture of a viscus:** It can result in outpouring of blood, cystic fluid or contaminated material, favoring ascites. Pancreatic ascites results from leakage of pancreatic enzymes into the peritoneum (e.g. pancreatitis).
- **Ascites associated with malignancy:** Ascites may result from primary peritoneal malignancies (e.g. mesothelioma or sarcoma), abdominal malignancies (e.g. gastric or colonic adenocarcinoma), or metastatic disease from breast or lung carcinoma or melanoma.

## **Clinical Features**

### ***Symptoms***

- Distension of abdominal (increase in abdominal girth) and bloated feeling often accompanied by peripheral edema.
- Ascitic fluid may cause elevation of diaphragm and compromise respiratory function and produce dyspnea and orthopnea.
- Indigestion and heart burns due to gastroesophageal reflux may develop because of increased intra-abdominal pressure.
- **Malnourishment** and patients have **muscle wasting and excessive fatigue and weakness.**

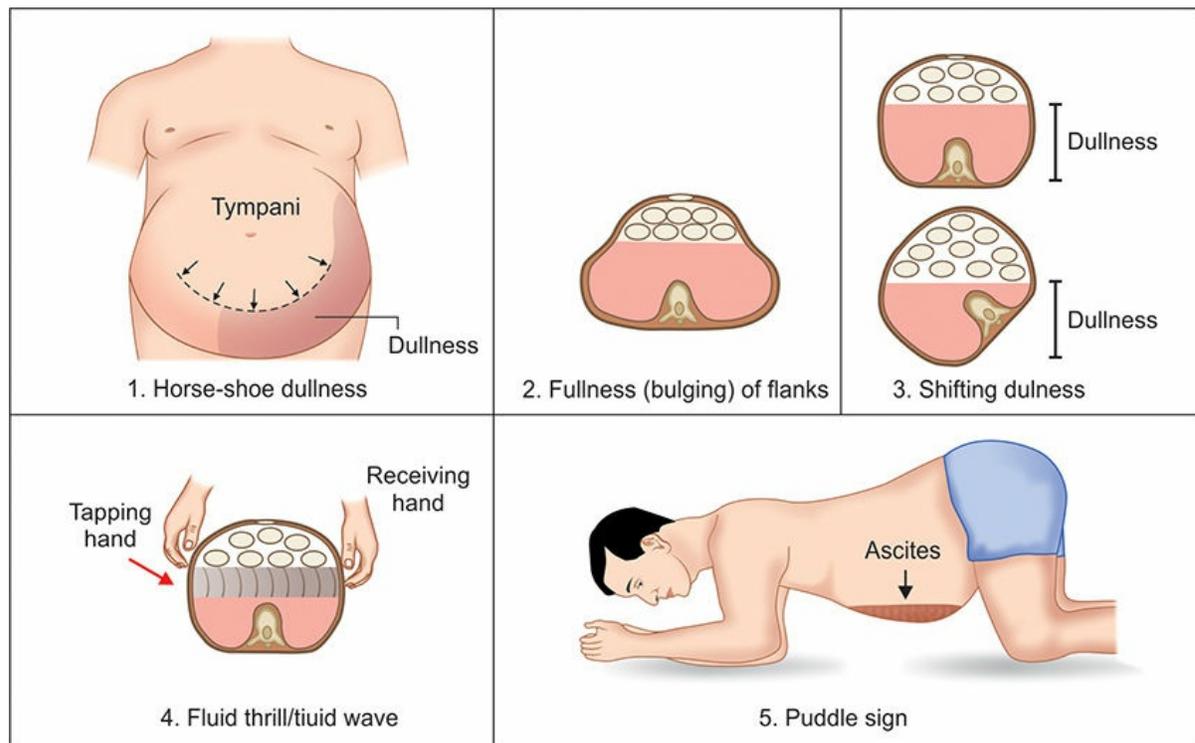

### ***Signs (Fig. 11.21 and Box 11.36)***

- **Distension of abdomen and fullness of flanks (bloated feeling).**
- **Umbilicus appear flat or everted.**

- **Skin over the abdominal wall appear stretched** and shiny.
- In the erect posture, hypogastrium appears prominent.

**Box 11.36:** Five signs of ascites.

1. Horse shoe dullness
2. Shifting dullness
3. Puddle sign
4. Fullness of flank
5. Fluid thrill/ fluid wave

**Fig. 11.21:** Signs of ascites.

- Abdominal wall may show two types of distended veins:
  - **Caput medusa** in which veins radiate out from the umbilicus with blood flow away from the umbilicus. They represent collaterals developed due to portal hypertension.
  - **Prominent veins in the flanks** with blood flow from below upwards. They represent the IVC collaterals developed due to compression of IVC by severe ascites.
- **Abdominal dullness:** It indicates the presence of fluid in the abdominal cavity.

- Dullness in the paraumbilical zone is detected with smaller amounts of fluid. This is elicited by asking the patient to assume knee elbow position and paraumbilical region percussed. Normally, the percussion note is tympanitic. With mild ascites the dullness is found only in the flanks.

### **Q. What is Puddle sign?**

- **Puddle sign/Lawson's sign:** It can detect even ascites as low as 120 mL. Patient is asked to lie in prone position for 5 minutes, followed by knee elbow position. Place the diaphragm of the stethoscope on the most dependent part of the abdomen. Repeatedly flick one flank lightly. Diaphragm is gradually moved to the opposite flank. A marked change in the intensity and character of percussion note indicates the presence of fluid.
- With moderate ascites both the flanks and hypogastric areas are dull (**horseshoe-shaped dullness**). The epigastrium and umbilical regions show resonant note due to floating intestines.
- With massive ascites the whole of the abdomen is dull except for a small region over the umbilicus.
- For elicitation **shifting dullness** at least of 500–1000 mL of fluid is required.
- **Fluid thrill** can be elicited in tense ascites (fluid more than 2000 mL).

### **Secondary effects**

- **Edema of scrotum.**
- **Pedal edema:** Due to hypoproteinemia and a functional block of IVC caused by tense ascites.
- **Pleural effusion:** Mainly on the right side. Pleural effusion is due to defects in the diaphragm that allows the ascitic fluid to pass into the pleural cavity.
- **Cardiac apex: Shifted upwards** because of raised diaphragm.
- **Distension of neck veins:** Secondary to an raised right atrial pressure, which follows tense ascites and raised diaphragm.
- **Meralgia paresthetica:** It can develop due to compression of lateral cutaneous nerve of thigh.

- Divarication of recti and hernia.

## Investigations

**Ultrasonography:** It is very sensitive and can detect even small amounts of ascitic fluid and also useful in identifying the cause.

- **Paracentesis and evaluation of ascitic fluid** (refer Table 11.37).
- **Laparoscopy and biopsy of peritoneum.**

Aspirate about 10–20 mL of ascitic fluid and ascitic tap (Fig. 11.22) the following tests are performed:

**Fig. 11.22:** Ascitic tap.

- **Cell count:** A neutrophil count above 250 cells/mm<sup>3</sup> usually indicates spontaneous bacterial peritonitis.
- **Gram stain and culture:** for bacteria and acid-fast bacilli.
- **Protein:** Total ascitic fluid protein more than 1.5 g/dL indicates an increased risk of spontaneous bacterial peritonitis.
- **SAAG (Serum ascites albumin gradient):** It is the differences between serum albumin and ascitic fluid albumin. SAAG is useful for differentiating ascites caused by portal hypertension from nonportal hypertensive ascites. It is calculated by subtracting the ascitic albumin concentration from the serum albumin concentration and does not change with diuresis. It is **better indicator** than simple estimation of protein in the ascitic fluid. SAAG is not a ratio, its the difference.

Classification of ascites based on SAAG is presented in Table 11.35. Corrected SAAG = Uncorrected SAAG  $\times$  0.16  $\times$  (Serum globulin g/dL + 2.5).

- **Cytology:** For malignant cells to exclude neoplasms causing ascites.
- **Amylase:** To exclude pancreatic ascites. It is increased in acute pancreatitis.

Ascitic fluid changes in cirrhosis are presented in Table 11.36.

Causes of high and low serum-ascites albumin gradient (Table 11.35)

**Table 11.35: Causes of high and low serum-ascites albumin gradient.**

<b>Causes of high serum-ascites albumin gradient (&gt; 1.1 g/dL)</b>	<b>Causes of low serum-ascites albumin gradient (&lt; 1.1 g/dL)</b>
• Portal hypertension, e.g. cirrhosis of liver	• Peritoneal tuberculosis
• Hepatic outflow obstruction	• Carcinoma involving peritoneal cavity
• Alcoholic hepatitis	• Pancreatitis
• Cardiac failure	• Nephrotic syndrome
• Myxodema	• Biliary ascites
• Fatty liver of pregnancy	• Serositis
• Budd-Chiari syndrome	• Bowel infarction
• Hepatic veno-occlusive disease	
• Right-sided heart failure	
• Constrictive pericarditis	

**Table 11.36: Ascitic fluid changes in cirrhosis.**

<b>Features</b>	<b>Findings</b>
Appearance	Clear, straw colored or light green
Specific gravity	Less than 1.018
Protein	Less than 2.5 g/dL
Total cell count	Normal (<250/L)
Differential cell count	Mesothelial cells and lymphocytes
Gram's stain	Negative
Culture	Negative
Malignant cells	Absent
Serum ascites albumin gradient (SAAG)	1.1g/dL

## Differential Diagnosis of Ascites (Table 11.37)

## Nature of Ascitic Fluid

The ascitic fluid may be transudate or exudate. Differences between transudates and exudates are listed in Table 11.38.

**Table 11.37:** Examination of ascitic fluid and its interpretation.

<i>Feature</i>	<i>Interpretation</i>
<b>Gross appearance</b>	
<ul style="list-style-type: none"> <li>• Clear, straw-colored or light green</li> </ul>	<ul style="list-style-type: none"> <li>• Cirrhosis, infective (e.g. tuberculosis, following intra-abdominal perforation), malignancy, chronic pancreatitis, heart disorders (congestive cardiac failure, constrictive pericarditis, hepatic vein obstruction (e.g. Budd-Chiari syndrome), Meigs' syndrome (ovarian tumor), hypoproteinemia (e.g. nephrotic syndrome)</li> </ul>
<ul style="list-style-type: none"> <li>• Hemorrhagic</li> </ul>	<ul style="list-style-type: none"> <li>• Malignant tumors, tuberculosis, acute pancreatitis, ruptured ectopic pregnancy, trauma to abdomen</li> </ul>

**Culture**

- |                     |                         |
|---------------------|-------------------------|
| • Pyogenic bacteria | • Bacterial peritonitis |
| • Mycobacteria      | • Tuberculosis          |

**Table 11.38:** Differences between transudative and exudative ascites.

<b>Characteristics</b>	<b>Transudate</b>	<b>Exudate</b>
Cause	Non-inflammatory process	Inflammatory process
Mechanism	Ultrafiltrate of plasma, due to increased hydrostatic pressure with normal vascular permeability	Increased vascular permeability
Appearance	Clear, serous	Cloudy/turbid purulent/hemorrhagic/chylous
Color	Straw yellow	Yellow to red
Specific gravity	<1.018	>1.018
Protein	Low, <2 g/dL, mainly albumin	High, >2 g/dL
Clot	Absent	Clots spontaneously because of high fibrinogen
Cell count	Low (<250/uL)	High (>250/uL)
Type of cells	Few lymphocytes and mesothelial cells	Neutrophils in acute and lymphocytes in chronic inflammation
Bacteria	Absent	Usually present
Lactate dehydrogenase (LDH)	Low	High
Examples	Cirrhosis, nephrotic syndrome, heart failure	Peritonitis, Malignancy

**Table 11.39:** Various causes of ascites categorized depending on the nature of ascitic fluid.

<b>Transudates (High SAAG)</b>	<b>Exudates (Low SAAG)</b>
• Cirrhosis and portal hypertension (common cause)	• Tuberculous peritonitis
• Nephrotic syndrome	• Malignant peritonitis
• Hypoproteinemia (protein-losing enteropathy, malnutrition)	• Bacterial peritonitis
• Congestive cardiac failure (common cause)	• Pancreatic ascites (acute pancreatitis)
• Constrictive pericarditis	• Miscellaneous (exudate/transudate)
• Beriberi	• Meigs' syndrome (may be transudate also)*
• Inferior vena cava (IVC) obstruction	• Chylous ascites (lymphatic obstruction)

- Hypothyroidism (rare cause)

- Budd-Chiari syndrome

(SAAG: serum ascites albumin gradient)

**Causes:** Various causes of ascites are listed in Table 11.39.

### Management

- **General measures:**

- Hospitalization is necessary, if there is massive ascites.
- Check serum electrolytes, renal function tests at the start of treatment and twice a week.
- Weigh the patient daily. Measure abdominal girth and strict intake and output monitoring daily.

- **Bed rest** alone induces diuresis in a small proportion of people because renal blood flow increases in the horizontal position, but in practice is not helpful. Ascites treatment algorithm is shown in Flowchart 11.5.

- **Dietary restriction of sodium** by reducing sodium intake to 40 mmol in 24 hours and maintain an adequate protein and calorie intake with a palatable diet.

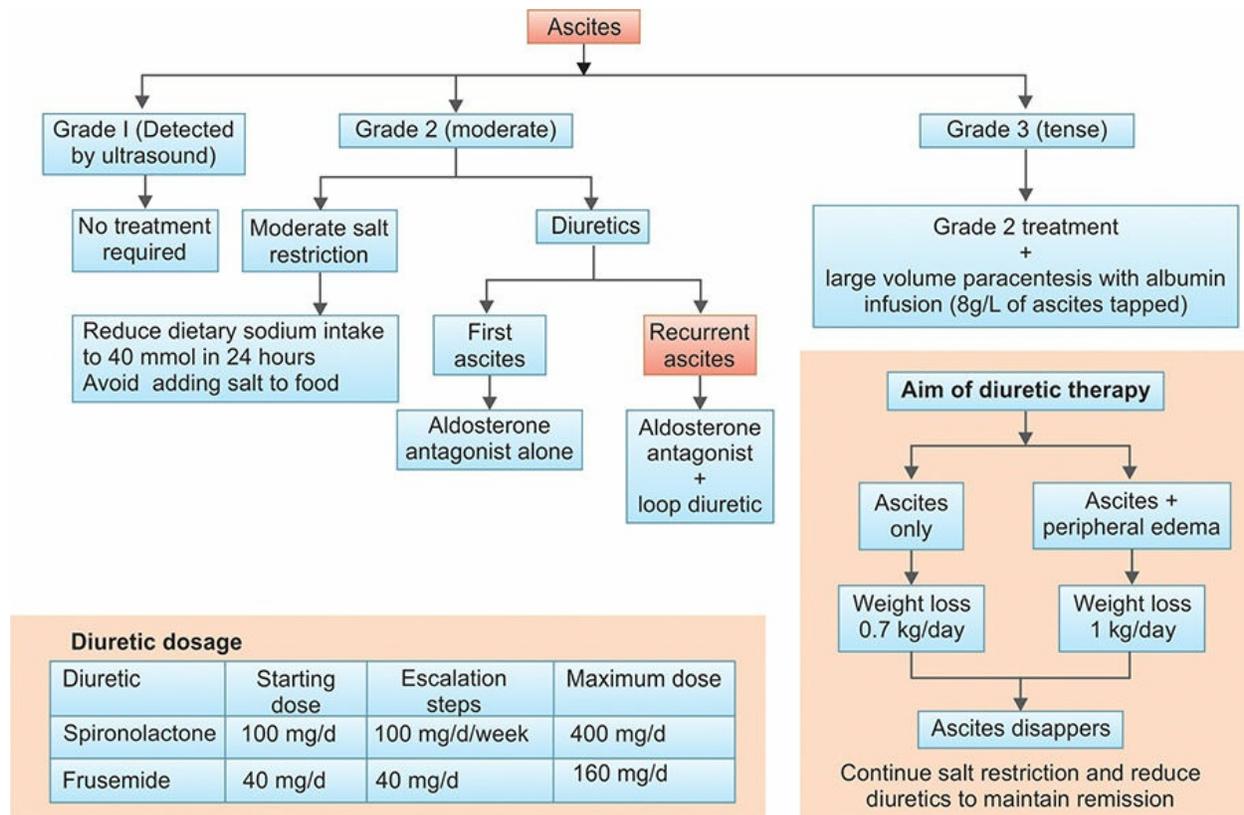

- **Drugs:** Many contain significant amounts of sodium (up to 50 mmol daily). Examples include antacids, antibiotics (particularly the penicillins and cephalosporins) and effervescent tablets. Sodium-retaining drugs (non-steroidal, corticosteroids) should be avoided.

- **Fluid restriction to 1000–1500 mL/day** is necessary if the serum sodium is under 128 mmol/L.

- **Diuretics**

- **Aim of diuretic therapy: To produce a net loss of fluid** of about 700 mL per day (0.7 kg weight loss in patients with ascites alone or 1.0 kg if both ascites and peripheral edema is present). The maximum rate at which ascites can be mobilized is 500–700 mL per day. This is to prevent diuretic-induced renal failure and/or hypernatremia.
- Diuretics are administered in a step-wise manner.
- **Aldosterone antagonists:** As there is **secondary hyperaldosteronism**, the diuretic of first choice is the one of the aldosterone antagonists (potassium-sparing diuretics) e.g. **spironolactone, triamterene, amiloride**. Spironolactone is started at a low dose of 25 mg QID (100 mg daily), and gradually stepped up every week to a maximum of 400 mg/day (providing there is no hyperkalemia). Chronic administration of spironolactone produces gynecomastia. Eplerenone 25 mg once daily does not produce gynecomastia.
- **Loop diuretics:** When a large dose of spironolactone has failed, add a loop diuretic, such as **furosemide 20–40 mg or bumetanide 0.5 mg or 1 mg daily**. Usually spironolactone is combined with furosemide. Disadvantages of loop diuretics include development of hyponatremia, hypokalemia and volume depletion.
- **Stop all diuretics, if severe hyponatremia** (sodium <120 mEq/L), progressive renal failure or worsening of hepatic encephalopathy occurs. Vaptans may improve serum sodium in patients with cirrhosis and ascites.

**Flowchart 11.5:** Ascites treatment algorithm

### Treatment of Refractory Ascites

**Q. Write short essay/note on indication, procedure and complications of abdominal paracentesis.**

**Refractory ascites** is defined as fluid overload that (1) is unresponsive to sodium-restricted diet and high-dose diuretic treatment (400 mg per day of spironolactone and 160 mg per day furosemide), or (2) recurs rapidly after therapeutic paracentesis.

They are managed on the following lines:

- Intravenous salt-poor albumin, 25 g in 3 hours.**
- Oral midodrine 7.5 mg three times daily.**

**Box 11.37:** Indications for large-volume paracentesis.

- Refractory ascites.
- Used to relieve symptomatic tense ascites, e.g. cardiorespiratory distress due to gross ascites.
- Impending rupture of a hernia.

### 3. Large-volume Paracentesis

- **Indications (Box 11.37)**

- **Procedure:**

- Remove 3–5 L of fluid over 1–2 hours.
- Salt-free albumin (8 g/L of ascitic fluid removed) if volume is more than 4–5 liters is removed. If albumin is not available, dextran-70 may be used. Strict monitoring is necessary.

- **Complication:** Hypovolemic and renal dysfunction (postparacentesis circulatory dysfunction) more likely with removal of > 5 L and worse liver function.
4. **Shunts:**
    - **Transjugular intrahepatic portosystemic shunt (TIPS):** It is used for resistant ascites, if there is no spontaneous portosystemic encephalopathy and no disturbance of renal function.
    - **Le Vein shunt:** It is a peritoneovenous shunt that allows the peritoneal fluid to drain directly into the internal jugular vein.
  5. Slow low-dose continuous albumin, Furosemide with or without Terlipressin **SIFA(T)** infusion.
  6. Liver transplantation.

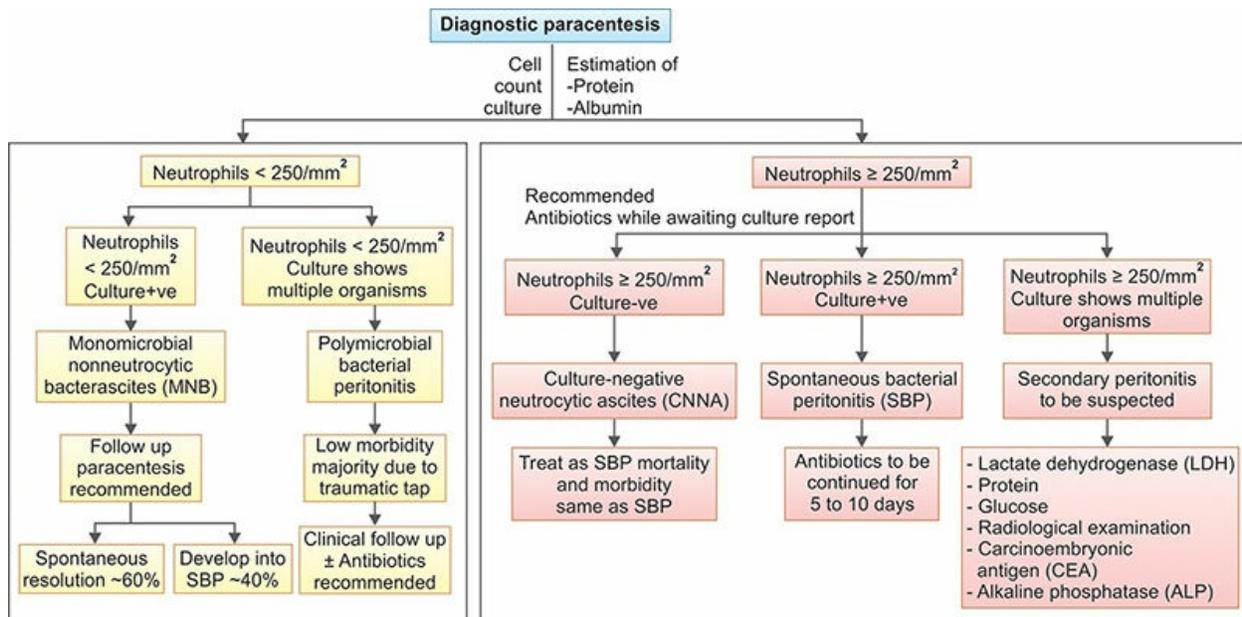

## Bacterial Peritonitis

**Types:** (1) Acute bacterial peritonitis or (2) Chronic bacterial peritonitis.

### 1. Acute Bacterial Peritonitis

**Causes:** Appendicitis, perforated peptic ulcer or typhoid ulcer, cholecystitis, diverticulitis, gangrene of the small intestine and ulcerative colitis.

**Flowchart 11.6:** Approach to the patient with ascites following diagnostic paracentesis

### Symptoms

Fever, nausea, thirst, vomiting, severe abdominal pain. No flatus.

### Signs

- Hippocratic facies
- Tachycardia, hypotension, and shock

- Board like rigidity, tenderness and rebound tenderness
- Absent peristaltic sounds.

### *Investigations (Box 11.38)*

#### **Box 11.38:** Investigations in acute bacterial peritonitis.

- **Plain radiograph of abdomen**
  - Dilated loops of intestine
  - Gas under the diaphragm if there is intestinal perforation
- **Ascitic fluid (Flowchart 11.6)**
  - Exudate, turbid or purulent
  - Shows intestinal contents in the fluid
  - Cell counts: Markedly increased, polymorphs  $>250/\text{mm}^3$
  - Gram stain: Positive for bacteria
  - Culture: It shows growth of organism

**Treatment:** It is a **surgical emergency**.

- Correction of fluid and electrolyte balance.
- Broad spectrum antibiotic therapy.
- Treat the shock.
- Surgical treatment depending on the causes.

## **2. Chronic Bacterial Peritonitis**

- Associated with subacute intestinal obstruction.
- Ascitic fluid: exudate, protein is high and contains large number of chronic inflammatory cells.
- Classification of ascitic fluid infections are listed in Table 11.40.

**Treatment** of the underlying cause.

#### **Table 11.40:** Classification of ascitic fluid infection.

- Culture-negative neutrocytic ascites
- Monomicrobial non-neutrocytic bacterascites
- Polymicrobial bacterascites (needle perforation of the bowel)
- Secondary bacterial peritonitis
- Spontaneous bacterial peritonitis

## ***Spontaneous Bacterial Peritonitis (SBP)***

**Q. Write short note on diagnosis and management of spontaneous bacterial peritonitis (SBP).**

Patients with cirrhosis and ascites are highly susceptible to infection of ascitic fluid.

### *Definition*

Spontaneous bacterial peritonitis is a **common and severe complication of ascites** characterized by **spontaneous infection of ascitic without an evident intra-abdominal surgically treatable source.**

### *Pathogenesis*

- **Causative agents:** Most common organisms are Escherichia coli, Klebsiella or enterococci or other gut bacteria. Others include streptococci and enterococci.
- **Route of infection:** The infecting organisms in the gut flora traverse the intestine into mesenteric lymph nodes, leading to bacteremia and seeding of the ascitic fluid by hematogenous spread.

### *Clinical features*

- Spontaneous bacterial peritonitis should be **suspected in any patient with ascites who clinically deteriorates.**
- It may present as **sudden deterioration or hepatic encephalopathy in a cirrhotic patient with ascites.**
- Features include **fever, abdominal pain or discomfort and rebound abdominal tenderness** or they may present without any of these features.

### *Investigations*

- **Peripheral blood: Leukocytosis.**
- **Ascitic fluid:**
  - **Cloudy fluid**
  - **Leucocyte count: More than 500/mm<sup>3</sup>.** A raised neutrophil count of  $> 250/\text{mm}^3$  in ascites is alone sufficient for diagnosis and to start treatment immediately.
  - pH: Less than 7.3.
  - **Culture: Positive.** Monomicrobial E. coli is the most common

organism.

- Investigations to rule out abdominal sources of peritonitis by imaging.

### Diagnosis

With **clinical suspicion, a diagnostic aspiration** (paracentesis) should always be performed in patients with gastrointestinal bleeding, shock, fever, worsening liver and/or renal function, and hepatic encephalopathy for making the diagnosis.

### Treatment

- **Third-generation cephalosporin:** such as **cefotaxime or ceftazidime** being the most commonly used antibiotic. This is modified on the basis of culture results. Dose of Cefotaxime: 2 g IV 8 hourly for 5 days.
- **Alternative therapy** in patients without shock or hepatic encephalopathy.
  - **Amoxicillin/clavulanate** (1.2 g IV 8 hourly followed by 625 mg orally).
  - **Ciprofloxacin** (200 mg IV 12 hourly followed by 500 mg BID orally).
  - **Ofloxacin** (400 mg twice daily).

Note: Quinolones should not be given if patient is on norfloxacin for prophylaxis.
- Antibiotic therapy and albumin (1.5 g/kg body weight within 6 hours of detection and 1g/kg on day 3) reduces risk of type 1 hepatorenal syndrome.

**Box 11.39:** Indications for prophylaxis for spontaneous bacterial peritonitis.

- **Patients with acute gastrointestinal bleeding** (antibiotic prophylaxis also reduces the rate of re-bleeding).
- Patients with a **previous episode(s) of SBP** and recovered.
- Patients with **low total ascites protein content** <1.5 g/dL or severe liver disease and no prior history of SBP.

### Prophylaxis for SBP

Recurrence is common (70% within a year) and prophylaxis is indicated (Box 11.39).

- **Drugs:**
  - In **patients with upper GI hemorrhage: cefotaxime or norfloxacin** (400 mg BID for 7 days).
  - In **patients with low ascitic protein content** or previous episode of spontaneous bacterial peritonitis: long term quinolones such as **norfloxacin** (400 mg/day).
  - Alternative but less effective drugs: include cotrimoxazole (800 mg sulfamethoxazole + 160 mg trimethoprim once a day) or ciprofloxacin (750 mg once a week).

## Tuberculous Peritonitis

- **Pathogenesis:** Tuberculosis spreads to involve peritoneum by or more of the following sources:
  - Through hematogenous seeding of peritoneum.
  - Through lymphatics or mesenteric nodes.

- From genitourinary source.

### ***Clinical Features***

- **Night sweats, weight loss, loss of appetite, malaise and evening rise of temperature.**
- Gradual abdominal distension and **‘doughy feel’ of the abdomen.**
- Multiple palpable masses in the abdomen produced due to matted omentum and loops of intestine.

### ***Investigations (Table 11.41)***

**Table 11.41:** Investigations in tuberculous peritonitis.

<i>Ascitic fluid</i>	
<ul style="list-style-type: none"> <li>• Usually straw colored.</li> <li>• <b>Protein: more than 2.5g/dL.</b></li> <li>• <b>Lymphocytes more than 70%.</b></li> <li>• Ziehl-Neelsen staining: <i>It may show acid fast bacilli.</i></li> </ul>	<ul style="list-style-type: none"> <li>• Culture of ascitic fluid for tubercle bacilli.</li> <li>• ADA levels: Raised</li> <li>• <b>Peritoneal biopsy under laparoscopy:</b> Shows <b>granuloma</b> and helps in confirmation of diagnosis</li> </ul>

**Treatment:** Antituberculous chemotherapy.

## **Malignant Ascites**

### ***Causes***

- **Primary tumors of stomach, colon, ovary or other intra-abdominal tumors** may produce exudation fluid into the peritoneal cavity.
- **Peritoneal metastasis:** from any primary.
- **Periumbilical subcutaneous metastatic tumor** deposits (known as ‘Sister-Joseph’s nodules’), e.g. carcinoma of stomach.

### ***Investigations***

- **Ascitic fluid (Box 11.40)**
- **Biopsy of the peritoneum** by laparoscope: **It shows the tumor** and useful for confirmation of diagnosis.

**Treatment:** Palliative

- Repeated paracentesis.

- Intraperitoneal instillation of chemotherapeutic drugs: It may reduce rate of reaccumulation of ascites. The drugs include methotrexate, nitrogen mustard or immunotherapy (interferon alfa).

**Box 11.40:** Ascitic fluid findings in malignant ascites.

- Appearance: **Exudate and hemorrhagic**
- **Protein: High**
- **Specific gravity: High**
- Microscopy: Sediment shows **malignant cells**.

## *Meigs' Syndrome*

**Q.** Write short note on Meig's syndrome.

Features of Meig's syndrome are presented in Box 11.41.

## *Chylous Ascites*

- Characterized by the **presence of chyle** (intestinal lymph) in the peritoneal cavity. Ascitic fluid is milky or creamy due to the presence of chylomicrons.
- **Causes:**
  - Injury/trauma to the main lymph ducts in the abdomen.
  - Malignancy (e.g. lymphoma) or tuberculosis causing obstruction of the intestinal lymphatics.
  - Filariasis.
  - Intestinal obstruction associated with rupture of a major lymphatic channel.
  - Congenital lymphangiectasia.
- **Clinical features:**
  - Acute abdominal pain with signs of peritoneal irritation.
  - Distended, non-tender, fluid filling the abdomen (chylous ascites).
- **Ascitic fluid:**
  - **Milky or creamy**
  - **High fat (triglycerides > 1000 mg/dL) content.**
  - **Sudan III staining demonstrates fat globules.**

**Box 11.41:** Features of Meig's syndrome.

- Pleural effusion is most commonly **right sided**, may be an exudates or transudate.
- **Ascites**
- **Pelvic tumor** (commonly fibroma of the ovary) in females. Both ascites and pleural effusion resolve following excision of the pelvic tumor.

### *Ascites Praecox*

#### **Q.** What is ascites praecox?

- In ascites praecox, ascites occurs early and is disproportionately prominent as well as appears before the edema. It occurs in constrictive pericarditis, acute Budd Chiari syndrome, tuberculous peritonitis, and malignant peritonitis.
- In constrictive pericarditis, ascites appears first, followed by edema. This sequence is one of the cardinal features, distinguishing ascites from congestive heart failure in which edema appears first and ascites much later. Edema is minimal in constrictive pericarditis and occurs in the later part of the disease.

## DRUG AND TOXIN-INDUCED HEPATITIS

### **Q.** Write a short note on drug-induced liver injury (DILI).

#### Types of Drug and Toxin-induced Hepatitis

- **Direct toxic hepatitis:** It is characterized by a predictable and dose-related toxicity, short latent period and absence of extrahepatic manifestations.
- **Idiosyncratic drug reactions:** These are characterized by unpredictable, most often dose-independent toxicity with variable latent period and presence of extrahepatic manifestations (e.g. fever, rashes, arthralgia and eosinophilia). However, for many drugs, idiosyncratic hepatotoxicity can be dose dependent. Examples: Drugs such as chlorpromazine, isoniazid and halothane.

#### **Treatment**

- Withdrawal of the drug/toxin.
- Supportive therapy.

### Clinicopathologic Classification of Drug-induced Liver Disease (Table 11.42)

**Table 11.42:** Clinicopathologic classification of drug-induced liver disease

(DILI).

<b>Category</b>	<b>Implicated drugs: Examples</b>
Hepatic adaptation	Phenytoin, warfarin, rifampin, flavaspidic acid
Dose-dependent hepatotoxicity (necrosis)	Acetaminophen (Paracetamol), nicotinic acid, amodiaquine, hycanthone, carbon tetrachloride, mushroom ( <i>Amanita phalloides</i> ), yellow phosphorus
Other cytopathic toxicity, acute steatosis	Valproic acid, didanosine, HAART agents, fialuridine, l-asparaginase, some herbal medicines
Acute hepatitis	Isoniazid, dantrolene, nitrofurantoin, halothane, sulfonamides, phenytoin, disulfiram, acebutolol, etretinate, ketoconazole, terbinafine, troglitazone, rifampicin, methyl dopa, ibuprofen, ketoconazole, fluconazole, zidovudine, chlorothiazide, oxyphenisatin
Chronic hepatitis	Nitrofurantoin, etretinate, diclofenac, minocycline, nefazodone, phenytoin, isoniazid
Granulomatous hepatitis	Allopurinol, carbamazepine, hydralazine, quinidine, quinine, phenylbutazone, sulfonamides, allopurinol
Cholestasis without hepatitis	Oral contraceptives, androgens
Cholestatic hepatitis	Chlorpromazine, tricyclic antidepressants, erythromycins estolate, amoxicillin-clavulanic acid, methimazole, chlorpromazine, chlorpropamide, methyltestosterone, anabolic steroids, cyclosporine, nimesulide
Cholestasis with bile duct injury	Chlorpromazine, flucloxacillin, dextropropoxyphene
Chronic cholestasis	Chlorpromazine, Haloperidol, erythromycin, cimetidine/ranitidine, nitrofurantoin, imipramine, azathioprine
Hepatic fibrosis	Methotrexate
Vanishing bile duct syndrome	Chlorpromazine, flucloxacillin, trimethoprim-sulfamethoxazole
Sclerosing cholangitis	Intra-arterial floxuridine, intralesional scolicedals
Steatosis (fatty change)	Zidovudine, amiodarone, indinavir, ritonavir, methotrexate, tetracyclines, valproic acid
Steatohepatitis	Perhexiline, amiodarone,
Vascular disorders	Contraceptive drugs, anabolic steroids, azathioprine
Tumors	Contraceptive pill, danazol

## HEPATIC VENOUS OUTFLOW TRACT (HVOT)

## OBSTRUCTION

**Q. Discuss the etiology, pathology, clinical features, investigations and management of hepatic venous outflow tract (HVOT) obstruction.**

**Q. Describe veno-occlusive disease or sinusoidal obstruction syndrome.**

- **Obstruction to the hepatic-venous outflow** can occur at different levels. These include:
  - **Small central hepatic veins—Veno-occlusive disease.**
  - **Large hepatic veins—Budd-Chiari syndrome.**
  - Inferior vena cava
  - Heart
- **Clinical features:** It **depends on the cause** and on the speed with which obstruction develops. Common features are congestive hepatomegaly and ascites.

### Budd-Chiari Syndrome

**Q. Explain briefly about Budd-Chiari syndrome.**

- **Definition:** Budd-Chiari syndrome is characterized by **obstruction of hepatic venous outflow owing to occlusion of the hepatic vein.**
- **Level of obstruction:** It may be at any level from the small hepatic veins to the junction of the IVC with the right atrium.
- **Classic Budd-Chiari syndrome results from thrombosis of one or more hepatic veins at their openings into the inferior vena cava.**

### *Etiology (Box 11.42)*

**Box 11.42:** Various causes of Budd-Chiari syndrome.

#### ***Hepatic vein obstruction***

Venous thrombosis

- Hypercoagulability states
  - Hematological disorders
  - Polycythemia vera
  - Paroxysmal nocturnal hemoglobinuria
  - Antithrombin III, protein C or protein S deficiencies
  - Antiphospholipid syndrome
  - Sickle cell disease

- Leukemia
- Pregnancy
- Use of oral contraceptive pills

Compression (may also produce thrombosis)

- Hepatic infections
- Hydatid cyst
- Liver abscess
- Obstruction due to tumors
- Renal cell carcinoma
- Adrenal tumors
- Hepatocellular carcinoma
- Posterior abdominal wall sarcomas

**Radiation injury**

**Congenital venous webs**

**Trauma to the liver**

**Idiopathic (40 to 50% of cases)**

## *Clinical Features*

Budd-Chiari syndrome: It comprises of a triad of **(1) abdominal pain, (2) ascites and (3) hepatomegaly** with hepatic histology showing centrilobular sinusoidal distension and pooling.

- **Acute form** (acute Budd-Chiari)
  - Follows sudden venous occlusion (e.g. by renal cell carcinoma, hepatocellular carcinoma, and polycythemia).
  - Acute upper abdominal pain, nausea, vomiting, tender hepatomegaly, marked ascites and mild jaundice.
  - With total venous occlusion: Delirium, coma and hepatocellular failure.
- **Fulminant form** (fulminant Budd-Chiari syndrome)
  - Presents with fulminant hepatic failure usually in the setting of an additional predisposing factor (e.g. factor V Leiden mutation).
  - Occurs particularly in pregnant women.
- **Chronic form** (chronic Budd-Chiari)
  - More gradual occlusion and more usual presentation.
  - Pain in abdomen, tender hepatomegaly and gross ascites.
  - **Enlarged caudate lobe** of the liver becomes palpable.
  - Jaundice is mild or absent.

- Splenomegaly with portal hypertension.
- Negative hepatojugular reflux, i.e. pressure over the liver fails to fill the jugular veins.
- Bilateral pedal edema and distended veins over **abdomen, flanks and back (Fig. 11.23), with IVC obstruction.**
- Features of cirrhosis and portal hypertension in patients who survive the acute event.
- Hepatocellular carcinoma may develop.

**Fig. 11.23:** Budd-Chiari dilated veins in back and lumbar region.

### ***Investigations***

- Liver function tests vary considerably
  - **Features of acute hepatitis:** Mild hyperbilirubinemia, raised alkaline phosphatase, low serum albumin and raised transaminases.
- **Ascitic fluid examination:** Typically shows a **high protein content** (>2.5 g/dL, i.e. exudate) in the early stages however, this often falls later in the disease.
- **Ultrasound:** It may show enlargement of the caudate lobe, intrahepatic collaterals, echogenic areas and ascites. It also may show compression of

the inferior vena cava, if present.

- **Pulsed Doppler sonography or a color Doppler:** It may show **obliteration of the hepatic veins and reversed flow or associated thrombosis in the portal vein with high accuracy.** This may be sufficient to establish the diagnosis. Doppler ultrasonography, with sensitivity and specificity rates >80%, is the diagnostic procedure of first choice.
- **Noninvasive CT or MRI:** It may also demonstrate **occlusion of the hepatic veins and inferior vena cava** with diffuse abnormal parenchyma on contrast-enhancement. It may also demonstrate **enlargement of the caudate lobe** which has independent blood supply and venous drainage.
- Hepatic venography is only necessary if CT and MRI are unable to demonstrate the hepatic venous anatomy clearly. It helps to determine extent of block and caval pressures.
- **Liver biopsy:** It shows **centrilobular congestion hemorrhage, fibrosis and cirrhosis depending on the duration of the disease.**
- **Other investigations:** To identify a cause (e.g. blood tests and coagulation studies).

#### Management

- **Predisposing causes should be removed or treated** as far as possible.
- **In the acute situation with recent thrombosis:** Treated with **thrombolytic therapy** consisting of intrahepatic venous streptokinase (in very early cases of thrombosis), **followed by heparin and oral anticoagulation (warfarin).**
- **Short hepatic venous strictures:** Treated with angioplasty.
- **Extensive hepatic vein occlusion:** Insertion of a covered TIPSS followed by anticoagulation may be useful in opening of the hepatic veins.
- **Ascites:** **Initially treated medically with low-salt diet, diuretics** as well as treating the underlying cause (e.g. polycythemia). If not relieved may be treated with surgical shunts such as Le Vein shunt and portosystemic shunts.
- **Percutaneous balloon angioplasty** for membranous obstruction of the IVC and hepatic vein.
- Congenital web can be treated radiologically or resected surgically.
- **Liver transplantation is indicated for chronic Budd-Chiari syndrome** and for progressive liver failure, followed by lifelong anticoagulation.
- Without transplantation or shunting, particularly acute and fulminant types is associated with poor prognosis.

## Veno-occlusive Disease

Veno-occlusive disease (VOD) **also known as sinusoidal obstruction**

**syndrome** is a rare condition characterized by **widespread occlusion of the small central hepatic veins**.

### ***Etiology***

- Develops as a complication of
  - **Total body irradiation/myeloablative regimens** used before hematopoietic stem cell transplantation. It carries a high mortality.
  - A variety of **antineoplastic drugs** have been implicated as causes of sinusoidal obstruction syndrome including gemtuzumab ozogamicin, actinomycin D, dacarbazine, cytosine arabinoside, mithramycin, and 6-thioguanine.
  - **Chronic immunosuppression with azathioprine or 6-thioguanine.**
  - **Ingestion of herbal teas made with pyrrolizidine alkaloids in *Senecio* and *Heliotropium* plants.**
  - **Ingestion of alkaloids in inadequately winnowed wheat or in ‘bush tea’.**
  - **Hepatic irradiation.**

### ***Clinical Features***

**Similar to those of the Budd-Chiari syndrome.** Classically, sinusoidal obstruction syndrome manifests with mild hyperbilirubinemia (bilirubin levels >2 mg/dL), painful hepatomegaly, weight gain of >2%, and development of ascites.

### ***Investigations***

- **Large hepatic veins appear patent radiologically.** This is in contrast to Budd-Chiari syndrome.
- **Transjugular liver biopsy** (with portal pressure measurements) **confirms diagnosis.**
- **Liver biopsy: Evidence of venous outflow obstruction.**

#### **Treatment**

- **Supportive** and includes control of fluid overload, ascites and hepatocellular failure.
- **Defibrotide** is a novel oligodeoxyribonucleotide with anti-ischemic, antithrombotic, and thrombolytic activity but minimal systemic anticoagulant effect. Several studies have shown efficacy of defibrotide in the prevention and treatment of sinusoidal obstruction syndrome, with no major toxicity.

# HEPATOCELLULAR CARCINOMA (HCC)

**Q. Discuss the etiology, clinical features, investigations and management of hepatocellular carcinoma.**

Hepatocellular carcinoma (HCC) is the **most common primary malignancy of liver** from hepatocytes or their precursors.

**Predominantly in males** with M: F ratio of 2.4: 1. The number of men and number of women with hepatocellular carcinoma in the absence of cirrhosis are almost equal.

## Etiology (Table 11.43)

**Table 11.43: Risk factors for hepatocellular carcinoma.**

<i>Major risk factors</i>	<i>Minor risk factors</i>	
• Chronic hepatitis : HBV/HCV	• Hereditary hemochromatosis	• Oral contraceptives
• Alcoholic cirrhosis	• Wilson disease	• Cigarette smoking
• Aflatoxin B <sub>1</sub> (a fungal toxin contaminating food)	• Primary biliary cholangitis	• Betel quid chewing
• Non-alcoholic steatohepatitis (NASH)	• Tyrosinemia	• Thorotrast and arsenic exposure
	• α <sub>1</sub> -Antitrypsin deficiency	• Obesity
	• Glycogen storage disease	• Ataxia telangiectasia
	• Hormones: Anabolic steroids, estrogens and androgens	• Hypercitrulinemia
		• Acute intermittent porphyria
		• Gallstones and cholecystectomy > <b>one in second column and other in third column</b>

## Clinical Features

- Usually develops in patients with underlying cirrhosis.
- **Non-specific symptoms** include ill-defined upper abdominal pain in the right hypochondrium, malaise, weakness, anorexia, fatigue, weight loss and ascites. Rapid development of these symptoms in a patient with

cirrhosis is suggestive of HCC. Fever due to tumor necrosis.

- On examination:
  - **Liver is enlarged, irregular, and nodular with pain or tenderness.**
  - **Friction rub or a hepatic bruit over the liver due to vascularity of tumor.**
- Blood-tinged ascites. Bone pain, dyspnea due to metastasis.

### ***Paraneoplastic Syndromes Associated with Hepatocellular Carcinoma (Table 11.44)***

**Table 11.44:** Paraneoplastic syndromes associated with hepatocellular carcinoma.

Carcinoid syndrome	Porphyria
Hypercalcemia	Sexual changes—isosexual precocity, gynecomastia, feminization
Hypertrophic osteoarthropathy	Systemic arterial hypertension
Hypoglycemia	Thyrotoxicosis
Neuropathy	Thrombophlebitis migrans
Osteoporosis	Watery diarrhea syndrome
Polycythemia (erythrocytosis)	Dermatomyositis, pemphigus foliaceus, pityriasis rotunda

**All patterns of HCCs have a strong tendency for invasion of vessels.** The portal vein and its branches are infiltrated by tumor. Occasionally, long, snakelike tumor masses may **invade the portal vein** and occlude portal circulation. Rarely tumor may invade inferior vena cava and extend into the right side of the heart through the hepatic veins. It may metastasize to the lungs.

### **Investigations**

- **Serum marker**
  - **Alpha-fetoprotein:** About 50% hepatocellular carcinoma is associated with high serum (>500 ug/L) or rising levels of alpha-fetoprotein. However,  $\alpha$ -fetoprotein levels are often raised in other neoplastic and non-neoplastic liver diseases and in some extrahepatic disorders. AFP concentrations are normal in up to 20% of small HCCs.
  - **$\alpha$ -L-fucosidase:** It is raised in HCC and also in cirrhosis.
  - **Serum des- $\gamma$ -carboxy prothrombin:** It is raised in a majority of hepatocellular carcinoma.

- **Plasma microRNA** expression is also marker of HCC.
- **Serum alkaline phosphatase: Very high.**
- Ultrasound scans show filling defects.
- CT scan (**triple-phase**) or MRI abdomen have 75-85% sensitivity in picking HCC.
- **Hepatic artery angiography shows ‘tumor blushes’.**
- Liver scintigraphic scans.
- **Liver aspiration or biopsy** particularly under ultrasonic guidance confirms the diagnosis.

### Management/Treatment

Treatment is different for patients with cirrhosis and those without. Therapy depends on tumor size, multicentricity, extent of liver disease (Child-Pugh score) and performance status.

- **Surgical resection:** It is indicated when lesions 1–3 in number and < 5 cm in size; without metastasis; with child score A. Local or segmental resections are preferred to major resections. After successful resection tumor recurs in the cirrhotic liver in about 70% of patients after 5 years.
- **Nonsurgical therapy:** Majority of patients diagnosed in the advanced stage of HCC and cannot be treated by surgical resection. These patients can be treated by following non-surgical therapy.
  - **Local ablation strategies:**
    - ◆ **Radiofrequency ablation (RFA):** Percutaneous radiofrequency ablation uses heat to kill tumor cells. A single electrode inserted into the tumor under CT or ultrasound guidance.
    - ◆ **Transarterial embolisation (TAE):** Hepatic artery embolization with Gelfoam and doxorubicin.
    - ◆ **Transarterial chemo-embolization (TACE):** With drugs such as doxorubicin but is contraindicated in decompensated cirrhosis and when HCC is multifocal can be combined with RFA.
  - **Local injection therapy:** Numerous agents can be used for local injection into tumors and includes percutaneous ethanol injection (PEI) or percutaneous acetic acid injection (PAI). PEI causes not only direct destruction of tumor cells, but also destroy normal cells in the vicinity. It usually requires multiple injections (average three) and the maximum size of tumor treated is 3 cm.
  - Conventional chemotherapy and radiotherapy are unsuccessful.
  - Chemotherapy using **sorafenib:** This drug is a multikinase inhibitor with activity against RAF, VEGF and PDGF signaling.
  - **Nivolumab** against programmed cell death 1 receptor (PD-1) has been used as immunotherapy
- **Liver transplantation:** Indicated in presence of localized tumor and underlying advanced liver disease. Unfortunately, the underlying liver disease (e.g. hepatitis B and C) may recur in the transplanted liver.

### Prognosis

Depends on size of tumor, the extent of spread (e.g. presence of vascular invasion), and liver function in those with cirrhosis.

# LIVER TRANSPLANTATION

## Q. Discuss briefly about liver transplantation.

- Transplantation of liver is useful in treating patient with end-stage liver disease or acute/fulminant liver failure and 5-year survival rate in good centers is about 75%.
- **‘Split’ livers:** In which one liver is used for two recipients. It is helpful in tackling organ shortage and in shortening the time on the waiting list.
- **Orthotopic liver transplantation:** It is the most common form of liver transplantation. Orthotopic means that the graft is placed in its correct anatomical location. In this technique, donor organ after removal of the native organ is transplanted in the same anatomic location.
- **Auxiliary partial orthotopic liver transplantation (APOLT),** also called partial or split liver transplantation.
  - In this technique, a segment of donor liver is transplanted in a recipient who has undergone hemi-hepatectomy to make room for the graft.
  - **Advantage:**
    - ◆ If the donor’s liver fails, the recipient’s own organ can function as a backup until a new liver is found.
- **Living donor liver transplantation:** In this technique a portion of healthy person’s liver is removed and used for transplantation.
  - **Living related donors: In this,** the donor of the liver segment is a first-degree living relative.
- **Bioartificial liver:** Cultured hepatocytes are used in patients with acute liver failure till donor liver becomes available.

## Indications (Table 11.45)

**Table 11.45:** Indications for liver transplantation.

<p><i>Cirrhosis due to</i></p> <ul style="list-style-type: none"> <li>• <b>Acute/fulminant liver failure</b> (e.g. seronegative hepatitis, drug-induced liver injury).</li> <li>• Chronic viral hepatitis C and B</li> <li>• Alcoholic liver disease (after successful demonstration of abstinence)</li> </ul>	<p><i>In children</i></p> <ul style="list-style-type: none"> <li>• <b>Biliary atresia</b></li> <li>• <b>Inborn errors of metabolism:</b> Wilson’s disease, glycogen storage diseases, Crigler-Najjar syndrome type I, familial hypercholesterolemia, <math>\alpha_1</math>-antitrypsin deficiency Familial amyloid polyneuropathy, Primary hyperoxaluria</li> </ul>
--	---

- Other causes of cirrhosis (e.g. non-alcoholic steatohepatitis, autoimmune diseases, primary biliary cholangitis)
- **Hepatocellular carcinoma** with no single lesion >5 cm or no more than three lesions with the largest being 3 cm or smaller.
- **Failure of previous liver transplant.**

## Contraindications

- **Absolute contraindications**
  - Poor expected outcome of transplantation (e.g. multisystem organ failure, malignancy or infection of extrahepatic or extrabiliary tract, hepatocellular carcinoma with metastatic spread advanced cardiac or pulmonary disease, and HIV infection).
- **Relative contraindications**
  - Comorbidities that reduce survival (e.g. renal insufficiency, primary hepatobiliary malignancy >5 cm, hemochromatosis, spontaneous bacterial peritonitis, patient older than 65 years, etc.).

## Complications of Liver Transplantation (Table 11.46) and immunosuppression (Box 11.43)

**Table 11.46:** Complications of liver transplantation.

<i>Hepatic complications</i>	<i>Non-hepatic complications</i>	
<ul style="list-style-type: none"> <li>• Preservation-reperfusion injury with graft failure due to ischemia</li> <li>• Acute graft rejection</li> <li>• Surgical complications—relating to the anastomosis of bile duct and blood vessels such as failure or obstruction of biliary anastomosis.</li> </ul>	<ul style="list-style-type: none"> <li>• Chronic graft rejection</li> <li>• Recurrent disease</li> <li>• Infection and drug-induced liver injury</li> <li>• Jaundice (due to blood transfusion, use of drugs and anesthetic agents, etc.).</li> </ul>	<ul style="list-style-type: none"> <li>• Infections/sepsis</li> <li>• Fluid overload</li> <li>• Renal dysfunction</li> <li>• Intraperitoneal bleed</li> </ul>

## Box 11.43: Complications of immunosuppression.

- Infections
- Metabolic syndrome
  - Hypertension
  - Diabetes mellitus
  - Obesity
  - Dyslipidemia

- Cardiovascular risk
- Acute and chronic renal disease
- Metabolic bone disease
- De novo malignancy

## PYOGENIC ABSCESS

**Q. Discuss the etiology, clinical features, investigations and management of pyogenic liver abscess (bacterial liver abscess).**

### Etiology

- Bacterial infections in the liver may be manifest as pyogenic abscess. Most common organism includes *E. coli*, *Streptococcus milleri*, *Klebsiella pneumoniae* and *Bacteroides*. Other organisms include *Enterococcus faecalis*, *Proteus vulgaris* and *Staphylococcus aureus*. Often the infection is mixed. Tuberculosis and melioidosis can present with liver abscess.
- **Route of infection:** The organisms may reach the liver through one of the following routes:
  1. **Portal vein:** Major source is intra-abdominal infections (e.g. appendicitis, diverticulitis, colitis and perforated bowel).
  2. **Arterial blood supply:** During systemic bacteremia, organism may reach liver via hepatic artery.
  3. **Ascending infection** in the biliary tract (ascending cholangitis).
  4. **Direct invasion** of the liver from a nearby source (e.g. subphrenic abscess, perinephric abscess), or a penetrating injury.

### Clinical Features

- **Fever, chills, rigors and right upper quadrant pain** radiating to right shoulder.
- Weight loss, anorexia, nausea and vomiting. Can manifest as PUO
- Pleuritic chest pain.
- **Tender hepatomegaly.**
- Mild jaundice may develop when there is extrahepatic biliary obstruction.
- Respiratory findings at the base of right lung (pleural effusion, crepitations) or a pleural rub in the right lower chest.

## Investigations

- **Serum bilirubin:** Raised in 25% of cases.
- **Serum alkaline phosphatase:** Markedly elevated.
- **Blood cultures:** Positive in only 30% of cases.
- **Normochromic normocytic anemia**, usually accompanied by a polymorphonuclear leukocytosis.
- **ESR and CRP** are often raised.
- Chest radiograph: Elevation of the right dome of diaphragm, and in severe cases right basilar atelectasis and pneumonia or effusion
- Ultrasonography: confirms the diagnosis
- CT scan of abdomen: helpful when ultrasound is normal.
- Needle aspiration of pus for culture and sensitivity.

### Management

- **Antibiotics:** Initiate treatment with antibiotics (combination of ampicillin, gentamicin and metronidazole) to cover Gram-positive, Gram-negative and anaerobic organisms till the causative organism is identified. Later, change the antibiotic according to the culture and sensitivity reports. Duration of treatment is 4-8 weeks.
- **Ultrasound-guided aspiration of the abscess:** Indications are listed in Box 11.44.
- **Surgical drainage** via a large-bore needle for those who fail to respond (Fig. 11.24).
- **Treat the underlying cause.**

**Box 11.44:** Indications for ultrasound-guided aspiration of liver abscess.

- Large abscess (>6 cm).
- Abscess in the left lobe.
- Lack of response within 48 to 72 hours of medical therapy.
- Ultrasonography suggestive of large abscess impending rupture.

## Amebic Liver Abscess

**Q. Write short essay/note on diagnosis and management of amebic liver abscess/hepatic amebiasis.**

Liver involvement by *Entamoeba histolytica* produces amebic liver abscess. The term amebic hepatitis is not used at present.

### Pathogenesis

- *Entamoeba histolytica* trophozoites from the base of an amebic ulcer in

**colon** may reach liver **through the portal circulation**. The capillary system of the liver acts as an efficient filter and holds these trophozoites. **Trophozoites** multiply, **kill hepatocytes**, cause coagulation necrosis of the liver cells and produce single or multiple abscesses.

- Amebic abscess ranges from 8–12 cm in diameter and appears well circumscribed. In most of the cases, the abscess is single and confined to the **posterosuperior aspect of the right lobe of the liver**. This is because right lobe portal laminar blood flow is supplied predominantly by the superior mesenteric vein, whereas the left lobe portal blood flow is supplied by the splenic vein. Abscess cavity is filled with a thick, dark brown, odourless, semisolid necrotic material, which resembles **anchovy paste (sauce) in color and consistency**.

**Fig. 11.24:** Drainage of abscess with pig tail.

### ***Clinical Features***

- Symptoms are similar to pyogenic abscesses (such as fever, anorexia, weight loss and malaise). Concurrent diarrhea is present in less than one-third of patients.
- **Insidious/gradual onset** with low-grade fever, sweats, malaise, weight loss, chills and rigors. Few may have an acute onset of fever. Later phase

there may be swinging temperature and sweating usually without marked systemic symptoms or associated cardiovascular signs.

- **Pain:** Patient may have pain in the right hypochondrium due to stretching of the liver capsule. Diaphragmatic irritation by abscess may cause referred pain in the right shoulder.
- Past history of dysentery may be present. Jaundice is rare.
- **Physical examination:** The patient looks ill, shows an enlarged, tender liver, intercostals point tenderness in the posterolateral of a lower right intercostals space (intercostal tenderness) and bulging of the intercostals spaces, upward extension of the liver dullness on percussion. There may be signs of an effusion or consolidation in the base of the right side of the chest.

## ***Complications***

### 1. **Due to rupture of abscess:**

- Spontaneous external rupture may produce 'granuloma cutis'.
- Rupture into bronchus may result in expectorates large amounts of the typical 'anchovy-sauce' pus.
- Rupture into pleural space may produce massive pleural effusion.
- Rupture into peritoneal cavity may produce peritonitis.
- Rupture below the diaphragm to produce subdiaphragmatic abscess.
- Rupture into stomach.
- Abscess in the left lobe of liver may rupture into pericardium resulting in pericarditis and rarely cardiac tamponade.

### 2. **Due to direct extension** into lung may produce amebic lung abscess.

### 3. **Due to hematogenous spread:** Metastatic brain abscess, splenic abscess.

## ***Diagnosis***

- **Blood:** Polymorphonuclear leukocytosis is a characteristic finding.
- **Liver function tests:** May be abnormal.
  - Most consistent abnormality is raised alkaline phosphatase.
  - Level of aspartate aminotransferase (AST) reflects the severity of the disease. Jaundice is uncommon, and its presence is indicative of a grave prognosis.
- **Chest radiography:** Demonstrate abscess (a raised right hemidiaphragm on chest X-ray). Other findings include right-sided pleural effusion and right basal pneumonitis.

- **Ultrasound:** Ultrasonic scanning of liver is very useful for establishing the diagnosis and localization of the abscess. The defect produced by abscess in the liver usually persists for several months after the complete recovery of the patient.
- **Isotope liver scans and computed tomography:** Can also assist to detect abscess.
- Serologic tests: For ameba includes indirect hemagglutination test, amebic complement fixation test, ELISA or counter immunoelectrophoresis can detect antibodies in the blood and are more useful in amebic liver abscess.
- **Amebic fluorescent antibody test:** It is positive in about 90% of patients with liver abscess and in 60–70% with active colitis. **Nested-multiplex PCR** has a sensitivity of 75-100%.
- **Aspiration of amebic liver abscess:** Needle aspiration yields the characteristic ‘anchovy-sauce’ or ‘chocolate-brown’ pus (Fig. 11.25). The pus is usually thick in consistency, yellow or green in color, and characteristically odourless. It consists of liquefied necrotic liver tissue and does not contain polymorphonuclear leucocytes. As the parasites are localized in the abscess wall, pus may not show free amebae. Ameba may be demonstrated in the terminal portion of the aspirate, or by a needle biopsy of the abscess wall.

**Fig. 11.25:** Anchovy sauce appearance of amebic abscess.

**Treatment**

- **Metronidazole** 800 mg three times daily for 7 to 10 days or **tinidazole** 2 g orally daily as a single dose for 5 days is usually adequate in liver abscess. Severe cases may need intravenous administration of metronidazole (500 mg 8 hourly).
- **Chloroquine:** It may be given at a dose of 300 mg twice daily for 2 days, followed by 150 mg twice daily for another 19 days. It is usually administered to those patients who do not respond adequately to metronidazole.
- **Emetine and dehydroemetine** are lethal to the trophozoites of *E. histolytica*. However, because of their toxicity they are rarely used. Dehydroemetine is less toxic than emetine. Toxicity includes cardiac arrhythmias, muscle weakness, vomiting precordial pain, and diarrhea.
- **Therapeutic aspiration of the abscess:** If a liver abscess is large or likely to burst, or if the response to chemotherapy is not prompt, aspiration is required and repeated if required. Rupture of an abscess into the pleural cavity, pericardial sac or peritoneal cavity needs immediate aspiration or surgical drainage.
- **Percutaneous drainage:** It is achieved by placing a large bore catheter into the abscesses for draining the abscess. It is usually performed when therapeutic aspiration fails and its indications are:
  - Large abscess and associated risk of spontaneous rupture (especially left lobe abscesses).
  - If abscess is ruptured already (drainage of both abscess and extraneous collection).
  - Absence of response to medical therapy with signs of persistent sepsis or enlarging abscesses or persistent symptoms.
  - Evidence of liver failure.
- **After treatment** of the invasive disease, luminal amebicide such as diloxanide furoate 500 mg orally TID for 10 days; or aminosidine (paromomycin) 25–35 mg/kg/day orally in three divided doses for 7–10 days should be given to clear luminal cysts or parasite. Alternative agents include iodoquinol 650 mg orally TID for 20 days, and nitazoxanide.

Clinical comparison between pyogenic and amebic liver abscess (Table 11.47).

**Table 11.47:** Pyogenic and amebic liver abscess: clinical comparisons.

<b>Parameter</b>	<b>Pyogenic liver abscess</b>	<b>Amebic liver abscess</b>
Number	Often multiple	Usually single
Location	Either lobe of liver	Usually right hepatic lobe, near the diaphragm
Presentation	Subacute	Acute
Jaundice	Mild	Moderate
Diagnosis	US or CT guided aspiration	US or CT and serology

## METABOLIC LIVER DISEASE

## Iron Overload

**Q. What are various disorders associated with iron overload?**

**Q. Discuss the etiology, pathology, clinical features, investigations and management of hereditary (primary) hemochromatosis ('bronze diabetes').**

### *Classification of Iron Overload (Box 11.45)*

In secondary iron overload, iron accumulates in Kupffer cells rather than hepatocytes compared to that of hereditary hemochromatosis.

### Hereditary Hemochromatosis

- Hereditary hemochromatosis (HH) is an inherited **autosomal recessive** disorder characterized by **abnormal (excessive) accumulation of iron** in various parenchymal organs leading to eventual fibrosis and functional organ failure.
- In symptomatic patients of hemochromatosis the total body iron is increased to 20–40 g, compared with 3–4 g in normal individuals.
- Associated with **high incidence of hepatocellular carcinoma**.
- Most of the hereditary hemochromatosis is inherited as autosomal recessive genetic disorder and associated with HLA-B3, B7 and B14 histocompatibility antigens.

### **Box 11.45:** Classification of iron overload.

#### *Hereditary*

- Mutations of genes encoding HFE, transferrin receptor 2 (TfR2), or hepcidin
- Mutations of genes encoding hemojuvelin (HJV)

#### *Hemosiderosis (secondary hemochromatosis)*

- Parenteral iron overload
  - Exogenous: Multiple blood transfusions, repeated iron injections, long-term hemodialysis
  - Endogenous: Sickle cell disease
- Ineffective erythropoiesis with increased erythroid activity:  $\beta$ -Thalassemia, sideroblastic anemia, porphyria cutanea tarda
- Increased oral intake of iron
- Chronic liver disease : Chronic alcoholic liver disease.

### *Pathology*

The **excess iron is deposited** commonly in the **liver, joint, heart, pancreas, endocrine glands** (e.g. pituitary gland) **and skin**.

### ***Clinical Features***

- **Age and gender:** Overt clinical manifestations occur **more frequently in males** over the age of 40 years. About 90% of the patients are males. Females are protected because of loss of iron during menstruation and pregnancy.
- **Symptoms:**
  - It may develop due to toxic damage of cells by accumulated iron and consequent fibrosis.
  - Symptoms may be **vague**-muscle aches, weakness, abdominal and/or joint pain.
  - **Classic triad:** Consists of **bronze skin pigmentation** (Fig. 11.26) (due to melanin deposition in exposed parts, axillae, groins and genitalia), **hepatomegaly and diabetes mellitus** (**'bronzed diabetes'**) is observed in patients with gross iron overload.
  - **Late features:** Hypopituitarism, loss of libido, testicular atrophy, cardiac complaints (cardiomyopathy, heart failure and cardiac arrhythmias), hypothyroidism, cirrhosis with hepatosplenomegaly, spiders, loss of body hair, jaundice and ascites.
  - Cirrhosis.

**Fig. 11.26:** Skin pigmentation in hemochromatosis.

### ***Complications***

- **Chondrocalcinosis:** develops due to asymmetrical deposition of calcium pyrophosphate in both large and small joints and leads to an arthropathy. It has a characteristic radiologic findings: squared-off bone ends and hook-like osteophytes in the second and third metacarpophalangeal (MCP) joints.
- **Hepatocellular carcinoma (HCC)** in 30% of patients with cirrhosis.
- **Multiorgan failure.**
- Susceptibility to specific infections (bacteria whose virulence is increased in the presence of excess iron). These include *Listeria monocytogenes*, *Yersinia enterocolitica* and *Vibrio vulnificus*.

### ***Investigations***

- **Serum iron profile:**
  - **Serum iron** is **elevated** ( $>30 \mu\text{mol/L}$ ).
  - **Total iron binding capacity (TIBC): reduced.**
  - **Fasting transferrin saturation** (serum iron divided by the total iron

binding capacity) is **high (> 45%)** which is **highly sensitive for diagnosis**.

- **Serum ferritin is elevated** (usually >500 µg/L or 240 nmol/L). It is less sensitive than transferrin saturation in screening for hemochromatosis because it is also increased in alcoholic liver disease, hepatitis C infection, non-alcoholic steatohepatitis. It is also an acute phase reactant and increased in other inflammatory and neoplastic conditions.
- **Biochemical tests** for liver function are **often normal**, even with established cirrhosis.
- **Genetic testing:** It is performed if iron studies are abnormal.
- **CT scan:** Shows **increased density of liver** due to deposits of iron.
- **Magnetic resonance imaging (MRI):** It is **sensitive** to detect liver iron content.
- **Liver biopsy:** Not necessary for diagnosis. It shows **iron deposition** and hepatic **fibrosis** leading on to cirrhosis.
- **Screening:** All first-degree family members of hereditary hemochromatosis must be screened to detect early and asymptomatic disease.

#### Treatment and Management

- Treatment **should be started before permanent organ damage** occurs due to iron toxicity. The excess iron should be removed as rapidly as possible and prolongs life and may reverse tissue damage.
- **Phlebotomy/Venesection:** Venesection of 500 mL blood (removes 250 mg of iron) is performed twice-weekly until the serum iron is normal. This may take 2 years or more.
- **Chelation therapy:** Rarely in patients who cannot tolerate venesection because of severe cardiac disease or anemia, chelation therapy with desferrioxamine can be used. Dose is 40–80 mg/kg/day subcutaneously. It removes about 10–20 mg of iron/day. Deferiprone, deferasirox are other chelators.
- **Erythrocytapheresis** is an apheresis technique whereby red cells are removed in an isovolemic manner and the patient's plasma is returned to the patient, larger amounts of iron can be removed per session than by phlebotomy.
- Treatment of diabetes.
- Treatment of cirrhosis: There is a risk of malignancy if cirrhosis is present.
- Treatment of congestive heart failure and cardiac arrhythmias.
- **Dietary limitations:** (i) Dietary iron intake to be restricted, (ii) agents for reducing iron absorption (tannates in tea, phytates, oxalates, calcium, and phosphates) to be used, (iii) avoidance of excessive ethanol, (iv) avoidance of ascorbic acid (vitamin C) supplements, and (v) avoidance of uncooked seafood.

## Wilson's Disease

**Q. Discuss the etiology, pathology, clinical features, investigations and management of Wilson's disease (hepatolenticular degeneration).**

**Q. Explain in brief about Kayser-Fleischer ring.**

- **Wilson disease (progressive hepatolenticular degeneration)** is a very rare **inborn error of copper metabolism** characterized by **increased total body copper**.
- Excess **copper deposition** in various organs: **(1) liver, (2) basal ganglia of the brain, (3) cornea, (4) kidneys, and (5) skeleton**.
- **Potentially treatable** condition.

### *Etiology*

- **Autosomal recessive** disorder.
- Consanguinity is risk factor.
- **Molecular defect within a copper-transporting ATPase** encoded by a gene (**ATP7B**) located on chromosome 13. More than 300 mutations have been identified and is rare in India and Asia.
- **Defect:** Excessive accumulation of copper in the body due to:
  - Failure of incorporation of copper into proceruloplasmin and leads to **low serum ceruloplasmin**.
  - Failure of biliary copper excretion, causing its accumulation in the body.

### *Pathology*

**Liver:** Microscopic features are **not diagnostic** and vary from that of **chronic hepatitis to macronodular cirrhosis**. Stains for copper show a periportal distribution of copper.

### *Clinical Features*

- **Age of presentation** is usually between **5 and 30 years**.
  - Children usually present with hepatic problems.
  - Young adults usually present with more neurological problems.
- **Features of liver involvement:** Varies from (1) acute hepatitis going on

to (2) fulminant hepatic failure, to (3) chronic hepatitis or (4) cirrhosis.

- **Features of brain involvement:** **Dysarthria**, involuntary movements, tremors (especially asymmetric, resting and intention tremors, wing beating), **ataxia** and eventually dementia.
- **Psychiatric manifestations:** Phobia, depression, compulsive behavior.

- **Kayser-Fleischer rings**

- It is a **characteristic sign** due to deposition of **copper in the Descemet's membrane** of cornea.
- Appears as **greenish-brown or golden-brown ring at the corneoscleral junction** (around the periphery of the cornea), appearing first at the upper periphery gradually disappear with effective medical treatment or liver transplantation.
- Best identified by slit-lamp examination.
- It may be absent in young children and disappears with treatment.
- May be associated with 'sunflower cataracts'.
- **Kayser-Fleischer rings (Fig. 11.27) are not specific for Wilson disease;** they are found occasionally in patients with other types of chronic liver disease, usually with a prominent cholestatic component, such as primary biliary cholangitis, primary sclerosing cholangitis, or familial cholestatic syndromes, and rarely in patients with nonhepatic diseases.

**Fig. 11.27:** Kayser-Fleischer ring

- **Other manifestations:** Kidney (renal tubular damage), skeleton (osteoporosis, arthropathy).

## Investigations

- **Slit-lamp examination** of the eyes for Kayser-Fleischer ring.
- **Serum copper: Reduced** but can be normal.
- **Serum ceruloplasmin levels: Low** and less than 29 mg/dL.
- **Urinary copper: Usually increased** 100–1000  $\mu\text{g}$  in 24 h (1.6–16  $\mu\text{mol}$ ); normal levels  $<40 \mu\text{g}$  (0.6  $\mu\text{mol}$ ). The **penicillamine challenge**: 500 mg dose of penicillamine at the beginning of the 24-hour urine collection and then again at 12 hours. Urinary copper excretion greater than 1600  $\mu\text{g}$  per 24 hours ( $>25$  micromol) is diagnostic.
- **Liver biopsy**: Gold standard. Diagnosis depends on the amount of copper in the liver ( $>250 \mu\text{g/g}$  dry weight).
- **Hemolysis and anemia** may be found.

## Treatment and Management

- Treatment should be started early and will show improvement both clinically and biochemically.
- **Chelating drugs**
  - **Penicillamine with pyridoxine**: It should be given lifetime in the dose of 1–1.5 g daily and effectively chelates copper.
- For asymptomatic cases and maintenance therapy (after maximal improvement with penicillamine).
  - **Trientine dihydrochloride**: in the dose of 1.2–1.8 g/day.
  - **Zinc acetate**: Indicated in chronic hepatitis and cirrhosis. Dose 150 mg/day. It blocks absorption of copper from intestine. However, it **should not be administered with penicillamine or trientine** since both these drugs chelate zinc.
  - **Other drugs**: (1) intramuscular **dimercaprol** (2) **ammonium tetrathiomolybdate** (3) **potassium sulfide** and (4) **carbacylamine resins**.
  - **Liver transplantation**: In fulminant hepatic failure and decompensated/advanced cirrhosis.
  - All siblings and children of the patient should be screened for Wilson's disease and treated even if they are asymptomatic, and if there is evidence of copper accumulation.

## $\alpha_1$ -Antitrypsin Deficiency

**Q.** Write a short note on  $\alpha_1$ -antitrypsin.

### Clinical Features

- In neonates produces cholestatic jaundice.
- In adults:
  - **Liver: Chronic hepatitis, cirrhosis, hepatocellular carcinoma and cholangiocarcinoma.**

- **Lung: Emphysema, chronic bronchitis**
- **Others:** Panniculitis, vasculitis, pancreatitis, glomerulonephritis.

### **Investigations**

- **Serum  $\alpha_1$ -antritrypsin is low** (normal above 150 mg/dL).
- **Serum protein electrophoresis shows absence of  $\alpha_1$ -globulin peak.**
- **Liver biopsy:**  $\alpha_1$ -AT accumulates in periportal hepatocytes and can be seen as **periodic acid-Schiff (PAS)-positive, diastase-resistant globular inclusions** in these **hepatocytes**. The injury to these hepatocytes results in progressive fibrosis and cirrhosis.

#### **Treatment**

- **No treatment** apart from dealing with the complications of liver disease.
- Stop cigarette smoking and alcohol intake.
- Liver or lung transplantation.

## **BILIARY CIRRHOSIS**

**Q. What is biliary cirrhosis? Discuss the etiology, pathology, clinical features, investigations and management of primary biliary cholangitis.**

- It is a type of **cirrhosis** of the liver **secondary to prolonged obstruction of biliary system** (anywhere between the small interlobular bile ducts and the papilla of Vater).
- Obstruction results in progressive destruction of bile ducts.

### **Classification**

Biliary cirrhosis may be subdivided into primary biliary cholangitis and secondary biliary cirrhosis.

1. **Primary biliary cholangitis:** It is a probably an **autoimmune disorder** of the intrahepatic biliary tree.
2. **Secondary biliary cirrhosis:** It is due to **prolonged obstruction of the extrahepatic biliary tree.**

### **Primary Biliary Cirrhosis Presently called as Primary Biliary Cholangitis**

**Gender:** It usually affects **middle-aged women**, with a female to male ratio of more than 6:1.

**Age:** Peak incidence between **40 to 50 years** of age (perimenopausal).

### ***Etiology and Pathogenesis***

- PBC is thought to be an **autoimmune disorder**, but its exact pathogenesis is not known.
- **Genetic and environmental** factors play role in the pathogenesis of the PBC. Probably an environmental factor acts on a genetically predisposed individual via molecular mimicry initiate autoimmunity.

### ***Clinical Features***

- It is **insidious** in onset and asymptomatic patients are discovered during routine examination or investigations.
- Commonly present with **pruritus** (often the earliest symptom), **fatigue**, and **skin pigmentation** (due to melanin deposition) abdominal discomfort.
- **Features of liver involvement:**
  - **Intense pruritus** (probably due to bile salts) occurs months to years before jaundice and is more at night. Scratch marks.
  - **Progressive jaundice (bottle green color)**
  - **Clubbing** of fingers
  - Hepatosplenomegaly
  - Hepatic decompensation, portal hypertension, ascites and variceal bleeding develop
- **Hypercholesterolemia**
  - **Xanthelasmas** (cholesterol-rich macrophages) around the eyes (Fig. 11.28).
  - **Xanthomas** over joints, tendons, hand creases, elbows and knees.
  - Pain, tingling and numbness over feet and hands due to peripheral neuropathy produced by lipid infiltration of peripheral nerves.
- **Malabsorption**
  - Steatorrhoea and diarrhea due to malabsorption of fat.
  - Easy bruising and ecchymosis due to vitamin K deficiency.

- Osteomalacia and/or osteoporosis due to malabsorption of vitamin D.
- Night blindness due to vitamin A deficiency.
- Dermatitis due to vitamin E deficiency.
- **Extrahepatic manifestations:** These include autoimmune disorders such as Sjögren syndrome, keratoconjunctivitis sicca (dry eyes and mouth), systemic sclerosis, autoimmune thyroiditis, rheumatoid arthritis, Raynaud phenomenon, membranous glomerulonephritis and celiac disease.

**Fig. 11.28:** Xanthelasma around the eyes.

### ***Investigations***

- **Antimitochondrial antibodies** are characteristic and are essential for the diagnosis of PBC. They are found in 90–95% of patients. M2 antibody is specific. Other nonspecific antibodies (e.g. **antinuclear factor** and smooth muscle) may also be present.
- **Marked rise of serum 5'-nucleotidase** activity.
- **High serum alkaline phosphatase** (markers of cholestasis): Two-to five-fold rise
- **Hyperlipidemia and serum cholesterol is raised.**
- **Serum bilirubin:** Hyperbilirubinemia of the conjugated type occurs in late stages.
- **Serum transaminase:** Mild elevation of transaminases.
- **Serum IgM** may be **very high**.
- **Ultrasound:** It shows diffuse alteration in liver architecture.
- **MRCP (or ERCP):** It shows normal biliary tree.

- **Liver biopsy:** Portal tract infiltration by lymphocytes and plasma cells and about 40% have granulomas. Later portal tract fibrosis and, eventually progress to cirrhosis.

**Note:** Hepatic granulomas are not specific and are also found in sarcoidosis, tuberculosis, schistosomiasis, drug reactions, brucellosis, parasitic infestation (e.g. strongyloidiasis) and other conditions.

#### Management/Treatment

- **Ursodeoxycholic acid (10–15 mg/kg):** It improves bilirubin and aminotransferase levels. It should be started early in the asymptomatic phase.
- **Steroids:** They improve biochemical and histological disease but may lead to increased osteoporosis.
- **Other therapies:** include azathioprine, colchicines, methotrexate and cyclosporine may be beneficial in few patients.
- **Steatorrhoea:** It is treated by limiting intake of fat and substituting long chain triglycerides with medium chain triglycerides in the diet.
- **Malabsorption of fat-soluble vitamins (A, D and K) is managed by supplementation.**
- Calcium supplementation.
- **Pruritus** is difficult to control but following can be helpful.
  - **Cholestyramine** one 4 g sachet three times daily, but is unpalatable.
  - Antihistamines.
  - Rifampicin, naloxone hydrochloride, ondansetron and opiate antagonists (naloxone and naltrexone).
- Liver transplantation.

**Complications:** These include (i) cirrhosis, (ii) osteoporosis and osteomalacia, (iii) polyneuropathy, and (iv) increased risk of hepatocellular carcinomas.

## Secondary Biliary Cirrhosis

**Q. Write short note on secondary biliary cirrhosis.**

### *Definition*

Cirrhosis developing **secondary to prolonged** (for months) **obstruction** of the extrahepatic (large biliary duct) biliary tree.

### *Causes of Obstruction*

(1) gallstones, (2) bile duct strictures, and (3) sclerosing cholangitis.

- Patients with malignant tumors of bile duct or pancreas rarely survive long enough to develop secondary biliary cirrhosis.

## Cardiac Cirrhosis

### Q. Write short note on cardiac cirrhosis.

- **Cause:** Liver damage primarily due to congestion may develop in all types of **right heart failure**. Examples: valvular heart disease, constrictive pericarditis or cor pulmonale of long duration (more than 10 years).
- **Mechanism:** Right heart failure causes retrograde transmission of raised venous pressure via the IVC and hepatic vein into the liver. This leads to passive congestion of liver. When passive venous congestion becomes chronic/prolonged, the liver becomes enlarged, tender and shows a 'nutmeg appearance' (alternating red-congested and pale-fibrotic areas). Very rarely, prolonged, severe right—sided heart failure and hepatic congestion cause cardiac cirrhosis.
- **Clinical features**
  - Usually dominated by the heart disease.
  - Symptoms and signs of severe right heart failure.
- **Diagnosis**
  - Firm enlarged liver with signs of chronic liver disease in a patient with valvular heart disease, constrictive pericarditis or chronic corpulmonale.
  - Nonpulsatile liver despite the presence of tricuspid regurgitation.
  - Liver biopsy confirms the diagnosis (not required in most cases).

**Treatment** of the underlying cardiovascular disorder.

## Noncirrhotic Portal Fibrosis

### Q. Write a short note on noncirrhotic portal fibrosis (NCPF).

- NCPF is an idiopathic disease characterized by periportal fibrosis and involvement of small and medium branches of portal vein.
- It leads to development of portal hypertension and splenomegaly without features of liver cell failure.
- World wide it accounts for 3–5% of all patients with portal hypertension,

but in India it accounts for 15–20% of case of portal hypertension.

## ***Etiology***

Bacterial infections, exposure to toxins (arsenic, vinyl chloride monomer, copper sulfate, methotrexate, hypervitaminosis A, 6-mercaptopurine), immunological abnormalities and hypercoagulable states may play role.

## ***Clinical Features***

- Characterized by upper GI bleed, **massive splenomegaly** with anemia.
- Preserved liver function.
- **Ascites, jaundice and hepatic encephalopathy is uncommon.**

## ***Investigations***

- Liver function tests: Usually normal.
- Peripheral blood: Pancytopenia may develop due to hypersplenism.
- Doppler ultrasound: It shows patent splenoportal axis and hepatic veins.
- Splenoportovenography (SPV): It reveals massive dilatation of the portal and splenic veins, and the presence of collaterals.
- Liver biopsy: Lobular architecture maintained, portal fibrosis of variable degree, sclerosis and obliteration of small-sized portal vein radicals.

**Treatment:** Endoscopic sclerotherapy or banding to prevent variceal bleed and shunt surgery.

Differences between EHPVO, NCPF and cirrhosis are presented in Table 11.48.

**Table 11.48:** Differences between EHPVO, NCPF and cirrhosis.

<b><i>Features</i></b>	<b><i>EHPVO</i></b>	<b><i>NCPF</i></b>	<b><i>Cirrhosis</i></b>
Median age	10 years	28 years	40 years
Ascites	Absent	Absent	+++
Encephalopathy	Nil	Nil	Present
Deranged LFT	Nil	Nil	Present
Splenomegaly	Moderate- massive	Moderate	Mild- moderate
Abdominal vein	Nil	Nil	Anterior abdominal veins +
Liver–Gross	Normal	Normal	Shrunken, nodular
Liver biopsy	Normal	Portal fibrosis	Hepatic necrosis,

			fibrosis, regenerative nodules
Ultrasonography	Portal/splenic vein block and cavernoma	Dilated and patent portal vein	Coarse echotexture of liver. Dilated portal vein, ascites
Site of block	Extrahepatic presinusoidal	Intrahepatic presinusoidal	Intrahepatic sinusoidal and post sinusoidal

**Table 11.49:** Differential diagnosis of jaundice in an elderly patient.

- |   |   |
|---|---|
| <ul style="list-style-type: none"> <li>• Viral hepatitis</li> <li>• Drug-induced hepatitis</li> <li>• Gallstone disease</li> <li>• Alcoholic hepatitis</li> <li>• Weil's disease</li> <li>• Cirrhosis of liver</li> </ul> | <ul style="list-style-type: none"> <li>• Neoplastic               <ul style="list-style-type: none"> <li>– Hepatocellular carcinoma</li> <li>– Secondaries in liver</li> <li>– Carcinoma of head of pancreas</li> </ul> </li> </ul> |
|---|---|

**Differential diagnosis of jaundice** of 3 weeks' duration in an elderly person (Table 11.49).

**Q. Discuss the differential diagnosis of jaundice of 3 weeks' duration in an elderly person.**

### Common Causes of Painful Hepatomegaly (Table 11.50)

**Table 11.50:** Common causes of painful hepatomegaly.

• Hepatitis	– Amoebic liver abscess	• Malignancies
– Viral hepatitis	– Pyogenic liver abscess	– Hepatocellular carcinoma
– Drug-induced hepatitis	– Actinomycosis	– Secondaries
– Alcoholic hepatitis	– Congestive cardiac failure	
– Chronic hepatitis	– Acute Budd-Chiari syndrome	

**Q. What are the common causes of hepatomegaly with tenderness (tender hepatomegaly)?**

### Causes of Pulsatile Liver (Box 11.46)

**Q. Write short note on causes of pulsatile liver.**

**Box 11.46:** Causes of pulsatile liver.

- Tricuspid regurgitation (systolic)
- Tricuspid stenosis (diastolic)
- Aortic regurgitation

## Causes of Splenomegaly (Table 11.51)

**Q. Enumerate the common causes of splenomegaly.**

**Table 11.51: Classification of splenomegaly and their causes.**

<b>Mild splenomegaly (up to 5 cm)</b>	
Acute infections	Septic shock, infective endocarditis, enteric fever, infectious hepatitis, infectious mononucleosis, brucellosis, cytomegalovirus, toxoplasmosis
Chronic infections	Tuberculosis, syphilis, brucellosis, chronic bacteremia, HIV
Parasitic infestations	Malaria, kala-azar, and schistosomiasis
Inflammation	Rheumatoid arthritis, sarcoidosis, SLE
Others	Congestive cardiac failure, thalassemia minor
<b>Moderate splenomegaly (up to umbilicus) (5–8 cm)</b>	
Neoplastic	Lymphomas, acute leukemias, chronic lymphocytic leukemia, chronic myeloid leukemia
Non-neoplastic	Cirrhosis of liver (with portal hypertension), chronic hemolytic anemia, malaria, kala-azar, sarcoidosis, infectious mononucleosis, splenic abscess, amyloidosis, hemochromatosis, polycythemia vera
<b>Massive splenomegaly (below umbilicus) (more than 8 cm) (Fig. 11.29)</b>	
Common causes	Chronic myeloid leukemia, myelofibrosis, kala-azar, hairy cell leukemia, tropical splenomegaly, portal hypertension (extrahepatic portal vein thrombosis), hyperreactive malarial splenomegaly
Uncommon causes	Lymphomas, Gaucher's disease, Niemann-Pick disease, thalassemia major, splenic cysts and tumors of spleen, myeloid metaplasia, hairy cell leukemia, sarcoidosis, MAC infection in HIV patients

**Fig. 11.29:** Massive splenomegaly in chronic myeloid leukemia (CML).

## Causes of Hepatosplenomegaly (Table 11.52 and Fig. 11.30)

**Table 11.52:** Causes of hepatosplenomegaly.

<b>Infections:</b> Malaria, kala-azar, infective hepatitis, disseminated TB, bacterial endocarditis, infectious mononucleosis	<b>Hematological disorders:</b> Chronic hemolytic anemia, chronic myeloid leukemia, myelofibrosis, Hodgkin and Non-Hodgkin lymphoma
<b>Congestive states:</b> Congestive cardiac failure, constrictive pericarditis, cirrhosis of liver with portal hypertension, Budd-Chiari syndrome	<b>Storage disorders:</b> Gaucher's disease, glycogen storage disorders and amyloidosis

## Causes of Hepatosplenomegaly with Lymphadenopathy (Box 11.47)

**Box 11.47:** Causes of hepatosplenomegaly with lymphadenopathy.

- Lymphomas
- Infectious mononucleosis
- HIV
- Sarcoidosis
- Lymphocytic leukemia
- Disseminated tuberculosis
- Disseminated histoplasmosis

## Hepatomegaly (Fig. 11.31)

### Toxemia of Pregnancy and HELLP

**Q. Write short note on HELLP.**

The HELLP syndrome is characterized by **h**emolysis, **e**levated **l**iver enzymes and **l**ow **p**latelets.

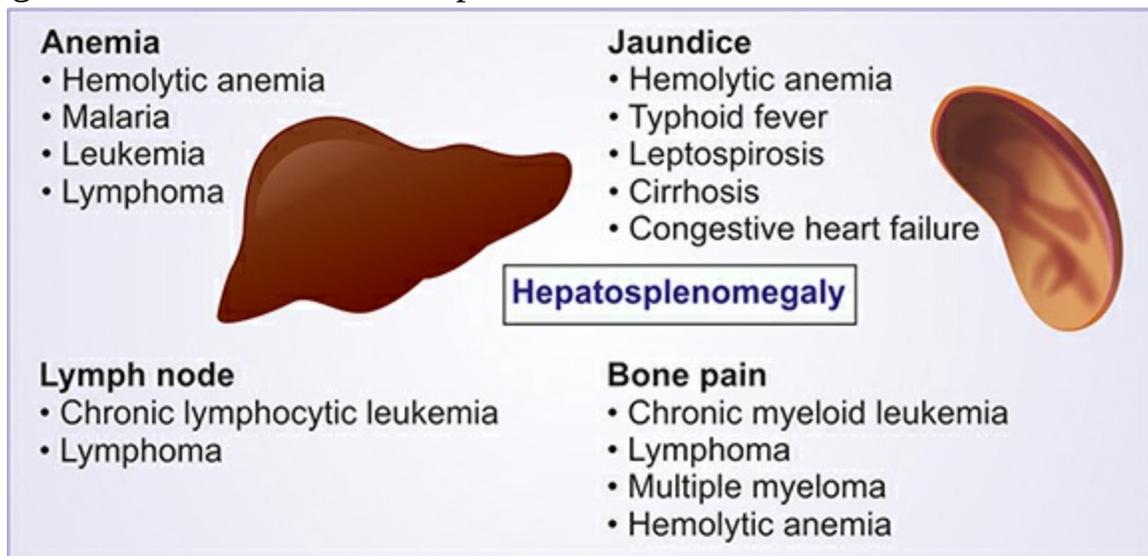

**Clinical features:** It is a variant of preeclampsia which develops in multiparous women.

Usually presents during 27–36 weeks of pregnancy with hypertension, proteinuria and fluid retention. Jaundice is observed in about 5% of patients.

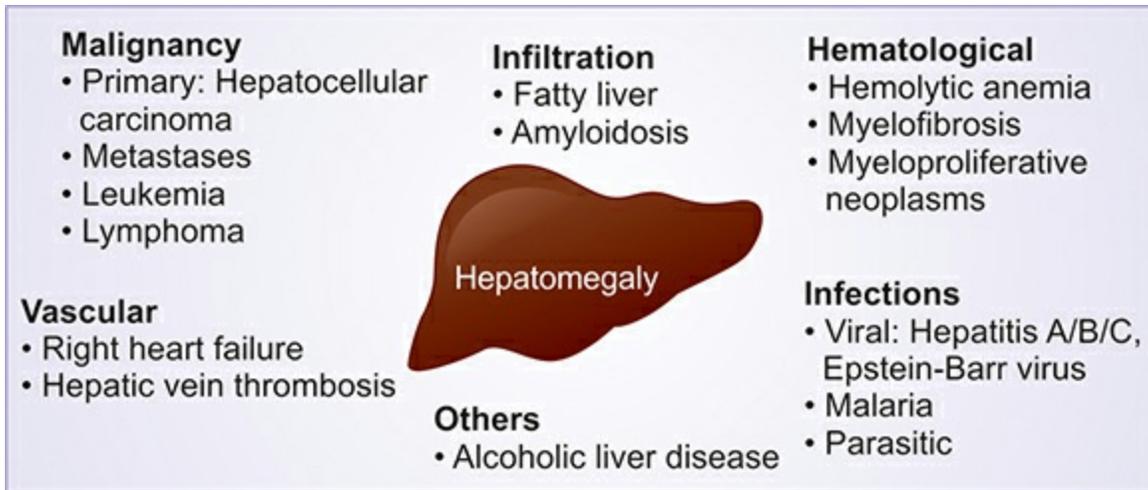

**Investigations:** Low hemoglobin level, fragmented red cells in peripheral smear, markedly elevated serum transaminases and raised D-dimers.

**Complications:** Infarction and rupture of liver, disseminated intravascular coagulation and placental abruption.

**Prognosis:** Maternal mortality is 1% and perinatal mortality may be 30%. Usually prompt resolution after delivery and it may recur in subsequent pregnancies in less than 5% of patients.

**Fig. 11.30:** Causes of hepatosplenomegaly according to the associated sign.

**Fig. 11.31:** Hepatomegaly according to underlying pathology.

**Management** include urgent delivery and control of the complications.

# Pancreas

# CHAPTER 12

## PANCREATITIS

### Acute Pancreatitis

**Q.** Discuss the etiology, clinical features, investigations, diagnosis, complications and management of acute pancreatitis.

#### *Definition*

Acute pancreatitis is best defined clinically by a patient presenting with two of the three criteria listed in Box 12.1.

**Box 12.1:** Criteria for diagnosis of acute pancreatitis.

- Symptoms: Epigastric pain, consistent with the disease.
- Laboratory findings: Serum amylase or lipase three times greater than the upper limit of normal.
- Radiologic imaging: Findings consistent with the diagnosis, by either computed tomography (CT) or magnetic resonance imaging (MRI).

#### *Classification of Acute Pancreatitis*

##### *Atlanta classification of acute pancreatitis*

- **Interstitial edematous acute pancreatitis:** Characterized by acute inflammation of the pancreatic parenchyma and peripancreatic tissues, but without tissue necrosis.
- **Necrotizing acute pancreatitis:** Characterized by inflammation associated with pancreatic parenchymal necrosis and/or peripancreatic necrosis.

##### *Classification of acute pancreatitis according to the severity*

- **Mild acute pancreatitis:** Not associated with organ failure and local or systemic complications.

- **Moderately severe acute pancreatitis:** No organ failure or transient organ failure (<48 hours) and/or local complications.
- **Severe acute pancreatitis:** Persistent organ failure (>48 hours) that may involve one or multiple organs.

**Box 12.2:** Mnemonic for causes of pancreatitis.

**I GET SMASHED**

- Idiopathic
- Gallstones
- Ethanol
- Trauma
- Steroid
- Mumps
- Autoimmune
- Scorpion bite
- Hyperlipidemia
- ERCP
- Drugs

**Etiology (Table 12.1) (Box 12.2)**

**Q. Describe etiology of acute pancreatitis.**

**Table 12.1:** Causes of acute pancreatitis.

<p><b>OBSTRUCTIVE CAUSES</b></p> <p><b>Gallstones</b> Obstruction of the pancreatic duct system: Ampullary or pancreatic tumors <i>Parasites: Ascaris lumbricoides and Clonorchis sinensis</i> organisms <i>Developmental anomalies:</i> Pancreas divisum, choledochocoele, annular pancreas</p>	<p><b>TOXINS</b></p> <p><b>Ethyl alcohol</b> Methyl alcohol Scorpion venom Organophosphates Insecticides <b>Smoking</b></p>
<p><b>DRUGS</b></p> <p><i>Definite association:</i> Azathioprine, 6-mercaptopurine, valproic acid, estrogens, corticosteroids, didanosine <i>Probable association:</i> Thiazides, ethacrynic acid, phenformin, procainamide, chlorthalidone, L-asparaginase</p>	<p><b>METABOLIC CAUSES</b></p> <p>Hyperlipoproteinemia <b>Hypertriglyceridemia</b> Hyperparathyroidism <b>Hypercalcemia</b> Renal failure Postrenal transplantation</p>
<p><b>TRAUMA</b></p> <p><i>Accidental:</i> Blunt trauma to the abdomen</p>	<p><b>INFECTIOUS</b></p> <p><i>Viral:</i> <b>Mumps</b>, rubella, viral hepatitis, <b>coxsackie</b></p>

<i>Iatrogenic injury:</i> Postoperative, postendoscopic retrograde cholangiopancreatography, endoscopic sphincterotomy, sphincter of Oddi manometry	<b>virus B</b> , echovirus, cytomegalovirus, human immunodeficiency virus <i>Bacterial:</i> Mycoplasma, <i>Campylobacter jejuni</i> , tuberculosis, <i>Legionella</i> species, <b>Leptospirosis</b>
<b>VASCULAR</b> <i>Ischemia:</i> Hypoperfusion (e.g. postcardiac surgery) or atherosclerotic emboli <i>Vasculitis:</i> Systemic lupus erythematosus, polyarteritis nodosa, malignant hypertension	<b>IDIOPATHIC</b> Pancreas divisum
<b>MISCELLANEOUS</b> Penetrating peptic ulcer Pregnancy associated Reye syndrome	<b>GENETIC</b> Mutations in the pancreatic trypsin inhibitor ( <i>SPINK1</i> ) gene and in the cystic fibrosis transmembrane regulator (CFTR)

## Pathogenesis (Fig. 12.1)

**Autodigestion of the pancreatic substance** is a currently accepted pathogenic theory of acute pancreatitis. According to this theory, acute pancreatitis develops as a consequence of premature and exaggerated activation of proteolytic enzymes within the pancreas itself (e.g. trypsinogen, chymotrypsinogen, proelastase, and lipolytic enzymes such as phospholipase A<sub>2</sub>).

### Activation of pancreatic enzymes

- **Activation of trypsin:** One of the proenzyme is trypsinogen, which is **prematurely activated to trypsin**. It is an important triggering event. Actions of trypsin are:
  - **Activates other proenzymes:** Trypsin converts many proenzymes into active forms (such as proelastase and prophospholipase). Activated enzymes elastase (from proelastase) and phospholipase (prophospholipase) can damage the elastic fibers of blood vessels and degrade fat cells.
  - **Activation of kinin, clotting and complement system:** Trypsin acts on kinin system and converts prekallikrein to its activated form kallikrein. This in turn can activate Hageman factor (factor XII), the clotting and complement systems.

*The severity of acute pancreatitis depends on the balance of two opposite sets of forces, namely the activity of released proteolytic enzymes and antiproteolytic factors. The latter consists of an intracellular pancreatic trypsin inhibitor protein and circulating  $\beta$ 2-macroglobulin,  $\alpha$ 1-antitrypsin*

and C1-esterase inhibitors.

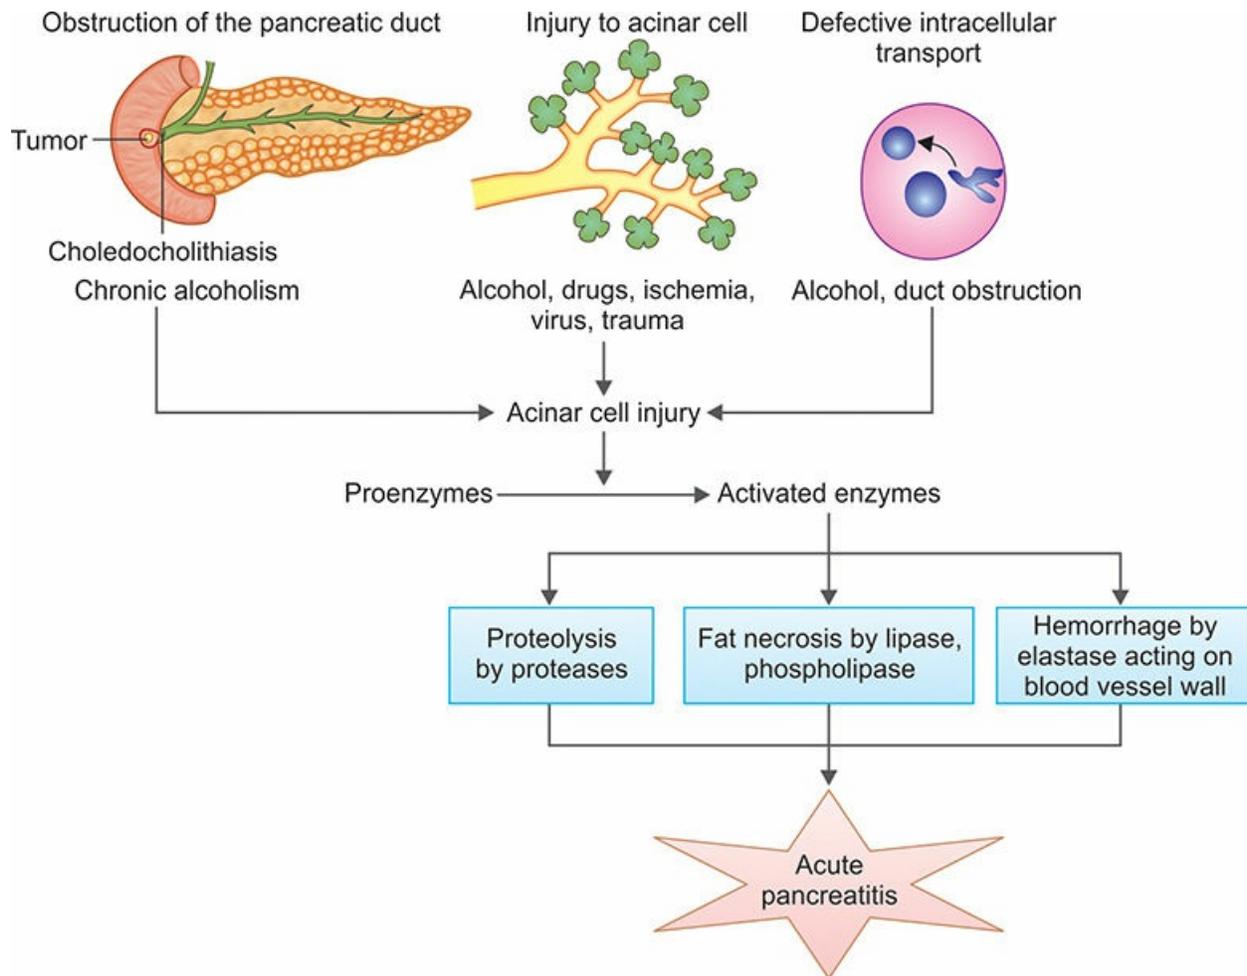

Fig. 12.1: Pathogenesis of acute pancreatitis.

## Clinical Features

**Q. Write short note on signs and symptoms of acute pancreatitis.**

### Symptoms

- **Abdominal pain:** It is the cardinal and major symptom of acute pancreatitis. Its characteristics are:
  - **Location:** Upper abdominal pain usually located in the **epigastric and periumbilical region** more on the left or right side, depending on the portion of the pancreas is involved.
  - **Onset:** **Sudden** onset and gradually increases in severity.
  - **Nature:** **Constant, steady, intense** (over 15–60 minutes)/dull and boring.

- ◆ Pain relief is often obtained by sitting with trunk flexed and knees drawn up.
  - ◆ When the retroperitoneum is involved, pain often **radiates to the upper back** as well as to the chest, flanks, and lower abdomen.
  - **Other symptoms:** These include anorexia, nausea, and vomiting.
- Acute pancreatitis may present as acute abdomen as a medical emergency.

### *Signs*

#### Early stages

- Distressed and anxious patient.
- **Marked epigastric tenderness** and **abdominal distension** (due to gastric and intestinal hypomotility). In the **early stages**, rebound **tenderness and guarding are absent** because the inflammation is mainly in the retroperitoneal region.
- Tachypnea due to ARDS, atelectasis and pleural effusion.
- In patients with gallstones **jaundice** may develop due to compression of the intrapancreatic portion of the common bile duct caused by edema of the head of the pancreas.

#### Severe disease

- **Low grade fever, tachycardia, and hypotension** are common.
- **Shock with oliguria** may develop due to:
  - Hypovolemia secondary to exudation of blood and plasma into the retroperitoneal space.
  - Vasodilation and increased vascular permeability produced due to increased formation and release of kinin peptides.
  - Systemic effects of proteolytic and lipolytic enzymes released from the pancreas into the circulation.
- **Abdominal examination** may show tenderness with guarding as well as diminished or absent bowel sounds (when paralytic ileus develops).
- **Respiratory system:** Lungs findings include basal rales, atelectasis, and pleural effusion.
- **Skin:** Erythematous skin nodules due to focal subcutaneous fat necrosis may be seen.
- **Purtscher retinopathy:** Ischemic injury to retina may be visible on

fundus examination.

- **Cullen's sign:** Faint bluish discoloration (bruising) around the umbilicus (Fig. 12.2) due to hemoperitoneum. It may be also found in association with ruptured ectopic pregnancy, ruptured aortic aneurysm, ruptured spleen and hepatocellular carcinoma, blunt abdominal trauma and spontaneous bleeding secondary to coagulopathy.
- **Grey Turner's sign:** Blue-red-purple or green-brown discoloration of the flanks (Fig. 12.2) due to tissue catabolism of hemoglobin.
- **Fox's sign:** Bluish discoloration over the inguinal ligament.

**Fig. 12.2:** Ecchymotic discoloration in the periumbilical region (Cullen's sign) or along the flank (Grey Turner sign).

### ***Laboratory Investigations***

**Q.** Write short note on diagnosis and treatment of acute pancreatitis.

**Q.** Write short note on investigation (including biochemical evaluation) in acute pancreatitis.

#### *Blood*

The diagnosis of acute pancreatitis is usually established by the finding of **raised level of serum amylase and lipase** and ultrasound or CT evidence of pancreatic swelling.

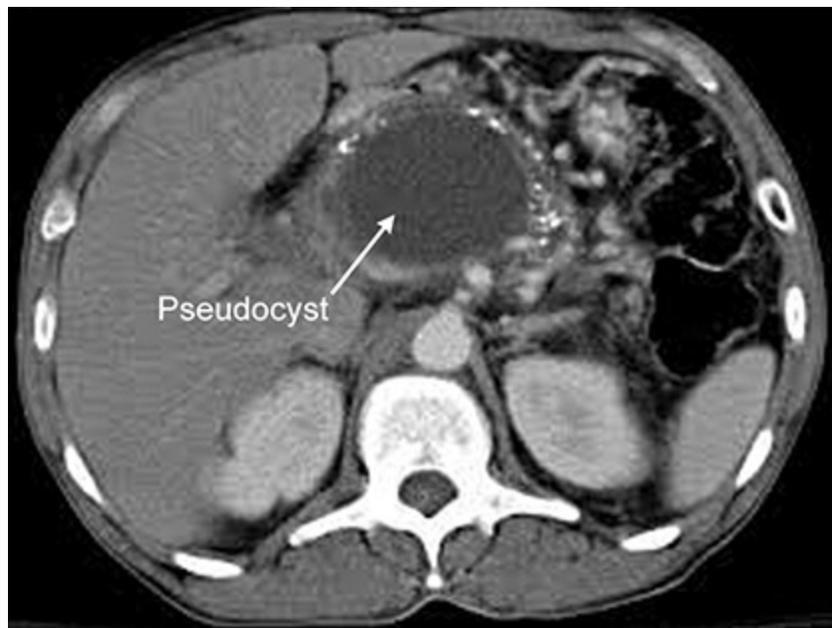

1. ***Serum amylase:***

- Levels markedly (three times the upper limit of normal) raised during the first 24 hours and then decline to normal within 3–5 days.
  - Persistently elevated serum amylase levels indicate development of complications such as pancreatic abscess or pseudocyst formation.
  - Amylase levels may be spuriously normal in 20% patients with alcoholic pancreatitis and 50% patients with hypertriglyceridemia.
  - Peritoneal amylase is massively raised in pancreatic ascites.
  - *Serum amylase concentrations are also elevated in other conditions like perforated bowel, salivary gland obstruction/ infection, ruptured ectopic pregnancy, renal failure, mesenteric infarction, etc.*
2. **Urinary amylase:** Levels may be diagnostic because they remain elevated over a longer period of time.
  3. **Serum lipase:**
    - Preferable to amylase for diagnosis as it remains elevated for a longer period of time (8–14 days) than levels of serum amylase. It has **greater diagnostic accuracy** and is a more useful indicator of acute pancreatitis.
    - Levels will be raised within 72 to 96 hours and takes longer time to clear from the blood.
    - Marked elevation of lipase in pleural or peritoneal fluid (> 5000 IU/dL) suggests acute pancreatitis.
  4. **C-reactive protein level:** It is useful in assessing severity and prognosis of acute pancreatitis.
  5. **Other blood investigations:**
    - **Leukocytosis:** Moderate to severe acute pancreatitis usually show leukocytosis.
    - **Hyperglycemia and glycosuria:** It occurs in 10% of cases. Possibly due to hyperglucagonemia, associated with relative hypoinsulinemia.
    - **Hypocalcemia:** It is due to precipitation of calcium soaps in necrotic fat. Persistent hypocalcemia is a poor prognostic sign.
    - **Other baseline investigations:** These include urea and electrolytes, liver biochemistry, LDH, triglycerides, and arterial blood gases.

### *Radiology*

The enlarged inflamed pancreas may be directly visualized by radiography.

- **Plain X-ray:**
  - **X-ray abdomen and chest:** Useful for excluding other causes of acute abdominal pain (e.g. gastroduodenal perforation or obstruction). A supine abdominal X-ray may reveal gallstones or pancreatic calcification. Nonspecific signs like ‘colon cut-off sign’, ‘sentinel loop sign’ can be seen.
- **Abdominal ultrasound scan:** Used as a screening test to evaluate gallbladder and biliary tree (to identify gallstones, biliary obstruction or pseudocyst formation). It may show pancreatic swelling, necrosis and peripancreatic fluid collections. However, the pancreas may not be visualized because of gas-filled loops of bowel.
- **CT scan of abdomen:** May show swollen pancreas (Phlegmon), pseudocyst (Fig. 12.3) or pancreatic abscess. Helpful in **assessing the severity**, the risk of morbidity and mortality and the complications of acute pancreatitis.

**Fig. 12.3:** CT image showing pseudocyst.

- **Contrast-enhanced CT scanning:** Should be performed after 72 hours of onset of symptoms to know the extent of pancreatic necrosis. Necrotizing pancreatitis shows decreased pancreatic enhancement on CT, following intravenous injection of contrast material.

It can detect complications such as fluid collections, abscess formation, pseudocyst and involvement of the colon, blood vessels and other adjacent

structures by the inflammatory process. The presence of gas within necrotic material suggests infection and possible abscess formation.

- **MRI abdomen and magnetic resonance cholangiopancreatography (MRCP):** Its uses are:
  - For assessing the degree of pancreatic damage/necrosis.
  - To identify gallstones within the biliary tree.
  - To differentiate between fluid and solid inflammatory masses.
- **Endoscopic retrograde cholangiopancreatography (ERCP):** Used for removing bile duct stones in few selected cases of gallstone-related pancreatitis.

### ***Determining the Severity of Acute Pancreatitis***

- **Course of acute pancreatitis:** Majority of cases of acute pancreatitis are mild and run a short, self-limiting course. About 25% develop a more complicated course and in about 10% this may be life-threatening.
- The **best scoring system** available is: **Ranson scoring system** (Table 12.2).
- The **modified Glasgow (Box 12.3) or the Imrie criteria** consists of 8 parameters and requires a 48 hour period of observation and scores 3 or more it indicates severe pancreatitis.
- **Acute physiology and chronic health evaluation (APACHE) II score:** It is based on common physiological and laboratory values, adjusted for age and the presence or absence of a number of other chronic health problems (>8 predicts severe disease).
- **Bedside index for severity in acute pancreatitis (BISAP),** also uses the first letter of each parameter for 1 point. *The BISAP score provides a single point for 5 parameters: blood urea nitrogen (BUN) greater than 25 mg/dL, impaired mental status, systemic inflammatory response syndrome, age greater than 60, and/or the presence of a pleural effusion, for a possible total of 5 points.* A BISAP score greater than 3 is associated with a seven- to twelve-fold increase in developing organ failure.
- **Computed tomography (CT) grading system of Balthazar and CT severity index (CTSI)** is presented in Table 12.3 (Added score >5 indicates severe pancreatitis).

**Box 12.3:** Modified Glasgow criteria.

---

- P** - PaO<sub>2</sub> <8 kPa
- A** - Age >55-year-old
- N** - Neutrophilia: WBC >15 × 10<sup>9</sup>/L
- C** - Calcium <2 mmol/L
- R** - Renal function, urea >16 mmol/L
- E** - Enzymes: LDH >600 IU/L; AST >200 IU/L
- A** - Albumin <32 g/L (serum)
- S** - Sugar: Blood glucose >10 mmol/L

Apart from the above scoring systems, individual laboratory tests have been suggested to establish severity.

- These include methemalbumin, alpha-2 macroglobulin, alpha-1 antitrypsin, C3 and C4 levels, phospholipase A2, C-reactive protein, trypsinogen-activated peptide (TAP) and granulocytic elastase.

**Table 12.2:** Ranson criteria for assessing severity of acute pancreatitis.

<i>Factors</i>	<i>Alcoholic pancreatitis</i>	<i>Gallstone pancreatitis</i>
<b>1. On admission</b>		
<ul style="list-style-type: none"> <li>• Age</li> <li>• WBC count</li> <li>• Blood glucose</li> <li>• Serum lactate dehydrogenase (LDH)</li> <li>• Serum aspartate aminotransferase (AST)</li> </ul>	<ul style="list-style-type: none"> <li>&gt;55 years</li> <li>&gt;16,000/cumm</li> <li>&gt;200 mg/dL</li> <li>&gt;350 IU/L</li> <li>&gt;250 IU/L</li> </ul>	<ul style="list-style-type: none"> <li>&gt;70 years</li> <li>&gt;18,000/cumm</li> <li>&gt;220 mg/dL</li> <li>&gt;400 IU/L</li> <li>&gt;250 IU/L</li> </ul>
<b>2. Within 48 h</b>		
<ul style="list-style-type: none"> <li>• Hematocrit decreases</li> <li>• Increase of blood urea nitrogen (BUN)</li> <li>• Serum calcium</li> <li>• PaO<sub>2</sub></li> <li>• Base deficit</li> <li>• Fluid deficit</li> </ul>	<ul style="list-style-type: none"> <li>&gt;10%</li> <li>&gt;5 mg/dL</li> <li>&lt;8 mg/dL</li> <li>60 mmHg</li> <li>&gt;4 mEq/L</li> <li>&gt;6 L</li> </ul>	<ul style="list-style-type: none"> <li>–</li> <li>&gt;2 mg/dL</li> <li>&lt;8 mg/dL</li> <li>–</li> <li>&gt;5 mEq/L</li> <li>&gt;4 L</li> </ul>

Number of criteria and approximate mortality (%): 0 to 2 = 0%; 3 to 4 = 15%; 5 to 6 = 50%; >6 = 100%.

**Table 12.3:** Computed tomography (CT) grading system of Balthazar and CT severity index (CTSI).

<b>Balthazar grades</b>	
Grade A	Normal pancreas consistent with mild pancreatitis
Grade B	Focal or diffuse enlargement of the gland, including contour irregularities and inhomogeneous attenuation but without peripancreatic inflammation
Grade C	Grade B plus peripancreatic inflammation
Grade D	Grade C plus associated single fluid collection
Grade E	Grade C plus two or more peripancreatic fluid collections or gas in the pancreas or retroperitoneum
<b>CTSI = Balthazar grade score plus necrosis score*</b>	
Balthazar grade score:	Necrosis score:
A = 0	Absence of necrosis 0
B = 1	Necrosis of up to 33% of pancreas 2
C = 2	Necrosis of 33% to 50% 4
D = 3	Necrosis of >50% 6
E = 4	

\*Score = morbidity [%]/mortality [%]: 0 to 3 = 8%/3%; 4 to 6 = 35%/6%; 7 to 10 = 92%/17%.

## ***Differential Diagnosis of Acute Pancreatitis (Table 12.4)***

### ***Complications of Acute Pancreatitis***

**Table 12.4:** Differential diagnosis of acute pancreatitis.

- |   |  |
|---|--|
| <ul style="list-style-type: none"> <li>• Perforation: Peptic ulcer/intestinal</li> <li>• Acute cholecystitis</li> <li>• Acute appendicitis</li> <li>• Bowel ischemia</li> </ul> | <ul style="list-style-type: none"> <li>• Acute myocardial infarction</li> <li>• Pneumonia</li> <li>• Abdominal aortic dissection</li> <li>• Diabetic ketoacidosis</li> <li>• Renal colic</li> <li>• Acute hepatitis</li> </ul> |
|---|--|

**Q. Write short note on complications of acute pancreatitis.**

#### **Local (pancreatic) complications**

- **Acute peripancreatic fluid collections (APFC)** do not have a well-defined wall, usually remain asymptomatic.
- **Pancreatic pseudocyst:** It represents a localized peripancreatic collection of pancreatic juice and debris usually developing in the lesser sac

following inflammatory rupture of the pancreatic duct. It may be palpable in the upper abdomen four to six weeks after onset of symptoms. Small pseudocysts are common and resolve as the pancreatitis recovers, but those larger than 6 cm can persist causing abdominal pain and may compress or erode surrounding structures.

- **Pancreatic necrosis** (sterile or infected): Necrosis may result in an acute necrotic collection (ANC) that contains a variable amount of fluid and necrosis or walled-off necrosis (WON), which consists of a mature, encapsulated collection.
- **Pancreatic abscess**: Localized collection of pus close to the pancreas and containing little or no pancreatic necrotic tissue.
- **Pancreatic ascites**: May develop due to leakage of fluid from a disrupted pancreatic duct into the peritoneal cavity.

Systemic complication are listed in Table 12.5.

**Table 12.5: Complications of acute pancreatitis.**

<i>Local</i>	<i>Systemic</i>
<ul style="list-style-type: none"> <li>• <b>Pseudocyst</b></li> <li>• <b>Necrosis</b>: Sterile/infected necrosis/walled-off necrosis</li> <li>• <b>Abscess</b></li> <li>• <b>Pancreatic ascites</b></li> <li>• Disruption of main pancreatic duct</li> <li>• Leaking pseudocyst</li> <li>• Involvement of contiguous organs by necrotizing pancreatitis</li> <li>• Massive intraperitoneal hemorrhage</li> <li>• Thrombosis of blood vessels (splenic vein, portal vein)</li> <li>• Bowel infarction</li> <li>• Obstructive jaundice</li> <li>• Abdominal compartment syndrome</li> </ul>	<ul style="list-style-type: none"> <li>• Systemic inflammatory response syndrome (SIRS) due to increased vascular permeability caused by release of cytokine, platelet aggregating factor and kinin</li> <li>• <b>Respiratory complications</b>: Pleural effusion, hypoxia–adult respiratory distress syndrome (ARDS) due to microthrombi in pulmonary vessels, pneumonia</li> <li>• <b>Cardiovascular</b>: Hypotension and shock, hypovolemia</li> <li>• <b>Gastrointestinal complications</b>: <b>Upper gastrointestinal bleeding</b> due to gastric or duodenal erosions and paralytic ileus</li> <li>• <b>Hepatobiliary complications</b>: Jaundice, common bile duct obstruction (obstructive jaundice), splenic or portal vein thrombosis, variceal hemorrhage</li> <li>• <b>Renal</b>: Oliguria, azotemia renal artery and/or renal vein thrombosis, acute tubular necrosis</li> <li>• <b>Metabolic</b>: Hyperglycemia (due to disruption of islets of Langerhans with altered insulin/glucagon release), hypocalcemia: due to sequestration of calcium in fat necrosis</li> <li>• <b>Hematological complication</b>: Disseminated</li> </ul>

intravascular coagulation (DIC), Increased factor VII or fibrinogen

- Fat necrosis (subcutaneous nodules), polyarthritis.
- Retinopathy (Purtscher's retinopathy): Sudden blindness
- **Central nervous system:** Psychosis, encephalopathy and coma

## Q. Write short note on treatment of acute pancreatitis.

### Management/Treatment

Steps involved (Box 12.4):

**Box 12.4:** Steps involved in the treatment of acute pancreatitis.

- Establishing the diagnosis and assessing the severity of acute pancreatitis
- Early treatment (resuscitation)
- Detection and treatment of complications
- Treatment of the underlying cause (e.g. gallstones).

### General supportive care

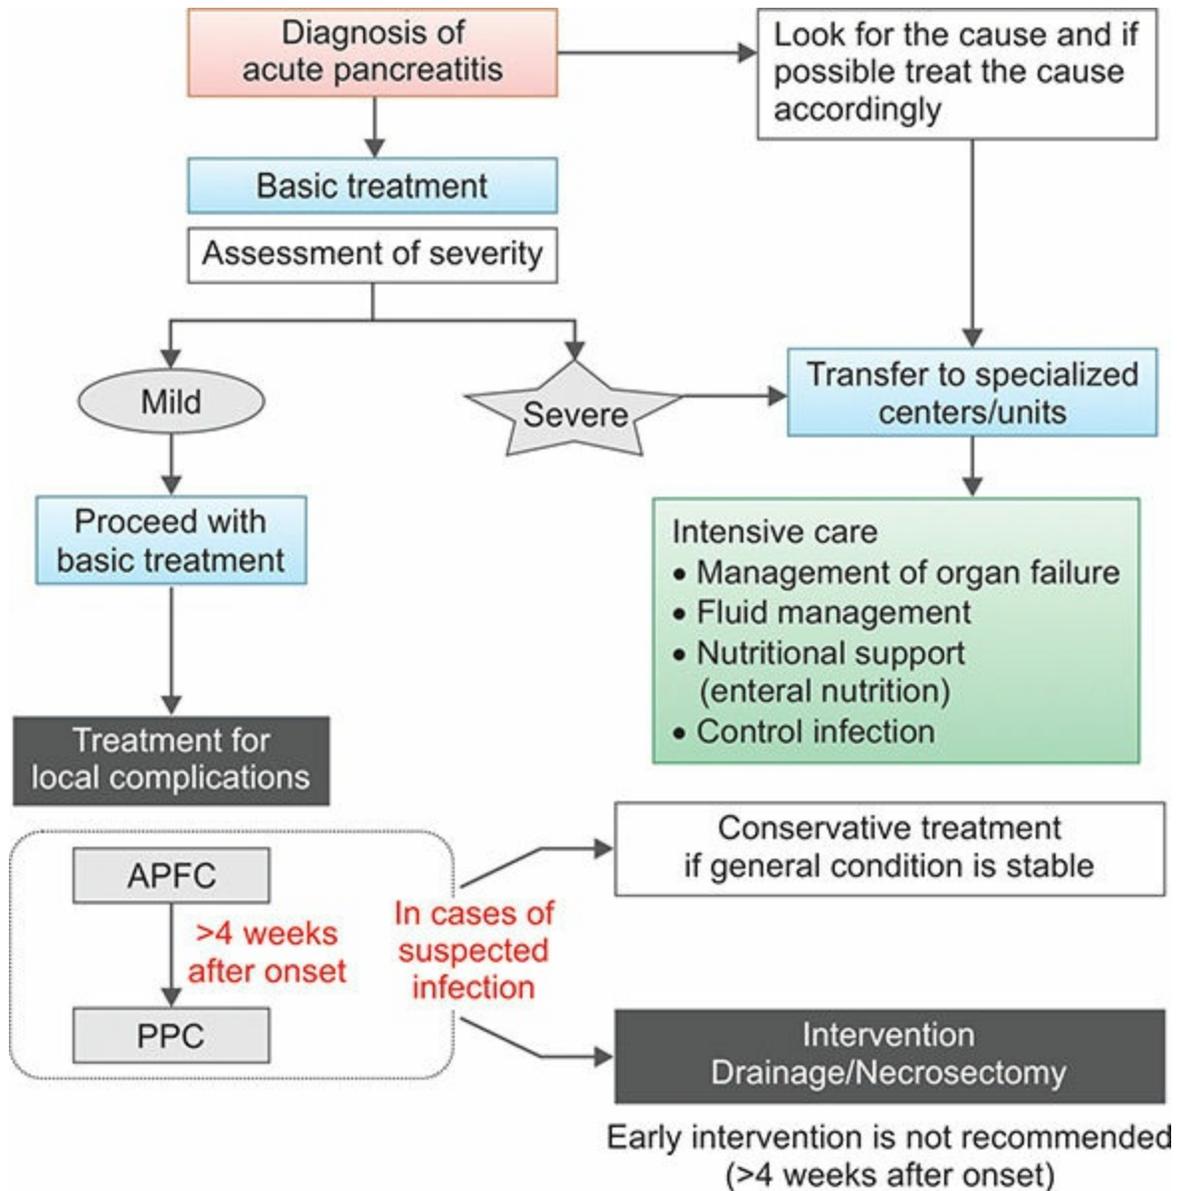

In about 85–90% of patients, acute pancreatitis is self-limited and subsides spontaneously. The initial management of acute pancreatitis is similar, irrespective of the cause.

- **Intravenous (IV) fluids:** To maintain normal intravascular volume. There may be large amount of fluid loss during early phase of acute pancreatitis.
- **Feeding:** *Nil orally* initially in severe pancreatitis. **Total parenteral nutrition** may be associated with a high risk of infection. Nasogastric/naso-jejunal administration of feed is possible in most of the patients followed by gradual oral intake. If tolerated, enteral feeding should be started as early as possible in patients with severe pancreatitis to decrease endotoxemia and reduce systemic complications.
- **Analgesia for pain:** Tramadol or other opiates are the drugs for pain control. Morphine and diamorphine are avoided, because they may exacerbate pancreatic ductular hypertension by causing contraction of sphincter of Oddi.
- **Nasogastric suction/aspiration:** Indications include (1) continuation of pain, (2) presence of protracted vomiting or (3) obstruction observed on plain X-ray abdomen. It prevents abdominal distension and vomiting and the risk of aspiration pneumonia.
- **Prophylactic antibiotics:** Carbapenems (imipenem or meropenem) or ceftazidime/cefuroxime may reduce the incidence of infected pancreatic necrosis.
- **Other drugs:** Proton-pump inhibitors, glucagon, octreotide, pentoxifylline and aprotinin (protease inhibitor).
- **Anticoagulation** with a low molecular weight heparin for prevention of deep vein thrombosis (DVT).
- Management of acute pancreatitis (Flowchart 12.1).
- **Indications for surgery (Box 12.5).**
- **Endoscopic retrograde cholangiopancreatography (ERCP)** is indicated within first 36–48 hours in severe pancreatitis associated with gallstone obstruction (particularly when complicated

by cholangitis or jaundice).

- Small percentage patients develop multiorgan failure (reflecting the extent of pancreatic necrosis) and all **severe cases** should be managed in a **high-dependency or intensive care unit**.

**Flowchart 12.1:** Management of acute pancreatitis.

(APFC: acute peripancreatic fluid collections; PPC: pancreatic pseudocyst)

## Chronic Pancreatitis

**Q.** Write short essay/note on chronic pancreatitis.

**Box 12.5:** Indications for surgery in acute pancreatitis.

- Infected pancreatic necrosis (pancreatic abscess).
- Complications: Most patients with complications such as acute peripancreatic fluid collections and or pseudocysts do not require surgical interventions unless they become infected or cause compression of other organs.
- When there is uncertainty of diagnosis.
- **Cholecystectomy:** It should be carried out in gallstone related pancreatitis as soon as feasible (within 2 weeks after the resolution of acute episode). This will prevent potentially fatal/recurrent episode of pancreatitis.

- Chronic pancreatitis is defined as **chronic inflammation of the pancreas** presenting as recurrent pain, characterized by the presence of **permanent and progressive morphologic or functional damage** to the pancreas.
- The pancreas shows **irreversible damage to the exocrine pancreas in the form of fibrosis causing exocrine deficiency** (malabsorption). In the **late stages**, there may be destruction of endocrine parenchyma producing endocrine deficiency (**diabetes mellitus**).

### *Etiology (Table 12.6)*

**Q. Write short essay/note on causes and complications of chronic pancreatitis.**

### *Pathogenesis*

Repeated attacks of acute pancreatitis may lead to chronic pancreatitis. Four models have been suggested which are responsible for the development of chronic pancreatitis.

- **Obstruction theory:** Some etiological agents cause increase protein concentrations, precipitation of these protein to form ductal plugs in pancreatic juice. The ductal plugs may calcify to form calculi which further obstruct the pancreatic ducts.
- **Necrosis-fibrosis theory:** The inflammation and scarring resulting from bouts of acute pancreatitis cause obstruction and stasis within the duct. It may subsequently form stones in the duct.
- **Toxic-metabolic theory:** Toxins such as alcohol and its metabolites can cause direct toxic damage to acinar cells, and eventually fibrosis.
- **Oxidative stress theory:** The pancreas is exposed to 'oxidative stress' either through the systemic circulation or through reflux of bile into the pancreatic duct. It also results in recurrent inflammation, tissue damage and fibrosis, and the activation of lysosomes and proenzymes.

**Table 12.6: Causes of chronic pancreatitis: Tigar-O classification system.**

**Toxic-metabolic**

- **Alcohol abuse (~70%)**
- Tobacco smoking
- Hypercalcemia (e.g. hyperparathyroidism)
- Chronic renal failure

**Idiopathic (~20%)**

- Early/late onset
- Tropical

**Genetic**

- Hereditary pancreatitis (cationic trypsinogen mutation)
- Cystic fibrosis due to cystic fibrosis transmembrane conductance regulator (CFTR) gene mutations
- SPINK1 mutations

**Autoimmune**

- Isolated autoimmune chronic pancreatitis
- Part of multi-organ disorders (Sjögren's syndrome, primary biliary cirrhosis)

**Recurrent and severe acute pancreatitis**

- Postnecrotic (severe acute pancreatitis)
- Recurrent acute pancreatitis

**Obstructive**

- Duct obstruction (e.g. tumor)
- Pancreas divisum
- Stenosis of sphincter of Oddi

## ***Clinical Features***

**Q. Write short note on chronic calcific pancreatitis.**

- Predominantly affects middle-aged alcoholic men. In southern India, severe chronic calcific pancreatitis may develop in non-alcoholics, probably as a result of *malnutrition and cassava consumption*.
- **Abdominal pain:** Due to increased pressure within the pancreatic ducts and direct involvement of pancreatic and peripancreatic nerves by the inflammatory process. Pain is variable in location, severity, and frequency.
  - May be **continuous or intermittent**.
  - May be **referred to back**.
  - Pain is often increased by eating of heavy meals. This may lead to a fear of eating with consequent weight loss.
  - No uniform relationship between pain and alcohol. Pain may be either

exacerbated by alcohol excess or may be relieved by drinking alcohol.

- It is partially relieved on stooping and bending forwards (Mohammedan Prayer sign).
- Features of maldigestion/**malabsorption**: Manifested as chronic diarrhea, **steatorrhea**, weight loss, fatigue.
- **Diabetes mellitus** develops in about 30% of patients.
- In late stages, mechanical obstruction of the common bile duct due to fibrosed head of pancreas can produce jaundice.

### *Physical examination*

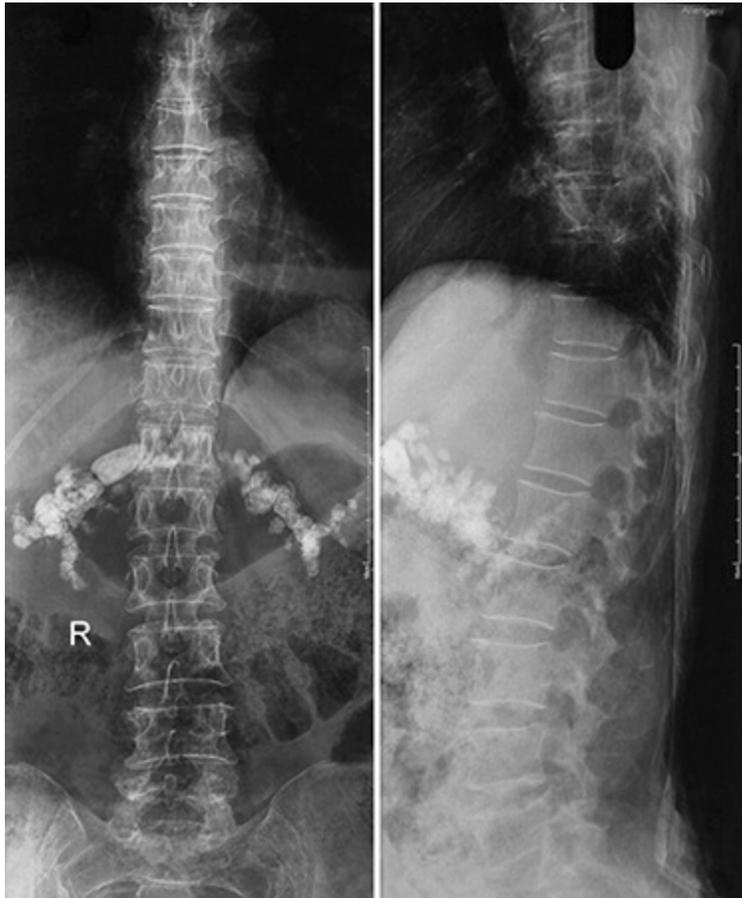

**Thin, malnourished** patient with **tenderness in the epigastric region**.

### *Investigations*

- **Serum amylase and lipase**: May be elevated but in advanced disease they are usually normal.
- **Plain X-ray of abdomen (Fig. 12.4)**: May show diffuse **calcifications** in pancreatic area (in ~30%) and usually indicate significant damage to the pancreas.
- **Transabdominal ultrasound scan**: Used for initial assessment.
- **Contrast-enhanced spiral CT scan**: Useful for a more detailed assessment. It may show pancreatic calcification, dilated pancreatic duct, pancreatic atrophy and dilatation/stricture of bile duct.
- **Endoscopic retrograde cholangiopancreatography (ERCP)** is the gold standard for accurate diagnosis and demonstrates pancreatic ducts.
- **MRI with MRCP**: Provides a direct view of the pancreatic duct and detects more subtle abnormalities of the pancreatic duct. **MRI and MRCP** are now the diagnostic procedures of choice.
- **Endoscopic ultrasonography (EUS)** is useful for specifically assessing complications of chronic pancreatitis including pseudocyst formation and possible development of malignancy.
- **Pancreatic exocrine function tests**:
  - Secretin/cholecystokinin (CCK) stimulation test: Collection of pure pancreatic juice after secretin/CCK injection (gold standard but invasive and seldom used).
  - Fecal chymotrypsin or elastase level: Abnormal in the majority of

moderate to severe chronic pancreatitis.

- 24-hour fecal fat, the Lundh test meal, oral glucose tolerance test and pancreolauryl or PABA test.
- **Gene mutation analysis:** In cases where the etiology is not known. Common mutations include PRSS1, SPINK-1 and CFTR encoding genes.

**Fig. 12.4:** Erect abdominal X-ray AP and lateral views showing calcific pancreatitis.

## ***Complications of Chronic Pancreatitis***

### **Q. Write short note on complications of chronic pancreatitis.**

- Pseudocyst formation, bile duct or duodenal obstruction, pancreatic ascites or pleural effusion, splenic vein thrombosis, pseudoaneurysms, and, pancreatic cancer are the complications of chronic pancreatitis.

#### **Treatment**

- **Long-term abstinence of alcohol** in patients with alcohol-related chronic pancreatitis may benefit. Smoking cessation prevents progression.
- **Treatment of abdominal pain:** About 60% of patients will become pain-free after about 6–10

years.

- **Opioids (tramadol) or non-steroidal anti-inflammatory drug (NSAIDs).** Tricyclic antidepressants (e.g. amitriptyline) and membrane stabilizing agents (e.g. pregabalin) may also be used for chronic pain.
- **Intractable pain** may be treated by **celiac axis nerve block.**
- **Surgery** includes **pancreatectomy and pancreateojejunostomy** performed for unremitting pain.
- **Endoscopic therapy** is useful in painful chronic pancreatitis to drain pancreatic duct in patients with obstructed ducts and treatment of complications (e.g. pseudocysts and bile duct obstruction with jaundice).
- **Steatorrhea:**
  - The steatorrhea seen in pancreatic insufficiency may be high, with up to 30 mmol of fat lost/24 h. This is treated with **pancreatic enzymes supplements** particularly lipase, 80,000–1,00,000 units before each meal.
  - An **acid suppressor (H<sub>2</sub>-receptor antagonist or proton pump inhibitor)** to prevent inactivation of pancreatic enzymes by gastric acid.
  - **Diet rich in medium-chain triglycerides** which do not require lipase for digestion may be given.
- **Treatment of diabetes:** With insulin.

## Tropical Pancreatitis

**Q. Describe the features of tropical pancreatitis.**

- **Juvenile form of chronic calcific pancreatitis** and is **not related to alcohol** intake.
- Almost **exclusively** observed **in tropical countries.** In India, it is more common in southern states namely Kerala and Tamil Nadu.

### *Etiology*

Exact etiology is **not known** and possible risk factors are listed in Box 12.6.

**Box 12.6:** Risk factors for tropical pancreatitis.

- Malnutrition
- Infections, e.g. Coxsackie and viral hepatitis
- Oxidant stress
- Diet rich in cassava, tapioca (contains cyanogenic glycosides)
- Familial.

### *Clinical Features*

- **Age and gender:** Young males.
- **Course:** **Accelerated course.**

- **Symptoms: Recurrent abdominal pain**, typically in **epigastric area with radiation to back**. Pain precipitated by heavy meals. Pancreatic exocrine deficiency presents with steatorrhea and malabsorption and endocrine deficiency presents with **diabetes mellitus**. Even without insulin **ketosis is uncommon** and frequent episodes of hypoglycemia with insulin are observed.
- **Signs:** Malnutrition, enlarged parotid glands, abdominal distention and a peculiar cyanotic hue of the lips.

### Investigations

Plain X-ray and ultrasound of abdomen: Shows multiple, large intraductal calculi.

**Blood:** Sugar, serum amylase, lipids, calcium need to be checked.

#### Treatment

- Similar to chronic pancreatitis described in page 857.
- Insulin for diabetes and requires a careful watch for hypoglycemia.

## Differences between Alcoholic Pancreatitis and Tropical Pancreatitis (Table 12.7)

**Q. How will you differentiate tropical pancreatitis from alcoholic pancreatitis?**

**Table 12.7:** Differences between alcoholic pancreatitis and tropical pancreatitis.

<i>Characteristics</i>	<i>Alcoholic pancreatitis</i>	<i>Tropical pancreatitis</i>
Age	35–45 years	20–40 years
Gender	Commonly males	Males > females
Steatorrhea	More common	Less common
Diabetes mellitus	Less common	More common
Intraductal calculi	Less common	Frequent
Development of pancreatic malignancy	Less common	More common

## Autoimmune Pancreatitis (AIP)/Autoimmune Chronic Pancreatitis (ACP)

- Autoimmune pancreatitis is a distinct **chronic inflammatory and sclerosing disease of the pancreas**.
- **IgG4-related disorder:** It is **one of the IgG4-related disorders** characterized by a **raised serum IgG4 level**. Other IgG4-related disorders are autoimmune cholangitis, Riedel's thyroiditis, aortitis and tubulointerstitial nephritis. Microscopically, IgG4-related disorders show **dense lymphoplasmacytic infiltrate with many IgG4-positive plasma cells**, a mild to moderate infiltration by eosinophils and an obliterative phlebitis in some organs, e.g. pancreas.
- **Age and gender:** It is more **common in men** (2:1) and usually manifests in **middle age** (>85% above the age of 50 years).
- **Clinical presentation:** It presents with **abdominal pain, weight loss or painless obstructive jaundice** (due to obstruction of the intrapancreatic bile duct), without acute attacks of pancreatitis. Other symptoms include vomiting, and glucose intolerance.
- **Association with other autoimmune disease:** AIP may also develop in association with other autoimmune disorders. These disorders include Sjögren's syndrome, primary sclerosing cholangitis (PSC), inflammatory bowel disease, retroperitoneal fibrosis (most commonly presenting as hydronephrosis due to entrapment of the ureter).
- **Laboratory findings:** Elevated serum immunoglobulins (IgG or IgG4), and the presence of other autoantibodies including those directed towards nuclear and smooth muscle antigens.
- **Imaging:** It shows diffuse enlargement of pancreas, narrowing of the pancreatic duct and stricturing of the lower bile duct.

**Treatment:** Glucocorticoid therapy usually produces rather dramatic improvement with rapid resolution of both symptoms and radiographic abnormalities. This is the hallmark of autoimmune pancreatitis. Some patients require azathioprine.

## PANCREATIC CANCER

- Pancreatic cancer is the fifth most common cause of cancer death in the Western World.
- **Age and gender:** Its incidence increases with age and the majority occur in the **elderly over the age of 60**. **Males** are affected twice as often as females.

## Etiology

- **Risk factors:** Excess intake of alcohol, cigarette smoking, high fat and protein diet, excessive intake of coffee and tea consumption and chronic calcific pancreatitis.
- **Genetic predisposition:** About 5 to 10% of patients with pancreatic cancer have a family history of the disease. FAMMM (familial atypical multiple mole melanoma syndrome), HNPCC (hereditary nonpolyposis colorectal cancer syndrome), hereditary pancreatitis, MEN, and Peutz-Jeghers syndrome have an increased risk of pancreatic cancer.

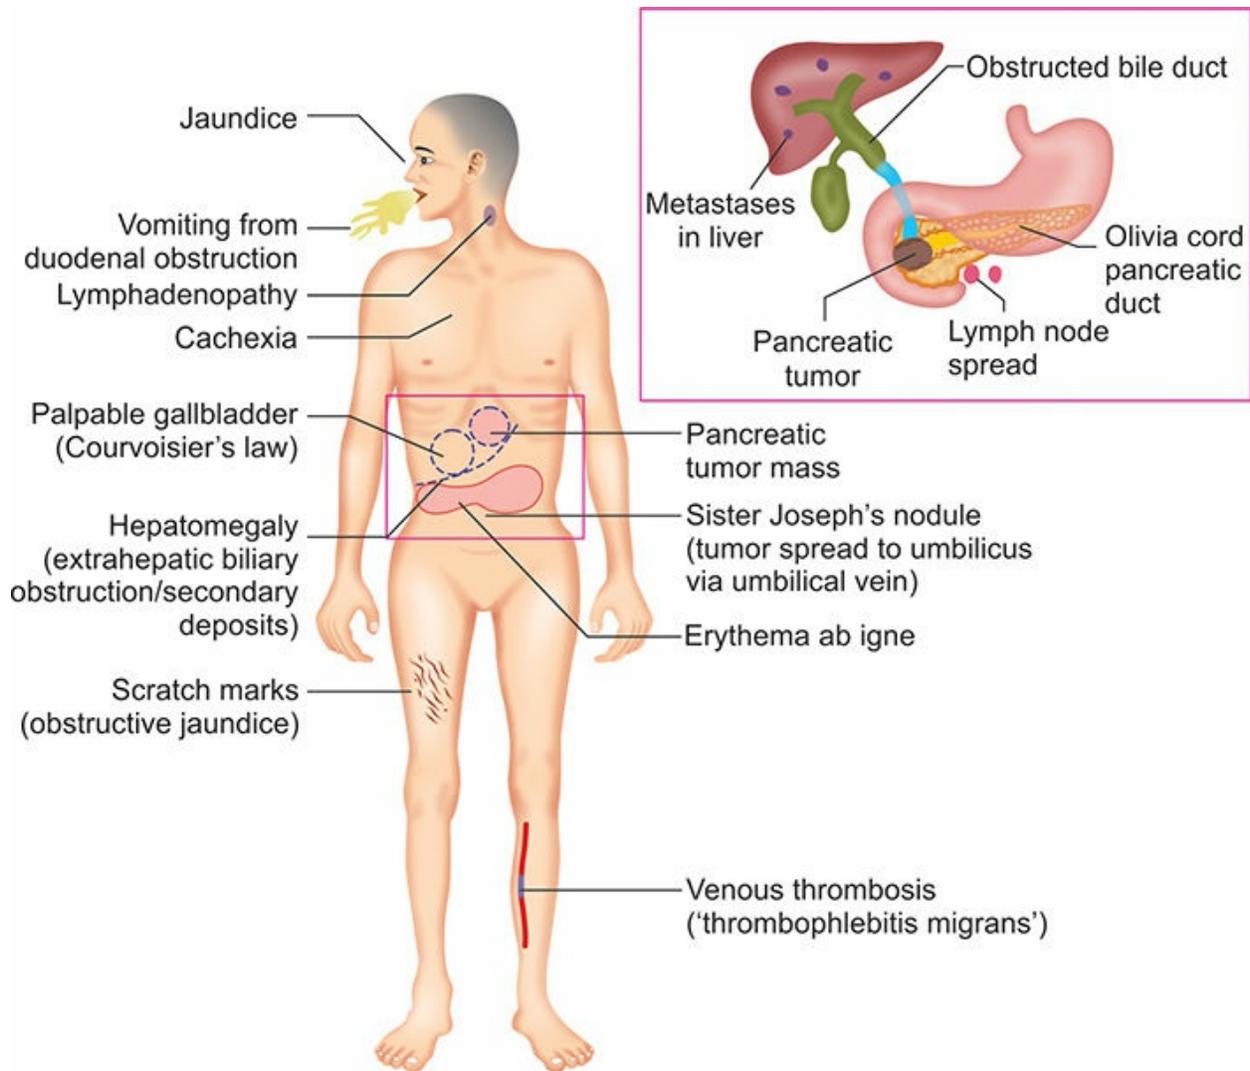

## Pathology

- Ductal adenocarcinoma accounts for 85–90% of pancreatic tumors.
- **Location:** About 60–70% of these tumors are localized in the head of the gland, 5–10% in the body, and 10–15% in the tail.
- **Spread:** Local spread, lymphatic spread as well as hematogenous spread occurs rapidly.

## Clinical Features (Fig. 12.5)

### Symptoms

- **Central abdominal pain:** Pain is common symptom and is usually incessant and gnawing, **epigastric, radiate** from the upper abdomen **to the back**, increasing on lying down and relieved by sitting up or bending forwards. Weight loss, obstructive jaundice and steatorrhea are often found. The pain results from invasion of the celiac plexus.
- **Others:** Loss of weight and cachexia.
- Symptoms **depend upon the site of the tumor.**
  - **Carcinoma of the head of pancreas:** They present early because of the obstruction to the common bile duct by the tumor produces **obstructive jaundice** (due to obstruction of bile flow), often with severe **pruritus** (secondary to cholestasis). Other symptoms include clay-colored stools with or without melena or silver stools. Obstruction of the pancreatic duct may cause episodes of pancreatitis.
  - **Carcinoma of the body and tail of the pancreas:** May be silent till quite large and widely disseminated.

**Fig. 12.5:** Features of carcinoma of the pancreas.

### ***Physical Signs***

- **General: Pallor, jaundice** and weight loss may be present. Scratch marks and erythema ab igne is seen.
- **Abdominal mass: A mass may be felt** in the epigastrium; the liver may be enlarged (hepatomegaly) due to biliary obstruction or secondary involvement (hepatic metastasis).
- **Courvoisier's law:** A distended non-tender gallbladder may be palpable in a jaundiced patient due to distal biliary obstruction by a pancreatic cancer.
- **Due to spread of tumor:**
  - With peritoneal involvement and **ascites**, shifting dullness and fluid

thrill can be elicited. On per rectal examination, nodules (**Blumer's shelf**) or peritoneal fluid may be felt.

- Involvement of the left supraclavicular node (**Virchow's node**) and umbilicus (**Sister Mary Joseph's node**) indicates advanced carcinoma.
- **Other presenting physical signs:** Migratory thrombophlebitis–recurrent venous thrombosis (Trousseau sign), diabetes, polyarthritis, paraneoplastic syndromes (Cushing syndrome), skin nodules (secondary to localized fat necrosis and associated inflammation) and hypercalcemia may be seen in some cases.

## Investigations

- **Blood:** It may show anemia. Liver function tests may show features of obstructive jaundice with elevated alkaline phosphatase. Urobilinogen is absent in urine whereas bile salts and bile pigments are evident. Occult blood may be present in stool.
- **Radiology:** **Barium meal** shows widening of the 'C' loop (**pad sign**) and reverse '3' sign in periampullary carcinoma. Hypotonic duodenography reveals a 'rose thorn' appearance. Endoscopic retrograde cholangiography increases the diagnostic yield; USG and CT scan are helpful in localizing the tumor.
- Ultrasound, contrast CT and ERCP yield in localization of tumor, assessing the spread as well as operability, guided biopsy/cytology helps to confirm diagnosis.
- **Tumor markers:** Carcinoembryonic antigen (CEA) and **CA-19-9** (high sensitivity (80%) but a high false-positive rate).

## Prognosis

Overall survival is about 3–5%, with median survival of 6–10 months for locally advanced cancer and 3–5 months for those with metastases.

### Treatment

- **Surgical resection:** It is the only method of effecting cure. Resectable tumors in the head and periampullary region are removed by Whipple's pancreaticoduodenectomy or its modifications.
- **Chemotherapy:** For inoperable cases chemotherapy with gemcitabine, capecitabine, nab-paclitaxel, cisplatin, docetaxel, oxaliplatin, irinotecan, 5- fluorouracil, mitomycin, streptozotocin and high-dose methotrexate, alone or in combination, may be beneficial. Tyrosine kinase inhibitors of EGFR (e.g. erlotinib) and monoclonal antibodies cetuximab is under trials.
- Radiotherapy may be supportive.

- **Palliative treatment:**

- **Pain:** Palliation for pain may be achieved with either analgesic nerve blocks (coeliac axis block/neurolysis, percutaneous cordotomy) or with duct drainage (pancreaticogastric anastomosis).
- Jaundice can be relieved by choledochojejunostomy or percutaneous/endoscopic stenting–endoprostheses (elderly and with very advanced disease).

## ENDOCRINE TUMORS OF PANCREAS

### Insulinoma (Beta Cell Tumor)

- **Most common** of endocrine tumors; **10% are malignant** and produce pronounced hypoglycemia.

#### *Clinical Features*

- Higher incidence in **women**.
- **Whipple's triad (Box 12.7)**.

#### **Box 12.7:** Whipple's triad.

- **Attack of hypoglycemia** (mental confusion, weakness, fatigue and convulsions) **while fasting**. Neuroglycopenic symptoms (anxiety, nervousness, dizziness and confusion) may develop during fasting. In some psychoses, seizures related to hypoglycemia and weight gain is seen.
- **Blood sugar <50 mg/dL during an attack.**
- **Relief of symptoms by administration of glucose.**

#### *Diagnosis*

##### **Fasting blood levels of insulin and glucose:**

- **Inappropriately elevated serum level of insulin** (>54 u/mL) for the level of glucose **establishes the diagnosis**.
- Blood **insulin-to-glucose ratio of >0.4 is diagnostic**.
- Blood fasting **C-peptide level** of >1.7 mg/mL is a good indicator.
- **Proinsulin level** is elevated and is used as a tumor marker.
- Suppression and stimulation (tolbutamide, calcium, glucagon) tests may be performed.

#### *Radiology*

- **Selective angiography** is best investigation, with few false positive results.

- **USG** is positive in 20–40% of cases.
- **CT with intravenous contrast** shows a dense blush.
- **MRI:** Bright spots are seen on T2 weighted images. In the presence of somatostatin receptors, octreotide scan may be useful. Portal venous sampling has 75% accuracy.
- **Calcium angiography:** It can determine the location of insulinoma whereas endoscopic USG has 80% positivity.

#### Treatment

- **Aim:** To localize and remove the tumor safely.
- **Hypoglycemia** can be **managed medically** (by using diazoxide, octreotide, lanreotide).
- **Surgery:**
  - If tumor is **small** and in the **head:** Removed by **enucleation**.
  - If in the **body or tail:** Remove it either by **enucleation** or by **distal** (subtotal) **pancreatectomy**.
  - If the tumor is **malignant and is operable:** **Resection**.
- **For metastasis** (liver, adjacent lymph nodes):
  - Hepatic artery embolization, RFA and cryoablation or radioembolization.
  - Streptozotocin, chlorozocin, 5-FU, either alone or in combination.

## Gastrinoma (Delta Cell Tumor)

(Synonym: **Zollinger-Ellison syndrome**)

- Second most common islet cell tumor (0.1–0.4/million population/year), but with MEN I it is the most common functional pancreatic neoplasm; 20% of ZES have MEN I.

**Q. Write short essay/note on etiology, clinical features and treatment of Zollinger-Ellison syndrome.**

### Pathology

- **Sites:** Most commonly in the pancreas, less commonly in the duodenum (23%), rarely in the gastric antrum.
- **Effects:** It produces excessive gastrin.
- **Characteristics:**
  - Often **solitary and malignant**.
  - When occurs as part of **MEN I, they are multiple and less malignant**.
  - Duodenal gastrinomas are less malignant than pancreatic tumors. They

are slow growing even in the presence of metastasis.

### ***Clinical Features***

- More frequent in **middle-aged men**. With MEN I, the symptoms occur earlier (3rd decade).
- **Zollinger-Ellison syndrome** is characterized by **hyperacidity and non-healing ulcers** (gastric, duodenal, jejunal, or in atypical locations). Epigastric pain with duodenal ulcer is seen in 90% of cases; 1/3rd have diarrhea, and weight loss is common (40% of cases). Esophagitis, dysphagia (30%), stricture and perforation may occur.

### ***Diagnosis***

- **ZES:** About 30–40% do not have evidence of peptic ulcer disease and 40% have duodenal instead of pancreatic tumor.
- **Gastric acid hypersecretion** (basal acid output >15 mEq/L) and **elevated fasting gastrin** (> 100 pg/mL) are suggestive. Provocative tests using secretin, calcium or gastrin may be used.
- **Immunohistochemistry:** Demonstration of gastrin in neoplastic cells by immunoperoxidase is confirmatory.
- **Tumor localization:** Using ultrasound, CT scan and endoscopic USG.
  - **Selective angiography** is best for primary and metastatic gastrinomas (40–60% accuracy) and with secretin stimulation, the accuracy increases to 70%.
  - Portal venous sampling for gastrin.

### **Treatment**

#### ***Medical***

- **Control acid secretion** using H<sub>2</sub> blockers. Dose: 2 grams ranitidine, 0.3 g famotidine or 80 mg omeprazole/pantoprazole per day. Parenteral ranitidine may be used.

#### ***Surgery***

- Accurately **identification of duodenal or pancreatic tumor** by inspection, palpation and if needed by intraoperative USG or transillumination duodenotomy.
- Surgical management
  - Excision, gastrectomy, enucleation based on tumor size, number and location.
- **Patients with MEN I having gastrinoma:**
  - **Surgery is not indicated.**
  - Four-gland parathyroidectomy with autografts is the initial procedure of choice to control hyperparathyroidism. Gastric acid hypersecretion is controlled as in sporadic gastrinoma

(mentioned above).

- If liver metastasis is present and resectable: Resection.
- Chemotherapy: Doxorubicin, 5-FU, streptozotocin shows 40% response. Interferon and octreotide may also be used.

## Glucagonoma (Alpha Cell Tumor)

Rare  $\alpha$ -cell tumor.

### *Clinical Features*

- Functional tumors: They produce the **glucagonoma syndrome** comprising abnormal glucose tolerance test, normocytic normochromic anemia, necrolytic migratory erythema (pathognomonic), red tongue, angular stomatitis, weight loss, tendency to develop infection, and depression.
- **Elevated fasting plasma glucagon >500 pg/mL is diagnostic.**

**Treatment:** Preoperative control of diabetes, treatment of venous thrombosis and correction of nutritional status with total parenteral nutrition. Surgical resection is done after localizing the tumor.

## Somatostatinoma (Delta Cell Tumor)

Rare malignant D cell tumors of the pancreas and 30% occur in the duodenum and small bowel. They affects both the sexes equally, with approximate age of 50 years. They cause diabetes mellitus, gallstones and diarrhea/steatorrhea.

**Diagnosis:** High fasting serum somatostatin levels.

**Treatment:** Octreotide therapy may be tried and the tumor surgically resected after localization. Cholecystectomy may be required for cholelithiasis.

## VIPoma (WDHA Syndrome; Verner-Morrison Syndrome; Pancreatic Cholera)

- Endocrine pancreatic tumor producing vasoactive intestinal polypeptide (VIP).
- **Symptoms:** Severe secretory diarrhea secondary to the stimulation of adenyl cyclase within the enterocyte (Verner–Morrison syndrome). Large-volume diarrhea (>3 L/day), hypokalemia, and hypo- or achlorhydria form part of the syndrome; hence the term **Watery Diarrhea, Hypokalemia, Achlorhydria (WDHA) syndrome.**

**Diagnosis:** Presence of severe secretory diarrhea, detection of elevated fasting levels of plasma VIP (>250 pg/mL) and localization of pancreatic islet cell tumor.

**Treatment**

- Correction of dehydration, hypokalemia and other metabolic abnormalities.
- Octreotide may be tried for symptomatic relief.
- Surgical removal of the tumor.
- For unresectable and metastatic tumors chemotherapy with 5-FU and streptozotocin. Interferon has also been used. Palliative debulking for incurable and metastatic tumors.

# Kidney

# CHAPTER 13

## FUNCTIONAL ANATOMY OF KIDNEY

**Q.** Describe the nephron with the help of a diagram. What are the functions of the kidney?

### Unit of Kidney

The **nephron is the structural and functional unit** of the kidney. It consists of the glomerulus and its tubule, and the common collecting system. Each kidney consists of about 1 million nephrons. Different components of a nephron are shown in Figure 13.1.

### Functions of Kidney

- **Excretion** of many metabolic breakdown products (including ammonia, urea and creatinine from protein, and uric acid from nucleic acids), drugs and toxins.
- Regulation of **water and electrolyte balance**
- Maintenance of **acid-base balance**
- **Reabsorption** of essential substances
- Secretion of hormones like **erythropoietin and renin**
- Metabolism of **vitamin D**
- **Regulation of blood pressure**

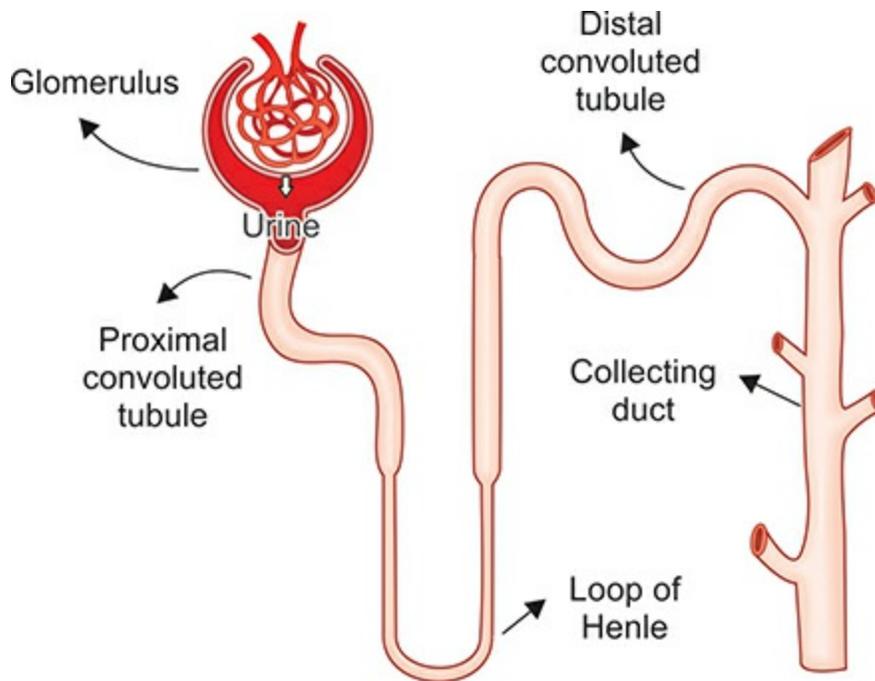

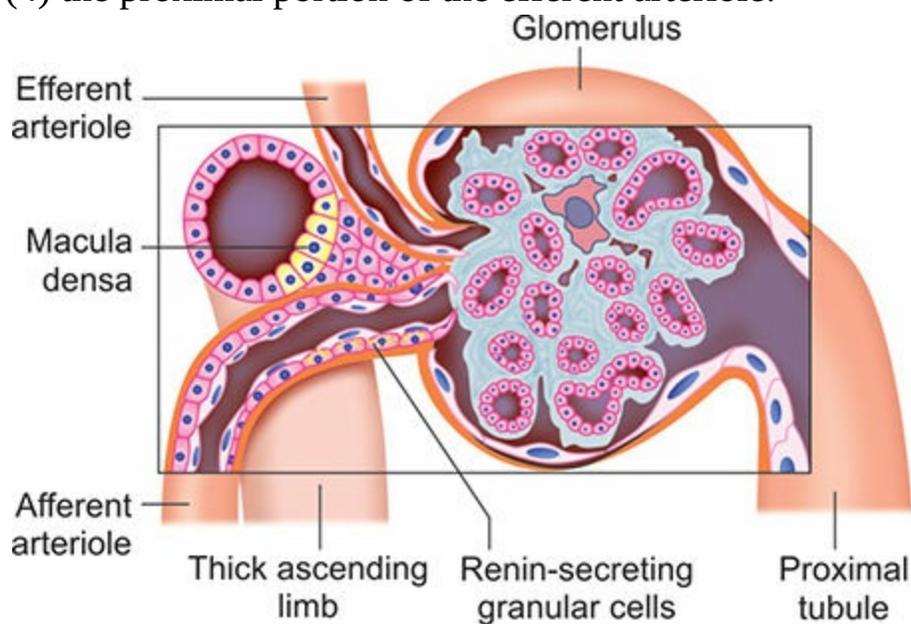

Fig. 13.1: Different components of the nephron.

## Juxtaglomerular Apparatus

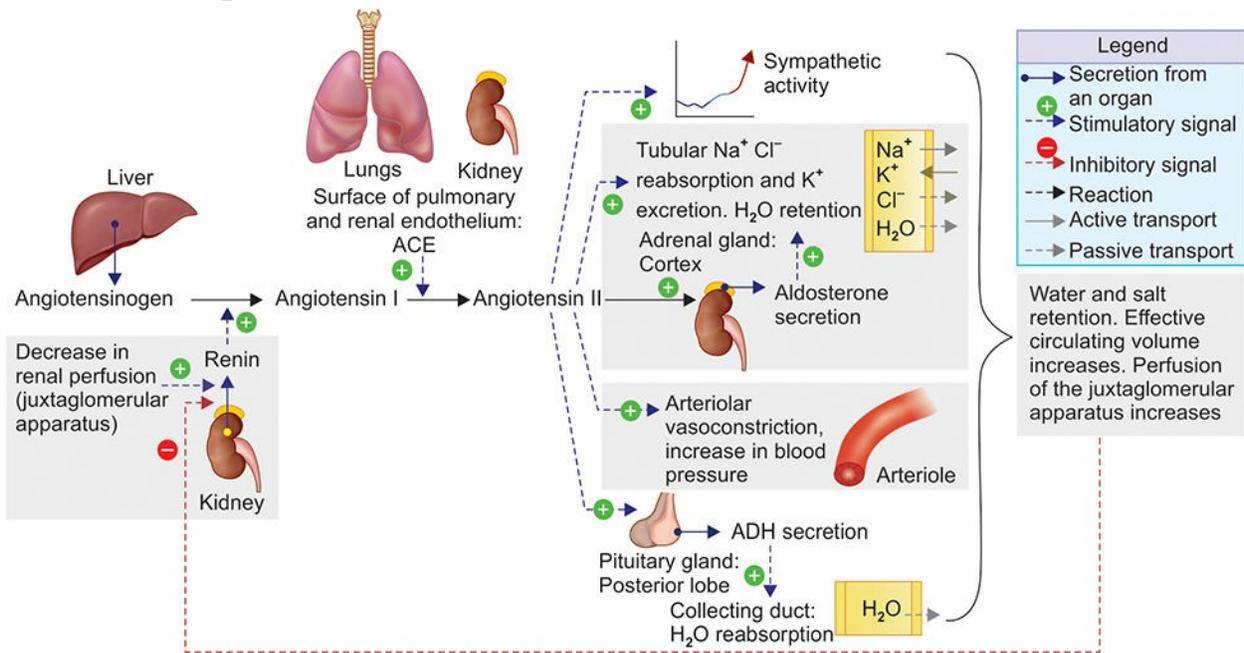

**Q. Write a short note on the juxtaglomerular apparatus.**

**Components of juxtaglomerular apparatus (Fig. 13.2):** It consists of (1) macula densa, (2) the extraglomerular mesangium and (3) the terminal portion of the afferent glomerular arteriole (contains renin-producing granular cells) and (4) the proximal portion of the efferent arteriole.

**Fig. 13.2:** Diagrammatic representation of glomerulus and juxtaglomerular apparatus.

- 1. Macula densa:** The afferent arterioles and the thick ascending limb of loop of Henle are in contact for a short distance. The macula densa is a plaque of tall and columnar cells within this thick ascending limb of the loop of Henle and contains large, tightly packed cell nuclei (hence termed macula densa). This anatomical arrangement allows changes in the renal tubule to influence the behavior of the adjacent glomerulus (tubuloglomerular feedback).
- 2. Extraglomerular mesangium.**
- 3. Terminal portion of the afferent glomerular arteriole:** Shows thickening due to specialized myoepithelioid cells (juxtaglomerular cells) that contain large secretory granules of renin.
- 4. Proximal portion of the efferent arteriole.**

**Fig. 13.3:** Renin-angiotensin-aldosterone system.

## Renin

Renin is **secreted and stored in the juxtaglomerular cells.**

*Factors controlling release of renin*

- Pressure changes in the afferent arteriole
- Sympathetic tone
- Sodium, chloride and osmotic concentration of the fluid in the distal convoluted tubule at the macula densa

- Local prostaglandin and nitric oxide release.

*Mechanism of action of renin*

- **Renin** acts on angiotensinogen in the blood and **converts angiotensinogen to angiotensin I**.
- **Angiotensin I** (decapeptide) is **converted to angiotensin II** (octapeptide) by **Angiotensin Converting Enzyme (ACE)**, which is present in the lung, luminal border of endothelial cells, glomeruli and other organs.
- **Angiotensin II** has **two major systemic effects: Systemic vasoconstriction and sodium and water retention** by release of aldosterone from the adrenal cortex.
- Aldosterone produces constriction of the efferent arteriole of the glomerulus and thereby increases glomerular filtration pressure.

*Consequences of renin action*

- By above mentioned mechanisms, the kidneys **'defend' circulating blood volume, blood pressure and glomerular filtration during circulatory shock**.
- However, the same mechanisms can lead to systemic hypertension in renal ischemia.

Renin-angiotensin-aldosterone system is presented in Figure 13.3.

## APPROACH TO RENAL DISEASES

### Azotemia

**Definition:** It is a **biochemical abnormality** characterized by an **elevation of the blood urea nitrogen (BUN) and creatinine** levels. It is mainly due to a decreased glomerular filtration rate (GFR).

**Causes:** Azotemia can be divided into prerenal, renal and postrenal.

### Glomerular Filtration Rate

- Measurement of the glomerular filtration rate (GFR) is required to know the exact level of renal function. It is necessary to calculate GFR when the serum (plasma) urea or creatinine is within the normal range.
- GFR for an average adult is about 125 mL/minute. Formula for calculation of GFR is presented in Table 13.1.
- The most common methods utilized to estimate the GFR are: measurement of the creatinine clearance; and estimation equations based upon serum creatinine such as the Cockcroft-Gault equation, the Modification of Diet in Renal Disease (MDRD) study equations.

### Measurement

$$\text{Renal clearance (C)} = \frac{UV}{P}$$

C = Renal clearance, U = Urinary concentration of any substance, P = Plasma

concentration of the same substance,  $V$  = Minute volume of urine.

### ***Inulin Clearance***

- It is the **gold standard but is not practical**.
- Inulin is a polysaccharide that **passes freely through the glomerular capillary wall**. It is **neither absorbed nor excreted by the tubules** and hence, the quantity of inulin excreted in urine (UV) is identical to the amount filtered by the glomeruli. Therefore, the **renal clearance of inulin can be used to measure GFR**.

### ***Creatinine Clearance***

**Q. Write short note on creatinine clearance and mention the formula for its calculation.**

- The measurement of creatinine clearance, which approximates to that of inulin is the **most commonly used for measurement of GFR**.
- **Principle:** Creatinine clearance is based on the fact that **daily production of creatinine** (mainly from muscle cells) is **remarkably constant** and little affected by protein intake. Thus, serum creatinine and urinary output vary very little throughout the day and renal creatinine clearance given an estimate of the glomerular function of the kidney.
- **Cockcroft-Gault equation:** If serum creatinine level is stable, creatinine clearance (hence GFR) can also be calculated by using the Cockcroft-Gault formula (Table 13.1):

**Table 13.1:** Formulas used to estimate eGFR/Creatinine clearance (Cr.Cl).

MDRD	$\text{GFR} = 186 \times \text{Serum Cr}^{-1.154} \times \text{age}^{-0.203} \times 1.212 \text{ (if patient is black)} \times 0.742 \text{ (if female)}$
Cockcroft-Gault	$\text{CrCl} = [(140 - \text{age}) \times \text{TBW}] / (\text{S.cr} \times 72) (\times 0.85 \text{ for females})$
The Schwartz Equation: It is a simple bedside formula to estimate glomerular filtration rate (GFR) in children	
$\text{GFR (mL/min/1.73 m}^2\text{)} = \frac{\text{Height (cm)} \times 0.55}{\text{Serum creatinine (mg/dL)}}$	

### **Cystatin C**

Cystatin C is filtered at the glomerulus and not reabsorbed. The serum cystatin C concentration may correlate more closely with the GFR than the serum creatinine concentration.

## Renal Function Tests (Table 13.2)

**Table 13.2:** Renal function tests.

<i>Functional integrity</i>	<i>Test/s performed</i>
Glomerular function	<ul style="list-style-type: none"> <li>GFR: Inulin clearance, creatinine clearance, serum urea and creatinine, serum electrolytes, uric acid, serum osmolality</li> </ul>
Renal blood flow	<ul style="list-style-type: none"> <li>Proteinuria (albumin), para-amino hippuric acid excretion test</li> </ul>
Tubular function	<ul style="list-style-type: none"> <li>Urine osmolality, concentration and dilution test</li> <li>Urine electrolytes, e.g. Na, K, Ca, phosphate, uric acid</li> <li>Urine HCO<sub>3</sub>, ammonia, pH after acid loading</li> </ul>
<i>Structural integrity</i>	
<ul style="list-style-type: none"> <li>Plain X-ray KUB (kidney, ureter, bladder)</li> </ul>	<ul style="list-style-type: none"> <li>Antegrade and retrograde pyelography</li> </ul>
<ul style="list-style-type: none"> <li>Ultrasound</li> </ul>	<ul style="list-style-type: none"> <li>Renal arteriography</li> </ul>
<ul style="list-style-type: none"> <li>IVP (intravenous pyelogram)</li> </ul>	<ul style="list-style-type: none"> <li>CT scan, CT urogram, MRI</li> </ul>
<ul style="list-style-type: none"> <li>Renal scan</li> </ul>	<ul style="list-style-type: none"> <li>Kidney biopsy</li> </ul>

## Ultrasonography

**Q. Write short essay/note on the role of ultrasonography in the diagnosis and management of renal diseases.**

Ultrasonography has the **advantage over X-ray techniques** of avoiding ionizing radiation and intravascular contrast medium. In renal diseases it is the **method of choice for the diagnosis of:**

- **Assessing the renal size and for guiding renal biopsy** or other interventional procedures.
- To **demonstrate pelvicalyceal dilatation** as an indication of renal obstruction when chronic renal obstruction is suspected (in suspected acute ureteric obstruction either intravenous urography or unenhanced spiral CT are the methods of choice).

- To **distinguish solid from cystic renal masses**.
- **Diagnosis of polycystic kidney disease**.
- **In malignant renal tumors**, it can provide **additional information** regarding extension of the tumor to renal veins, vena cava, lymph nodes or liver.
- To **detect intrarenal and/or perinephric fluid** (e.g. pus, blood).
- To **assess size of the prostate and bladder capacity**.

## Examination of the Urine

**Q. Write short essay on routine examination of urine.**

### *Physical Examination*

#### *Appearance*

**Q. Write short note on causes of red colored urine.**

- **Normal** urine is **straw to amber colored** due to the presence of urochrome pigment, excretion of which is generally proportional to the metabolic rate.
- **Urine color interpretation (Table 13.3).**

**Table 13.3:** Interpretation of urine color.

<i>Color</i>	<i>Interpretation</i>
Straw yellow	Normal
Deep yellow	Concentrated urine, jaundice
Red urine	Hematuria, hemoglobinuria, myoglobinuria, porphyria, beet root ingestion, drugs (e.g. rifampicin, pyridium)
Cloudy	Infection
Milky	Chyluria, pyuria, phosphaturia
Dark on standing	Porphyria, alkaptonuria (presence of homogentisic acid)

#### *Volume*

A healthy adult excretes about 600 to 2000 mL of urine in 24 hours. Volume is measured by collecting 24-hour urine samples in a measuring cylinder.

**Q. Write short note on oliguria and anuria.**

- **Oliguria:** Decreased production of **urine usually <300 mL of urine per day** 0.5 mL/kg/h (in an adult of average size). On an average diet, about 300 to 500 mL urine/day is required to excrete the solute load at maximum concentration.
  - **Causes of oliguria** (Table 13.4).
- **Anuria:** Anuria (no urine) refers to (almost) **total absence of urine (<100 mL/day)**. Anuria more commonly suggests reduced production of urine or obstruction to urine flow from both kidneys (until proved otherwise). Bladder outflow obstruction must always be considered first.
  - **Causes of anuria** (Box 13.1)

**Table 13.4: Causes of oliguria.**

<i>Non-renal conditions</i>	<i>Renal diseases</i>
• Excess loss of fluid	• Acute glomerulonephritis
• Hypovolemia	• Nephrotic syndrome
• Shock	• Acute tubular necrosis (ATN)
• Congestive heart failure	• Acute interstitial nephritis
• Cirrhosis	• Obstructive nephropathy
• Pancreatitis, sepsis	
• Peritonitis	

**Q. Write short note on polyuria and its causes.**

- **Polyuria:** Polyuria is defined as **persistent large increase in urine volume of >3 L/day**. This term should exclude normal individuals who take large amount of fluid and therefore, form large volumes of urine. Polyuria may be either due to (1) increased urinary solute excretion (osmotic/solute diuresis) or (2) pure water diuresis.
  - **Causes of polyuria** (Box 13.2).

**Box 13.1: Causes of anuria.**

- Obstruction:
  - Bilateral ureteric obstruction
  - Prostatic or urethral obstruction
  - Renal stones

- Tumors
- **Renal ischemia:** Bilateral renal arterial or venous occlusion

*All causes of oliguria can lead to anuria.*

### **Box 13.2:** Causes of polyuria.

1. Pathological polyuria:
  - Increased excretion of solute (osmotic diuresis): Hyperglycemia, administration of mannitol, hypercalcemia
  - Defective renal concentrating ability: Diabetes insipidus, papillary necrosis, diuretic phase of ATN
  - Failure of production of ADH: Idiopathic (50%), mass lesion, trauma, infection
  - Drugs/toxins: Diuretics, lithium, alcohol
2. Primary (or psychogenic) polydipsia: Excess fluid intake

### *Specific gravity and osmolality*

Urine specific gravity is used as a measure of the concentrating power of the kidney. It is a measure of the weight of dissolved particles in urine. Urine osmolality reflects the number of dissolved particles.

**Normal specific gravity** of a 24-hour urine sample is **1.003 to 1.035**, average being 1.016.

#### **Use:**

- Specific gravity provides information about the renal status and hydration.
- It is used only in the differential diagnosis of oliguric renal failure or the investigation of polyuria or inappropriate ADH secretion.
- **Fixed specific gravity:** When **specific gravity is fixed** at 1.010, this is known as **isosthenuria**. It is indicative of severe renal damage (chronic renal failure/chronic kidney disease) or acute tubular necrosis with disturbance of both the concentrating and diluting abilities of the kidney.

### *Urinary pH*

Normal urine is usually acidic with pH varying from 4.6 to 8. Measurement of urinary pH is not necessary except in the investigation and treatment of renal tubular acidosis.

### ***Chemical Examination***

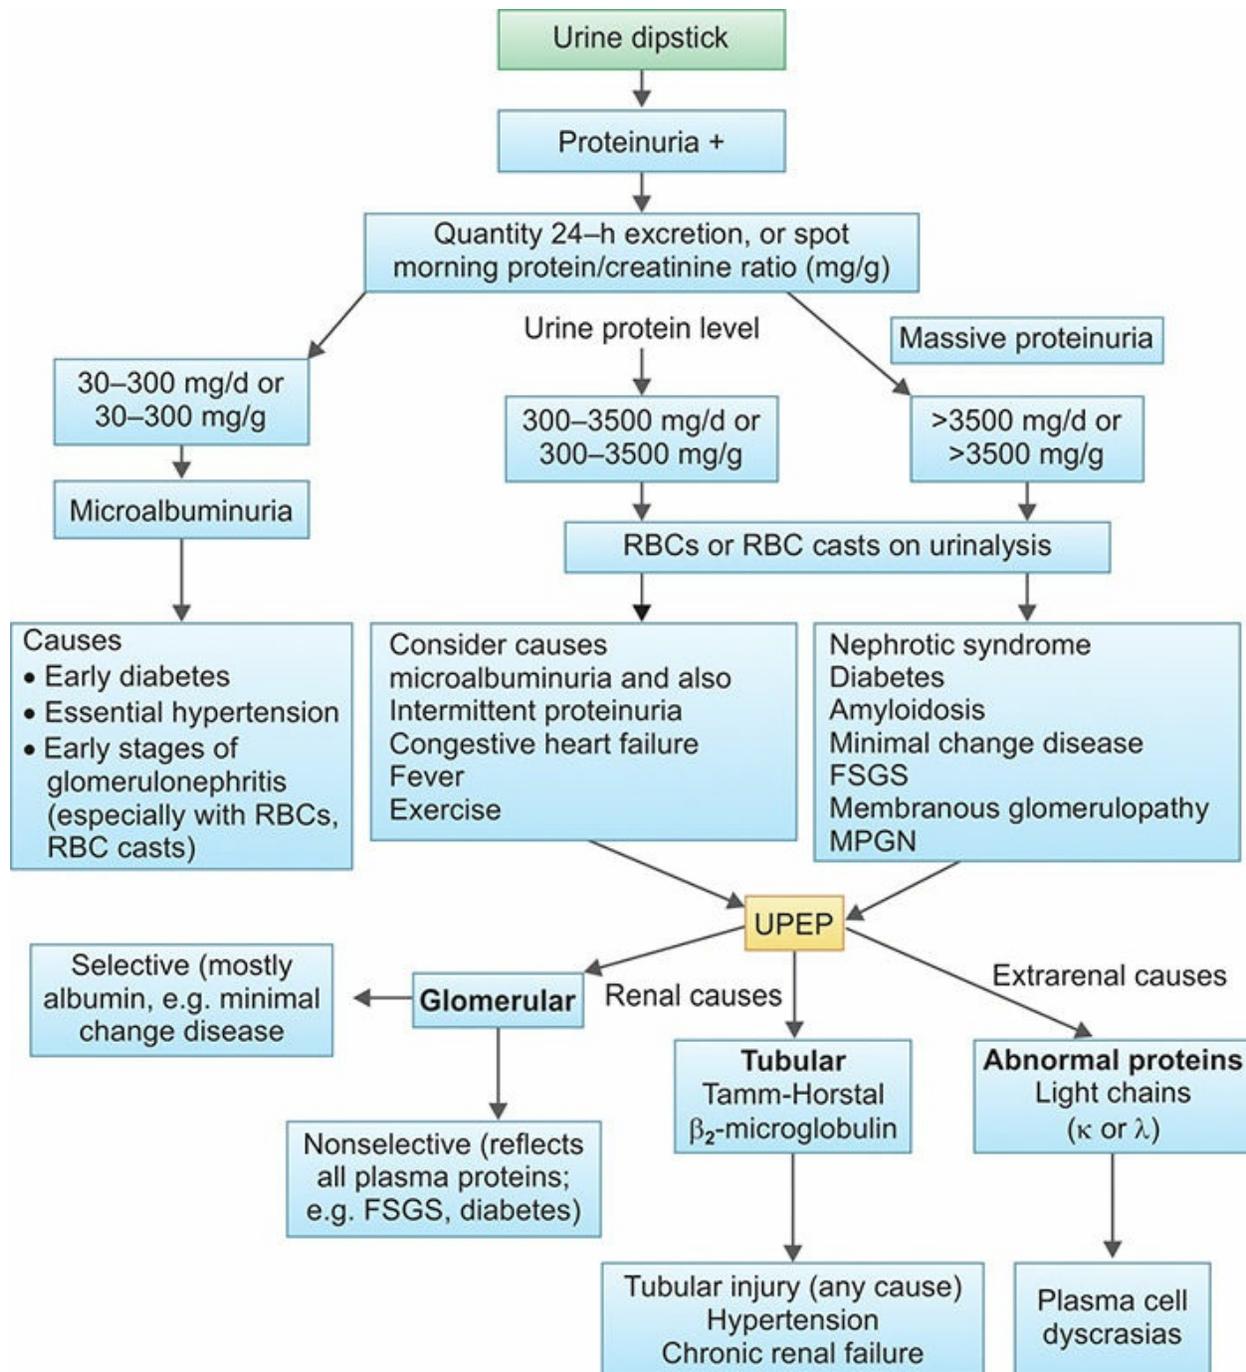

Urine should be examined for the presence of protein, blood and sugar in all patients suspected of having renal disease.

## Proteinuria

**Q.** Write short note on proteinuria and microalbuminuria and their causes.

- Healthy adults may daily excrete <150 mg of total proteins and <30 mg/d of albumin.
- Proteinuria is defined as the **urinary excretion of >150 mg of protein/day**. It is one of the most common signs of renal disease. Pyrexia, exercise and adoption of the upright posture (*postural proteinuria*) may also increase urinary protein output. Algorithm approach to proteinuria is presented in Flowchart 13.1.
- **Amount of pathological proteinuria:** It may be 'mild' (<1.0 g/day), 'moderate' (1.0-3.5 g/day) or 'massive'/'heavy'(>3.5 g/day).

**Flowchart 13.1:** Algorithm approach to proteinuria.

(UPEP: urine protein electrophoresis)

## Microalbuminuria

- Normal urine contains <30 mg of albumin/day (<20 µg of albumin per minute).
- **Definition:** Microalbuminuria is the **presence of albumin (small amounts) in urine about >30 to <300 mg/day**. It is defined as the

persistent elevation of the urinary albumin excretion of 30–200 mg/L (or 20–200 mg/min) in an early morning urine sample. It indicates early and possibly reversible glomerular damage.

- It is so named because conventional dipsticks cannot detect albumin levels of 30 to 300 mg/day (if urine volume is normal). An increase in albumin excretion between these two levels so-called microalbuminuria.
- **Significance:** The presence of albumin in the urine is a sign of glomerular abnormality.
  - **Diabetes mellitus:**
    - ◆ Microalbuminuria is an **early indicator of diabetic glomerular disease**. It is widely used as a predictor of the development of nephropathy in diabetics (Raised fractional excretion of magnesium is a more sensitive marker than microalbuminuria in detecting early diabetic nephropathy).
    - ◆ In diabetic patients presence of microalbuminuria is associated with **increased cardiovascular mortality**.
  - **Essential hypertension:** In hypertensive patients, microalbuminuria predicts cardiovascular morbidity and mortality.
  - **Normotensive individuals:**
    - ◆ **Risk marker for the presence of cardiovascular disease predicts progression of nephropathy** when it increases to frank albuminuria (>300 mg/day).
    - ◆ **Atherosclerosis:** Persistent microalbuminuria is also associated with an increased risk of atherosclerosis and cardiovascular mortality.

#### Treatment

- Microalbuminuria can be reduced, and its progress to overt proteinuria can be prevented or retarded by **aggressive reduction of blood pressure (especially with ACE inhibitors or angiotensin receptor blockers)**, and control of diabetes mellitus.
- **Blood pressure should be maintained at or below 130/80 mm Hg in patients with diabetes or kidney disease.**

#### *Albumin: Creatinine Ratio*

Measurement of 24-hour urinary excretion rates provides the most precise measure of microalbuminuria. However, it is often difficult to obtain 24-hour urine, it is more convenient to measure urinary albumin: creatinine ratio in a

random urine sample and generally **albumin: creatinine ratio (ACR)** of 2.5 to 20 corresponds to albuminuria of 30–300 mg daily respectively (Table 13.5).

### ***Tamm-Horsfall Mucoprotein (Uromodulin)***

**Q. Write short note on Tamm-Horsfall mucoprotein.**

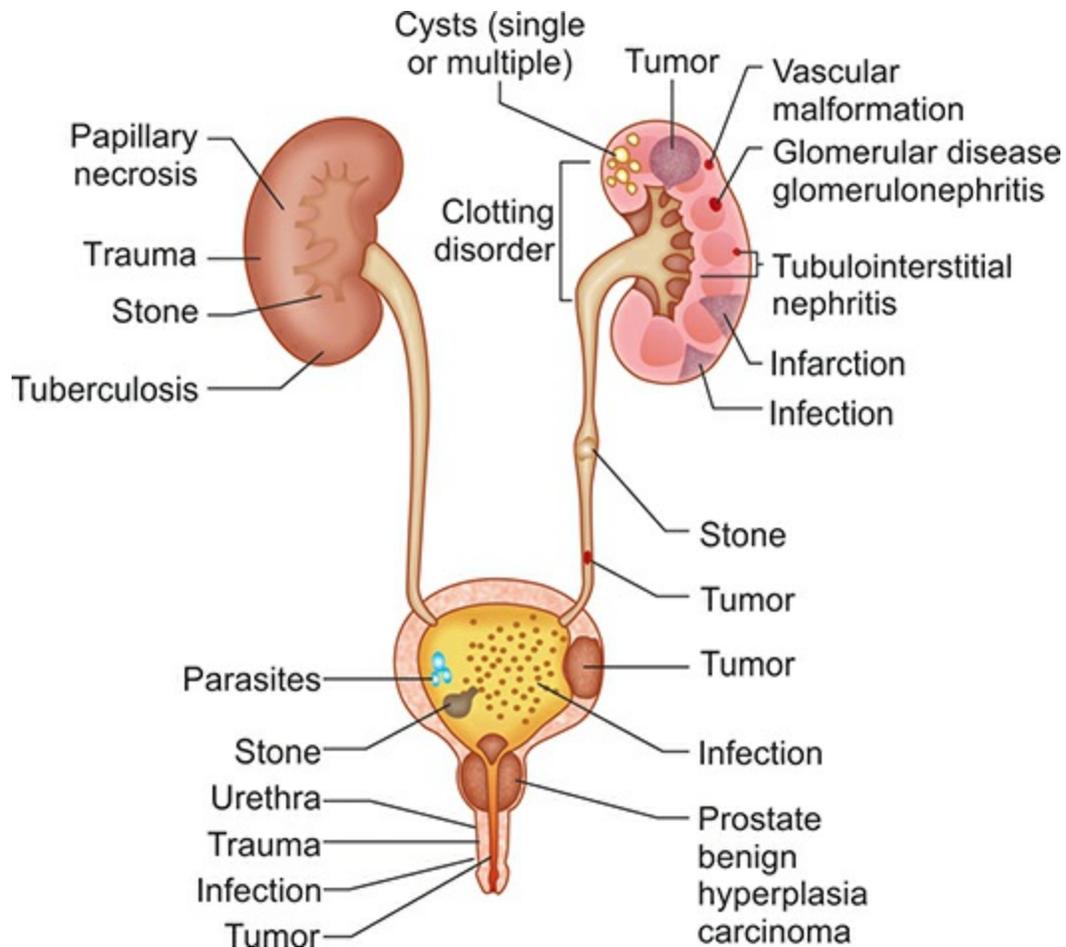

- It is a **protein present in normal urine** produced in the thick ascending limb of the loop of Henle. It is excreted at a rate of 25 mg/day.
- Function is not known. Probably it may have some immunomodulatory activity and may protect against urinary tract infection (UTI).

It is a **constituent of all types of urinary casts**. It is involved in the **pathogenesis of cast nephropathy** (observed in renal failure associated with multiple myeloma) in which intratubular casts occlude the flow of urine.

### **Hematuria**

**Q. Enumerate the common causes of hematuria/the causes of painless hematuria. How will you clinically localize evaluate the site of bleeding?**

- Hematuria may be visible on gross examination and reported by the patient as bloody urine (**macroscopic/overt hematuria**), or invisible and detected on dipstick/chemical testing of urine (**microscopic hematuria**—three or more red blood cells per high-power field).
- **Site of bleeding:** Bleeding may occur at any site within the urinary tract and common causes of hematuria are illustrated in Figure 13.4. Features that may help to localize the site of bleeding in the urinary tract are mentioned in Table 13.6.

**Fig. 13.4:** Sites and common causes of bleeding from the urinary tract.

**Table 13.5:** Classification of proteinuria based on albumin-creatinine ratio (ACR).

<i>Category</i>	<i>Albumin creatinine ratio mg/g</i>	<i>Albumin creatinine ratio mg/mmol</i>
Normal	<30	<2.5
Microalbuminuria	30–300	2.5–25
Clinical albuminuria	>300	> 25
Nephrotic	>3000	>250

**Table 13.6:** Probable site of bleeding and its features.

<i>Probable site of bleeding</i>	<i>Suggestive features</i>
Urethra	Blood is seen at the start of voiding and then the urine becomes clear
Urinary bladder or above	Blood diffusely present throughout the urine

Glomerular origin	<ul style="list-style-type: none"> <li>• Cola colored urine</li> <li>• Red-cell casts (glomerulonephritis)</li> <li>• Dysmorphic erythrocytes (irregular outer cell membrane)</li> <li>• Acanthocytes (erythrocytes with one or more membrane protrusions of variable size and shape)</li> </ul>
Renal pelvis and lower urinary tract	Pink or red colored urine
Prostate or bladder base	Blood only at the end of micturition
Lower urinary tract origin	Isomorphic erythrocytes in urine Microscopic clots of clumped erythrocytes in urine

**Table 13.7:** Various causes of painless hematuria.

<i>Site of hematuria</i>	<i>Causes</i>
Kidney	<ul style="list-style-type: none"> <li>• Glomerulonephritis, IgA nephropathy</li> <li>• Pyelonephritis: Severe acute pyelonephritis, papillary necrosis (more common in diabetes mellitus and sickle cell trait or disease)</li> <li>• Tumors: Renal cell carcinoma</li> <li>• Others: Infective endocarditis, renal tuberculosis, benign familial hematuria, microscopic polyangiitis, Wegener's granulomatosis</li> </ul>
Ureter	Neoplasms
Bladder	Neoplasms, trauma, schistosomiasis
Prostate	Prostatitis, neoplasms
Urethra	Trauma

## ***Causes of Painless Hematuria (Table 13.7)***

### ***Patient's Evaluation of Hematuria***

*Physical examination (Box 13.3)*

**Box 13.3:** Physical examination required in the evaluation of hematuria.

- Blood pressure
- Cardiovascular examination
- Abdominal examination
- Prostatic evaluation.

*Investigations*

- **Urine examination:**

- **Proteinuria**
- **Culture of urine for acid fast bacilli**
- **Microscopy:**
  - ◆ **Morphology of RBC** (assessed by phase contrast microscopy of fresh urine)
  - ◆ **Urine cytology:** For malignant cells especially in patients with risk factors such as smoking, analgesic abuse, industrial toxin exposure (e.g. aniline, benzidine, aromatic amines), age >50 years, pelvic irradiation, urinary schistosomiasis.
- **Renal function tests**
- **Blood:**
  - Platelet count
  - Coagulation studies
  - Autoantibodies (ANA, ANCA)
- **Radiological investigations:**
  - Ultrasound for kidneys, ureters, bladder and prostate, CT, MRI
  - Intravenous pyelography
- **Cystourethroscopy.**

## Glycosuria

- Blood glucose level varies between 70 to 120 mg/dL. This may increase to 120 to 160 mg/dL after a meal. Normally, all the glucose in the blood is filtered through the glomerulus and reabsorbed at the proximal tubules.
- If the renal threshold (the lowest blood glucose level that will result in glycosuria) is exceeded (usually >180 to 200 mg/dL), the excess glucose will not be reabsorbed into the blood and will be eliminated in the urine as in cases of diabetes mellitus. The presence of detectable amounts of **glucose in urine** is termed **glycosuria (for details refer page 84 and Box 3.3)**.

## Bacteriuria

Dipstick tests used for detection of bacteriuria detect nitrite produced from the reduction of urinary nitrate by bacteria. It is also for the detection of leucocyte esterase, an enzyme specific for neutrophils.

## Microscopy

Microscopic examination of urine should be done in all patients suspected of having renal disease, on a 'clean' midstream sample.

## Cells

They are expressed as number of cells per low power or high power field.

- **Red blood cells (RBCs):** Presence of RBCs (more than 3/hpf) in the urine

indicates bleeding at any point in the urinary system from the glomerulus to the urethra. In glomerular diseases, the urine show red cells with cellular protrusions or fragmentation and are named as **dysmorphic** (distorted morphology) red blood cells.

- **White blood cells:** Increased number of WBCs (mainly neutrophils more than 5/hpf) in urine is known as **pyuria**. It is indicative of an inflammatory reaction within urinary tract such as urinary **tract infection** (UTI), stones, tubulointerstitial nephritis, papillary necrosis, tuberculosis and interstitial cystitis. The causative organism of infection may be identified by bacteriological examination. When accompanied by **leukocyte casts** or mixed leukocyte–epithelial cell casts, increased urinary leukocytes are considered to be of **renal origin**.

## **Casts**

**Q. Write short note on urinary casts.**

Casts are one of the organized elements which are **formed only in the kidney** and are **indicative of a renal disease**. They are cylindrical bodies, moulded in the shape of the distal tubular lumen formed by solidification of **Tamm Horsfall protein**, a glycoprotein secreted in the distal convoluted tubules and collecting tubules. These proteins form a fibrillar meshwork (basic matrix) and can trap any elements including cells, cell fragments or granular material.

*Types of urinary casts and their significance (Fig. 13.5)*

## **Crystals (Figs. 13.6A to C)**

They may be found in patients with renal calculi. Calcium oxalate and urate crystals can be found in normal urine that has been left to stand.

# **ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)**

**Q. Discuss the classification, causes, pathogenesis, clinical features, diagnosis, investigations and management of acute renal failure.**

**Q. Write short essay/note on acute kidney injury.**

Renal failure is the failure of renal excretory function due to reduced glomerular filtration rate. Acute kidney injury (AKI) was previously known as acute renal failure (ARF). The other term used for this is **azotemia**.

## Definition

AKI is a clinical syndrome, defined as a **abrupt, deterioration of kidney function**, which is usually, but not invariably, reversible over a period of days or rarely over a few weeks. The deterioration in renal function is sufficiently severe to result in retention of nitrogenous wastes in the body (uremia) and other waste products normally cleared by the kidneys.

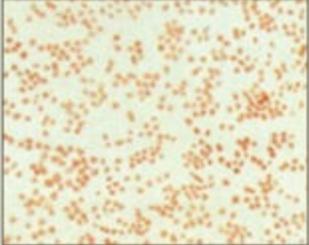

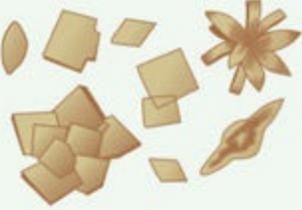

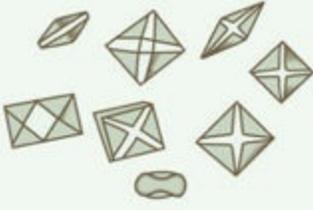

- It is **usually** but not invariably accompanied by **oliguria**.
- Conventionally the term ARF is often used in reference to the subset of patients with a need for acute dialysis support.

## Classification of AKI

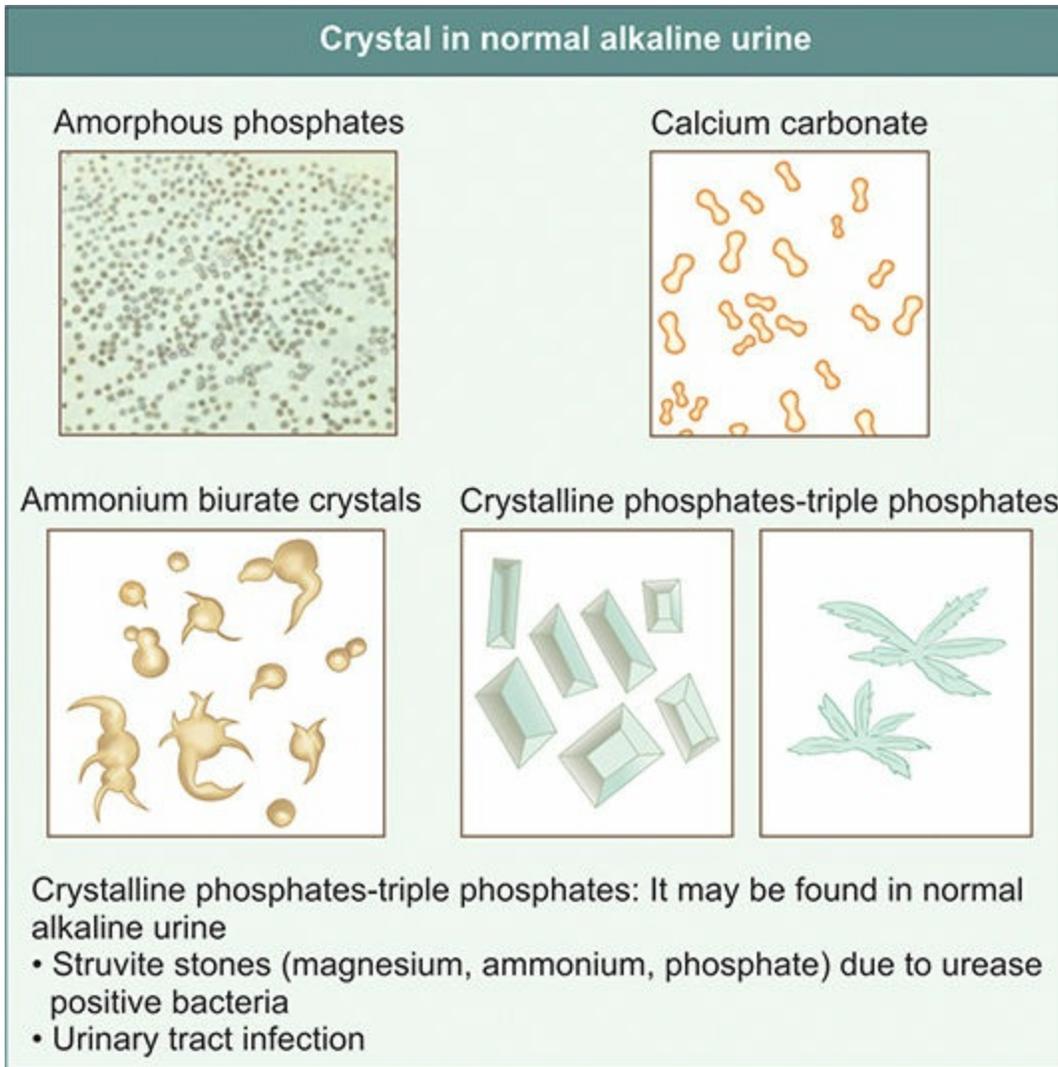

Acute kidney injury is a medical emergency. It may produce sudden, life-threatening biochemical disturbances. ***AKI includes an increase in serum creatinine by  $\geq 0.3$  mg/dL (27 micromol/L) within 48 hours or an increase to  $\geq 1.5$  times the presumed baseline value that is known or presumed to have occurred within the prior seven days, or a decrease in urine volume to  $< 3$  mL/kg over six hours*** (Kidney Disease: Improving Global Outcomes [KDIGO]-AKI).

Cast and its appearance	Significance
<b>Hyaline cast</b> 	<ul style="list-style-type: none"> <li>• Nonspecific. Present in normal urine</li> <li>• Acute glomerulonephritis (AGN)</li> <li>• Chronic glomerulonephritis (CGN)</li> <li>• Fever</li> <li>• Congestive heart failure</li> </ul>
<b>Waxy cast</b> 	<ul style="list-style-type: none"> <li>• End stage kidney</li> <li>• Chronic/advanced renal failure</li> <li>• Amyloidosis</li> </ul>
<b>Cellular casts</b>	
<b>1. Red blood cell (RBC) cast</b> 	<ul style="list-style-type: none"> <li>• Always indicates renal disease</li> <li>• AGN</li> <li>• Lupus nephritis</li> <li>• Goodpasture syndrome</li> <li>• Subacute bacterial endocarditis</li> <li>• Renal infarction</li> </ul>

**Fig. 13.6C:** Abnormal crystals found in urine.

**Table 13.8: RIFLE criteria for classification of acute kidney injury.**

<i>Grade</i>	<i>GFR criteria</i>	<i>Urine output criteria</i>
Risk (Stage 1)	Increased serum creatinine x 1.5 times within 48 hours	Urine output <0.5 mL/kg/hour x 6 hours
Injury (Stage 2)	Increased serum creatinine x 2 to 3 times	Urine output <0.5 mL/kg/hour x 12 hours
Failure (Stage 3)	Increased serum creatinine x 3 times or serum creatinine (acute rise of = 0.5 mg/dL)	Urine output <0.3 mL/kg/hour x 24 hours OR Anuria for 12 hours OR Initiation of renal replacement therapy
Loss	Persistent AKI = complete loss of renal function >4 weeks	
End-stage kidney disease	Persistent renal failure >3 months	

### ***RIFLE Criteria (Table 13.8)***

- The distinction between acute and CKD or acute on chronic kidney disease, cannot easily be done in case of uremia. Acute Dialysis Quality Initiative group proposed the **RIFLE (Risk, Injury, Failure, Loss, Endstage renal disease) criteria** to classify AKI.
- These criteria indicate an increasing degree of renal damage are of predictive value for mortality.

### ***Acute Kidney Injury Network (AKIN) Classification***

AKIN has proposed a modification of the RIFLE criteria. It includes less severe AKI, a time constraint of 48 hours, and gives a correction for volume status before classification. According to this, AKI is classified into **three stages**.

- **Stage 1** is same as Risk category of RIFLE with **addition of increase in serum creatinine by 0.3 mg/dL** within 48 hours.
- **Stages 2 and 3** are same as Injury and Failure categories of **RIFLE**.

## **Etiopathogenesis**

### **Causes**

**Q. Write short essay/note on causes of acute renal failure/acute kidney injury.**

At rest normal kidney receives about 25% of the cardiac output. The etiology of AKI is diverse.

*Classification (Table 13.9 and Fig. 13.7)*

**Q. Define and enumerate the causes of acute kidney injury/azotemia.**

Causes of AKI are traditionally divided into three broad anatomical categories: Prerenal, intrarenal (intrinsic renal parenchymal disease), and postrenal causes. Most common cause is **ATN followed by prerenal causes.**

- **Prerenal causes:**
  - Precipitating event is **renal hypoperfusion** which may be due to **reduction in the volume of extracellular fluid** or disease states associated with decreased effective arterial volume or other causes.
  - Kidneys are inadequately perfused and the GFR is markedly reduced and produces oliguria (urine output <400 mL/day).
- **Renal causes:**
  - **Intrinsic diseases of kidney** causing AKI are classified according to the primary histologic site of injury: **Tubules, interstitium, vasculature, or glomerulus.**
  - **Renal tubular epithelial cell injury**, commonly known as **acute tubular necrosis (ATN)** and occurs more commonly due to ischemia of any cause, but can also be damaged by specific renal toxins. ATN results in ischemia and necrosis of the tubular epithelial cells. However, when the causative factors are removed the tubular cells can regenerate.
- **Postrenal causes:** These include obstruction of the urinary tract at any point in its course from the tubule to the urethra.

**Table 13.9: Classification of causes of acute kidney injury.**

<i>Prerenal causes</i>	<i>Renal causes</i>	<i>Postrenal causes</i>
<b>Systemic</b> <ul style="list-style-type: none"> <li>• <b>Hypovolemia:</b> Hemorrhage, severe vomiting, diarrhea, loss of plasma (e.g. burn), pancreatitis, diabetic ketoacidosis, excess of diuretics, etc.</li> <li>• <b>Decreased cardiac output:</b> Heart failure, septic shock</li> </ul>	<b>Tubular and interstitial diseases (acute tubular necrosis-ATN, acute interstitial nephritis -AIN)</b> <ul style="list-style-type: none"> <li>• <b>Ischemia:</b> Due to any cause</li> <li>• <b>Sepsis/infections</b></li> </ul>	<b>Extrarenal obstruction:</b> Enlargement of prostate, urethral stenosis, tumors, stones, retroperitoneal fibrosis, carcinoma cervix, stricture, phimosis, congenital valves, neurogenic bladder

<ul style="list-style-type: none"> <li>• <b>Decreased effective circulating blood volume:</b> Congestive heart failure, liver failure (hepatorenal syndrome)</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Nephrotoxins:</b> Drugs (cephalosporins, sulfonamides, NSAIDs, contrast agents, aminoglycosides, rifampicin), infections, transfusion reactions, malaria crush injury (rhabdomyolysis), heavy metals, septic abortion</li> </ul>	<b>Intrarenal obstruction:</b> Uric acid crystals
<b>Local</b> <ul style="list-style-type: none"> <li>• <b>Renal vessel diseases:</b> Renal artery obstruction</li> <li>• <b>Impaired renal autoregulation</b> Drugs such as ACE inhibitors, NSAIDs, cyclosporine.</li> </ul>	<b>Vascular diseases:</b> Vasculitis, malignant hypertension, TTP-HUS <b>Glomerular diseases:</b> Glomerulonephritis (acute, rapidly progressive and others)	

## Clinical Features (Table 13.10)

### General Symptoms

- Irrespective of the cause ARF present with symptoms related to uremia. These include **anorexia, nausea, vomiting, intellectual clouding, drowsiness, fits, coma, pruritus, hemorrhagic episodes** (e.g. epistaxis and gastrointestinal hemorrhage) and **dyspnea** due to fluid overload.
- **Physical findings** include asterixis, myoclonus, pericardial rub, and evidence of fluid overload in the form of edema, elevated JVP and crepitation.

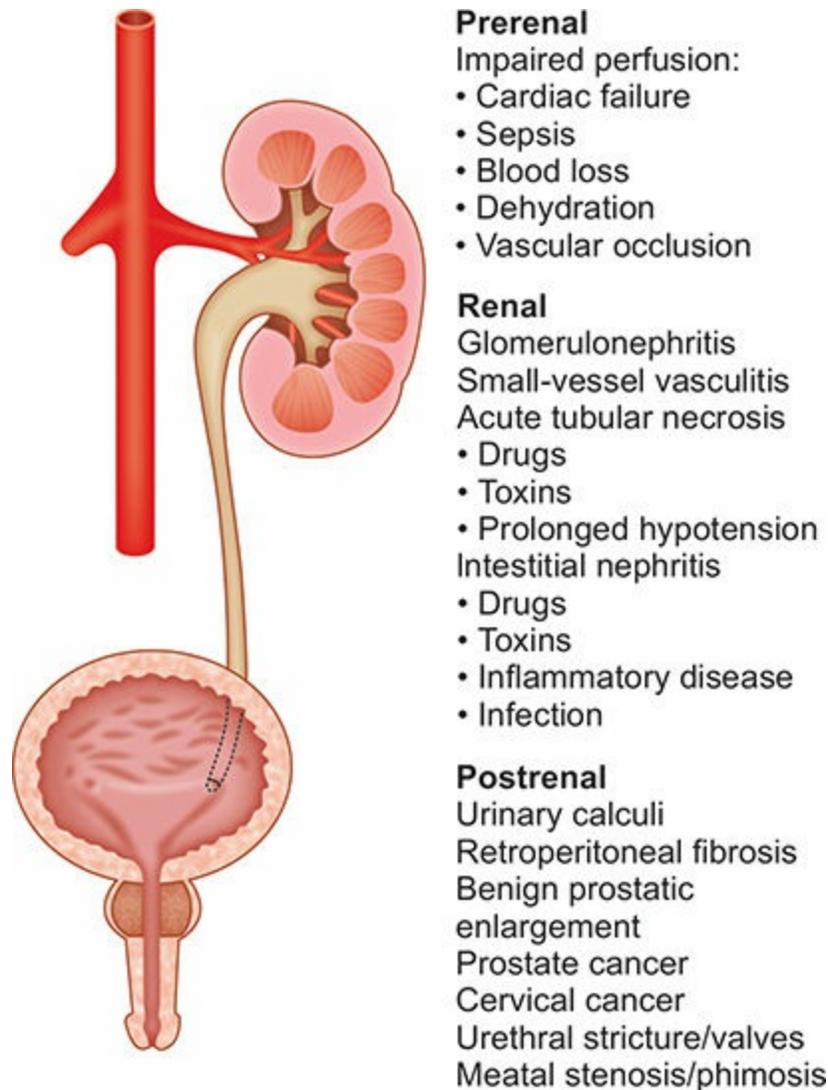

Fig. 13.7: Causes of acute kidney injury.

**Q. How will you differentiate renal from prerenal failure?**

**Q. Describe clinical and laboratory differences between prerenal and renal azotemia.**

### ***ARF Due to a Prerenal Disorder***

- Clinical features are **those of the predisposing conditions** together with those of rapidly developing uremia. Patients usually have a **low blood pressure** (hypotension), tachycardia, **poor peripheral perfusion and a decreased urine output**.

### ***ARF Due to Renal Causes***

**Acute tubular necrosis** is the most important cause of ARF due to intrinsic renal diseases. The clinical course in ATN/ARF is divided into 3 phases:

– **Oliguric (initiation) phase:**

- ◆ Clinical features depend on the initiating event that caused the ischemic form of AKI. Patients develop symptoms due to fluid overload and azotemia. Fluid overload results in raised jugular venous pressure, pedal edema, ascites and pulmonary edema.
- ◆ Mild reduction of urine output and increase in BUN. Hyperkalemia occurs commonly during this phase. This phase usually **lasts for about 10–14 days**. About 40% of the patients may have normal urine output and is called non-oliguric renal failure. The electrolyte disturbances are less in these patients.

– **Maintenance phase:** During this phase, there is sustained decrease in urine output in the range of 40 to 400 mL/day (**oliguria**), **salt and water overload, rising BUN level, hyperkalemia, metabolic acidosis, and other features of uremia**. This phase lasts for days to weeks.

– **Diuretic (recovery) phase:**

- ◆ During this phase there is a **steady increase in urine output** and in a few days the patient develops **polyuria with a urine output that may reach up to 3 L/day**. During this phase the tubular concentrating capacity is defective, and there is uncontrolled loss of large amounts of water, sodium, and potassium (leading to **hypokalemia**) in the urine. Once the renal tubular function returns to normal, BUN, creatinine levels and urine volume also return to normal.

ARF due to glomerulonephritis presents with hypertension, proteinuria and hematuria.

Drug-induced acute tubule-interstitial nephritis patients may present with fever, skin rash and arthralgia.

**Table 13.10:** Clinical features of acute kidney injury.

<i>Type of acute kidney injury</i>	<i>History findings</i>	<i>Physical examination findings</i>
<b>Prerenal</b>	Volume loss (e.g., history of vomiting, diarrhea, diuretic overuse, hemorrhage, burns) Reduced fluid intake	Orthostatic hypotension and tachycardia Cardiac disease Poor skin turgor
	Cardiac disease	Dilated neck veins, S3 heart sound,

		pulmonary rales, peripheral edema
	Liver disease	Ascites, caput medusae, spider angiomas
<b>Intrinsic renal</b>		
Acute tubular necrosis	History of receiving nephrotoxic medications (including over-the-counter, illicit, and herbal), hypotension, trauma or myalgias suggesting rhabdomyolysis, recent exposure to radiographic contrast agents	Muscle tenderness, compartment syndrome, assessment of volume status
Glomerular	Lupus, systemic sclerosis, rash, arthritis, uveitis, weight loss, fatigue, hepatitis C virus infection, human immunodeficiency virus infection, hematuria, foamy urine, cough, sinusitis, hemoptysis	Periorbital, sacral, and lower-extremity edema, rash, oral/nasal ulcers, hypertension
Interstitial	Medication use (e.g. antibiotics, proton pump inhibitors), rash, arthralgias, fever, infectious illness	Fever, drug-related rash (Skin) eosinophilia
Vascular	Nephrotic syndrome, trauma, flank pain, anticoagulation (atheroembolic disease), vessel catheterization or vascular surgery	Skin changes, livedo reticularis, fundoscopic examination (showing malignant hypertension), abdominal bruits
<b>Postrenal</b>	Urinary urgency or hesitancy, gross hematuria, polyuria, stones, medications, cancer	Bladder distention, pelvic mass, prostate enlargement

### ***ARF Due to Postrenal Causes***

ARF due to bilateral postrenal obstruction usually causes anuria. The patient may give a past history of pain in the loin, renal colic, prostatism and difficulty in micturition or hematuria.

### **Investigations**

#### ***Serum Creatinine and Urea***

- The rate of rise in serum creatinine and urea is determined by the rate of

protein catabolism (tissue breakdown).

- **Raised serum creatinine and urea** levels are the most consistent findings. In ARF due to prerenal causes, there is a disproportionate elevation of serum urea in relation to serum creatinine.

**Q. List the causes of raised serum creatinine (Box 13.4).**

- **Drawbacks: Rise in creatinine is an unreliable indicator of early renal injury** because:
  - Normal serum creatinine level is influenced by several non-renal factors (age, gender, muscle mass, medications, hydration and nutrition status and tubular secretion).
  - **More than 50% loss of renal function must be lost before serum creatinine rises.**
  - **Serum creatinine does not reflect true GFR.** This is because several hours to days must elapse before a new equilibrium between presumably steady state production and decreased excretion of creatinine is established.

**Box 13.4:** Causes of raised serum creatinine.

- Azotemia: Prerenal, renal and post-renal
- Large amount of consumption of meat
- Hypothyroidism, acromegaly and gigantism
- Rhabdomyolysis
- Drugs: Statins, fibrates

**Table 13.11:** Urine finding in different types of acute kidney injury.

Type of acute kidney injury	Urine findings
<b>Prerenal</b>	Normal or hyaline casts
<b>Intrarenal</b>	Muddy-brown, granular, epithelial casts
• Tubular cell injury	
• Interstitial nephritis	Pyuria, hematuria, mild proteinuria, granular and epithelial casts, eosinophils
• Glomerulonephritis	Hematuria, marked proteinuria, red blood cell casts, granular casts
• Vascular disorders	Normal or hematuria, mild proteinuria
<b>Postrenal</b>	Normal or hematuria, granular casts, pyuria

**Table 13.12: Urinary abnormalities in ARF.**

	<i>Prerenal</i>	<i>Renal</i>	<i>Postrenal</i>
Sp. gravity	>1.020	1.010	—
Urine osmolality (mOsm/kg)	>500	250–300	400
Urine/plasma osmolality	>1.1	1–1.1	1–1.1
Urinary sodium (mEq/L)	<20	>40	<30
FENa	<1%	>1%	Variable
Urine/plasma creatinine	>40	<20	<20
Renal failure index	<1	>2	>2
Urinary sediment	Scanty	Active	Scanty
Urinary proteins	Minimal	Moderate to severe	Minimal

***Newer Novel Biomarkers for AKI***

These markers can diagnose early AKI and include (1) neutrophil gelatinase-associated lipocalin (NGAL), (2) kidney injury molecule-1 (KIM-1), (3) interleukin 18 (IL-18) and (4) cystatin C.

***Other Investigations***

- **Other biochemical findings:** Include **hyperkalemia, hypocalcemia, hyperphosphatemia and hyperuricemia.**
- **Urine analysis (Tables 13.11 and 13.12):**
  - In **glomerulonephritis:** Proteinuria, red cells and red cell casts.
  - In **ATN:** **Mild** proteinuria, epithelial cells and coarsely granular casts.
  - In allergic interstitial nephritis: White cells, red cells and eosinophils.
  - In acute tubule-interstitial nephritis: Proteinuria, glycosuria, aminoaciduria and potassium wasting.
- **Electrocardiogram:** May show features of hyperkalemia.
- **Chest radiograph:** May show pulmonary edema and pleural effusion.
- **Others**
  - In **RPGN:** Systemic causes (e.g. Wegener’s granulomatosis) must be excluded by appropriate investigations (e.g. cANCA). A **kidney biopsy may be necessary.**
  - In **postrenal ARF:** Renal imaging by plain abdominal X-ray and

ultrasonography may be useful.

- **Fractional excretion of sodium (FENa)** (Table 13.13): The ratio of sodium clearance to creatinine clearance, increases the reliability of this index. However, it may remain low in some renal diseases.

**Table 13.13:** Values of FENa (Fractional excretion of sodium) and BUN-to-serum creatinine ratio in various causes of acute kidney injury.

<i>Etiology of acute kidney injury</i>	<i>FENa (Fractional excretion of sodium)</i>	<i>BUN-to-Serum creatinine ratio</i>
<b>Prerenal</b>	<1%	>20
<b>Intrarenal</b>	≥1%	<10–15
• Tubular necrosis	≥1%	
• Interstitial nephritis	<1%	
• Glomerulonephritis (early)	<1%	
• Vascular disorders (early)		
<b>Postrenal</b>	≥1%	>20

## Complications of Acute Kidney Injury (Box 13.5)

### Box 13.5: Complications of acute kidney injury.

- **Metabolic:** Hyperkalemia, hypocalcemia, hyperphosphatemia, hypermagnesemia, hyperuricemia, metabolic acidosis (increased anion gap)
- **Cardiovascular:** Cardiac arrhythmias, pulmonary edema, pericarditis/pericardial effusion
- **Gastrointestinal:** Gastrointestinal hemorrhage
- **Neurologic:** Encephalopathy, neuropathy, seizures
- **Hematologic:** Anemia, bleeding—platelet dysfunction
- **Miscellaneous:** Infections (pneumonia, urinary tract infection, septicemia)

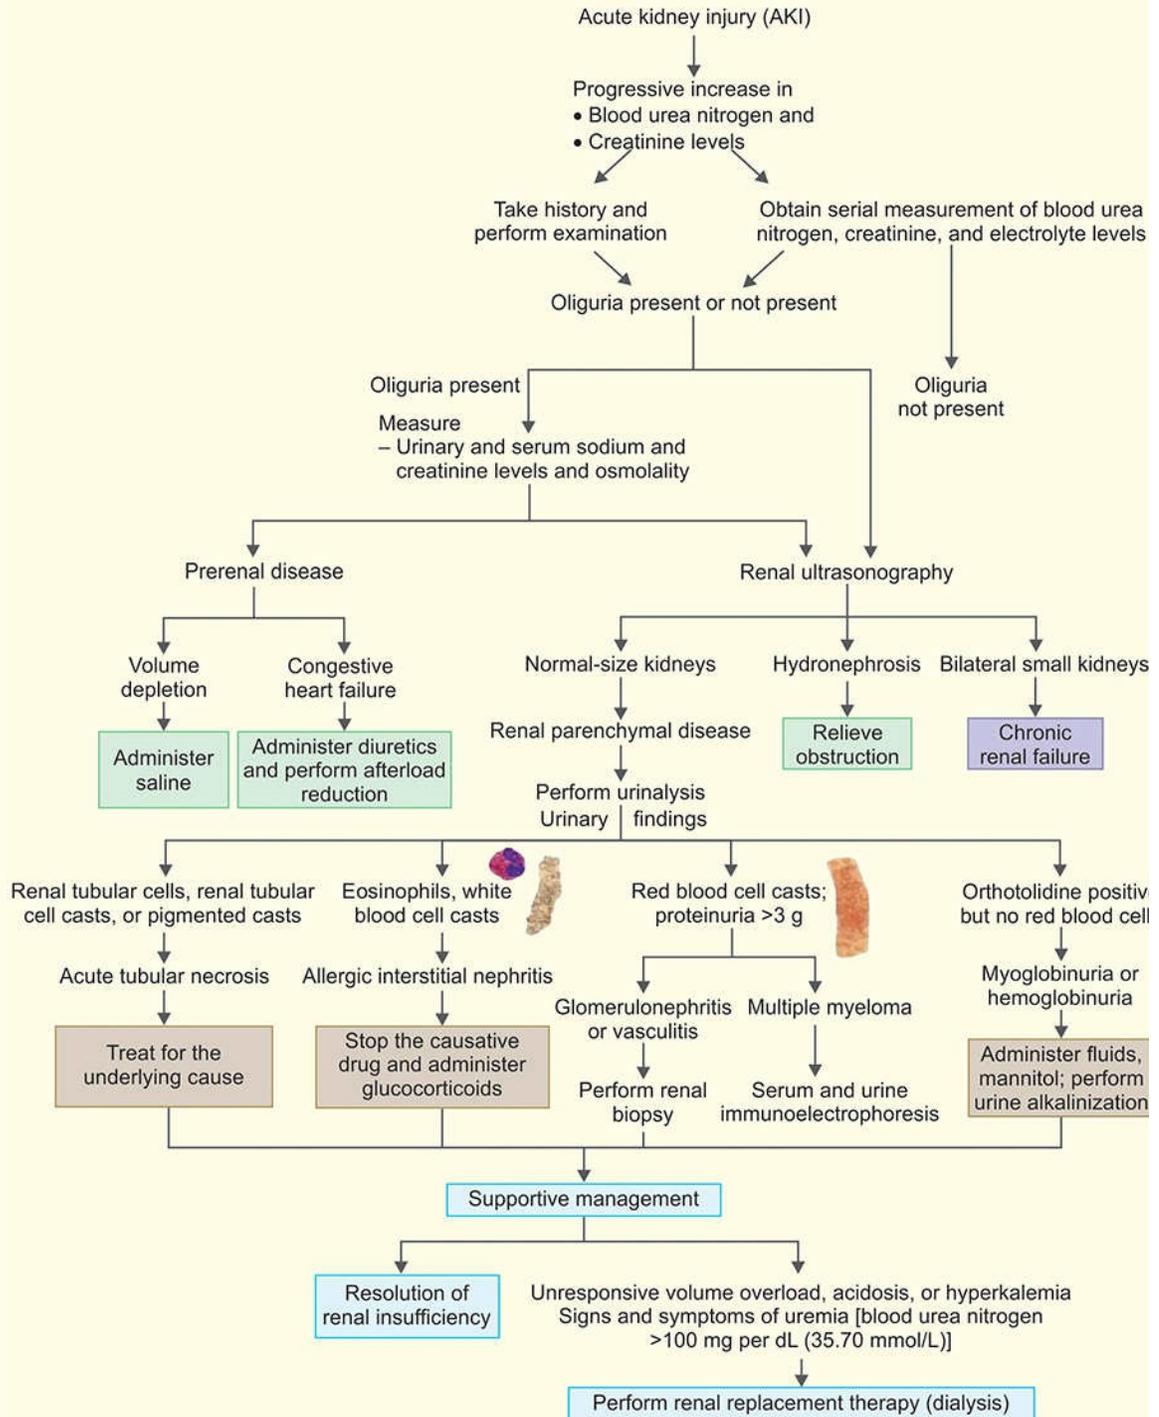

**Q. Mention the complications of acute kidney injury (acute renal failure).**

#### Management (Flowchart 13.2)

##### *General measures and management of complications*

- **Fluid balance:** Advisable to **restrict fluid intake**.
  - Amount of fluid to be given **depends upon** the **degree of edema, and fluid loss** through urine, gastrointestinal tract and skin.
  - Usually intake restricted to about **400 mL/day** in addition to the above-mentioned fluid losses.

**Flowchart 13.2:** Approach to acute kidney injury.

- **Sodium balance: Sodium is restricted** to avoid volume expansion and overhydration
  - **Hyponatremia** is common and is usually **due to excessive fluid administration**.
  - Hyponatremia may occur occasionally, due to excessive administration of sodium bicarbonate for correction of acidosis.
- **Potassium balance: Hyperkalemia is the leading cause of death** in ARF. Treatment is discussed page 927 (refer Table 14.20).

- **Acid-base balance:** In most patients **acidosis** is of moderate degree and does not require treatment. However, in **advanced cases intravenous sodium bicarbonate** may be necessary. Acidosis if accompanied by severe hyperkalemia and fluid overload is best treated with dialysis.
- **Calcium-phosphorus balance:** Both **hypocalcemia and hypercalcemia** are observed in the **maintenance phase** of ARF and are not serious clinical problems. **Phosphate retention** occurs in patients can be **controlled with aluminium hydroxide lanthanum carbonate, sevelamer, calcium acetate or calcium carbonate** (bind phosphate within the GIT and eliminated in stool).
- **Diet**
  - **Restrict dietary proteins** to about 40 g/day. Suppress endogenous protein catabolism to a minimum level by giving as much energy as possible in the form of carbohydrates and fats. Patients treated by blood purification techniques are given 70 g or more protein/day.
  - **Hypercatabolic patients** may **need higher nitrogen intake** to prevent negative nitrogen balance.
  - **Restrict the salt intake.**
  - **Vitamin supplements** are usually necessary.
- **Systemic complications of ARF: Infections and gastrointestinal bleeding** are two important complications.
  - **Infectious complications** (very high (80%)) includes pulmonary, urinary and wound infections (in post-traumatic and postoperative patients). Infections should be treated promptly by **appropriate antibiotics.**
  - **Gastrointestinal bleeding** (in 40% of patients) may prove fatal and treated by proton pump inhibitors and gastroprotective agents. Qualitative platelet dysfunction, which results in a hemorrhagic diathesis.
- **Use of drugs: Great care is necessary** in the use of drugs and nephrotoxic drugs should be avoided.

#### *Treatment of the underlying cause of the AKI*

- **Identify the cause** (by simple initial investigations such as ultrasound or may require additional investigations, including renal biopsy) and **correct it, if possible.**

#### *Specific therapy:*

- **No specific treatment** for ATN, other than restoring renal perfusion.
- **Intrinsic kidney disease may require specific therapy** (e.g. immunosuppressive drugs such as corticosteroids and cyclophosphamide in some causes of **rapidly progressive glomerulonephritis**).
- **'Postrenal' obstruction** requires **urgent relief of obstruction.** Once the blood chemistry returns to normal, the underlying cause should be treated whenever possible.
- **Drug-induced** acute tubule-interstitial nephritis usually recovers after stopping the offending drug, but sometimes, short course of steroids may be helpful.
- **If conservative measures fail, dialysis and hemofiltration** may be necessary. These techniques purify blood and/or remove excess fluid. Main indications of dialysis and hemofiltration in ARF are listed in Table 13.14.

**Q. Write short note on indications for dialysis in acute renal failure.**

**Table 13.14: Indications of dialysis or hemofiltration in acute renal failure (ARF).**

- |   |  |
|---|--|
| <ol style="list-style-type: none"> <li>1. Fluid overload refractory to diuretics and refractory pulmonary edema*</li> <li>2. Severe metabolic acidosis (pH &lt;7.1)*</li> <li>3. \* Absolute indications.

Preventive strategies for conditions with high risk of acute kidney injury are presented in Table 13.15.

**Table 13.15: Preventive strategies for conditions with high risk of acute kidney injury.**

<b>Risk factors</b>	<b>Preventive strategies</b>
Cancer chemotherapy (risk of tumor lysis syndrome)	<ul style="list-style-type: none"> <li>• Hydration and allopurinol administration a few days before chemotherapy initiation</li> </ul>
Exposure to nephrotoxic medications	<ul style="list-style-type: none"> <li>• Avoid nephrotoxic medications if possible. Use appropriate dosing, intervals, and duration of therapy</li> </ul>
Exposure to radiographic contrast agents	<ul style="list-style-type: none"> <li>• Avoid use of intravenous contrast media when risks outweigh benefits</li> <li>• If use of contrast media is essential, use iso-osmolar or low-osmolar contrast agent with lowest volume possible</li> <li>• Use of N-acetylcysteine may be considered</li> </ul>
Hemodynamic instability	<ul style="list-style-type: none"> <li>• Optimal fluid resuscitation, a mean arterial pressure goal of &gt; 65 mm Hg is widely used; isotonic solutions (e.g. normal saline)</li> <li>• Vasopressors are recommended for persistent hypotension (mean arterial pressure &lt;65 mm Hg) despite fluid resuscitation</li> <li>• Dopamine is not recommended</li> </ul>
Hepatic failure	<ul style="list-style-type: none"> <li>• Avoid hypotension and gastrointestinal bleeding</li> <li>• Early recognition and treatment of spontaneous bacterial peritonitis; use albumin, 1.5 g per kg at diagnosis and 1 g per kg at 48 hours</li> </ul>

	<ul style="list-style-type: none"> <li>• Albumin infusion during large volume paracentesis</li> <li>• Avoid nephrotoxic medications</li> </ul>
Rhabdomyolysis	<ul style="list-style-type: none"> <li>• Maintain adequate hydration</li> <li>• Alkalinization of the urine with intravenous sodium bicarbonate in select patients</li> </ul>
Undergoing surgery	<ul style="list-style-type: none"> <li>• Adequate volume resuscitation/prevention of hypotension, sepsis, optimizing cardiac function</li> </ul> <p>Consider holding renin-angiotensin system antagonists preoperatively</p>

**Cause of death:** Most common causes of death in ARF (in the absence of dialysis) are hyperkalemia and pulmonary edema, followed by infection and uremia.

## GLOMERULAR DISEASES

The syndromes of glomerular disease are mentioned in Box 13.6.

**Box 13.6:** Syndromes of glomerular disease.

1. Acute nephritic syndrome
2. Rapidly progressive glomerulonephritis
3. Nephrotic syndrome
4. Chronic nephritis
5. Asymptomatic urinary abnormalities (hematuria, proteinuria or both)

## GLOMERULONEPHRITIS

- **Glomerulonephritis: Inflammation of glomeruli** and **most are** due to an **immunologically mediated injury**.
- **Glomerulopathy:** Glomerular diseases **without apparent inflammation**. There is an overlap between these terms.

### Causes of Glomerulonephritis (Table 13.16)

#### *Pathogenesis*

Main mechanism is antibody mediated glomerular injury.

#### 1. **Immune complex-mediated:**

- Glomerular injury develops due to deposition of **circulating antigen-antibody complexes** (immune complexes) in the glomerulus. There is

trapping of circulating antigen-antibody complexes within glomeruli which results in glomerular damage. The antibodies are not against any of glomerular constituents, and the immune complexes localize within the glomeruli.

- The antigen may be exogenous (e.g. bacteria as in post streptococcal glomerulonephritis (PSGN) or endogenous (e.g. antibodies to host DNA in patients with SLE).

2. **Anti-GBM antibody-induced glomerulonephritis:** It develops due to injury by antibodies to the insoluble **fixed (intrinsic) glomerular basement antigens**. Anti-GBM antibody-induced glomerulonephritis is responsible for <5% of cases of glomerulonephritis. This type of injury is caused due to antibodies which are produced against intrinsic fixed antigens (that are normal components) of the GBM proper.

Characteristics of acute nephritic syndrome are presented in Box 13.7.

**Table 13.16:** Causes of glomerular diseases.

***Primary glomerulonephritis/glomerulopathies***

- Acute proliferative glomerulonephritis: Post-infectious, others
- Rapidly progressive (crescentic) glomerulonephritis
- Minimal-change disease
- Membranous glomerulopathy
- Membranoproliferative glomerulonephritis
- Focal segmental glomerulosclerosis
- IgA nephropathy
- Chronic glomerulonephritis

***Systemic diseases with glomerular involvement***

- Systemic immunological diseases: Systemic lupus erythematosus
- Metabolic diseases: Diabetes mellitus
- Vasculitis: Microscopic polyarteritis/polyangiitis, Wegener granulomatosis, Henoch-Schönlein purpura
- Amyloidosis
- Goodpasture syndrome
- Bacterial endocarditis

***Hereditary disorders***

- Alport syndrome
- Thin basement membrane disease
- Fabry disease

### Terms used in glomerular diseases

- **Focal:** Some glomeruli, but not all show the lesion.
- **Diffuse (global):** Most of the glomeruli (>75%) show the lesion.
- **Segmental:** Only a part of the glomerulus is affected (most focal lesions are also segmental, e.g. focal segmental glomerulosclerosis).
- **Proliferative:** Increase in cell numbers due to hyperplasia of one or more of the resident glomerular cells with or without inflammation.
- **Membranous:** Capillary wall thickening due to deposition of immune deposits or alterations in basement membrane.
- **Crescent formation:** Proliferation of parietal epithelial cell with mononuclear cell infiltration in Bowman's space.

Spectrum of glomerular diseases are presented in Figure 13.8 and various causes of proliferative and non-proliferative glomerulonephritis are shown in Figure 13.9.

### Box 13.7: Characteristics of acute nephritic syndrome.

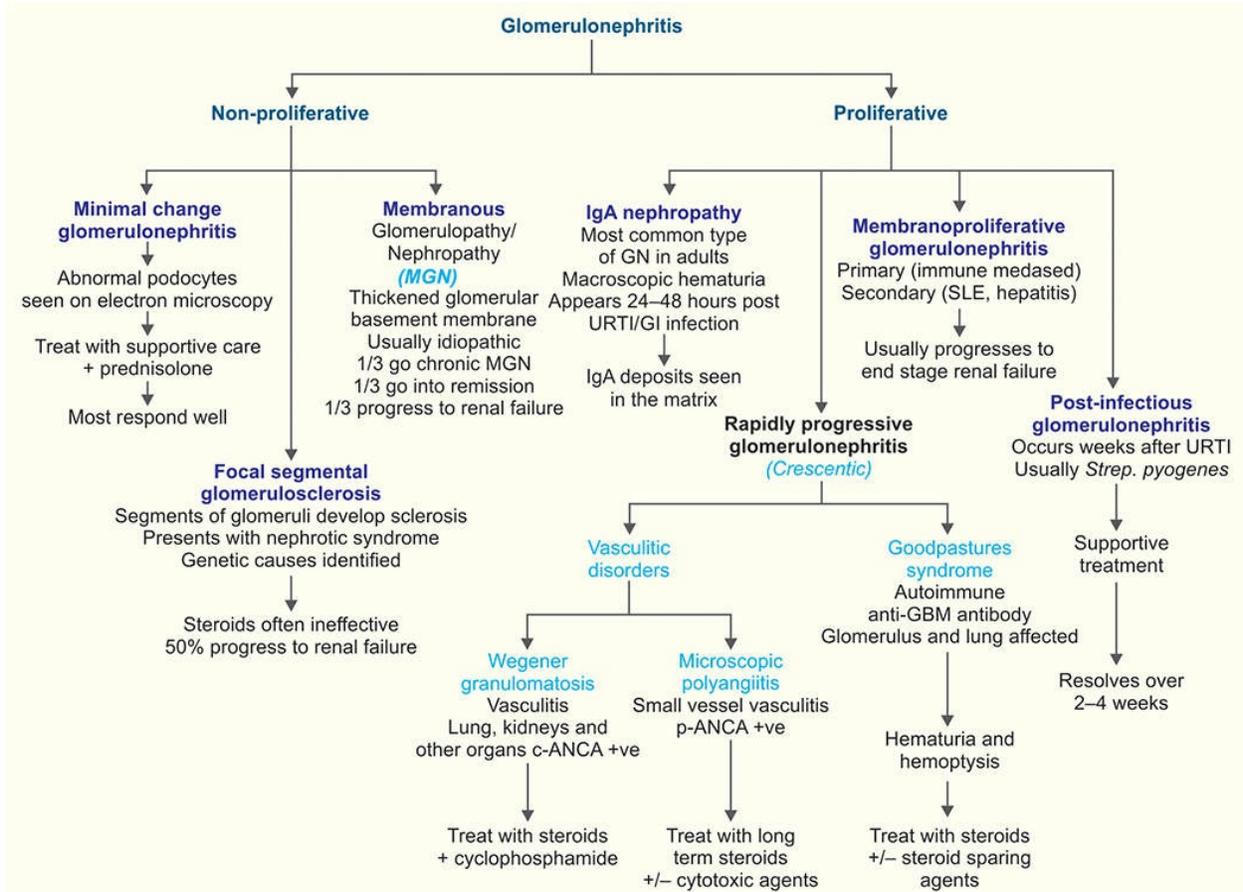

1. **Hematuria** (gross or microscopic)
2. **Red cell casts in the urine**
3. **Azotemia** (temporary)
4. **Temporary oliguria** (due to decreased glomerular filtration rate)
5. **Hypertension**
6. Proteinuria\*
7. **Edema\***(periorbital, leg or sacral)

\*Not as severe as in nephrotic syndrome.

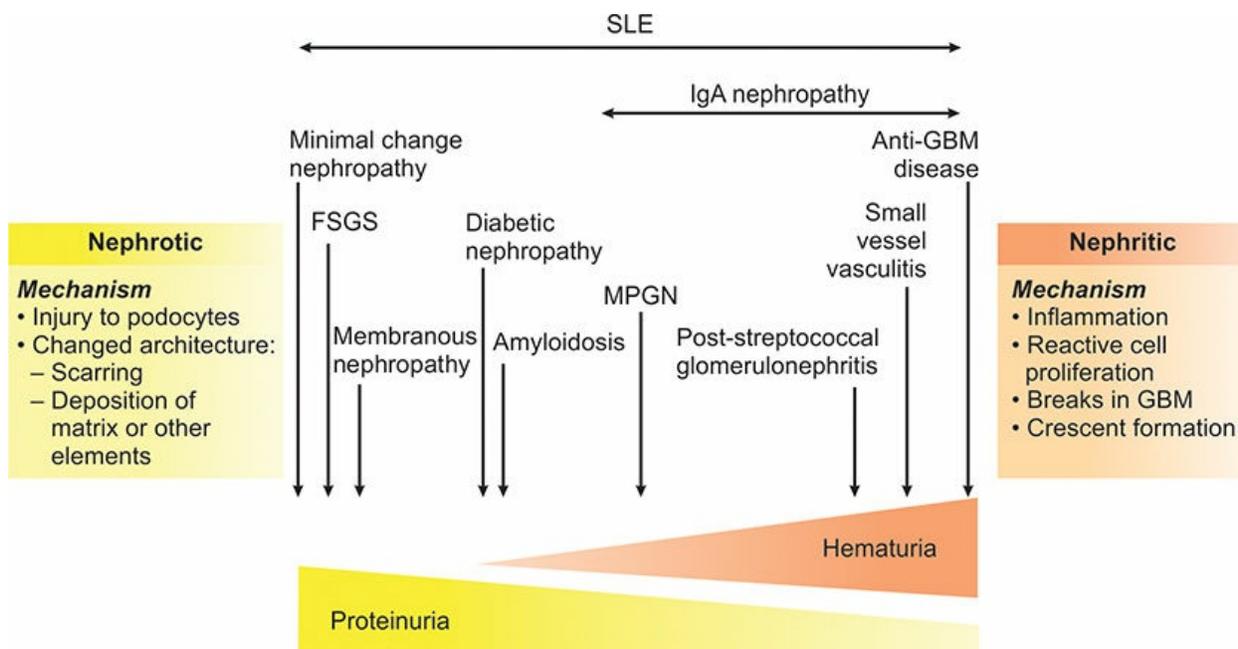

## Acute Proliferative Glomerulonephritis

These are immune complexes mediated diseases. The inciting antigen may be:

- **Exogenous**, e.g. postinfectious glomerulonephritis which commonly follows streptococcal infection, but may also associated with other infections
- **Endogenous**, e.g. nephritis of SLE
- It is characterized histologically by cellular proliferation (mesangial and endothelial) associated with infiltration by leukocytes (neutrophils, macrophages).

**Fig. 13.8:** Spectrum of glomerular diseases.

**Fig. 13.9:** Various causes of proliferative and non-proliferative glomerulonephritis

## Poststreptococcal (Postinfectious) Glomerulonephritis (PSGN)

**Q. Write short essay/note on acute glomerulonephritis or acute nephritic syndrome and its causes and clinical features.**

**Q. Discuss the etiology, pathogenesis, clinical features, diagnosis, complications and management of acute post-streptococcal glomerulonephritis (acute glomerulonephritis-AGN).**

**Poststreptococcal glomerulonephritis** is specific subtype of postinfectious glomerulonephritis. It is common in developing countries and one of the common causes of **acute nephritic syndrome**.

**Age group:** Most frequently seen in **children between 6 to 10 years** of age, but may be develop in adults.

### *Etiology and Pathogenesis*

- The **primary Streptococcal infection** usually involves the **pharynx** (pharyngitis) or the **skin** (impetigo/pyoderma). Skin infections are usually associated with overcrowding and poor hygiene.
- Only certain strains of **Group A  $\beta$ -hemolytic streptococci** are nephritogenic. More than 90% are due to **types 12, 4, and 1**.
- Commonly associated with poor personal hygiene, overcrowding and skin diseases like scabies.
- **It is an immunologically mediated disease and evidences to support this are:**
  - **Latent period:** It manifests usually after a latent period of **1 to 4 weeks** following primary streptococcal infection. Cutaneous infections are associated with longer latent period. This latent period is compatible with the time required for the production of antibodies and the immune complex formation.
  - **Antibodies against streptococcal antigens:** Majority of patients show increased titers of antibodies against one or more streptococcal antigens. These antibodies include: anti-streptolysin O, anti-deoxyribonuclease B (anti-DNase B), anti-strepokinase, anti-hyaluridase and antinicotinyl adenine dinucleotidase.
  - **Hypocomplementemia:** Immune complexes activate and utilize complement components and more than 90% of patients reveal

decreased complement (C3 and C4) levels in the blood (hypocomplementemia).

- **Immune-complex deposits:** Electron microscopy shows glomeruli with electron dense deposits of immune complexes. Immunofluorescence shows granular fluorescence to the immune deposits.
- **Streptococcal antigens in the glomeruli:** Many *cationic antigens* unique to nephritogenic strains of streptococci can be demonstrated in the glomeruli. Example, nephritis-associated streptococcal plasmin receptor (NAPlr), Streptococcal pyogenic exotoxin B (SpeB) and its zymogen precursor (zSpeB).

### **Clinical Features**

- Onset is often abrupt.
- Usually the affected child suddenly develops **malaise, fever, nausea, oliguria, and hematuria** (characteristically, urine appears **smoky or red or cola-colored urine**) 1 to 4 weeks after recovery from a sore throat.
- **Periorbital edema** (causes puffiness of face), and **mild to moderate hypertension** is usually observed. Edema initially appears in areas of low tissue pressure (periorbital areas), followed by involvement of dependent portions of the body, and may be associated with ascites and/or pleural effusion.
- In adults clinical features are atypical. They may present with the sudden appearance of **hypertension or edema, and elevation of BUN.**

### **Investigations (Table 13.17)**

**Table 13.17: Various laboratory findings in acute PSGN.**

<b>Blood findings</b>	<b>Urinary findings</b>
<ul style="list-style-type: none"> <li>• Raised <b>antistreptococcal antibody</b>, titers, e.g. antistreptolysin O (ASO) titer.</li> <li>• Significant <b>reduction in serum concentration of complement (C3)</b> components.</li> <li>• Urea and creatinine: May be elevated and indicates renal impairment.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Oliguria</b></li> <li>• <b>Mild (variable degree) proteinuria</b> (usually less than 1 gm/day)</li> <li>• <b>Hematuria (smoky or cola-colored urine)</b></li> <li>• Urine microscopy               <ul style="list-style-type: none"> <li>– Red cells (particularly dysmorphic, i.e. distorted and fragmented red cells),</li> <li>– Red cell casts</li> </ul> </li> </ul>

**Renal Biopsy:** Diffuse acute inflammation in the glomerulus with neutrophils and deposition of

immunoglobulin (IgG) and complement. Electron microscopy shows electron-dense deposits in the subepithelial aspects of the capillary walls.

**Q. Write short essay/note on diagnostic criteria and management of nephritic syndrome.**

**Q. Write short essay/note on urinary findings in acute glomerulonephritis.**

#### Management/Treatment

- **Supportive treatment during acute PSGN:** These include **rest, salt restriction, diuretics and antihypertensives.**
- **Dialysis is necessary when there is severe oliguria, fluid overload and hyperkalemia.**
- Steroids and cytotoxic drugs are of no value. However, if recovery is slow or if RPGN develops, corticosteroids (methylprednisolone) may be of some help.

#### Complications

**Q. Write short note on the complications of acute post-streptococcal glomerulonephritis/nephritic syndrome.**

(1) Rapidly progressive glomerulonephritis (RPGN), (2) pulmonary edema, (3) hypertensive encephalopathy and (4) renal failure.

#### Prognosis

**Majority** of patients with the epidemic form of PSGN have an **excellent prognosis.**

- **Children: Prognosis is good** and more than 95% totally recover. Minority may develop a rapidly progressive glomerulonephritis.
- **Adults: Less benign.** They may recover promptly or develop rapidly progressive glomerulonephritis or progress to chronic glomerulonephritis (hypertension and/or renal impairment).

**Prevention:** Pharyngitis caused by Streptococci should be treated promptly by antibiotics which protects against development of glomerulonephritis.

### Rapidly Progressive Glomerulonephritis/Crescentic Glomerulonephritis

**Q. Write short essay/note on the causes, clinical features, investigations and treatment of rapidly progressive glomerulonephritis.**

**Q. Write short essay/note on crescentic glomerulonephritis.**

**Definition:** Rapidly progressive glomerulonephritis (RPGN) is a **syndrome**, characterized by **rapid and progressive loss of renal function** (usually a 50% reduction in the GFR within 3 months) associated with **severe oliguria and signs of nephritic syndrome**. If not treated death occurs due to renal failure within weeks to months. Histologically, it is characterized by **extensive crescents** (usually >50%).

### ***Crescent***

Crescents are formed by the **proliferation of the parietal epithelial cells** lining Bowman capsule along with the **infiltration of monocytes and macrophages**.

### ***Classification***

RPGN classified into three types based on immunological findings (Table 13.18). Each type may be idiopathic or associated with a known disorder.

**Table 13.18: Classification of rapidly progressive glomerulonephritis.**

#### ***Type of RPGN***

TYPE I (ANTI-GBM ANTIBODY) (linear deposits of IgG and C3 on IF)

- Goodpasture syndrome

TYPE II (IMMUNE COMPLEX) (granular deposits of immune complex)

- Idiopathic immune complex-mediated RPGN
- IgA nephropathy
- Membranous glomerulopathy
- Mesangiocapillary GN
- Associated with secondary GN
- Post-infectious glomerulonephritis (post-streptococcal GN)
- Lupus nephritis
- Henoch-Schönlein purpura
- Mixed cryoglobulinemia

TYPE III (PAUCI-IMMUNE) (no deposits on IF)

- Idiopathic
- Wegener granulomatosis
- ANCA-associated
- Microscopic polyangiitis
- Renal-limited necrotizing crescentic glomerulonephritis

- Churg-Strauss syndrome

(GBM: glomerular basement membrane; ANCA: antineutrophil cytoplasmic antibodies).

**Table 13.19: Usual clinical features of RPGN.**

- |  |  |
|--|--|
| • <b>Hematuria with RBC casts</b> in the urine | • <b>Variable hypertension and edema</b> |
| • <b>Moderate proteinuria</b>                  | • <b>Oliguria and uremia</b>             |

In **Goodpasture syndrome** patient may present with recurrent hemoptysis or life-threatening pulmonary hemorrhage

(RPGN: rapidly progressive glomerulonephritis).

## ***Clinical Features (Table 13.19)***

### ***Investigations***

- **Blood**
  - Leukocytosis and anemia
  - **Blood urea and serum creatinine levels: Usually raised.**
- **Urinalysis**
  - **Moderate proteinuria** (1–4 g/day)
  - **Microscopic hematuria**
  - **RBC and WBC casts.**
- **Others**
  - **Complement levels (C3 and C4): May be decreased** in immune-complex mediated RPGN.
  - **Circulating anti-GBM antibodies:** In Goodpasture syndrome.
  - **ANCA:** In pauci-immune RPGN.
  - **Serum cryoglobulin levels:** May be raised in cryoglobulinemia.
- **Abdominal ultrasound: Normal sized kidneys.**
- **Chest X-ray:** Patients with Goodpasture syndrome and vasculitides may show **diffuse opacities** if associated with pulmonary hemorrhage.
- **Renal biopsy: Shows crescents.**

### **Treatment**

It depends on the factors involved in the pathogenesis.

- **Supportive therapy:**
  - **Control of infection.**

- **Control of volume status** (dialysis may be needed).
- **Specific therapy:**
  - **Plasma exchange** to remove circulating antibodies and in patients presenting with life-threatening pulmonary hemorrhage.
  - **Steroids methyl prednisolone—500–1000 mg/day for 3 days to suppress inflammation** from antibody already deposited in the tissue.
  - **Immunosuppressive therapy** (e.g. cyclophosphamide, azathioprine, mycophenolate) such as cyclophosphamide to suppress further antibody synthesis.
  - **Infliximab and rituximab.**

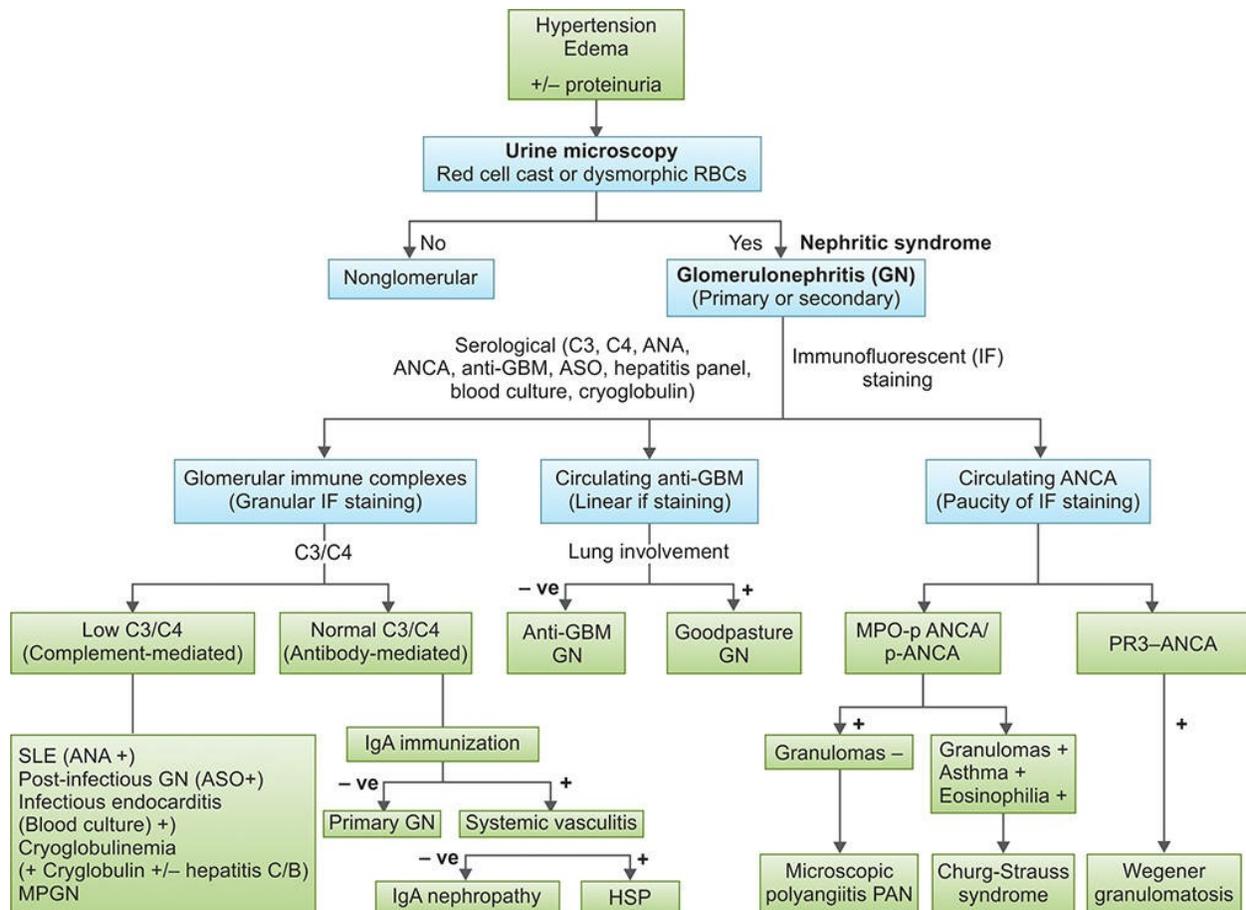

## Complement Levels in Nephritic Syndrome (Table 13.20)

Algorithm of approach to the patient presenting with acute glomerulonephritis/nephritic syndrome is presented in Flowchart 13.3.

**Table 13.20:** Complement levels in nephritic syndrome.

<i>Low complement</i>	<i>Normal complement</i>
<ul style="list-style-type: none"> <li>• Post-infectious glomerulonephritis</li> <li>• Mesangiocapillary glomerulonephritis</li> <li>• Systemic lupus erythematosus</li> <li>• Infective endocarditis</li> <li>• Essential mixed cryoglobulinemia</li> </ul>	<ul style="list-style-type: none"> <li>• IgA nephropathy</li> <li>• Idiopathic crescentic glomerulonephritis</li> <li>• Anti-GBM disease</li> <li>• Vasculitides: Henoch-Schönlein purpura, Wegener's granulomatosis, microscopic polyangiitis</li> </ul>

**Flowchart 13.3:** Algorithm of approach to the patient presenting with acute glomerulonephritis/nephritic syndrome.

[NA: antinuclear antibody; ANCA: antineutrophil cytoplasmic antibody; ASO: antistreptolysin O; MPO-ANCA: anti-myeloperoxidase (previously called p-ANCA); PR3-ANCA: anti-proteinase-3; PAN, polyarteritis nodosa]

## Nephrotic Syndrome

**Q. Discuss the etiology, pathogenesis, clinical features, diagnosis and management of nephrotic syndrome.**

**Q. Define nephrotic syndrome. Discuss the differential diagnosis in a 30-year-old male presenting with anasarca.**

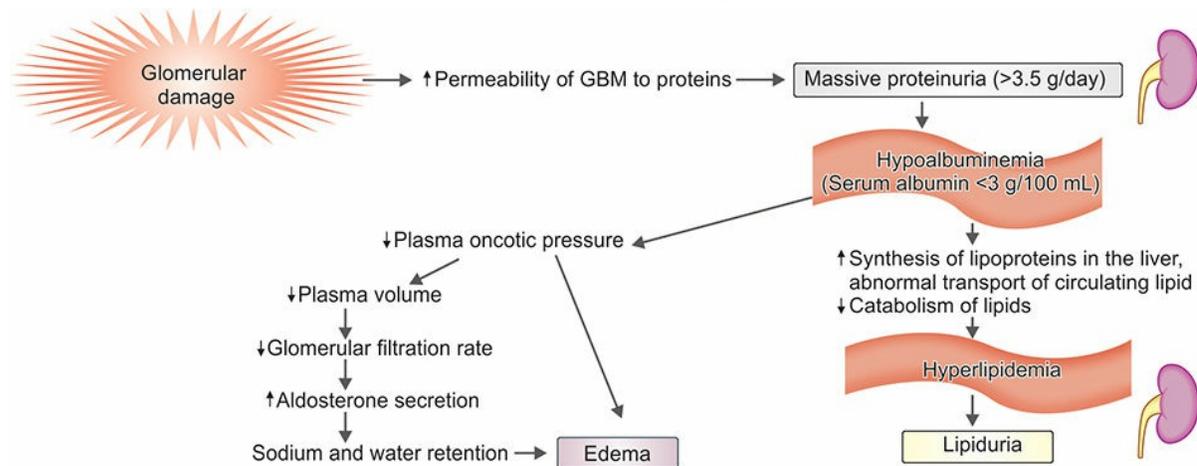

Features of nephrotic syndrome are mentioned in Box 13.8

**Box 13.8:** Characteristics of nephrotic syndrome.

- Massive/heavy proteinuria (>3.5 g of protein/24 hours)
- Hypoalbuminemia
- Generalized edema
- Hyperlipidemia and lipiduria

## Pathophysiology (Fig. 13.10)

- **Massive proteinuria** is characterized by **daily loss of 3.5 g or more of protein** (less in children) in the **urine**.
  - Normally, the glomerular capillary wall acts as a size and charge dependent barrier for the plasma filtrate.
  - Proteinuria in nephrotic syndrome is due to **increased permeability of glomerular capillary wall to plasma proteins**. This increased permeability is due to glomerular inflammation, change in the surface electrical charge, and an alteration in the pore size.

**Fig. 13.10:** Various characteristic features of nephrotic syndrome and its mechanism. (GBM: glomerular basement membrane).

- The **major proportion of protein** lost in the urine is **albumin**, and rarely globulins. Consequences of protein loss are listed in Table 13.21.
- **Hypoalbuminemia**
  - Massive proteinuria decreases the serum albumin levels (hypoalbuminemia).
  - **Hypoalbuminemia decreases the colloid osmotic pressure** of the blood resulting in a disturbance in the Starling forces acting across peripheral capillaries.
  - The **hypovolemia also triggers the renin-angiotensin-aldosterone system**. This causes **increased reabsorption of sodium and water** by the kidney, resulting in edema.
- **Generalized edema**
  - Soft and pitting

- **Most marked in the periorbital regions** (Fig. 13.11) and dependent portions of the body.

**Fig. 13.11:** Facial and periorbital puffiness in nephrotic syndrome.

- Associated with pleural effusions and ascites.
- **Hyperlipidemia and lipiduria**
  - **Hyperlipidemia:** Most patients with nephrotic syndrome have raised blood levels of cholesterol, triglyceride, very-low-density lipoprotein, low-density lipoprotein, Lp(a) lipoprotein, and apoprotein. It **increases risk of atherosclerosis and cardiovascular disease**.
  - **Causes of hyperlipidemia:** **Increased synthesis** of lipoproteins in the liver due to low plasma colloid oncotic pressure. **Abnormal transport** of circulating lipid. **Decreased catabolism** of lipids
- **Lipiduria:** Hyperlipidemia is followed by leakage of lipoproteins across the glomerular capillary wall → leaked lipoprotein is reabsorbed by tubular epithelial cells → then shed along with the degenerated cells → **appears in urine either as free fat or as oval fat bodies**.

**Table 13.21: Consequences of protein loss.**

<i>Nature of protein loss</i>	<i>Consequences</i>
Hypoalbuminemia	Edema and may also produce pleural effusion and ascites. Subungual edema may manifest as parallel white lines in the fingernail beds Increased susceptibility to infections
Urinary losses of plasma proteins like thyroxine binding globulin	Abnormalities in thyroid function tests, hypothyroidism
Deficiency of antithrombin III (due to urine loss)	Hypercoagulable state (consequences include DVT, pulmonary embolism, myocardial infarction and stroke) and renal vein thrombosis
Loss of globulins in urine	Severe IgG deficiency leading to infections like spontaneous bacterial peritonitis
Loss of cholecalciferol binding protein	Vitamin D deficiency state
Loss of transferrin	Microcytic hypochromic anemia
Loss of metal binding proteins	Metal deficiency, e.g. zinc, copper
Loss of drug binding proteins	Altered drug pharmacokinetics

### ***Causes of Nephrotic Syndrome (Table 13.22 and Fig. 13.12)***

**Q. Write short essay on causes/etiology, pathogenesis, clinical features, investigations and treatment of minimal change disease.**

- **Minimal change disease**
  - Minimal change disease (MCD) is named so because the **glomerular changes are absent or minimal and glomeruli appear normal under light microscopy**. But under electron microscopy, it shows **diffuse effacement (loss) of foot processes** of visceral epithelial cells (podocytes).
  - MCD is the **major cause of nephrotic syndrome in children (80%)**, but it is less common in adults (20%).
  - **Age:** Peak incidence between 2 and 6 years of age.
- **Focal and segmental glomerulosclerosis (FSGS)**
  - FSGS is characterized by the **sclerosis that involves only part of the capillary tuft (i.e. segmental) of some glomeruli (i.e. focal)**.
  - Accounts for about **one-third of cases of nephrotic syndrome in adults**.
  - Usually manifest as nephrotic syndrome or heavy proteinuria,

hypertension, renal insufficiency and occasionally hematuria.

– **Classification (Box 13.9)**

• **Membranous nephropathy**

– Characterized by **uniform diffuse thickening of the glomerular capillary wall**. This is due to the accumulation of **electron-dense deposits along the subepithelial side** of the glomerular basement membrane.

– **Common cause (~30%) of the nephrotic syndrome in adults.**

– **Gender and age:** Male predominance and high incidence between 30 to 50 years of age.

– **Causes (Box 13.10)**

– About 75% of patients present with nephrotic-range proteinuria and 50% present with microscopic hematuria.

**Table 13.22: Causes of nephrotic syndrome.**

**A. Primary (idiopathic) glomerular disease**

- Membranous glomerulopathy (~30% in adults)
- Minimal-change disease (~65% in children)
- Focal segmental glomerulosclerosis (FSGS~ 35% in adults)
- Membranoproliferative glomerulonephritis
- IgA nephropathy
- Mesangial proliferative

**B. Infection-related**

- Malaria (quartern malaria)
- Infective endocarditis
- Hepatitis B and C
- HIV
- Syphilis

**C. Systemic diseases**

- Diabetes mellitus
- Amyloidosis
- Systemic lupus erythematosus
- Polyarteritis nodosa
- Wegener's granulomatosis

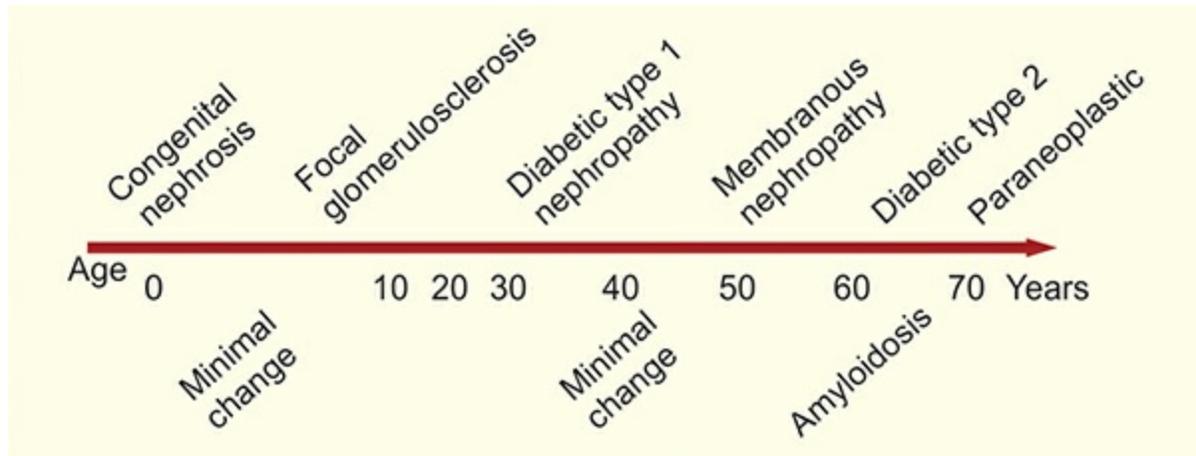

**D. Drug and toxins**

Penicillamine, gold, street heroin, captopril

**E. Malignancy**

- Carcinoma
- Melanoma
- Hodgkin's disease, chronic lymphatic leukemia

**F. Others: Bee-sting allergy, hereditary nephritis**

**Fig. 13.12:** Etiology of nephrotic syndrome by age.

**Box 13.9:** Classification of focal and segmental glomerulosclerosis.

**Primary (idiopathic)**

**Secondary**

- Viruses: HIV infection
- Drugs: Heroin addiction
- Sickle-cell disease
- Massive obesity
- Congenital (e.g. unilateral agenesis) and acquired (e.g. reflux nephropathy) reductions in renal mass

**Hereditary forms:** Inherited mutations in genes that encode podocyte proteins, e.g. podocin,  $\alpha$ -actinin 4

**Box 13.10:** Causes of membranous nephropathy.

**Primary/idiopathic:** No identifiable cause in about 85% of patients

**Secondary (20–30% cases):** In association with:

- **Therapeutic drugs:** Penicillamine, captopril, nonsteroidal anti-inflammatory drugs (NSAIDs), gold
- **Malignant neoplasms,** e.g. carcinomas of the lung and colon, lymphomas and melanoma
- **Autoimmune disease,** e.g. SLE, thyroiditis
- **Infections:** Chronic hepatitis B, hepatitis C, quatern malaria, syphilis, schistosomiasis

## Investigations in Nephrotic Syndrome

**Q. Write a short note on urinary findings in nephrotic syndrome.**

- **Urine examination**
  - **Proteinuria:** Twenty-four hour urinary protein estimation.
  - **Microscopy:** Red cells and red cell casts and waxy casts may be present. However, in minimal change disease RBCs and red cell casts are not seen. Shows lipiduria
- **Serum albumin: Reduced**
- **Serum cholesterol: Raised**
- **Renal biopsy: May be necessary** for histological diagnosis.
- **Other investigations:** Depending on the suspected secondary causes appropriate investigations are to be performed.

### Management

#### A. General measures

*Measures to reduce proteinuria:* These measures are necessary if immunosuppressive drugs and other specific measures against the underlying cause do not benefit.

- **ACE inhibitors and/or angiotensin II receptor antagonists:** They **reduce proteinuria** in all types of GN and also slow **the rate of progression of renal failure** by lowering glomerular capillary filtration pressure. Blood pressure and renal function should be monitored regularly during their administration.

*Measures to control complications*

- **Treatment of edema:**
  - Initially, it is treated by **dietary salt (sodium) restriction, rest and a thiazide diuretic** (e.g. chlorthalidone, bendroflumethiazide). The weight loss should not be more than 1 kg/day. Aggressive diuretic therapy may precipitate ARF due to reduction in intravascular volume.
  - **If not responsive, furosemide 40–120 mg daily** with the **addition of amiloride** (5 mg daily), and serum potassium concentration should be monitored.
  - **Gut mucosal edema** in nephrotic syndrome may **cause malabsorption of diuretics** (as well as other drugs). Thus, if there is **resistance to oral diuretic treatment parenteral administration is required.**
  - In diuretic-resistant patients and those with oliguria and uremia in the absence of severe glomerular damage (e.g. in minimal-change nephropathy) edema may be treated by **infusion of salt-poor albumin as a temporary measure combined with diuretic therapy.** However, most of infused albumin will be excreted by the kidneys within 1–2 days.
  - **Dietary proteins:** It is advisable to **take normal protein** and should be about 0.8–1.0 g/kg. A high-protein diet (approximately 80–90 g protein daily) increases proteinuria and may be harmful in the long term. However, malnutrition should be prevented.
- **Hypercoagulable state:** Develops due to loss of coagulation factors (e.g. antithrombin) in the urine and an increase in production of fibrinogen by liver. It **predisposes to venous thrombosis and thromboembolism.** Therefore, **avoid prolonged bed rest.** Long-term **prophylactic**

**anticoagulant therapy** is desirable and it is indicated in patients who have already developed deep venous thrombosis or arterial thrombosis.

- **Lipid abnormalities:** They **increase in the risk of myocardial infarction or peripheral vascular disease**. Hypercholesterolemia is treated with an **HMG-CoA reductase inhibitor and dietary restrictions of lipids**.
- **Vitamin D supplementation:** To be given if there is biochemical evidence of vitamin D deficiency.
- **Sepsis:** It is a **major cause of death** in nephrotic syndrome. The increased susceptibility to infection is partly due to loss of immunoglobulin in the urine. They are particularly **susceptible to pneumococcal infections** and pneumococcal vaccine should be given to these patients. Early detection and aggressive treatment of infections should be done. Vaccinations prophylactically is advisable.

### **B. Treatment of underlying cause**

#### *Minimal change disease*

- **In children:**
  - **Initial treatment** by **high-dose corticosteroid** therapy with prednisolone 60 mg/m<sup>2</sup> daily (up to a maximum of 80 mg/day) for a maximum of 4–6 weeks.
  - Followed by alternate day prednisolone at a dose of 40 mg/m<sup>2</sup> (1 mg/kg in adults) for further 4–6 weeks.
  - **More than 95% of children respond** to the above therapy. Children who respond within the first 4 weeks of corticosteroid therapy are termed ‘steroid responsive’. Those who relapse on withdrawal of corticosteroid therapy are termed ‘steroid dependent’.
  - **Relapse:**
    - ◆ One-third of patients relapse on steroid withdrawal, and remission is once more induced with **steroid therapy**.
    - ◆ In patients who have frequent relapses or develop unacceptable corticosteroid side effects, long-term remission can be achieved by a course of **cyclophosphamide** 1.5–2.0 mg/kg daily is given for 8–12 weeks **with concomitant prednisolone** 7.5–15 mg/day. Steroid unresponsive patients may also benefit by cyclophosphamide. Not more than two courses of cyclophosphamide should be given because of the risk of side-effects (e.g. azoospermia).
    - ◆ An alternative to cyclophosphamide is **ciclosporin** 3–5 mg/kg/day, (ciclosporin is potentially nephrotoxic).
- **Adults: Response rates are significantly lower** and response may occur late (12 weeks with daily steroid therapy and 12 weeks of maintenance with alternate-day therapy).
- **Prognosis: Excellent**, although it may show remission and relapses.

#### *Focal and segmental glomerulosclerosis*

- **Steroids:** It is **beneficial in only 20–30% patients** and usually prednisolone is given in the dose of 0.5–2 mg/kg/day.
- **Cyclosporine** may be effective in reducing or stopping urinary protein excretion.
- **Cyclophosphamide, chlorambucil or azathioprine** may be used **as second-line therapy in adults**.
- About **50% progress to end-stage renal failure**.

#### *Membranous glomerulonephritis*

- **Oral high-dose corticosteroids are not useful for** producing either a sustained remission of nephrotic syndrome or preserving renal function.

- **Alkylating agents: Cyclophosphamide and chlorambucil** are effective. However, because of long-term toxicity, these drugs should be reserved for patients who have severe or prolonged nephrosis (i.e. proteinuria >6 g/day for >6 months), renal insufficiency and hypertension. **Cyclophosphamide, cyclosporine and chlorambucil** in combination with steroids may be helpful.
- **Anti-B lymphocyte therapy is more effective** against T lymphocytes than broad-spectrum immunosuppressive agents. Anti-CD20 antibodies (rituximab, which ablates B lymphocytes) improve renal function, reduce proteinuria and increase the serum albumin.
- **Prognosis:** Spontaneous remission may occur in 40%, 3–40% may develop repeated remissions and relapses and 10–20% patients may develop progressive renal failure.

## IgA Nephropathy (Berger's Disease)

### **Q. Write short essay/note on IgA nephropathy.**

- Characterized by **focal and segmental proliferative glomerulonephritis** with **predominant IgA deposition in the glomerular mesangium**.
- **Clinical features:**
  - Occurs in **children and young males**.
  - Presents with **asymptomatic/painless microscopic hematuria or recurrent macroscopic hematuria** generally within **1–2 days after an upper respiratory or gastrointestinal viral infection**.
  - Proteinuria occurs and in 5% it can be in the nephrotic range.
  - Occasionally, it may present as acute renal failure (ARF) or nephritic syndrome.
- **Diagnosis by renal biopsy:** Immunofluorescence microscopy shows prominent **IgA deposits** in the mesangial regions.
- **Prognosis:**
  - **Usually good**, especially in patients with normal blood pressure, normal renal function and absence of proteinuria at presentation.
  - Complete remission uncommon.
  - **Risk of development of end-stage renal failure** in about 25% of patients with proteinuria of more than 1g/day, elevated serum creatinine, hypertension, ACE gene polymorphism and presence of tubulointerstitial fibrosis on renal biopsy.

### **Management**

- **Steroids:** Used for patients with proteinuria of 1–3 g/day, mild glomerular changes only and preserved renal function. They reduce proteinuria and stabilize renal function.
- **Use of immunosuppressive therapy is controversial.**

- **Combination therapy:** In patients with progressive disease (creatinine clearance <70 mL/min), **prednisolone with cyclophosphamide** can be used for 3 months followed by maintenance with prednisolone and azathioprine.
- **Tonsillectomy:** May reduce proteinuria and hematuria in patients with recurrent tonsillitis.
- **Combination of ACE inhibitor and angiotensin II receptor antagonist:** Can be given to all patients, with or without hypertension and proteinuria. This combination therapy reduces proteinuria and preserves renal function.

## Hereditary Nephritis (HN) or Alport's Syndrome

- Most common familial nephropathies, characterized by familial occurrence of **progressive hematuria, nephritis and sensorineural loss of hearing.**
- Common in females. Male patients develop severe renal disease with progressive renal failure occurring before the fourth decade. Most females have a normal life-span.
- **Pathology:** Electron microscopy: Shows irregular thickening of GBM, splitting and splintering of the lamina densa and small, round, electron-dense granulations are present within the lucent zones. GBM lesion are the hallmark but not specific of Alport's syndrome.
- **Clinical presentation**
  - Major presentation: Macroscopic or microscopic hematuria and may be observed at birth.
  - Other presenting features: Proteinuria, edema, hypertension, renal failure and deafness.
    - ◆ Microscopic or recurrent episodes of macroscopic hematuria following upper respiratory infection (or physical exertion) may resemble postinfective glomerulonephritis.
    - ◆ Incidental leukocyturia and pyuria may lead to erroneous diagnosis of urinary tract infection.
    - ◆ Nephrotic syndrome can occur with increasing proteinuria. Hypertension develops with progressive renal insufficiency.
    - ◆ Deafness is more frequent in males and progression of hearing loss usually indicates poor prognosis.
    - ◆ Ocular changes include anterior lenticonus (most common) and associated posterior or anterior cataract.

**Treatment:** No specific measure to prevent progression of renal disease. Treatment includes renal

replacement therapy, by long-term hemodialysis or renal transplant. Hearing defect can be temporarily compensated by the use of hearing aid.

## TUBULOINTERSTITIAL DISEASES

- **Tubulointerstitial nephropathy** is an **inflammatory condition affecting primarily the renal tubules and interstitium.**
- **Structural changes in the glomeruli develop later** and results in progressive decline in GFR, glomerular proteinuria and volume-dependent hypertension.
- It accounts for **20 to 40 % of cases of chronic renal failure** and **10 to 25 % of cases of acute renal failure.**

### Acute Tubulointerstitial Nephropathy (Acute TIN)

Two most common causes of acute TIN are **drugs or toxins and infections.**

#### *Etiology (Box 13.11)*

##### *Drug-induced acute TIN*

- After exposure to a causative drug, **renal dysfunction may occur within a few hours** but can occur after weeks or months.
- Preceded or accompanied by the triad of **fever** (70–100%), **skin rash** (30–50%) and **eosinophilia (transient)**. Skin rash and eosinophilia are not found in TIN caused by NSAIDs.
- **Microscopic hematuria, pyuria and proteinuria** are present in almost all cases. **Eosinophiluria (> 50% of WBC) is a sensitive marker of drug-induced TIN.**
- Patients may need steroids (methylprednisolone 500–1000 mg/day for 3 days).

**Box 13.11:** Etiology of acute tubulointerstitial nephropathy.

#### **Drugs**

- Antimicrobials
- Analgesics/NSAIDs
- Diuretics
- Anticonvulsants
- Metabolic salts
- Indigenous medication

#### Infections

- Acute bacterial pyelonephritis
- Systemic infections

#### Immunological

- Transplant rejection
- SLE, Sjögren's syndrome, sarcoidosis

#### Metabolic

- Hypercalcemia, cystinosis, potassium depletion, hyperoxaluria

#### Hemopoietic

- Myeloproliferative diseases, plasma cell dyscrasias

#### Miscellaneous

- Irradiation, heat stroke

#### Idiopathic

### *Analgesic nephropathy*

- **Prolonged analgesic abuse** leads to a nephropathic process characterized by **capillary sclerosis, chronic tubulointerstitial diseases and papillary necrosis**.
- Imaging reveals shrunken kidneys with calcification of renal papillae.
- Risk of developing renal disease is **dependent upon the frequency and duration of analgesic consumption**, the cumulative amount of individual analgesic exceeding 3 kg (phenacetin, acetaminophen, or aspirin).

#### Treatment of Interstitial Nephritis

- Stop the offending agent
- Prednisone at a dose of 1 mg/kg per day (to a maximum of 40 to 60 mg) for a minimum of one to two weeks, beginning a gradual taper after the serum creatinine has returned to or near baseline.

## RENAL TUBULAR ACIDOSIS

### **Q. Write short essay/note on renal tubular acidosis.**

Renal tubular acidosis (RTA) is an uncommon disorder. The term RTA is used for **systemic acidosis** (accumulation of acid in the body) **caused by impairment of the ability of the renal tubules to excrete acids** leading to. Thus there is failure to maintain acid–base balance. The function of kidneys is otherwise normal.

### **Mechanism**

RTA can be due to a defect in one of three processes:

1. **Impaired acid secretion in the late distal tubule** or cortical collecting duct intercalated cells (classical distal RTA).
2. **Impaired bicarbonate reabsorption in the proximal tubule** (proximal RTA).
3. **Impaired sodium reabsorption in the late distal tubule** or cortical collecting duct. It is associated with reduced secretion of both potassium and  $H^+$  ions (hyperkalemia distal RTA).

Box 13.12 lists types of renal tubular acidosis (RTA).

**Box 13.12:** Types of renal tubular acidosis.

- Type 1 RTA or distal tubular RTA
- Type 2 RTA or proximal RTA
- Type 3 RTA or mixed RTA
- Type 4 RTA or hypoaldosteronism hyperkalemia RTA

**Box 13.13:** Causes of type 1 RTA.

- Primary/Hereditary
- Nephrocalcinosis (producing damage of cortical collecting duct)
- Chronic urinary tract obstruction
- Hypergammaglobulinemic states
- Drugs and toxins, e.g. ifosfamide, amphotericin B, lithium and toluene
- Renal transplant rejection
- Autoimmune disease, e.g. Sjögren's syndrome
- Cirrhosis of liver
- Sickle cell anemia

(RTA: Renal tubular acidosis).

## Types

### ***Type 1 ('Distal' Renal Tubular Acidosis)***

- Most common type of RTA.
- **Causes** (Box 13.13): It occurs due to a failure of  $H^+$  (hydrogen ion) excretion in the distal tubule.

### *Consequences*

- Acidosis
- Hypokalemia (few exceptions)

- Failure to lower the urine pH below 5.3 despite systemic acidosis
- Low urinary ammonium production
- **Renal calculus** formation due to hypercalciuria, hypocitraturia (citrate inhibits calcium phosphate precipitation), and alkaline urine (which favors precipitation of calcium phosphate). Calculus produces hematuria, pain and recurrent urinary infections.
- Nephrocalcinosis (Fig. 13.13): Deposition of calcium in the kidney parenchyma.
- Depletion/mobilization of calcium (demineralization) from bones causing rickets in children and osteomalacia in adults.

### *Diagnosis*

- Urinary pH >5.3 in presence of systemic acidosis
- Plasma bicarbonate ( $\text{HCO}_3^-$ ) <20 mEq/L mmol/L
- **Acid load test:**
  - Give ammonium chloride by mouth (100 mg/kg) and check pH of urine hourly and plasma  $\text{HCO}_3^-$  at 3 hours.
  - Plasma  $\text{HCO}_3^-$  should drop below 21 mmol/L.
  - Diagnosis is confirmed if urine pH remains >5.3 despite a plasma  $\text{HCO}_3^-$  of 21 mmol/L.

**Fig. 13.13:** Nephrocalcinosis in type 1 renal tubular acidosis (RTA).

### **Treatment**

- **Correction of the acidosis:** Oral sodium bicarbonate or sodium citrate reverses bone

demineralization.

- **Potassium supplements:** Potassium citrate in case of hypokalemia, stone formation and nephrocalcinosis.
- **Thiazide diuretics:** They cause volume contraction and increased proximal sodium bicarbonate reabsorption.

## ***Type 2 ('Proximal') Renal Tubular Acidosis***

- Very rare and is due to **failure of filtered sodium bicarbonate reabsorption in the proximal tubule**. It leads to appearance of bicarbonate in urine and subsequent acidosis.
- **Causes of type 2 RTA (Box 13.14):** Inherited forms of isolated type 2 RTA may show both autosomal dominant and recessive patterns of inheritance.

### **Box 13.14:** Causes of type 2 RTA.

- Inherited
- Paraproteinemia
- Amyloidosis
- Hyperparathyroidism
- Heavy metal toxicity
- Drugs and toxins such as antiretroviral drugs, ifosfamide, lead and cadmium.
- Wilson's disease

**Consequences:** Type 2 RTA usually occurs as part of a generalized tubular defect, together with urinary wasting of amino acids, phosphate and glucose (Fanconi's syndrome), as well as bicarbonate and potassium.

- Acidosis less severe than type 1 RTA
- Hypokalemia
- Inability to lower the urine pH below 5.5 despite systemic acidosis
- Appearance of bicarbonate in the urine despite a subnormal plasma bicarbonate
- Bone demineralization due to phosphate wasting.

#### **Treatment**

- **Large /massive doses of sodium bicarbonate:** May be required to overcome the renal 'leak' of bicarbonate.
- **Potassium supplementation:** Often necessary because loss of bicarbonate in urine potentiates hypokalemia.

### ***Type 3 Renal Tubular Acidosis (RTA)***

- It represents a combination of type 1 and type 2.
- **Inherited type 3 RTA:** It is caused by mutations resulting in carbonic anhydrase type II deficiency. It is characterized by osteopetrosis, cerebral calcification, and mental retardation.

### ***Type 4 Renal Tubular Acidosis (RTA)***

It is also known as ‘hyporeninemic hypoaldosteronism’ and is the most common RTA. Its features are listed in Box 13.15.

- Causes of type 4 RTA is presented in Table 13.23.

#### **Treatment of type 4 RTA**

- Treatment of aldosterone deficiency: With a mineralocorticoid (e.g. fludrocortisones) and glucocorticoid for cortisol deficiency (if present).
- Hyporeninemic hypoaldosteronism by fludrocortisones and accompanying hypertension and edema are treated by thiazide or loop diuretic. Diuretics are also necessary for the control of hyperkalemia.

Algorithm approach to renal tubular acidosis (RTA) is presented in Figure 13.14.

**Table 13.23: Causes of type 4 RTA.**

<b><i>Primary aldosterone deficiency</i></b>	<b><i>Hyporeninemic hypoaldosteronism</i></b>	<b><i>Aldosterone resistance</i></b>
Primary adrenal insufficiency	Renal dysfunction (e.g. diabetic nephropathy)	Drugs (e.g. amiloride, spironolactone, trimethoprim, pentamidine)
Congenital adrenal hyperplasia	ACE inhibitors	Pseudohypoaldosteronism
Deficiency of aldosterone synthase	HIV	
Potassium sparing diuretics	NSAIDs	
	Cyclosporine	

(RTA: Renal tubular acidosis).

### **Box 13.15: Features of type 4 renal tubular acidosis.**

- Hyperkalemia
- Reduced plasma bicarbonate and hyperchloremia
- Normal ACTH stimulation test
- Low basal 24 hours urinary aldosterone

- Reduced response of plasma renin and plasma aldosterone to stimulation
- Correction of hyperkalemia by fludrocortisone

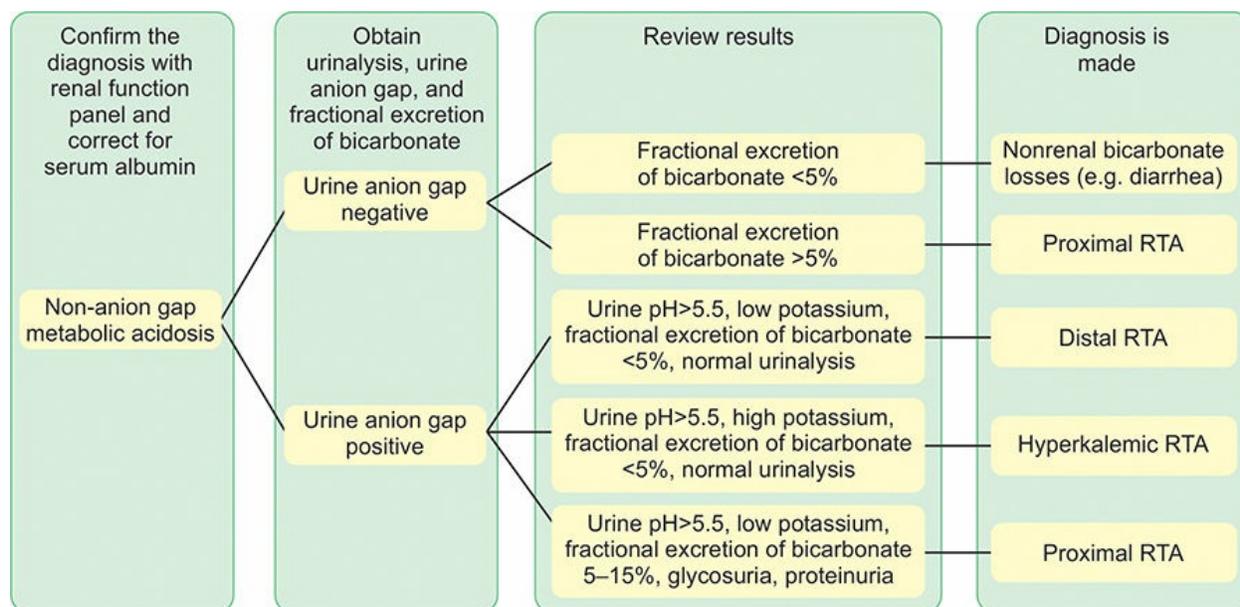

Fig. 13.14: Algorithm approach to renal tubular acidosis (RTA).

## CHRONIC KIDNEY DISEASE (CKD) (TABLE 13.24)

**Q. Write a short note on chronic kidney diseases.**

Chronic kidney disease (CKD) previously termed chronic renal failure or insufficiency.

**Chronic kidney disease (CKD)** refers to a spectrum of **longstanding** (more than 3 months), usually **progressive** processes associated with **irreversible worsening of renal function** and decline in glomerular filtration rate (GFR). **CKD spectrum ranges from abnormalities detectable only by laboratory testing to uremia.**

Revised chronic kidney disease classification based upon glomerular filtration rate and albuminuria KDIGO 2013 is presented in Figure 13.15.

**Table 13.24: Classification of CKD** (The National Kidney Foundation-Kidney Disease Outcomes Quality Initiative NKF-KDOQI) working group.

Stage	Description
-------	-------------

		<b>GFR (mL/minute/1.73 m<sup>2</sup>)</b>
1	Chronic kidney damage with normal or increased GFR	>90
2	Mild GFR loss	60–89
3	Moderate GFR loss stage 3A (GFR 45 to 59 mL/min) and stage 3B (GFR 30–44 mL/min)	30–59
4	Severe GFR loss	15–29
5	Kidney failure requiring dialysis (5D) or transplantation (5T)	<15

				Persistent albuminuria categories, Description and range		
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g (<3 mg/mmol)	30–300 mg/g (3–30 mg/mmol)	>300 mg/g (>30 mg/mmol)
GFR categories (mL/min/1.73 m <sup>2</sup> ) stage, description, and range	1	Normal or high	≥90			2
	2	Mildly decreased	60–89	1 if CKD	1	2
	3a	Mildly to moderately decreased	45–59	1	2	3
	3b	Moderately to severely decreased	30–44	2	3	3
	4	Severely decreased	15–29	3	3	4+
	5	Kidney failure	<15	4+	4+	4+

**Fig. 13.15:** Revised chronic kidney disease classification based upon glomerular filtration rate and albuminuria KDIGO 2013.

## Definition (Box 13.16)

**Q.** Write short essay/note on the clinical and biochemical features of chronic kidney disease (CKD).

## Causes of CKD (Table 13.25)

## Clinical Approach to CKD

### History

- Duration of symptoms
- Drug intake: These include nonsteroidal anti-inflammatory agents, analgesic and other medications (e.g. herbal medicines).
- Previous medical and surgical history, e.g. chemotherapy, SLE, malaria.
- Previous urinalysis or urea and creatinine values if performed.
- Family history of renal disease.

**Table 13.25: Important causes of chronic kidney disease.**

<b>I. Glomerulopathies *</b> <i>Proliferative GN</i> <i>Crescentic GN</i> <i>Membranoproliferative GN</i> <i>Mesangiocapillary GN</i>	<b>IV. Obstructive*</b> <i>Calculus</i> <i>Tumors</i> <i>Retroperitoneal fibrosis</i> <i>Prostatic enlargement</i>
<b>II. Systemic and metabolic diseases</b> <b>Diabetes*</b> <i>Systemic lupus erythematosus (SLE)</i> <i>Polyarteritis nodosa (PAN)</i> <i>Amyloidosis</i> <i>Gout</i>	<b>V. Vascular</b> <i>Essential hypertension (accelerated)*</i> <i>Renovascular</i> <i>Vasculitis (SLE, PAN, scleroderma)</i>
<b>III. Interstitial</b> <i>Chronic interstitial nephritis*</i> <i>Chronic pyelonephritis*</i> <i>Analgesic</i> <i>Tuberculosis</i> <i>Nephrocalcinosis</i>	<b>VI. Congenital</b> <i>Polycystic kidney*</i> <i>Medullary cystic disease</i> <i>Alport's syndrome</i>

\* common causes of chronic renal failure

## Symptoms

- Unfortunately, **early stages** of CKD may be **asymptomatic**, despite the progressive loss of kidney function and accumulation of numerous metabolites.
- Usually there is a rough correlation between serum urea and creatinine levels and symptoms. Symptoms are common when the serum urea level exceeds 40 mmol/L.

## Clinical Features (Table 13.26 and Fig. 13.16)

**Q. Write short essay/note on the clinical features of CKD.**

## Complications of Chronic Renal Failure

**Q.** Write short essay/note on the complications of chronic renal failure.

**Anemia:** Various causes of anemia in CRF are listed in Box 13.17.

**Box 13.16:** Definition of chronic kidney disease (CKD).

- Glomerular filtration rate (GFR) of  $<60 \text{ mL/minute}/1.73 \text{ m}^2$  for 3 months or more, with or without kidney damage or a urinary albumin to creatinine ratio  $>65 \text{ mg/mmol}$  or protein creatinine ratio of  $100 \text{ mg/mmol}$ .  
OR
- Kidney damage for 3 or more months with or without decreased GFR, as evidenced by any of the following:
  - **Microalbuminuria:** Albumin excretion rate  $30\text{--}300 \text{ mg/day}$  in urine or urinary albumin  $>30 \text{ mg/day}$  excretion of creatinine.
  - **Macroalbuminuria:** Albumin excretion rate in urine  $> 300 \text{ mg/day}$ .
  - **Pathologic abnormalities** such as abnormal findings on renal biopsy.
  - **Radiologic abnormalities** such as scarring or polycystic kidneys on renal ultrasound scan.

**Box 13.17:** Causes of anemia in CRF.

- Deficiency of erythropoietin (most important)
- Toxic effects of uremia on bone marrow precursor cells
- Bone marrow fibrosis secondary to hyperparathyroidism
- Deficiency of hematinic: Iron, vitamin B<sub>12</sub>, folate because of reduced dietary intake due to anorexia. Intestinal absorption of iron is also impaired.
- Increased red cell destruction: Abnormal red cell membranes
- Increased blood loss
  - Occult gastrointestinal bleeding
  - Blood sampling
  - Blood loss during hemodialysis
  - Capillary fragility
  - Due to platelet dysfunction and capillary fragility

(CRF: chronic renal failure).

**Table 13.26:** Clinical features of chronic kidney disease (CKD).

System	Clinical feature	Cause
Renal	Nocturia and polyuria	Impaired concentrating ability of kidney
Muscle	Generalized myopathy	Combination of poor nutrition, hyperparathyroidism and vitamin D

		deficiency
Gastrointestinal	Malaise, loss of appetite (anorexia), nausea, vomiting, diarrhea	Nitrogenous waste products
Metabolic	Paresthesia and tetany	Hypocalcemia
Endocrine	Loss of libido in both sexes Women: Amenorrhea, menorrhagia Males: Erectile dysfunction, oligospermia	Hypothalamic-pituitary axis dysfunction
Skeletal	Bone pain	Metabolic bone disease
Respiratory	Pleural effusion, interstitial lung disease, calcification	Salt and water retention
Hematologic	Symptoms due to anemia: Fatigue, lassitude	Anemia is normochromic and normocytic type. Various causes mentioned in Table 13.35
Skin	Pruritus/itching, rash, metastatic calcification	Retention of nitrogenous waste products of protein catabolism, hyperparathyroidism, calcium-phosphate deposition
Immune system	Infections	Leukocyte functional defects, reduced cellular immunity
Cardiovascular	Atherosclerosis, heart failure, hypertension	Hypertension, homocysteinemia, calcification of heart valves
Neurologic	Peripheral neuropathy, mental slowing, clouding of consciousness and seizures myoclonic twitching, coma, restless leg syndrome or sensory deficits	Uremic toxins
Serosal inflammation	Pericardial or pleural pain and fluid, peritoneal fluid	Water retention

**Q. Write short essay/note on renal osteodystrophy.**

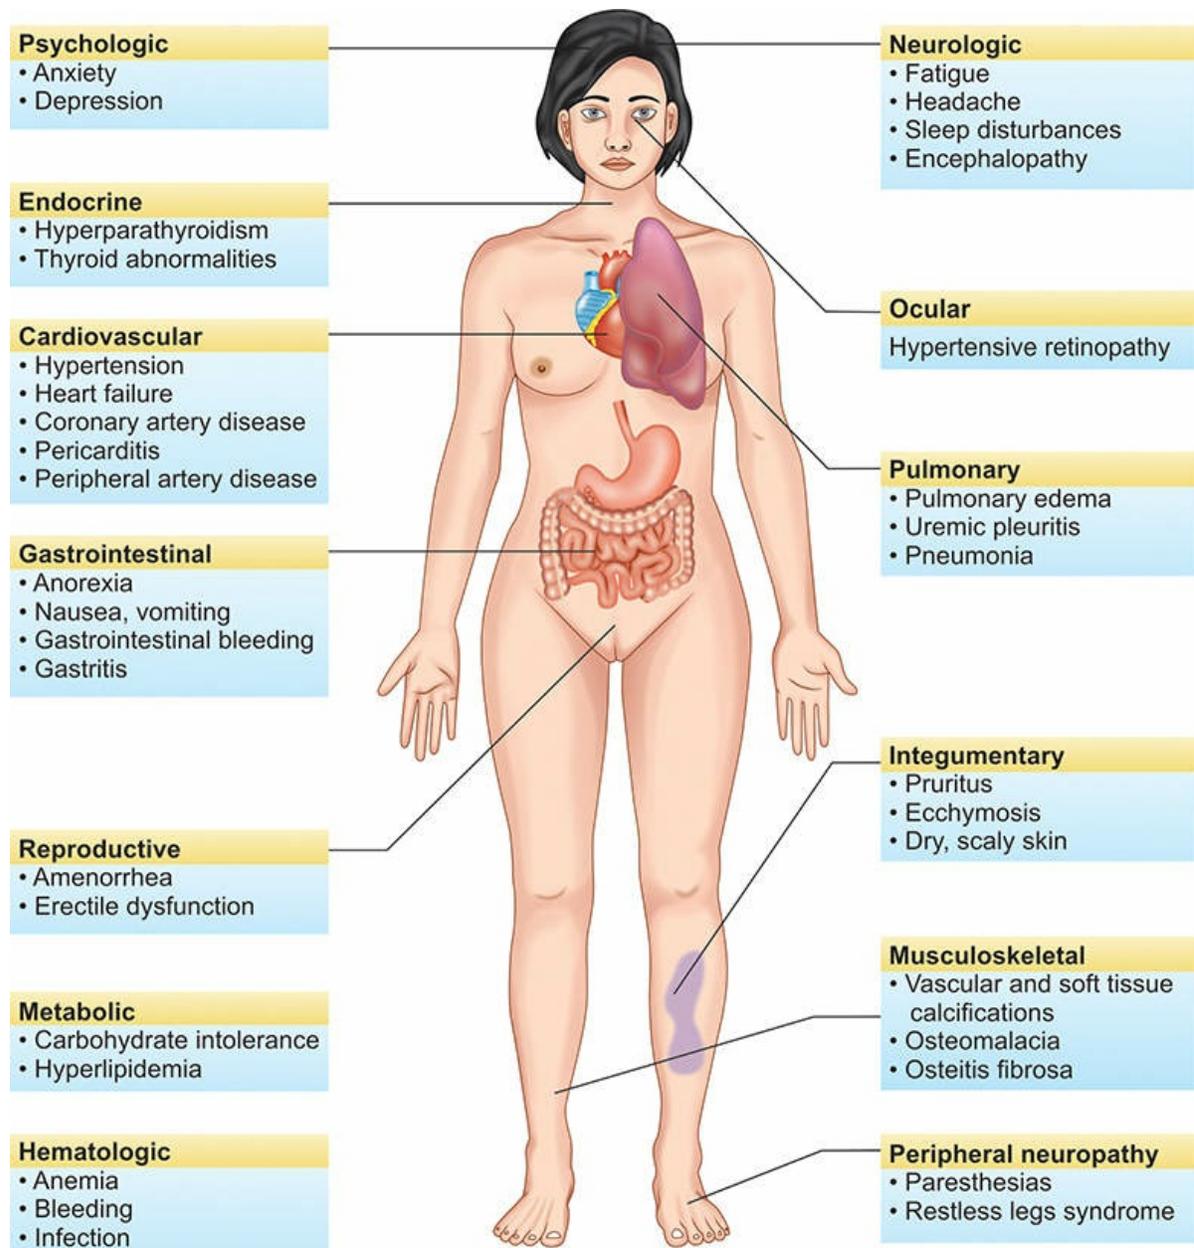

### ***Metabolic Bone Disease: Renal Osteodystrophy***

The term ‘renal osteodystrophy’ (bone mineral disorder), constitutes various forms of bone disease that may develop alone or in combination in chronic renal failure. It includes (1) hyperparathyroid bone disease (osteitis fibrosa cystica), (2) osteomalacia, (3) osteoporosis, (4) osteosclerosis, and (5) adynamic bone disease.

*Pathogenesis of bone disease (Fig. 13.17)*

- Phosphate retention owing to reduced excretion by the kidneys release of fibroblast growth factor 23 (FGF 23) and other phosphaturic agents by osteoblasts as a compensatory mechanism. Actions of FGF 23 are:

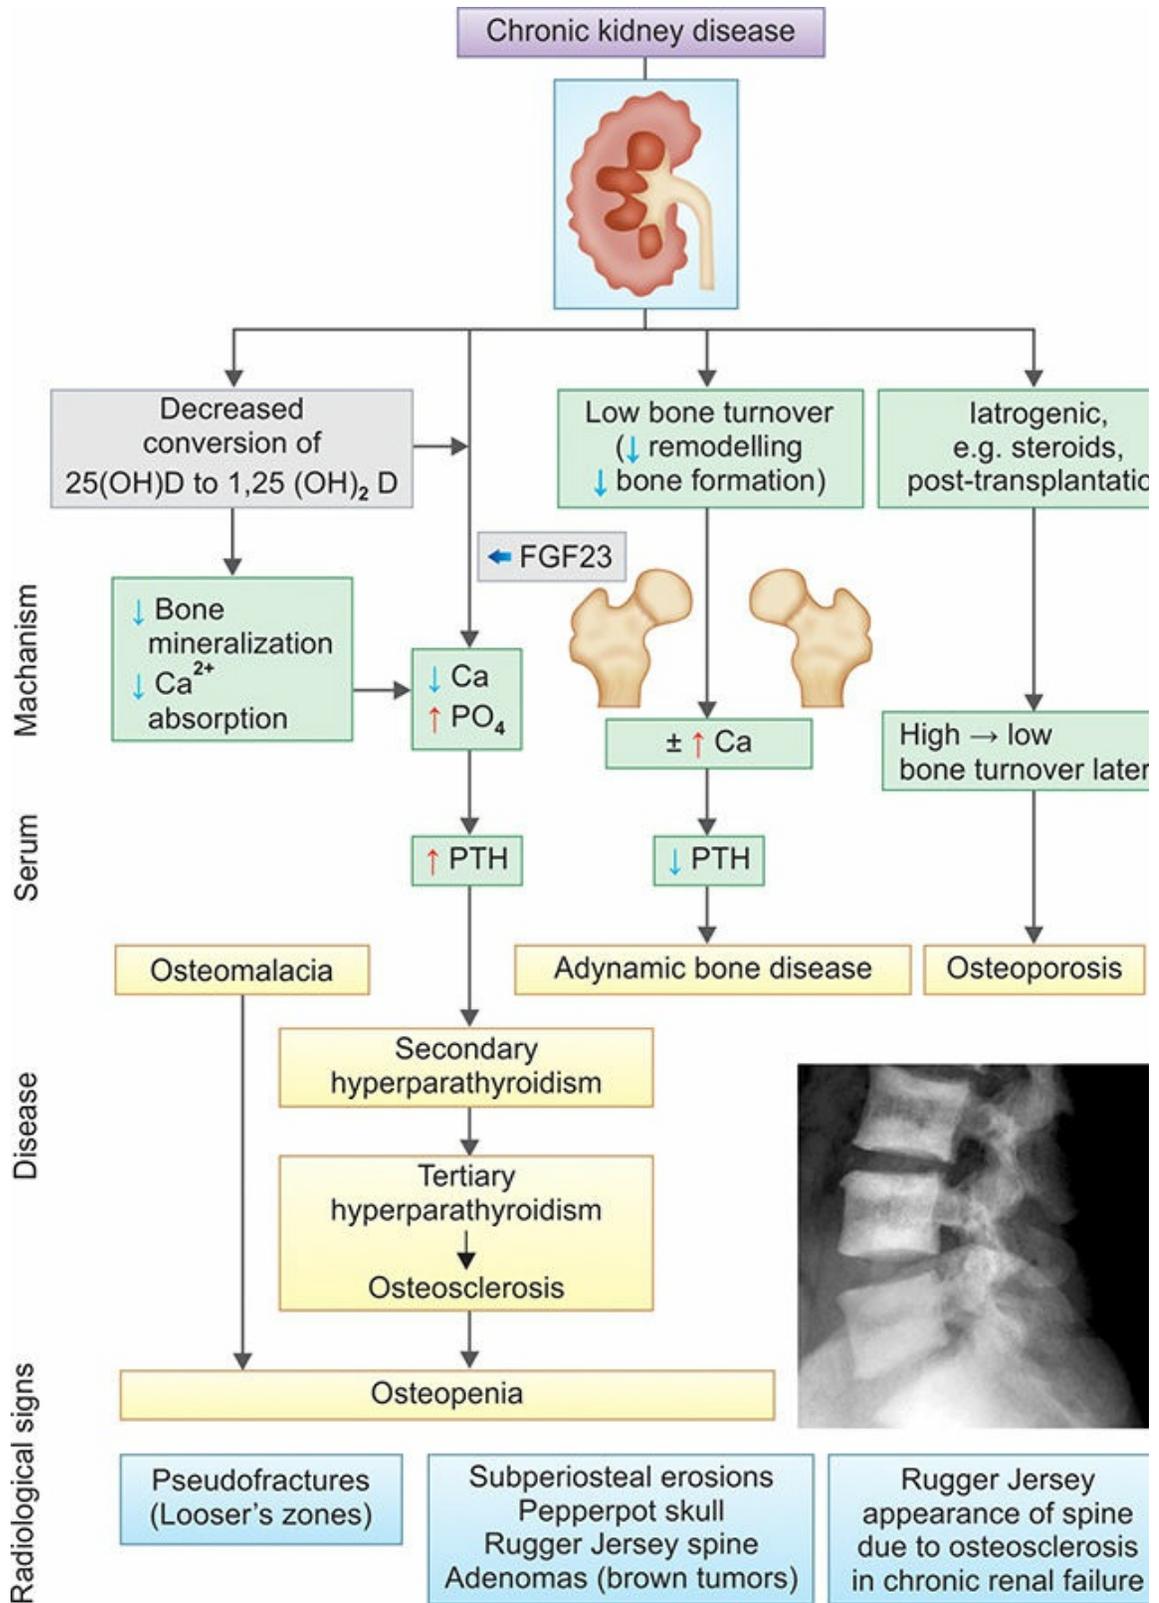

- Causes phosphaturia to normalize the plasma phosphate level.
- It downregulates  $1\alpha$ -hydroxylase to reduce intestinal absorption of phosphate.
- Decreased production of the  $1\alpha$ -hydroxylase enzyme by the kidney results in reduced conversion of  $25\text{-(OH)}_2\text{D}_3$  (25-hydroxyvitamin D) to the more metabolically active  $1,25\text{-(OH)}_2\text{D}_3$  (1,25-dihydroxycholecalciferol). Its consequences are:
  - Decreased activation of vitamin D receptors (VDR) in the parathyroid glands leads to increased release of parathyroid hormone (PTH) causing secondary hyperparathyroidism.
  - Decreased intestinal absorption of calcium causes hypocalcemia which leads in turn to increased PTH production by the parathyroid glands.

**Fig. 13.16:** Various clinical manifestations of chronic kidney disease (CKD).

- Phosphate retention also indirectly lowers ionized calcium and these together results in an increase in PTH synthesis and release. The raised serum phosphate combine with calcium in the extracellular space, causing ectopic calcification in blood vessels and other tissues.
- PTH causes reabsorption of calcium from bone and increased reabsorption of calcium from proximal renal tubules. This prevents hypocalcemia induced by  $1,25\text{-(OH)}_2\text{D}_3$  deficiency and phosphate retention.

- **Secondary hyperparathyroidism** causes increased osteoclastic activity, cyst formation and bone marrow fibrosis (osteitis fibrosa cystica).
- Long-standing secondary hyperparathyroidism finally causes hyperplasia of the glands with autonomous or '**tertiary**' **hyperparathyroidism**.
- **Osteomalacia:** It is due to impaired mineralization of osteoid caused by deficiency 1,25-(OH)<sub>2</sub>D<sub>3</sub> and hypocalcemia.
- **Osteosclerosis:** Literally means 'hardening of bone' characterized by increased bone density and is due to the direct result of longstanding parathyroid hormone excess. Alternating bands of sclerotic and porotic bone in the spine give rise to a characteristic '**rugger jersey**' appearance on X-ray (Fig. 13.17).
- **Osteoporosis** is probably related to malnutrition and is commonly found in CRF, often after transplantation and the use of corticosteroids.
- **Adynamic bone disease** is the condition of in which both bone formation and resorption are depressed.
- **Gastrointestinal complications:** (1) reduced gastric emptying and increased risk of reflux esophagitis, (2) increased risk of peptic ulceration and acute pancreatitis and (3) constipation (especially in patients on continuous ambulatory peritoneal dialysis (CAPD) and (4) gastrointestinal bleed.
- **Metabolic abnormalities**
  - **Gout:** Urate retention is a common in CRF.

**Fig. 13.17:** Lateral spine X-ray showing Rugger jersey appearance of spine.

[25-(OH)D<sub>3</sub>: 25-hydroxyvitamin D; 1,25-(OH)<sub>2</sub>D<sub>3</sub>: 1,25-dihydroxycholecalciferol; FGF23:

fibroblast growth factor 23; Ca: calcium; PO<sub>4</sub>: phosphate; PTH: parathormone]

- **Insulin requirement and resistance:** Insulin is catabolized by and to some extent excreted via the kidneys. Thus, insulin requirements in diabetic patients reduce as renal failure progresses. By contrast, end-organ resistance to insulin is observed in advanced renal impairment.
- **Lipid metabolism abnormalities:** Include (1) impaired clearance of triglyceride-rich particles and (2) hypercholesterolemia.
- **Endocrine abnormalities:** Include (1) hyperprolactinemia, (2) increased luteinizing hormone (LH) levels in both sex, (3) decreased serum testosterone levels, (4) absence of normal cyclical changes in female sex hormones, resulting in oligomenorrhea or amenorrhea, (5) abnormalities of growth hormone secretion and action, and (6) abnormal thyroid hormone levels.
- **Muscle dysfunction proximal myopathy.**
- **Nervous system**
  - *Central nervous system:*
    - ◆ Unusual combination of depressed cerebral function and decreased seizure threshold.
    - ◆ **Dialysis disequilibrium** develops if rapid correction of severe uremia is done by hemodialysis owing to osmotic cerebral swelling.
    - ◆ **Dialysis dementia** is a syndrome characterized by progressive intellectual deterioration, speech disturbance, myoclonus and fits.
  - *Autonomic nervous system:* (1) Increased circulating catecholamine level, (2) impaired baroreceptor sensitivity, and (3) impaired efferent vagal function.
  - *Peripheral nervous system:* (1) Median nerve compression in the carpal tunnel due to  $\beta_2$ -microglobulin-related amyloidosis, (2) restless legs syndrome and (3) polyneuropathy and (4) psychiatric problems (anxiety, depression, phobias and psychoses).
- **Cardiovascular disease: Increased (16-fold) incidence of cardiovascular disease,** particularly myocardial infarction, cardiac failure, sudden cardiac death and stroke, uremic pericarditis or dialysis pericarditis. Hypertension develops in about 80% of patients with CRF.
- **Malignancy: Raised** incidence of malignancy. Malignant change can occur in polycystic kidney disease. Lymphomas, primary liver cancer and

thyroid cancers can also develop.

### **Box 13.18:** Purpose of investigations in chronic renal failure.

- To identify the underlying cause wherever possible.
- To identify reversible factors (e.g. hypertension, urinary tract, obstruction, nephrotoxic drugs, and salt and water depletion).
- To screen for complications (e.g. anemia, renal osteodystrophy) and cardiovascular risk factors.

## **Investigations**

Box 13.18 lists the purpose of investigations in chronic kidney disease.

### ***Urinalysis***

- **Physical examination:** Fixed specific gravity around 1.010 (isosthenuria) is seen in CRF.
- **Chemical examination**
  - Hematuria may indicate glomerulonephritis.
  - Proteinuria, if heavy, is strongly suggestive of glomerular disease.
  - Glycosuria with normal blood glucose level is common in CRF.
- **Urine microscopy**
  - **White cells** in the urine usually indicate **bacterial urinary infection**, sterile pyuria suggests papillary necrosis or renal tuberculosis.
  - **Eosinophils** indicate **allergic tubulointerstitial nephritis** or cholesterol embolization.
  - **Red cells** source may be from anywhere in the urinary tract between the glomerulus and the urethral meatus.
  - **Red-cell casts** are suggestive of **glomerulonephritis**.
  - **Granular casts** indicate **active renal disease**.
  - **Broad casts** are seen in CRF.
- **Urine culture** should be performed. Early-morning urine samples should be cultured for tuberculosis.

### ***Urine Biochemistry***

- **24-hour creatinine clearance** is useful to know the severity of renal failure.
- **Urine osmolality** is a measure of concentrating ability.
- **Urine electrophoresis** and immunofixation for the detection of light chains in myeloma.

### ***Serum Biochemistry***

- **Serum urea and creatinine:** The most consistent abnormalities in CRF are **elevated** levels of urea and creatinine. The level of serum creatinine correlates with the degree of renal damage.
- **Electrophoresis and immunofixation for myeloma.**
- Extreme elevations of creatine kinase and a disproportionate elevation in

serum creatinine and potassium compared to urea suggestive of rhabdomyolysis.

- Other biochemical abnormalities include hypocalcemia, hyperphosphatemia, hyperuricemia and hyperkalemia.

### ***Hematology***

- **Anemia**
- **Eosinophilia** suggestive of allergic tubulointerstitial nephritis, vasculitis, or cholesterol embolism.
- **Peripheral smear with fragmented red cells (Burr cells) and/or thrombocytopenia** suggestive of **intravascular hemolysis** due to accelerated hypertension, hemolytic uremic syndrome or thrombotic thrombocytopenic purpura.
- **Markedly raised ESR** is suggestive of **myeloma**.

### ***Immunology***

- **Low complement components** may be seen in **active glomerular disease** (e.g. SLE, poststreptococcal glomerulonephritis).
- **Autoantibody screening** helpful autoimmune diseases (e.g. SLE).
- **Antibodies to streptococcal antigens** (ASOT, anti-DNase B) if post-streptococcal glomerulonephritis is suspected.
- **Antibodies to hepatitis B and C**
- **Antibodies to HIV** when HIV-associated renal disease is suspected.
- **Malaria** can cause glomerular disease in the tropics.

### ***Radiological Investigation***

- **Ultrasound:** Ultrasonography to assess the renal size and to exclude hydronephrosis. Renal ultrasound usually shows shrunken kidneys in CRF. *In diabetic glomerulosclerosis, amyloidosis, polycystic kidney diseases, HIV nephropathy bilateral hydronephrosis and myeloma, the kidneys may be of normal size.*
- **Plain abdominal radiography and CT** (without contrast) to exclude low-density renal stones or nephrocalcinosis. CT may also useful for the diagnosis of retroperitoneal fibrosis and useful in some patients with suspected obstructive nephropathy.

- **MRI:** Magnetic resonance angiography is useful in renovascular disease.

## ***Renal Biopsy***

**Aim:** To establish the nature and extent of renal disease, which helps in treatment and predicting prognosis. It should be performed in patient with unexplained renal failure and normal-sized kidneys (exception diabetic glomerulosclerosis), unless there are strong contraindications.

**Table 13.27: Reversible factors in chronic kidney disease.**

1. Hypovolemia: Vomiting, diarrhea, excessive diuresis, congestive heart failure
2. Urinary tract obstruction: Nephrolithiasis, papillary necrosis, bladder outlet obstruction
3. Infection
4. Uncontrolled or accelerated hypertension
5. Nephrotoxic drugs: Aminoglycosides, cephalosporins, tetracycline, amphotericin, radio-contrast agents, NSAIDs, diuretics
6. Electrolyte and metabolic disorders: Hyperphosphatasemia, hyperuricemia, acidosis
7. Vasculitis: Systemic lupus erythematosus, Wegener's granulomatosis, microscopic polyarteritis
8. Pregnancy: Eclampsia

### **Management of Chronic Renal Failure**

Management of CRF can be divided into three parts:

1. Establishing the diagnosis and etiology of CKD and to detect any reversible factors.
2. Measures to prevent/slow down the further damage to the kidney (progression of CKD).
3. Supportive measures (e.g. dialysis or transplantation) when necessary.
  - **Treatments aimed at specific causes of CKD:** Optimization glucose control in diabetes mellitus, immunomodulatory agents for glomerulonephritis, and emerging specific therapies to retard cytotogenesis in polycystic kidney disease. Any reversible factors should be detected and treated (Table 13.27).

### **Measures to Reduce the Symptoms and Progression of CRF**

- Following measures may stabilize or slow the decline of renal function.
- **Control of hypertension and proteinuria:** Goals of treatment include (1) blood pressure should be reduced <130/80 and proteinuria < 0.3 g/24 hours. If creatinine is below 3 mg/dL, ACE inhibitors and ARBs (inhibit the angiotensin-induced vasoconstriction of the efferent arterioles of the glomerular microcirculation) are the drugs of choice.
- **Diet**
  - **Protein restriction** to 0.60 and 0.75 g/kg per day, i.e. about 40 g/day (with higher amount of essential amino acids). It reduces symptoms associated with uremia and may also slow the rate of renal decline at earlier stages of renal disease.
  - **Avoid foods with high potassium.**
  - **Salt restriction** is necessary in most of the patients. However, patients with salt-losing nephropathy (tubulo-interstitial disease) require a high-salt intake.
- **Slowing progression of diabetic renal disease** by control of blood glucose and maintaining

HbA<sub>1c</sub> in the range of 7.0 to 7.5.

- **Use of lipid-lowering agents:** Hypercholesterolemia is common in patients with significant proteinuria, and in patients with CKD. Lipid lowering reduces vascular events in non-dialysis CKD.
- Cessation of smoking.
- Exercise and weight reduction.
- Avoid nephrotoxic medications.

### ***Corrections of complications***

Calcium and phosphate control and suppression of PTH

- **Treatment of hypocalcemia and hyperphosphatemia:** Both should be treated aggressively.
  - **Hypocalcemia:**
    - ◆ Treated with calcitriol or alfacalcidol (1- $\alpha$ -hydroxyvitamin D<sub>3</sub>) or paricalcitol (19-nor-1,25-dihydroxyvitamin D<sub>3</sub>) and calcium supplementation.
    - ◆ Serum calcium level should be monitored to avoid hypercalcemia. Oral calcium carbonate also decreases the bioavailability of dietary phosphates.
  - **Hyperphosphatemia:** Treated with phosphate binders. Previously, aluminium hydroxide was used to bind phosphate in the gut and was producing aluminium toxicity. Others include:
    - ◆ Calcium carbonate and calcium acetate (serum calcium should be monitored).
    - ◆ Polymer sevelamer carbonate (an anion-exchange resin).
    - ◆ Lanthanum carbonate (a non-aluminum, non-calcium phosphate-binding agent) has higher incidence of side effects.
- **Treatment of hyperparathyroidism:** By the use of
  - Calcium carbonate or acetate.
  - Vitamin D analogues.
  - Calcimimetics activate the calcium-sensing receptor in the parathyroid gland, thereby inhibiting PTH secretion. Cinacalcet is used in patients who are on dialysis.

### ***Maintenance fluid and electrolyte balance***

- **Fluid retention:** If there is evidence of fluid retention intake of dietary sodium is restricted and loop diuretics may be necessary.
- **Hyperkalemia:** Usually responds to dietary restriction of potassium intake. Occasionally, ion-exchange resins may be necessary to remove potassium in the gastrointestinal tract. If hyperkalemia occurs during diuretic therapy, reduce or stop potassium-sparing diuretics, ACE inhibitors and ARBs.
- **Acidosis:** Sodium bicarbonate may be effective, but can cause edema and hypertension owing to extracellular fluid expansion. Calcium carbonate, also used as a calcium supplement and phosphate binder is useful in treating acidosis.

## **Q. Write short essay/note on the management of anemia in chronic renal failure.**

### **Treatment of anemia in chronic renal failure**

- The anemia of erythropoietin (EPO) deficiency is treated with recombinant (synthetic) human EPO (erythropoietin-alpha or -beta, or the longer-acting darbepoetin-alpha). Administration of erythropoietin-alpha through subcutaneous route is contraindicated in CRF and the intravenous

route is used, initially 50 U/kg of epoetin-alpha over 1–5 min three times/week. EPO is less effective in the presence of iron deficiency, active inflammation or malignancy, and in patients with aluminium overload (found in dialysis).

- Blood pressure, hemoglobin concentration and reticulocyte count are measured every 2 weeks and the dose adjusted to maintain a target hemoglobin level of 10–12 g/dL.
- Hemoglobin >13 g/dL has been associated with increased incidence of cardiovascular mortality.
- **Specific treatment:** Renal replacement therapy (refer pages 908-12).

Table 13.28 lists the differences between acute kidney injury (AKI) and chronic kidney disease (CKD).

**Table 13.28:** Differences between acute kidney injury (AKI) and chronic kidney disease (CKD).

	<i>AKI</i>	<i>CKD</i>
Previous history of kidney disease	Absent	Present
Previous elevated creatinine >3 months	Absent	Present
Anemia	Absent	Present
Hypertension	+/-	++
Kidney	Not contracted	Contracted
Complications: Hyperphosphatemia, hypocalcemia, neuropathy, osteodystrophy, band keratopathy	Absent	Present

## CYSTIC DISEASES OF KIDNEY

### Polycystic Kidney Diseases

**Q.** Write a short essay/note on polycystic kidney diseases.

**Types:** *Two types*

1. **Autosomal-recessive (childhood) polycystic kidney disease (ARPKD):**

- A gene for ARPKD has been located on chromosome 6.
- All patients also have cysts in the liver and patients who survive infancy may develop **congenital hepatic fibrosis** and intrahepatic bile duct dilatation (Caroli disease).

## 2. Autosomal-dominant (adult) polycystic kidney disease (ADPKD):

- It is **more common** hereditary disorder. ADPKD is genetically heterogeneous disorder caused by **mutations in** either ***PKD1*** on chromosome 16 (85% of cases) or ***PKD2* gene** on chromosome 4 (15%).
- It characterized by **multiple thin-walled, spherical cysts in cortex and medulla of both kidneys**. These cysts expand and cause destruction of kidney parenchyma and leads to renal failure.
- **Associated extrarenal anomalies:**
  - **Cysts in other organs** such as liver (**polycystic liver disease** in more than 75% of cases) spleen, pancreas, thyroid, ovary, endometrium, seminal vesicles and epididymis.
  - Intracranial **berry aneurysms** in the circle of Willis (in 10–30%) which may rupture and cause subarachnoid hemorrhages.
  - **Mitral valve prolapse** and other cardiac valvular anomalies.
- **Clinical presentation**

### **Q. Write short note on clinical features and complications of adult polycystic kidney disease.**

- May be at **any age** from the second decade and majority of patients remain **asymptomatic until the fourth decade** of life.
- **Presenting manifestations**
  - ◆ Acute loin/**flank pain** (heaviness or dragging sensation), and/or hematuria (owing to hemorrhage into a cyst), UTI (pyelonephritis and renal cyst infection) or urinary tract stone formation and renal colic (due to passage of blood clots in the urine).
  - ◆ Vague abdominal/loin or discomfort due to increased size of the kidneys.
  - ◆ **Subarachnoid hemorrhage** due to rupture of berry aneurysm.
  - ◆ Hypertension and its complications
  - ◆ Complications of associated liver cysts
  - ◆ When sufficient quantity of nephrons are destroyed, patient develops **renal failure** and symptoms of uremia and/or anemia associated with chronic kidney disease.
  - ◆ **Polycythemia** (due to increased erythropoietin production) is a

rare complication and presentation of ADPKD.

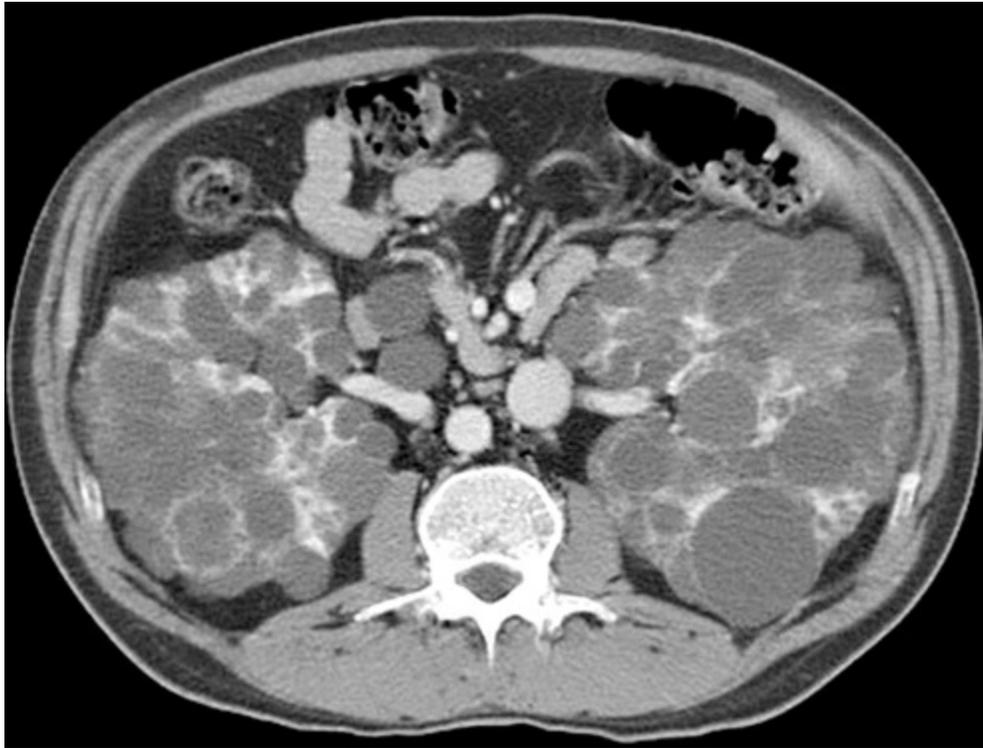

- **Physical examination:** Bilateral large **abdominal masses** of irregular kidneys.

**Investigation:**

- **Abdominal ultrasound** is used for establishing the definitive diagnosis.
- **MRI** is more sensitive than ultrasound and can detect small cysts (Fig. 13.18).
- **IVU:** Rarely performed nowadays and may demonstrate the characteristic ‘drooping water lily sign.’

**Treatment:** Consists of (1) control of hypertension, (2) control of pain, (3) treatment of infection, (4) renal dialysis or transplantation (if required) and (5) Vaptans and Somatostatin analogues have been tried in treatment of ADPKD.

- **Screening:** The children of patients with established ADPKD should undergo screening.

**Fig. 13.18:** MRI showing polycystic kidney.

### **Medullary Sponge Kidney (MSK)**

- MSK is characterized by non-progressive dilatation of collecting ducts and tubules.

- Usually inherited as autosomal dominant.
- May be associated with other developmental and genetic disorders.
- Often asymptomatic, and may manifest with hematuria, nephrolithiasis and infection.

## Medullary Cystic Disease (MCD) or Juvenile Nephronophthisis (JN)

- Two distinct genetic and age-related forms with similar renal morphology. Autosomal recessive manifests during childhood and is frequently associated with extrarenal abnormalities such as ophthalmologic, mental retardation, cerebellar ataxia, skeletal anomalies and hepatic fibrosis.
- The disease progresses to end-stage renal disease (ESRD) before the age of 25.

## OBSTRUCTIVE UROPATHY

- **Obstructive uropathy** is a term used for obstruction in the urinary passage involving the urethra, bladder, ureters or pelvi-calyceal system. It leads to impedance to urine flow and consequent damage to renal function.
- **Nature of obstruction:** It be acute or chronic.
  - **Acute obstruction:** The changes in kidney function are completely reversible after the relief of obstruction.
  - **Chronic obstruction:** It leads to irreversible structural and functional changes.

## Site and Cause of Urinary Tract Obstruction (Table 13.29)

## NEPHROLITHIASIS

- Nephrolithiasis (also known as kidney stones or renal calculi) is a common disorder characterized by the formation of aggregates of microscopic crystals into solid objects (stones).
- **Constituent:** Usually contain calcium or phosphate along with small amounts of proteins and glycoproteins.
- **Size:** They vary greatly in size from millimeters to centimeters.
- **Age and gender:** It usually appears during middle age and is more

common in men than women (M : F = 2:1).

- **Risk of recurrence:** Calculi recur in about 50% of cases within 3 to 5 years.

## Etiology (Table 13.30)

### Q. Write short note on predisposing factors for renal stones.

- Normal urine contains inhibitors of crystal formation (citrate, inorganic magnesium, pyrophosphate, glycosaminoglycans and nephrocalcin) that prevent the formation of calculi.
- When the chemical concentration of urine is altered, the calculus forming substances may exceed their maximum solubility in water and may favor crystal formation.

**Table 13.29:** Site and cause of urinary tract obstruction.

Site	Cause
Infundibular/pelvis	Congenital, calculi, infection, trauma, tumor
Ureteropelvic junction	Congenital stenosis*, calculi, trauma
Ureter	Obstructive megaureter*, ectopic ureter, ureterocele, calculi*, retroperitoneal tumor (lymphoma), inflammatory bowel disease, retroperitoneal fibrosis, chronic granulomatous disease (tuberculosis)
Bladder	Neurogenic dysfunction*, tumor (rhabdomyosarcoma), diverticula, ectopic ureter
Urethra	Posterior urethral valves*, diverticula, strictures, atresia, ectopic ureter, foreign body, phimosis*, priapism prostatic enlargement*, extrinsic compression due to tumor, lymph nodes

\*Relatively common.

**Table 13.30:** Predisposing factors for renal stones.

#### *Environmental and dietary factors*

- Conditions that favor low volume of urine: High atmospheric temperatures, low intake of fluid
- Diet: High protein, high sodium, low calcium
- High excretion of sodium, oxalate and urate excretion
- Low excretion of citrate

#### *Acquired causes*

- Hypercalcemia
- Ileal disease or resection (increases oxalate absorption and urinary excretion)
- Renal tubular acidosis (RTA) type I (distal)
- Infection: Urinary infection by urea-splitting organisms like *Proteus*, *Pseudomonas*, *Klebsiella*, *Staphylococcus*, and *Mycoplasma*.

#### ***Congenital and inherited disorders***

- Medullary sponge kidney
- Familial hypercalciuria
- Cystinuria
- Renal tubular acidosis (RTA) type I (distal)
- Primary hyperoxaluria

**Table 13.31: Types and causes of renal stones.**

<b>Type</b>
1. Calcium oxalate and/or calcium phosphate (~80%) <ul style="list-style-type: none"> <li>• Idiopathic hypercalciuria: Most common</li> <li>• Hypercalciuria and hypercalcemia</li> <li>• Hyperoxaluria: Enteric (oxalate-containing foods, salt, protein-meat) Vitamin C abuse, primary</li> <li>• Hyperuricosuria</li> <li>• Idiopathic</li> </ul>
2. Uric acid (~7%) <ul style="list-style-type: none"> <li>• Associated with hyperuricemia</li> <li>• Associated with hyperuricosuria</li> <li>• Idiopathic</li> </ul>
3. Struvite (Magnesium, Ammonium, Phosphate)~10% <ul style="list-style-type: none"> <li>• Urinary tract infection</li> </ul>
5. Cystine (~2%)
5. Others/unknown (~1%)

## **Types**

**Q. Write short note on types of renal stones.**

### ***Calcium Stones (Oxalate Calculus/Calcium Oxalate)***

- Most (80%) renal stones are **composed of calcium complexed with oxalate** (calcium oxalate) or **phosphate** (calcium phosphate) or a mixture of these (calcium oxalate + calcium phosphate). These stones are **radiopaque**.

- Causes (Table 13.31).

### ***Uric Acid Stones***

- Commonly found in patients **with hyperuricemia** (e.g. gout) and **diseases involving rapid cell turnover** (e.g. leukemias). However, more than 50% of patients have neither hyperuricemia nor increased urinary excretion of uric acid.
- **Uric acid is insoluble in acidic urine** and **urine pH below 5.5** may **predispose** to uric acid stones.
- Uric acid stones are **radiolucent** stones.
- Causes (Table 13.31).

### ***Struvite Stones or (Triple stones/Magnesium, Ammonium, Phosphate Stones)***

- They are composed of calcium phosphate often with magnesium and ammonium phosphate, and are **known as struvite stones or triple phosphate stones**.
- Causes (Table 13.31): These stones are unique in that they **develop after infections of the urinary tract by urea-splitting bacteria** (e.g. *Proteus*), which convert urea to ammonia → produces alkaline pH + slowing of urine flow (people with abnormal urinary drainage, such as those with ureteral reflux, neurogenic bladder, other forms of bladder dysfunction, or ureteral diversions) → precipitation of magnesium, ammonium, phosphate (struvite), and calcium phosphate (apatite).

### ***Cystine Stones***

- Cystine stones are uncommon and associated with **cystinuria**, which is due to genetic defects in the renal reabsorption of cystine or other amino acids.
- Stones form at **low urinary pH** (acidic urine).
- Cystine stones also are radiopaque.
- Recur frequently in most affected individuals.
- Diagnosis is suggested by a positive urine nitroprusside test and confirmed by analysis of the calculus.
- **Urine sediment:** It may show the characteristic **hexagonal cystine**

**crystals** and crystal formation is favored in acidic urine (low pH).

## Clinical Manifestations

- **Most common** presenting symptoms: (1) **Severe colicky flank and/or abdominal pain** radiating to the anterior abdominal wall and (2) **hematuria** (microscopic or gross). This symptom complex termed renal or ureteric colic. These symptoms are due to partial or full obstruction produced by stones while passing through the ureter.
- **Asymptomatic:** Stone is **incidentally discovered** in an abdominal computed tomography or ultrasound examination for other purposes.
- **Symptoms depending on the site of stone:**
  - **Stones in the renal pelvis usually are painless** unless infection or obstruction is present.
  - **Ureteral stones may cause nausea, vomiting, and severe abdominal and/or flank pain** radiating into the groin, urethra, or genitalia.
  - **Stones at the ureterovesical junction** may produce **dysuria, frequency, and urgency**, even in the absence of infection.
  - Once in the bladder, stones are normally passed out without difficulty, but they can remain there and grow to very large sizes in patients with bladder dysfunction.
- Fever and pyuria suggest associated urinary tract infection and must be confirmed by urine culture.
- Chronic and complete obstruction can result in hydronephrosis and loss of function in the affected kidney.

## Diagnosis/Investigations (Table 13.32)

- **CT-KUB** (CT of kidney, ureter and bladder) is the **gold standard** for diagnosis. It defines the size and location of any stones (including non-radiopaque stones, such as those containing uric acid and cysteine) in the urinary tract.
- **Abdominal ultrasound or intravenous pyelograms (IVP)** are generally inferior in sensitivity and specificity compared to the computed tomography scan.
- A **plain X-ray of the abdomen** (Fig. 13.19) has limited diagnostic utility, but may be useful to track progression of previously diagnosed radiopaque stones.

- **Urine analysis:** To confirm the presence of **blood** and check for **evidence of infection**. **Urinary sediment** should be examined under the microscope for crystals. Any stones passed in urine should be saved for analysis. Metabolic evaluation of stones should always be performed before starting on a therapeutic regimen. **Urine culture** should be done when clinically indicated.
- **Laboratory tests:** These include serum studies for renal function, electrolytes, calcium, magnesium, phosphate, and uric acid. If there is hypercalcemia, a parathyroid hormone level should be obtained.

**Fig. 13.19:** X-ray shows staghorn calculi.

### **Table 13.32:** Important investigations in patients with renal calculi.

1. Routine urine examination (albumin, RBC, WBC, casts and crystals and pH)
2. Renal functions (blood urea, serum creatinine)
3. Imaging (ultrasonography and IV urography)
4. To find out underlying cause

- Chemical analysis of calculus passed in urine
- Plasma calcium, phosphate and parathormone
- 24-hour urine for estimation of calcium, oxalate, urate, cysteine

## Treatment

### Acute Management

- **Acute colic** should be treated with an effective/powerful **analgesic**. Diclofenac orally or IV infusion or as a suppository is very effective. However, opiates may be needed.
- **Increase the water intake** to maintain a daily urine output of 2 L or more. If this is not possible, **intravenous fluids** should be given to **increase urinary output**.
- Stone removal **strategies** are **based on the size of the stone**.
  - Most small calculi (<5 mm in diameter) usually **pass spontaneously**.
  - **Alpha blockers** (e.g. tamsulosin) facilitate spontaneous expulsion of distal **ureteral stones of <6 mm size**.
  - **Stones >1 cm diameter** usually need **urological or radiological intervention**. Extracorporeal shock wave lithotripsy (ESWL) causes fragmentation of most of the stones into pieces <5 mm, which then pass spontaneously. Uteroscopy with a YAG laser (for larger stones) and percutaneous nephrolithotomy also can be used. Open surgery is rarely necessary.
- **Surgical removal** is attempted only if the stone passage becomes complicated. Complicating features include failure to pass stone in 3 to 7 days, acute renal failure, gross hematuria with clots, or infection. Open surgical procedures are very rarely performed. Endoscopic or surgical removal is recommended for: (a) persistent pain not relieved by analgesia, (b) stone obstructing a single kidney, or bilateral ureteral obstruction and/or pyonephrosis.

### Chronic Management

- **Fluid: Increase the urine volumes** (dilution) so that it reduces supersaturation and prevents new stone formation. Increase the fluid intake until daily urine output exceeds 2–3 L.
- **Avoid:** Vitamin D supplements (increase calcium absorption and excretion) and vitamin C supplementation (increases oxalate excretion).
- **Calcium-containing stones**
  - **Modification of diet** to reduce risks of stone formation in recurrent stone formers (>5 years between episodes).
  - **Thiazide diuretics** (e.g. 12.5–25 mg of hydrochlorothiazide) reduce urinary calcium excretion and are useful in hypercalciuric calcium stone formers.
  - **Potassium citrate** (60 mEq per day) in divided doses is used in hypocitraturia and also helps to prevent recurrence in patients with normal urinary citrate levels.
  - **Oxalate:** Avoid foods rich in oxalate (spinach, rhubarb).
- **Uric acid stones**
  - In patients with hyperuricosuria (>1,000 mg of uric acid per 24 hours) and normal serum calcium, **allopurinol** in the dose of 100 to 200 mg/day reduce uric acid synthesis.
  - **Alkalinization of the urine** to a pH of 7 or above to increase uric acid solubility and to dissolve uric acid crystals. This is achieved by supplementation with potassium citrate, potassium bicarbonate, or sodium bicarbonate in divided doses, or acetazolamide to alkalinize the nocturnal urine.
- **Cystine stones:** Decrease the urinary concentration of cystine below the solubility limit of 200 to 300 mg/L. Apart from the methods already described, alkalinization of the urine to a pH above 7.5

is critical. This usually can be achieved with Shohl's solution (contains sodium citrate).

## URINARY TRACT INFECTIONS

**Q. Discuss the etiopathogenesis, clinical features, investigations and management of urinary tract infection.**

### Definition

A urinary tract infection (UTI) is associated with multiplication of organisms in the urinary tract and is defined as the presence of more than  $10^5$  **organism/mL** in the midstream sample of urine (MSU).

**Table 13.33: Clinical spectrum of urinary tract infection.**

<i>Asymptomatic bacteriuria (ABU)</i>	<i>Symptomatic (disease)</i>
<p>Presence of bacteriuria (<math>&gt;10^5</math>/mL or two occasions in females and on one occasion in males) indicating UTI but without symptoms.</p> <ul style="list-style-type: none"><li>• Common in pregnancy</li><li>• Occurs in the absence of symptoms</li><li>• Does not usually require treatment</li></ul>	<ul style="list-style-type: none"><li>• Includes<ul style="list-style-type: none"><li>– Acute urethritis</li><li>– Acute cystitis</li><li>– Acute prostatitis</li><li>– Acute pyelonephritis</li><li>– Renal abscess</li><li>– Septicemia with septic shock</li></ul></li><li>• Requires antimicrobial therapy</li></ul>

### Clinical Presentation (Table 13.33)

#### Anatomic Classification of Urinary Tract Infections (UTI)

- **Lower urinary tract infections:** Include cystitis (bladder), prostatitis and urethritis.
- **Upper urinary tract infections:** Include infection of kidneys and their collecting systems (pyelonephritis) and perinephric abscess.

### Etiology

**Q. What are the predisposing causes of urinary tract infection? What antibiotics are commonly used?**

**Q. Write short note on:**

- **Clinical features and management of cystitis.**

- **Causes of dysuria.**

**Q. Write short essay on:**

- **Etiology and factors responsible for urinary tract infections.**
- **Risk factors for urinary tract infections.**

**Causative organisms:** Majority (~85%) of urinary tract infection are the caused by **gram-negative bacilli** which are normal inhabitants of the intestinal tract (enteric origin).

- **Most common pathogens:** *Escherichia coli* (80% cases), *Proteus*, *Klebsiella*, *Enterobacter*, and *Pseudomonas*.
- **Less common:** *Streptococcus faecalis*, staphylococci, and fungi.
- **In immunocompromised patients:** **Viruses** (polyoma virus, cytomegalovirus, and adenovirus).

### Pathogenesis (Fig. 13.20)

**Q. Differences between male and female urinary tract infection.**

**Route of infection:** Bacteria can reach urinary tract via the bloodstream, the lymphatics or by direct extension (e.g. from a vesicocolic fistula), but in majority of cases via the ascending transurethral (via the urethra) route.

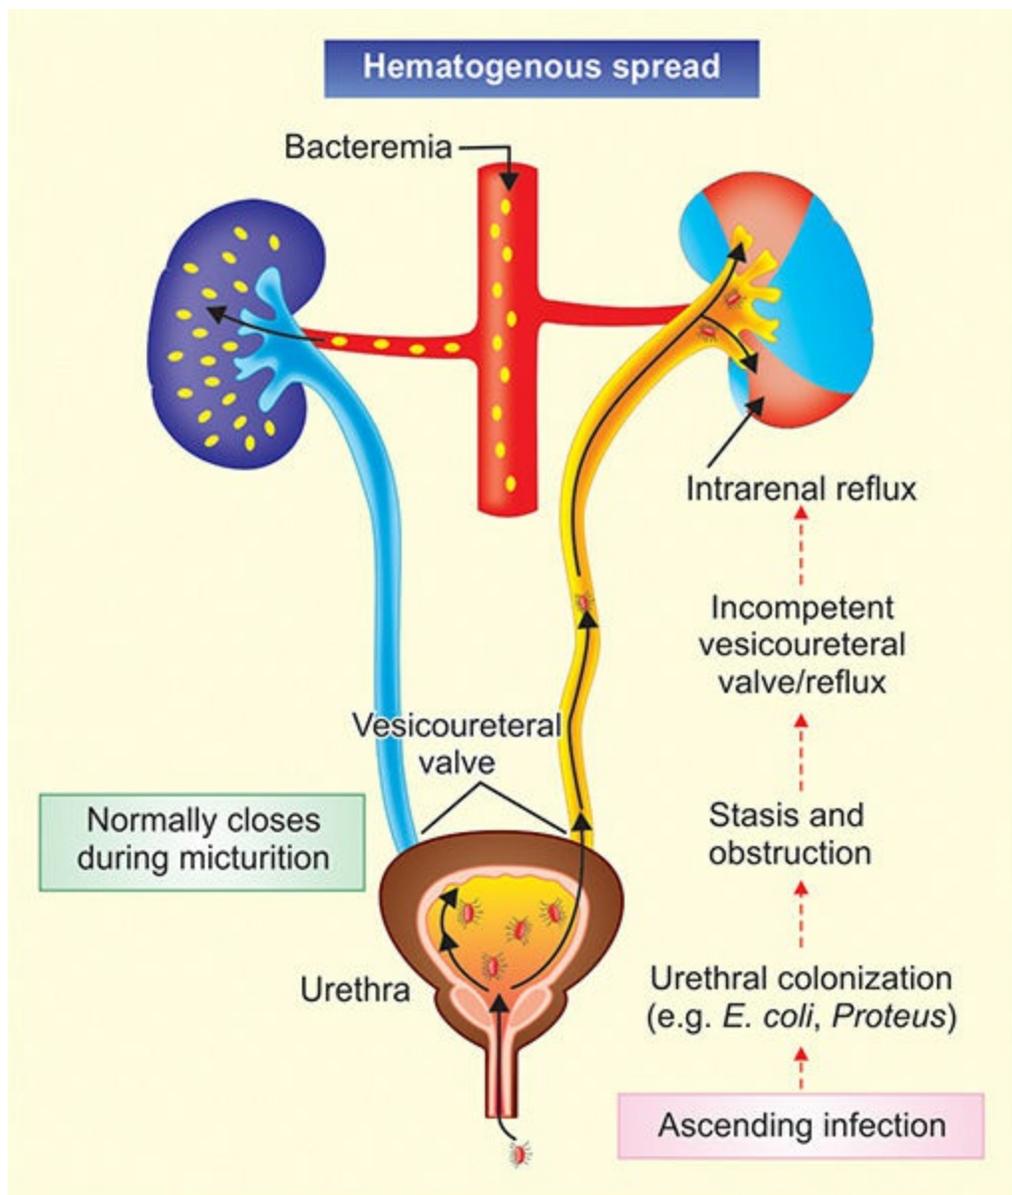

**A. Ascending infection:** It is the **most common route** of infection of the renal parenchyma, i.e. pyelonephritis. It is a form of endogenous infection, where the source of infecting organisms is the **patient's own fecal flora**. The infection ascends from the lower urinary tract into the renal parenchyma. Different steps in the pathogenesis of pyelonephritis are:

- **Colonization of the distal urethra and introitus** (in the female): By enteric or coliform bacteria from the perineum due to poor hygiene and hormonal effects.
- **Entry from the urethra to the bladder:** Organisms may enter the bladder during **urethral catheterization or other instrumentation**. Urinary infections are **more common in females**, because of:
  - Shorter urethra (4 cm).
  - Absence of prostatic fluid which has antibacterial properties
  - Hormonal changes in women which affect the adherence of bacteria to the mucosa.

- Trauma to the urethra during sexual intercourse facilitates entry of introital bacteria into the bladder.
- Gram-negative enteric organisms residing around the anal region also colonize the periurethral region.
- **Urinary tract obstruction and stasis of urine**

**Q. Write short note on causes of urinary tract infection in male.**

- **Obstruction/bladder dysfunction:** Causes incomplete emptying and increased residual volume of urine. Examples: benign prostatic hypertrophy, tumors, strictures, or calculi.
  - **Neurogenic bladder dysfunction:** Diabetes, spinal cord injury, tabes dorsalis and multiple sclerosis predisposes to UTI.
  - **Stasis:** Organisms introduced into the bladder can multiply when there is stasis.
- B. Hematogenous route:** It is less common route of infection. Because of rich blood supply, bacteria can seed the kidneys during the course of septicemia or infective endocarditis through the bloodstream. It occurs with nonenteric organisms (e.g. Staphylococci), fungi and viruses. Hematogenous infections occur in: (i) the presence of ureteral obstruction, (ii) debilitated patients and (iii) patients receiving immunosuppressive therapy.

**Fig. 13.20:** Pathogenesis of acute pyelonephritis. More common mode is ascending infection. Hematogenous infection results from bacteremic spread.

## Clinical Features (Table 13.34)

**Q.** Write short essay/note on the symptoms, diagnosis and treatment of acute urinary infection.

**Table 13.34:** Clinical features of urinary tract infection (UTI).

- |                                |  |
|--------------------------------|--|
| • Fever with chills and rigors | • Suprapubic pain and tenderness resulting from cystitis |
|--------------------------------|--|

- Micturition abnormalities
  - Increased frequency of micturition
  - Dysuria (painful voiding) or scalding micturition
  - Urgency
  - Strangury: Intense desire to pass more urine after the bladder has been emptied. It is due to detrusor spasm and occurs in cystitis.
- Urine:
  - Hematuria
  - Cloudy urine with an unpleasant odor

(UTI: urinary tract infection).

## Uncomplicated versus Complicated Infection (Table 13.35)

**Table 13.35:** Differences between uncomplicated versus complicated UT infection.

<i>Features</i>	<i>Uncomplicated urinary tract infection</i>	<i>Complicated urinary tract infection</i>
Characteristics	UTI occurring in patients with functionally normal urinary tracts	UTI occurring in patients with abnormal urinary tracts (e.g. with stones, or associated diseases such as diabetes mellitus) or infection that extends beyond the bladder
Lesions	Includes cystitis or urethritis due to bacterial colonization of the bladder or urethra	Infection of renal parenchyma and renal pelvis (pyelonephritis) or prostate (prostatitis)
Sex affected	Much more in females than in males	Infection in men often considered complicated
Predisposing factors	May not be obvious	Usually occurs in presence of obstructive lesions or following instrumentation on urinary tract
Clinical features	Burning on urination and frequent urination without fever or flank pain	Accompanied by fever or flank pain <ul style="list-style-type: none"> <li>• Costovertebral angle tenderness</li> <li>• Pelvic or perineal pain in men (prostatitis)</li> </ul>
Prognosis	Responds well to treatment and persistent or recurrent infection seldom results in serious kidney damage	May be difficult to treat and relapses after treatment are common
Sequelae	Rare	Common like sepsis, metastatic abscesses and renal failure

**Acute urethral syndrome:** About one-third of females with dysuria and pregnancy have either insignificant bacteria in midstream culture or completely sterile cultures and is known as acute urethral syndrome. It is

often due to infection with usual organisms (culture shows only  $10^2$  to  $10^4$  bacteria) or due to unusual organism (*N. gonorrhoeae*, *Chlamydia trachomatis*).

## Causes of Dysuria (Box 13.19)

### ***Factors Determining the Symptomatic Infection***

- **Virulence:** Ability of the organism to adhere to epithelial cells determines the degree of virulence.
- **Innate host defense:** The following hosts defence mechanisms are required for the prevention of UTI:
  - **Neutrophils:** Activation of neutrophils is necessary for bacterial killing and their impaired function predisposes an individual to severe UTI.
  - **Complement:** Complement activation with IgA production by uroepithelium (acquired immunity) plays a major role in defence against UTI.
  - **Commensal organisms** (e.g. lactobacilli): *Form* part of the normal host defence and their eradication by spermicidal jelly or disruption by certain antibiotics results in overgrowth of *E. coli*.
  - **Urine flow** and normal micturition: Wash out bacteria and stasis of urine predisposes to UTI.
  - **Uroepithelium—mannosylated proteins:** Such as Tamm-Horsfall proteins (THP), have antibacterial properties and are present in the mucus and glycocalyx covering uroepithelium. Normally, they interfere with bacterial binding to uroepithelium. Thus, disruption of this uroepithelium by trauma (e.g. sexual intercourse or catheterization) predisposes to UTI.
- Pregnancy is associated with an increased incidence of UTI. Factors that favor UTI include: (1) decreased ureteral tone (progestational activity), (2) decreased ureteral peristalsis and (3) transient incompetence of the vesicoureteral valves.

### **Box 13.19:** Causes of dysuria.

- Urinary tract infections (e.g. urethritis, cystitis, vaginitis, pyelonephritis)
- Sexually transmitted infections
- Genital herpes
- Chlamydia

- Gonorrhoea
- Inflammation and irritation of bladder and urethra: e.g. stones

## Honeymoon Cystitis (or ‘Honeymoon Disease’)

### **Q.** Write short note on honeymoon cystitis.

It is cystitis caused as a result of frequent or prolonged sexual activity, as would typically be expected in the honeymoon period of a marriage. It can occur when a woman has sex for the first time, or when a woman has sex after a long period of time without any sexual activity.

**Symptoms:** Same as with cystitis due to other cause.

During sex, *E. coli* on the skin around your anus can be transferred to urethra of women (for example, via partner’s fingers or penis.)

## Investigations

### *Urine Examination*

- **Dip stick tests:** Most gram-negative organisms reduce nitrates to nitrites and dip stick tests (nitrite test) are used to detect nitrite in urine. Dipsticks that detect significant pyuria depend on the release of esterases from leukocyte (leukocyte esterase test). Positive dip stick tests for both nitrite and leukocyte esterase are highly predictive of acute infection.
- **Microscopic examination:** For leukocytes, leukocyte casts and red cells.
- **Culture and sensitivity** of a freshly voided clean-catch midstream specimen of urine.

Box 13.20 lists causes of sterile pyuria.

### **Box 13.20:** Causes of sterile pyuria.

- Partially treated UTI
- Tuberculosis of urinary tract
- Calculi in urinary tract
- Infection with other organisms (e.g. *Chlamydia*, *Corynebacterium*, etc.)
- Tumors of bladder
- Chemical cystitis/drugs
- Prostatitis
- Interstitial nephritis
- Appendicitis

## ***Special Investigations***

- Prostatitis
  - Per rectal examination of the prostate.
  - Prostatic massage followed by urine culture.
- Cystitis: Cystoscopy.
- **Renal ultrasonography CT-KUB, MR urogram:** To identify obstruction, cysts and calculi.
- **Intravenous urography (IVU),** including a post-void film of bladder: To identify physiological and/anatomical abnormalities of urinary tract.
- Dimercaptosuccinic acid (DMSA) renal scan: For pyelonephritis.
- Micturating cystourethrogram (**MCU**) to identify vesicoureteric reflux and disturbed bladder emptying.
- In females with recurrent UTI, **pelvic examination** to exclude cystocele, rectocele and uterine prolapse.

### **Treatment**

- **Antibiotic therapy:** The choice of antibiotic depends on the result of urine culture and sensitivity of urine.
  - The commonly employed antibiotics include cotrimoxazole (Trimethoprim and sulfamethaxazole 1 double strength tablet two times daily), ampicillin (250 mg three times daily), amoxicillin (250 mg 250 mg 8-hourly three times daily), oral cephalosporin, nitrofurantoin (50 mg three times daily), and quinolones. Treatment is over 3–5 days in uncomplicated infections (nitrofurantoin for 7 days) and for 7–10 days in complicated infections.
- **Hospitalized patients:**
  - ##No risk factors for infection with a multidrug-resistant organism → ceftriaxone (1 gram IV once daily) or piperacillin-tazobactam (3.375 grams IV every six hours)
  - ##At least one risk factor for infection with a multidrug-resistant organism → antipseudomonal carbapenem (imipenem 500 mg IV every six hours, meropenem 1 gram IV every eight hours, or doripenem 500 mg IV every eight hours).
  - ##*Enterococcus* species or MRSA are suspected → add vancomycin, daptomycin, or linezolid.
  - ‘Single-shot’ treatment with 3 g of amoxicillin or 1.92 g of co-trimoxazole can be used in patients with bladder symptoms of less than 36 hours duration and without any previous history of UTI.
  - If patients has a calculi, catheter or other obstructions, no antibiotic is necessary unless symptomatic.
- **Fluid intake:** A high (2 L daily) fluid intake during treatment and for some subsequent weeks to initiate water diuresis, so as to maintain a high rate of urine flow.
- **Other measures:**
  - Regular complete emptying of urinary bladder at 2- to 3-hour intervals.
  - Alkalinization of urine

- Urinary analgesics (e.g. phenazopyridine) and antispasmodics (e.g. hyoscyamine) to be given for detrusor spasm.
- If patients presents for the first time with high fever, loin pain and tenderness, urgent renal ultrasound examination is performed to exclude an obstructed pyonephrosis. If this is present percutaneous nephrostomy is performed to drain it.
- Cranberry juice inhibits adherence of uropathogens to uroepithelial cells, hence advisable to prevent recurrent UTI.
- In females: The incidence of UTIs can be reduced by (1) adequate perineal hygiene, (2) emptying the bladder before bedtime and before and after intercourse and (3) application of 0.5% cetrimide cream to periurethral area before intercourse. Atrophic vaginitis should be identified and treated in post-menopausal women.
- Avoidance of constipation (may impair bladder emptying).
- **Asymptomatic bacteriuria:** It requires treatment (1) if a patient is pregnant, (2) in case of renal transplantation or (3) before planning for a urologic surgery. Treatment of asymptomatic bacteriuria in pregnant women decreases the occurrence of pyelonephritis.

## ACUTE PYELONEPHRITIS

**Q. Discuss the etiology, clinical features, investigations, diagnosis and management of acute pyelonephritis.**

**Q. Write short essay/note on common causes, diagnostic features and management of upper urinary tract infections.**

- **Definition:** Acute pyelonephritis is an acute suppurative inflammation of upper urinary tract affecting the tubules, interstitium, and renal pelvis. There is often coincident cystitis.

### Clinical Features

- **Classic triad:** (1) loin pain, (2) fever and (3) tenderness over the kidneys. Presence of this triad and significant bacteriuria usually indicates acute pyelonephritis.
  - Sudden onset of pain in one or both loins (costovertebral/renal angle), radiating to the iliac fossa and suprapubic area.
  - Fever with chills and rigors, and malaise.
  - **Tenderness and guarding in the renal angle.**
  - Dysuria, frequency, and urgency. Frequent passage of small amount of urine accompanied by scalding. Cloudy urine.
  - Acute pyelonephritis caused by the presence of obstruction (e.g. stone, tumor, bladder neck obstruction, enlarged prostate), can be very severe

and may progress to renal abscess.

- Rarely, acute pyelonephritis may be associated with necrotizing papillitis /papillary necrosis. Causes include diabetes mellitus, chronic urinary obstruction, analgesic nephropathy and sickle-cell disease.

## Investigations

**Q. Write short note on urinary abnormalities in acute pyelonephritis.**

- **Peripheral blood:** Characteristically shows leukocytosis.
- **Urine examination**
  - **Microscopy** shows numerous pus cells and organisms, WBC casts, some red cells and epithelial cells.
  - **Culture** of midstream urine (MSU) shows growth the causative organism.
- **Other investigations:** When the diagnosis is uncertain, other investigation are required to exclude anatomical abnormalities of the urinary tract. When acute pyelonephritis is severe, the possibility of any obstruction or abscess formation must be excluded. It is also necessary, if there is inadequate response or rapid recurrence of pyelonephritis following appropriate therapy.
  - **Ultrasonography:** Most frequently done, but is relatively insensitive.
  - **Computerized tomography (CT)** is performed if ultrasound is normal. It can detect calculi, obstruction, hemorrhage, gas, enlargement of kidney and inflammatory masses (damaging renal function).
  - **IVU** is usually not done at present.
  - **Radionuclide scan:** The radionuclide agent is injected into bladder through suprapubic route may be useful to detect reflux.
  - **Dimercaptosuccinic acid (DMSA) renal scan:** If performed within 2 days DMSA can help diagnosing acute pyelonephritis. It is advisable to scan after 4–6 months of an acute episode to detect renal parenchymal damage.

## Management

**Intravenous antibiotics:** Intravenous ampicillin, amoxicillin plus aminoglycosides (e.g. tobramycin), cephalosporin (e.g. Cefuroxime), quinolone (e.g. ciprofloxacin) or a combination beta-lactam/beta lactamase inhibitor (piperacillin-tazobactam) or carbapenem (meropenem) (discussed above on page

## Persistent or Recurrent UTI

### **Q. Write short essay/note on persistent or recurrent urinary tract infection and its management.**

- In some patients with UTI, the causative organism persists on repeat culture of urine in spite of treatment, or re-infection develops with any organism after an interval. Such cases, there is more probably an underlying cause is present and hence a more detailed investigation is necessary.
- Recurrent infections are common in females.
- Recurrent UTI, especially in the presence of an underlying cause may produce permanent renal damage. If an underlying cause cannot be treated, suppressive antibiotic therapy can prevent recurrence and reduce the risk of septicemia and renal damage.
- Culture and sensitivity of urine should be at regular intervals.

**Treatment:** Two or three antibiotics in sequence, rotating every 6 months often reduces the emergence of resistant organisms. Other methods discussed above on page 904.

## Emphysematous Pyelonephritis

### **Q. Write short note on emphysematous pyelonephritis**

- It is a type of severe acute pyelonephritis most often caused by *E. coli* and *K. pneumoniae*.
- The major risk factors for emphysematous UTIs are diabetes and urinary tract obstruction.
- The infections primarily occur in women at a mean age of about 60 years.
- Abdominal pain is the major clinical manifestation with renal angle tenderness. Pneumaturia may be seen after bladder catheterization.
- The diagnosis of emphysematous UTIs is made by abdominal imaging; computed tomography is more sensitive than plain films and can detect obstructing lesions.
- Treatment: Parenteral antibiotics, percutaneous drainage/nephrectomy.

# CHRONIC PYELONEPHRITIS

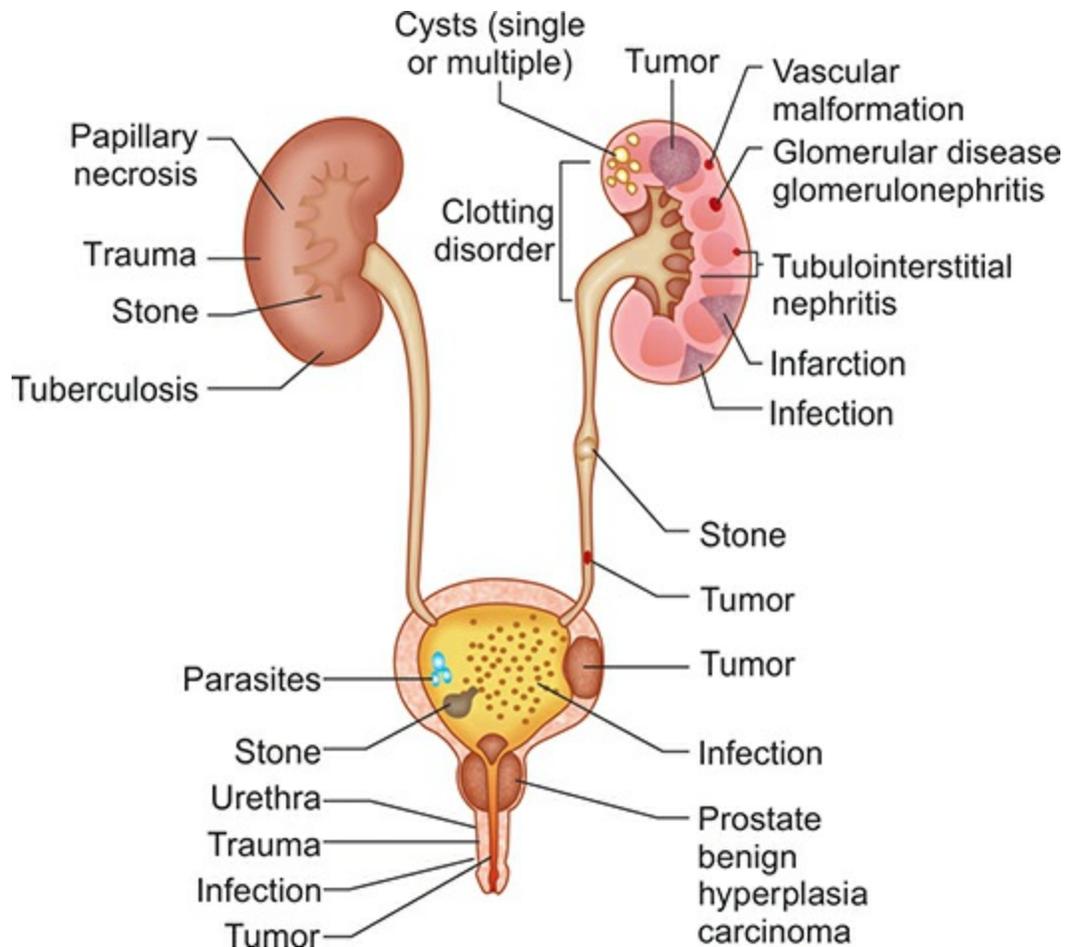

**Q. Write short essay on the clinical features, investigations and management of chronic pyelonephritis (reflux nephropathy).**

Chronic pyelonephritis is a chronic inflammation of tubulointerstitial tissue leading to scarring of calyces, pelvis and renal parenchyma.

## Types

- **Reflux nephropathy (chronic reflux-associated pyelonephritis/atrophic pyelonephritis):** It results recurrent UTIs from a combination of factors like:
  - **Congenital vesicoureteral reflux and intrarenal reflux:** Chronic pyelonephritis is so often associated with vesicoureteric reflux and some feel that it is better named ‘reflux nephropathy’. Reflux may be unilateral or bilateral and accordingly causes scarring of one or both the kidney.
  - **Superimposition of a urinary infection** acquired in infancy or early childhood.
- **Chronic obstructive pyelonephritis:** Develops due to **recurrent infections** superimposed on obstructive lesions, which lead to renal inflammation parenchymal atrophy, and scarring.

Chronic pyelonephritis is an important cause of renal damage and end-stage renal disease. Morphological changes are depicted in Figure 13.21.

**Fig. 13.21:** Morphological changes in reflux nephropathy compared with normal

## Clinical Features

- Reflux pyelonephritis may be of silent onset. Clinical features includes back pain, lassitude, or symptoms of uremia or hypertension. Other symptoms include frequency of micturition, dysuria, pyuria and bacteriuria.
- **Xanthogranulomatous pyelonephritis (XGP):** Predominantly affects elderly women. The condition is commonly associated with renal calculi or obstructive uropathy and is usually unilateral. The kidney is enlarged, and non-functioning and may even mimic a tumor.

## Investigations

- **Culture of the urine:** *E. coli* is the most common organism causing infection. Other organisms include *Proteus*, *Pseudomonas aeruginosa* and staphylococci.

- **Ultrasound of kidneys**
- **CT scan of the kidneys:** Diagnostically, it reveals irregular renal outlines, clubbed calyces and a variable decrease in the size of kidney. The condition may be unilateral or bilateral and may affect entire or part of the kidney.
- DMSA scan is more accurate than IVU.
- **Intravenous urogram:** Shows localized contraction of the renal substance associated with clubbing of the adjacent calyces.
- **Micturating cystourethrogram (MCU):** Reveals vesicoureteric reflux, but has been replaced by radionuclide cystography scan.
- **Cystoscopy and urography:** May detect any abnormality causing obstruction to the flow of urine.

### Management

- Eradicating predisposing factors:
  - Examples include treatment of calculi and malformations.
  - Surgery is performed if the vesicoureteric reflux persists and is indicated only when the disease is confined to one kidney. Most cases of childhood reflux likely to disappear spontaneously. Patients with end-stage renal failure require renal replacement.
- Treatment of infection: Meticulous early detection and control of infection can prevent further scarring and allow normal growth of the kidneys. Unfortunately, once the parenchyma is scarred it becomes susceptible to blood borne reinfection sometimes with a different and resistant organism. Thus, antibiotics may be of temporary benefit and progressive renal damage is common.
  - Use of appropriate antibiotics for 7 days.
  - If the infection cannot be eradicated suppressive therapy may be given several months with trimethoprim (100 mg at bed time) or nitrofurantoin (50 mg at bed time).
- Other measures:
  - Complete emptying of the bladder should be advised.
  - Double micturition is advised if reflux. This consists of emptying of the bladder and then again second time attempt to empty the bladder, after about 10–15 minutes.

Control of hypertension because severe hypertension is a relatively common cause of end-stage renal failure in childhood or adult life.

## TUBERCULOSIS OF THE URINARY TRACT

**Q. Describe renal tuberculosis.**

**Q. Briefly outline the clinical features, investigations and treatment of tuberculosis of the urinary tract.**

Tuberculosis of the urinary tract results from hematogenous spread from a distant primary focus of infection that is often impossible to identify.

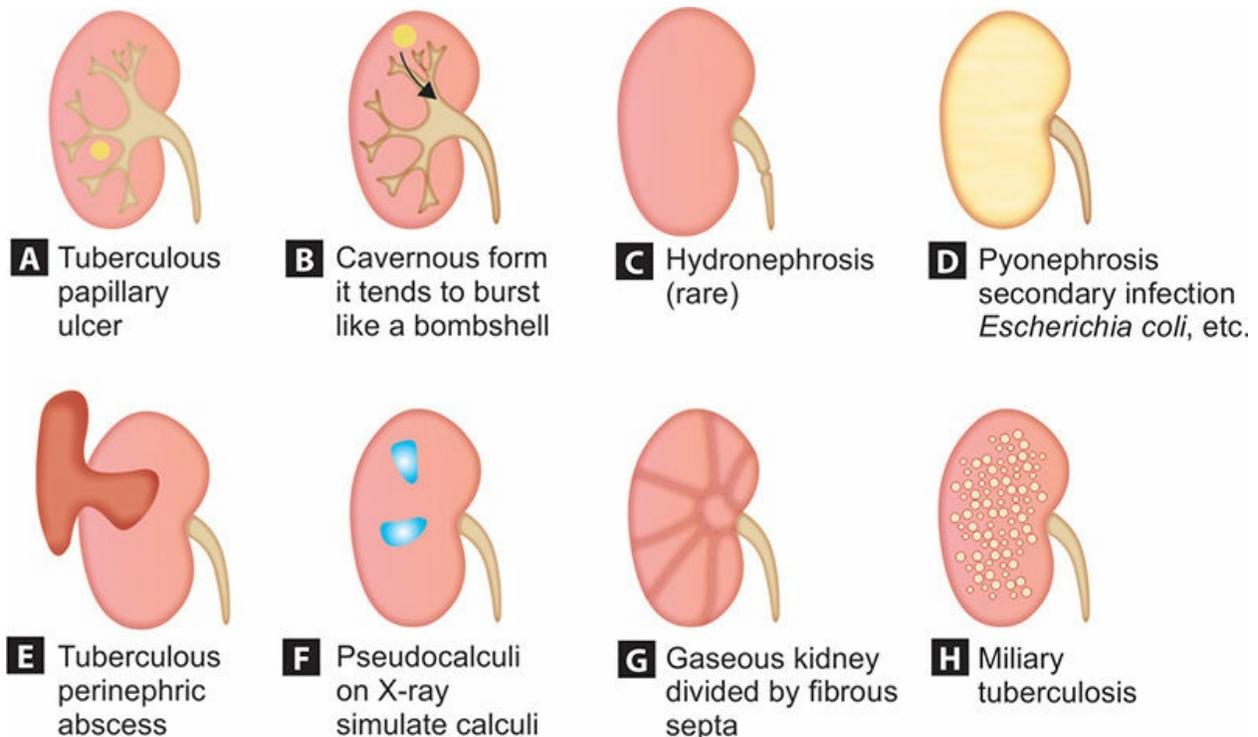

Types of lesions in renal tuberculosis (Fig. 13.22 and Table 13.36).

### **Etiology and Pathology (Figs. 13.22A to H)**

- Tuberculosis usually involves one kidney. Rarely, tuberculosis may be bilateral as part of the generalized process of military tuberculosis.
- Tuberculous granulomas in the region of renal pyramid may coalesce to form an ulcer and discharge mycobacteria and pus cells into the urine.
- Untreated lesions of renal tuberculosis may enlarge and form tuberculous abscess in the parenchyma.
- Fibrosis at the necks of the calyces and the renal pelvis may cause tuberculous pyonephrosis.
- Extension of tuberculous pyonephrosis or renal abscess may result in perinephric abscess and the kidney may be progressively replaced by caseous material (putty kidney). This may become calcified (cement kidney).
- Renal tuberculosis is often followed by infection of the ureters and bladder leading to ureteral stricture and contraction of bladder.
- Rarely, cold abscesses may form in the loin. In male, tuberculous epididymo-orchitis may develop even without any lesion in bladder.

**Table 13.36:** *Types of lesions in renal tuberculosis.*

<b>Types</b>	
• Tuberculous papillary ulcer	• Tuberculous perinephric abscess
• Cavernous form	• Pseudocalculi
• Hydronephrosis	• Caseous (putty) kidney
• Pyonephrosis	• Miliary

**Figs. 13.22A to H:** Various types of lesions in tuberculosis of kidney.

## Clinical Features

- Usually occurs between 20 and 40 years of age.
- Affects males more commonly than females (2:1).
- Affects right kidney more commonly than the left.

## Symptoms

These include a dull ache in the renal angle, increased frequency of micturition, dysuria and constitutional symptoms such as fever (evening rise of temperature) malaise and weight loss. Tuberculous cystitis present with hematuria and painful micturition.

- **Physical examination:** Shows an enlarged palpable kidney and tenderness in the renal angle.

## Investigation

- **Urine examination:**
  - **Microscopic examination:** **Sterile pyuria** is characterized by urine containing pus cells, but fails to grow any organism on routine culture. This is the **characteristic feature**.

- **Urine examination for tubercle bacilli:** Five early morning consecutive samples of urine should be examined (because there is usually intermittent excretion of tubercle bacilli). Alternatively, a 24-hours urine collection can be examined for acid-fast bacillus (AFB).
- **Culture of the urine:** Diagnosis of active tuberculous infection depends on culture of mycobacteria from early-morning urine samples.
- **Radiography**
  - **Plain KUB radiograph:** It may show calcification (pseudocalculi) in the renal parenchyma and ureter.
  - **Chest X-ray:** Should be done in all cases to exclude active or previous evidence of pulmonary tuberculosis.
- **IVU:** May reveal irregular contour of the kidney, hydrocalyx, cold abscess, displacement of adjacent calyces, and small contracted bladder (systolic or thimble bladder).
- **Ultrasonography:** May show dilated calyces, hydronephrosis, small abscesses and areas of calcification.
- **Excretion urography:** May show cavitating lesions in the renal papillary areas with calcification. May also show ureteral obstruction with hydronephrosis.
- **Cystoscopy:** May show a characteristic ‘golf hole’ appearance of the ureteric orifice due to sclerosing periureteritis.

#### Treatment

- **Antituberculous chemotherapy:** Similar to that for pulmonary tuberculosis. Renal ultrasonography or excretion urography should be done 2–3 months after initiation of treatment as ureteric strictures may first develop in the healing phase.
- Surgical treatment may be required in selected cases.

# RENAL REPLACEMENT THERAPIES (RRT)

**Q.** Write short essay/note on renal replacement therapy.

## Requirement

RRT may be required on a temporary measure in patients with AKI or on a permanent measure for CKD.

**Main options of renal replacement therapy (Table 13.37 and Box 13.21):**

(1) peritoneal dialysis, (2) intermittent hemodialysis (HD) combined with ultrafiltration, if necessary, (3) intermittent hemofiltration, (4) continuous arteriovenous or venovenous hemo-filtration, and (5) hemodiafiltration and (6) renal transplantation.

**Box 13.21:** Aim of renal replacement techniques.

- To replace all the excretory functions of the normal kidney namely excretion of nitrogenous wastes
- Maintenance of:
  - Plasma biochemistry
  - Normal electrolyte concentrations
  - Normal extracellular volume (fluid balance)

**Note:** They do not replace the endocrine and metabolic functions of the kidney

**Table 13.37:** Options of renal replacement therapy.

<b>Options</b>	
Dialysis <ul style="list-style-type: none"><li>• Hemodialysis</li><li>• Peritoneal dialysis</li></ul>	Clearance of small molecules and toxins using diffusion occurring across a membrane Dialysis with clearance occurring across a synthetic membrane Dialysis with clearance occurring across a native peritoneal membrane
Ultrafiltration	Fluid removal across a semipermeable membrane during dialysis by convection (solutes are moved under pressure across a membrane)
Hemofiltration	Continuous dialysis therapy which involves removal of plasma water and its dissolved constituents (e.g. $K^+$ , $Na^+$ , urea, phosphate) by convection flow across a high-flux semipermeable membrane, and concurrent reinfusion of an electrolytic solution of the

	desired biochemical composition
Hemodiafiltration	Combination of hemodialysis and hemofiltration
Continuous renal replacement therapies	Include hemofiltration and hemodiafiltration

## Hemodialysis

**Q. Write short note on hemodialysis.**

**Q. Describe the types and indications for dialysis. Enumerate complications of hemodialysis.**

Hemodialysis (Fig. 13.23) is the most common form of RRT used in end stage renal disease (ESRD) and also in acute kidney injury (AKI).

### *Basic Principles*

- In hemodialysis, blood from the patient is pumped through an array of semipermeable membranes (the dialyser, often called an ‘artificial kidney’).
- This brings the blood into close contact with dialysate (dialysis fluid) flowing countercurrent to the blood on the other side of membrane.
- This allows accumulated uremic toxins (e.g. urea and creatinine) and electrolytes (e.g. potassium) to diffuse across a semipermeable membrane (Fig. 13.24) from the blood (where they are in high concentrations), to the dialysis fluid on the other side (where they are in low concentrations). This in turn results in changes in the plasma biochemistry towards that of the dialysate due to the diffusion of molecules down their concentration gradients.

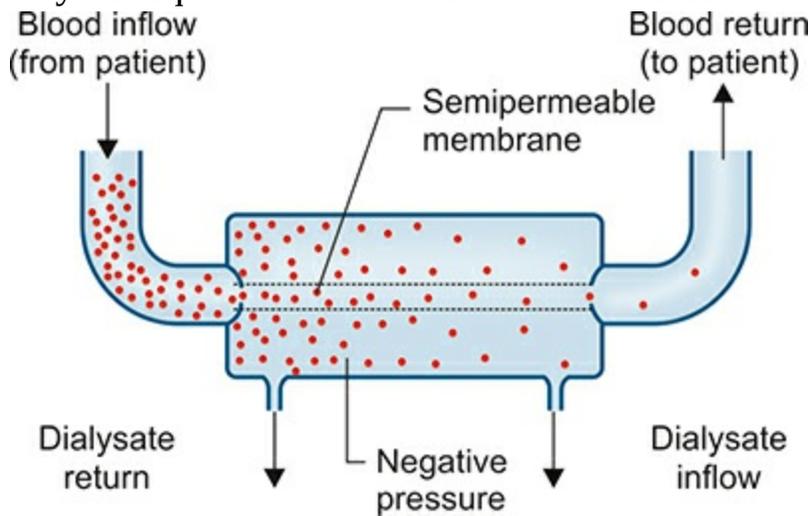

**Fig. 13.23:** Hemodialysis unit.

### ***Access for Hemodialysis***

Usually for adequate dialysis, required blood flow is 200–300 mL/minute and the dialysate flow is 500 mL/minute. Hemodialysis involves gaining access to the circulation through:

- **Arteriovenous fistula (Fig. 13.25):** For long-term dialysis access to the blood stream is achieved by surgical construction of an arteriovenous fistula, usually in the forearm using the radial or brachial artery and the cephalic vein.
- **Arteriovenous shunt:** In patients with poor-quality veins or arterial disease (e.g. diabetes mellitus) access is obtained by interposing a piece of synthetic material (polytetrafluoroethylene (PTFE) grafts) between native artery and native vein.
- **Central venous catheter:** If immediate dialysis is required, a large bore double lumen cannula may be inserted into a central vein (subclavian, jugular or femoral).

Each session of hemodialysis usually lasts for 4–5 hours. Two or three sittings/week may be required. Indications of RRT discussed under AKI.

**Fig. 13.24:** Hemodialysis showing changes across a semipermeable dialysis membrane.

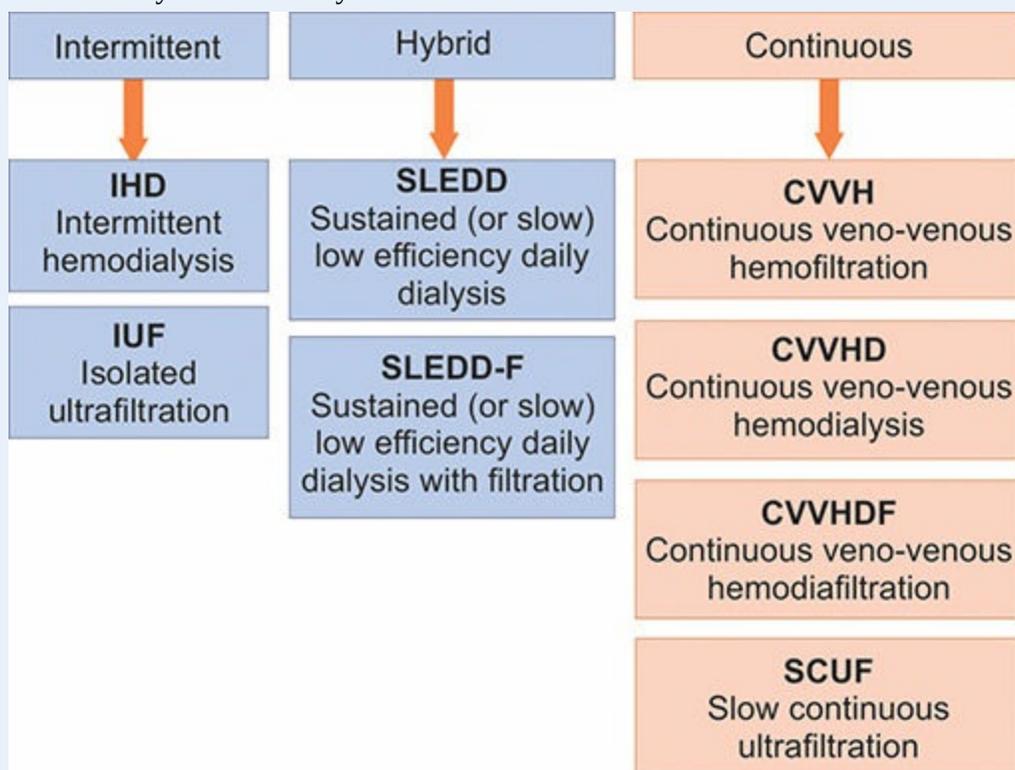

**Fig. 13.25:** Arteriovenous fistula (AV) created for dialysis.

Types of hemodialysis are depicted in Figure 13.26.

### **Complications**

**Q.** Write short essay/note on complications of hemodialysis.

- **Hypotension during dialysis:** It is the major complication and its contributing factors include: (1) excessive removal of extracellular fluid and hypervolemia, (2) shift of fluid into intracellular compartment (due to rapid reduction in urea in the extracellular compartment) and inadequate ‘refilling’ of the blood compartment from the interstitial compartment, (3) abnormalities of venous tone, (4) autonomic neuropathy, (5) acetate toxicity that causes vasodilatation, and (6) left ventricular failure.
- **Other complications:**
  - Cardiac arrhythmias due to potassium and acid-base shifts.
  - Hemorrhage due to anticoagulants and venous needle discontinuation.
  - Air embolism due to disconnected or defect lines and equipment malfunction.
  - Anaphylactic reactions to the dialyser may rarely occur to ethylene oxide (used to sterilize most dialysers) or in patients receiving ACE inhibitors (with polyacrylonitrile dialysers).
  - Hard-water syndrome due to failure to soften water resulting in a high calcium concentration prior to mixing with dialysate concentrate.
  - Hemolytic reactions
  - Infections usually occur with vascular access devices (catheter or fistula).
  - Pulmonary edema due to fluid overload. Other features include hypothermia, platelet consumption and electrolyte disturbances.
- **Dialysis disequilibrium syndrome:** May develop following a dialysis session. It is characterized by nausea, vomiting, restlessness, headache, hypertension, myoclonic jerks and in severe case, seizures and coma. This is because of rapid changes in plasma osmolality leading to cerebral edema.
- **Dialysis dementia:** May develop in patients on long-term hemodialysis. It is characterized by speech dyspraxia, myoclonic jerks, dementia, seizures and later, death. It is mainly due to aluminium toxicity and some may be due to viral infection.

**Fig. 13.26:** Types of hemodialysis

The rate of death from cardiac disease is higher in patients on hemodialysis when compared to patients on peritoneal dialysis or after renal transplantation.

## Acute Dialysis in Critically Ill Patients

### ***Continuous Renal Replacement Therapy (CRRT)***

#### *Advantages*

- It is used in critically ill patients who cannot tolerate large fluid shifts and hypotension that frequently occurs during standard hemodialysis.
- It allows slow and isotonic fluid removal. Thus produces excellent hemodynamic tolerance, even in patients with shock or severe fluid overload.
- Since dialysis is continuous, volume removal and correction of metabolic abnormalities can be modified at any time. This allows rapid adjustment in critically ill patients.

#### *CRRT modalities*

The most common is continuous veno-venous hemodiafiltration (Fig. 13.27). This combines convective and diffusive clearance through a dialyser with reinfusion of electrolyte-rich solutions.

#### *Indications*

CRRT is of choice in patients with ARF combined with hemodynamic instability, cerebral edema, severe fluid overload and encephalopathy.

#### *Complications*

Embolization, arteriovenous fistula formation, hemorrhage and infection from catheter access.

## Peritoneal Dialysis

**Q.** Write a short note on peritoneal dialysis and its indications. (Box 13.22).

- In peritoneal dialysis, the **peritoneal membrane of the patient acts as a semipermeable membrane**. Through this diffusion of water and solutes

takes place and this avoids the need of extracorporeal circulation of blood.

- **Very simple, low-technology** treatment when compared to hemodialysis.
- **Principle (Fig. 13.28A):** Solutes diffuse from blood across the peritoneal membrane to peritoneal dialysis fluid down a concentration gradient and water diffuses through osmosis.

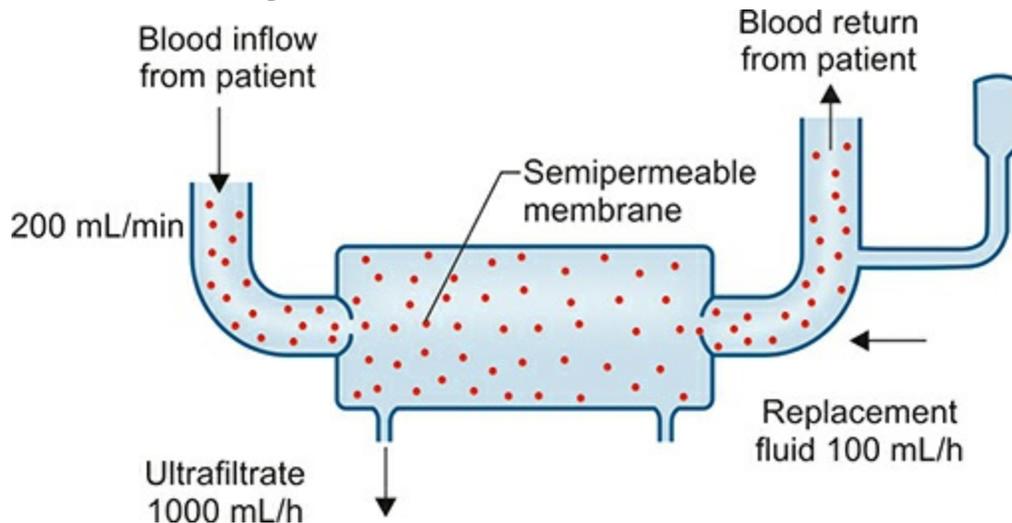

Fig. 13.27: Principles of hemofiltration.

### Box 13.22: Indications for peritoneal dialysis.

1. Preferred mode of dialysis for infants and young children
2. Patients with severe hemodynamic instability on hemodialysis
3. Patients with difficult vascular access

### Procedure

- A plastic or silicone tube /catheter is placed into the peritoneal cavity through the anterior abdominal wall (Fig. 13.28B).
- Dialysate is instilled into the peritoneal cavity, usually under gravity.
- Urea, creatinine, phosphate, and other uremic toxins pass across the peritoneal membrane into the dialysate because of their concentration gradients.
- Water (with solutes) is attracted into the peritoneal cavity by osmosis.
- The fluid is removed by gravity after 30–60 minutes, and the fluid is changed regularly to repeat the process several times. This is called as intermittent peritoneal dialysis and is mainly used in ARF.

When chronic peritoneal dialysis required, a soft catheter is inserted, with its

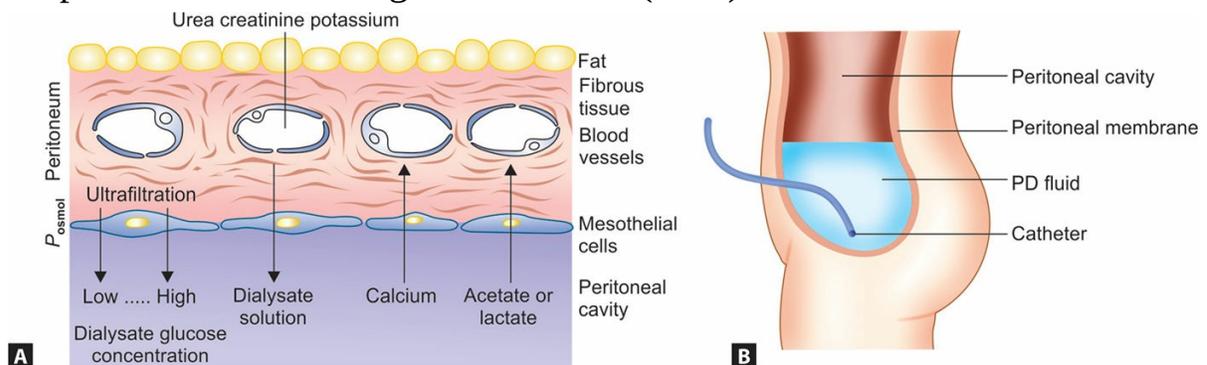

tip in the pelvis with an exit site in the lateral abdominal wall.

## Complications

- **Technical complications:** Catheter-related exit site infection, tunnel infection, peritonitis, pericatheter leakage, poor drainage, catheter migration rarely bowel perforation.
- **Raised intra-abdominal pressure:** Hernias, fluid leaks, rectal prolapse, vaginal prolapse, low back pain, scrotal edema, and decrease in appetite, **sclerosing encapsulating peritonitis**.

## Forms of Peritoneal Dialysis

- **Continuous ambulatory peritoneal dialysis (CAPD)**
  - In this type of peritoneal dialysis, dialysate is present within the peritoneal cavity continuously, except when dialysate is being exchanged.
  - Dialysate exchanges are performed three to five times a day.
  - About 1.5–3 L bags of dialysate are infused into the peritoneal catheter using a sterile no-touch technique.
  - Each exchange takes 20–40 minutes.
  - This technique is useful for maintenance of peritoneal dialysis in patients with end-stage renal failure (CRF).

**Figs. 13.28A and B:** (A) Principle of peritoneal dialysis; (B) Peritoneal dialysis.

- **Nightly intermittent peritoneal dialysis (NIPD):**
  - In this type of peritoneal dialysis, an automated device is used to perform exchanges each night (while the patient is asleep).
  - Apart from that night, sometimes dialysate is left in the peritoneal cavity during the day, to increase the time during which biochemical exchange is occurring.

- **Tidal dialysis:** In this type of peritoneal dialysis, a residual volume of dialysate is left within the peritoneal cavity with continuous cycling of smaller volumes in and out.

Differences between hemodialysis and peritoneal dialysis are presented in Table 13.38.

**Table 13.38:** Differences between hemodialysis and peritoneal dialysis.

<i>Features</i>	<i>Hemodialysis</i>	<i>Peritoneal dialysis</i>
Efficiency	Efficient	Less efficient
Duration and time interval	4 hours three times per week is usually adequate	4 exchanges per day are usually required. Each taking 30–60 minutes (continuous ambulatory peritoneal dialysis) or 8–10 hours each night (automated peritoneal dialysis)
Interval between dialysis	2–3 day between treatments	A few hour between treatments
Conduction of dialysis	Needs visits to hospital (although home treatment is possible for some patients)	Performed at home
Requirement	Requires adequate venous circulation for vascular access	Requires an intact peritoneal cavity without major scarring from previous surgery
Diet and fluid restriction	Required between treatments	Diet and fluid less restricted
Speed of removal of fluid and associated symptoms	Fluid removal compressed into treatment periods. May cause symptoms and hemodynamic instability	Slow continuous fluid removal. Usually asymptomatic
Infections	Infections related to vascular access may occur	Peritonitis and catheter-related infections may occur
Dependency of patient	Patients are usually dependent on others	Patients can take fully responsibility for their treatment

## Renal Transplantation

**Q. Write a short essay/note on renal transplantation.**

Successful renal transplantation offers the best chance of long-term survival with almost complete rehabilitation in ESRD.

### *Advantages*

- Treatment of choice for most patients with advanced (end-stage) renal

failure.

- Method of renal replacement therapy having significant survival advantage when compared to dialysis patients.
- Freedom from dietary and fluid restriction.
- Corrects anemia and infertility in CRF patients.
- Reduces the need for parathyroidectomy.

**Donor** is usually a living close relative or a cadaveric donor.

### ***Factors Determining the Success***

- **Donor:** Living donors should be healthy and should be **free of hypertension, diabetes, or malignant disease**. With the acceptance of the concept of brain death in India, cadaveric transplants are being also performed at present.
- **ABO (blood group) compatibility** between donor and recipient is required.
- **Matching donor and recipient for HLA type:**
  - It is preferable to have a donor with a HLA-identical that of the recipient. Matching for HLA-DR antigens (class II) appears to be most important for graft survival. Matching at the HLA-B locus (class I) has only a minor effect on graft outcomes.
  - Complete compatibility at HLA-A, HLA-B and HLA-DR offers the best chance of long survival of the graft, followed by a single HLA mismatch (i.e. antigen possessed by the donor and not possessed by the recipient).
  - Class I antigens (HLA-A, B and C) are detected by a lymphocyte assay and class II (HLA-DR) by mixed lymphocyte culture.
- **Cross-matching:** Pre-sensitization (i.e. presence of antibodies against donor ABO blood group and HLA class I antigens) is detected by a cross-matching. Transplantation is contraindicated if it is positive.

**Table 13.39:** Absolute and relative contraindications for renal transplantation.

<b><i>Absolute contraindications</i></b>	<b><i>Relative contraindications</i></b>
<b>Renal</b> <ul style="list-style-type: none"><li>• Reversible renal involvement</li></ul>	<ul style="list-style-type: none"><li>• Age: Very young children (&lt;1 year) or older people (&gt; 75 years)</li></ul>

- Active glomerulonephritis
- Active vasculitis or recent anti-GBM disease
- Previous sensitization to donor tissue

#### **Non-renal**

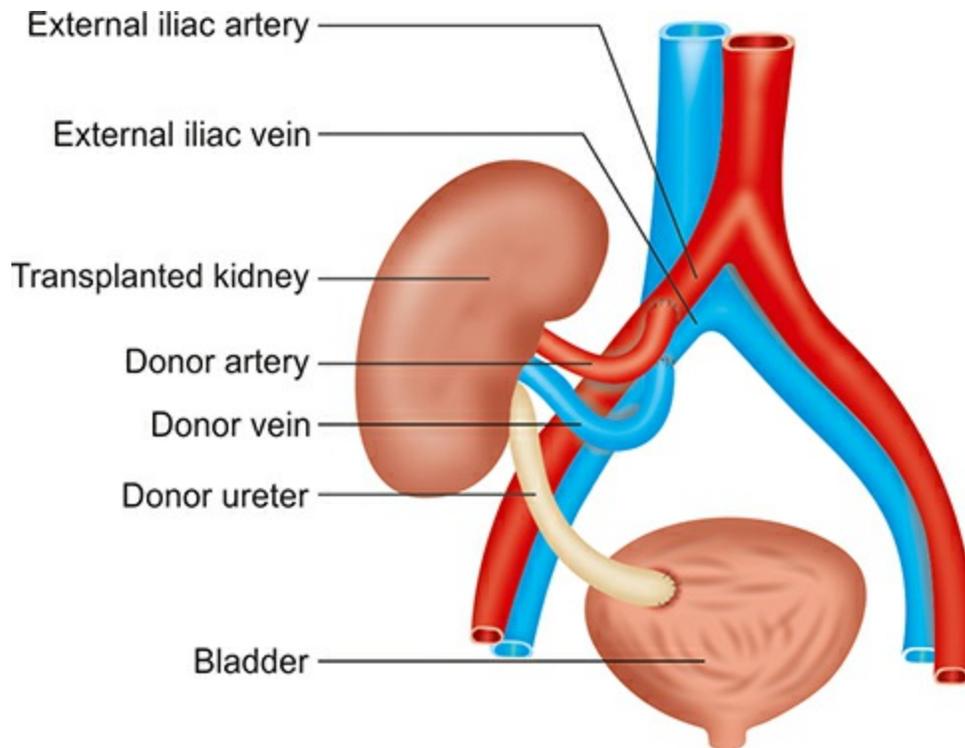

- Disseminated or active untreated cancer
- Severe occlusive aorto-iliac vascular disease
- Severe psychiatric disease
- Persistent substance abuse
- Severe mental retardation
- Severe heart disease/refractory congestive heart failure
- Active infection

- Iliofemoral occlusive disease
- Diabetes mellitus
- Severe diseases of lower urinary tract: Bladder dysfunction or urethral abnormalities
- Chronic liver disease
- Treated malignancy
- Significant comorbidity

### ***Contraindications (Table 13.39)***

#### ***Technique***

- Before transplantation, the recipient receives a hemodialysis to ensure a relatively normal metabolic state.
- In transplantation, donor human kidney (either from a cadaveric donor or from a living close relative) is placed in an extraperitoneal pouch in the **iliac fossa** of the recipient (Fig. 13.29).
- The renal artery and vein of donor kidney are anastomosed to the recipient's iliac vessels. The donor ureter is placed into the recipient's bladder. The recipient's original kidneys are left undisturbed.
- Eighty percent of grafts now survive for 5–10 years in the best centers, and 50% for 10–30 years.

**Fig. 13.29:** Renal transplantation.

### ***Immunosuppressive Therapy***

- Unless the donor is genetically identical (i.e. an identical twin), immunosuppressive treatment is required to prevent rejection.
- Immunosuppressive therapy varies from center to center and combination of drugs is often used.
- Commonly used drugs include corticosteroids, antiproliferative agents (e.g. azathioprine, mycophenolate mofetil), calcineurin inhibitor (e.g. ciclosporin, tacrolimus, sirolimus), and antibodies (polyclonal anti-thymocytic globulin (ATG) and anti-lymphocytic globulin (ALG) and monoclonal (OKT3) antibodies). Newer drugs include basiliximab and daclizumab (antibodies against interleukin-2 receptor).

### ***Complications***

- **Acute tubular necrosis (ATN):** It is the commonest cause of cadaveric graft dysfunction (up to 40–50%).
- **Technical failures:** These include (1) occlusion or stenosis of the arterial anastomosis, (2) occlusion of the venous anastomosis, and (3) urinary leaks owing to damage to the lower ureter, or defects in the anastomosis

between ureter and recipient bladder.

- **Transplantation rejection:** In spite of prophylactic use of immune suppressants before or at the time of transplantation, most recipients undergo one or more type of rejection.

- **Hyperacute rejection.**

- ◆ A special type of complement mediated rejection occurs if the host has **preformed anti-donor** antibodies (for example, anti-ABO blood type antibodies) in the circulation before transplantation. These antibodies bind to endothelium of graft organ, activates complement followed by vascular thrombosis.
- ◆ Occurs within minutes. The transplanted kidney must be removed immediately to prevent a severe systemic inflammatory response and generalized clotting.

- **Acute rejection**

- ◆ **Time of occurrence:** Within days to weeks after transplantation in the non-immunosuppressed host.
- ◆ **Type:** Either cellular or humoral immune mechanisms may predominate.
  - ◇ **Acute cellular rejection:** Occurs within few months after transplantation and develops renal failure.
  - ◇ Acute humoral rejection (rejection vasculitis): Main target of the antibodies is the graft vasculature ◇ manifest as vasculitis. Caused by anti-donor antibodies
  - ◇ Features: Acute rejection is characterized by deterioration of renal function, hypertension, weight gain, tenderness and swelling of the graft, fever and appearance of protein, lymphocytes and renal tubular cells in the urine sediment.
  - ◇ If the diagnosis is not clear, percutaneous needle biopsy is performed for histopathological examination.

#### Treatment

- Use additional immunosuppressant including intravenous pulses of methylprednisolone and antilymphocyte antibody.
- Antibody-mediated rejection is less likely to respond to corticosteroids and may be treated with plasma exchange (to remove the antibody) and intravenous immunoglobulin.

- **Chronic rejection:** Few patients may develop irreversible chronic graft rejection.

- **Other Complications**

- **Infection** is the most important cause of morbidity and mortality. Risk of infections can be divided into three distinct time periods.

1. **First month post-transplant:** These include (a) infections present in the recipient before transplant and aggravated by immunosuppressive therapy (e.g. tuberculosis, systemic fungal infections, hepatitis B or C, HIV or smouldering bacterial infections); (b) infections transmitted through contaminated allograft; and (c) routine post-surgical bacterial infections of the wound, IV lines and urine catheters.
2. **1–6 months post-transplant:** These include: (a) viral infections (e.g. cytomegalovirus, Epstein-Barr virus, hepatitis viruses and HIV) and (b) superinfection with opportunistic bacteria or fungi (e.g. *Pneumocystis carinii*, *Listeria monocytogenes* and aspergillus).
3. **More than 6 months post-transplant:** These include (a) chronic progressive disease due to viral infections acquired earlier (e.g. progressive CMV chorioretinitis, progressive liver disease due to hepatitis B or C virus, and EBV-associated lymphoproliferative disorders); (b) opportunistic infections with pathogens such as *Pneumocystis carinii*, *Cryptococcus*, *Listeria monocytogenes* and *Nocardia asteroides* in patients with chronic graft dysfunction who have received multiple courses of anti-rejection therapy; and (c) infections similar to those in the community.

- **Post-transplantation lymphoproliferative disorders:** Epstein-Barr virus-associated malignancies are common in those who received biological agents and in children.
- **Malignancy:** Immunosuppressive therapy is associated with increases the risk of skin tumors (e.g. basal and squamous cell carcinoma). Incidence is 5–6% in Western countries and lower (2%) in India.
- **Cardiovascular disease** is responsible for deaths in 20–30% of patients, especially the elderly and diabetics.
- **Post-transplant hypertension** develops in up to 80% of patients early in the postoperative course and in 50% of stable recipients on maintenance immunosuppression.
- **Post-transplant osteoporosis** is common due to treatment with steroids.
- **Recurrent and de novo renal disease** is common (e.g. primary FSGS, type II membranoproliferative glomerulonephritis, diabetic nephropathy and IgA nephropathy, hyperoxaluria).
- **Vascular:** Renal artery thrombosis and renal artery stenosis.
- **Urologic:** Ischemic necrosis of the lower end of the ureter may produce urinary leak, calyceal-cutaneous fistula. Vesico-ureteric reflux into the graft may lead to increased frequency of urinary tract infections.

# RENAL BIOPSY

**Q. Write short note on renal biopsy and its indications.**

It is used to establish the nature and extent of renal disease. Biopsy is performed transcutaneously with ultrasound guidance. Biopsy material is examined under light microscopy, electron microscopy and by immunofluorescence. Indications for renal biopsy are presented in Table 13.40 and contraindications and complications of renal biopsy are presented in Table 13.41.

**Table 13.40: Indications for renal biopsy.**

- Nephrotic syndrome/glomerular proteinuria in adults
- Nephrotic syndrome in children with atypical presentation/not responding to treatment (steroids)
- Chronic renal failure with normal sized kidney
- Unexplained acute renal failure
- Differential diagnosis of acute nephritic syndrome
- Isolated hematuria/ non-nephrotic proteinuria. Unexplained renal insufficiency when kidney dimensions are near normal on ultrasonography
- Impaired functioning of renal transplant
- Asymptomatic hematuria when other diagnostic tests cannot detect the cause
- Involvement of kidney in systemic diseases (e.g. systemic lupus erythematosus, amyloidosis)

**Table 13.41: Contraindications and complications of renal biopsy.**

<b>Contraindications</b>	<b>Complications</b>
<ul style="list-style-type: none"><li>• Coagulation disorders</li><li>• Thrombocytopenia</li><li>• Uncontrolled hypertension</li><li>• Solitary kidney</li><li>• Renal neoplasms (to avoid spread along needle track)</li><li>• Large and multiple renal cysts</li><li>• Acute urinary tract infections</li><li>• Urinary tract obstructions</li><li>• Kidney less than 60% predicted size</li></ul>	<ul style="list-style-type: none"><li>• Pain</li><li>• Infection</li><li>• Bleeding into the urine</li><li>• Bleeding around kidney</li><li>• Arteriovenous fistula</li><li>• Accidental biopsy of other organ or perforation of organs such as liver, spleen</li><li>• Rarely death</li></ul>

# **Fluid and Electrolyte Disturbances**

# CHAPTER 14

## DISORDERS OF SODIUM AND WATER BALANCE

**Q.** Write short note on the normal distribution of water in the body of an average adult male.

### Composition of Body Fluids

- Water is the most abundant constituent of the body (50% of body weight in women and 60% of the body weight in men is water).
- Total body water is distributed in two major compartments:
  1. Intracellular fluid compartment (IFC) = 55–75%
  2. Extracellular fluid compartment (ECF) = 25–45%. ECF consists of:
    - ◆ **Intravascular (plasma water)** compartment
    - ◆ **Extravascular (interstitial)** compartment: Ratio between intravascular and extravascular compartment is 1:3.

Distribution of water and electrolytes in the body are shown in Figure 14.1.

### Electrolytes (Table 14.1)

- Electrolytes are ions either positively (**cations**) or **negatively (anions) charged**.
- The electrolyte composition of intracellular and extracellular fluid is different and is shown on Table 14.1 and Figure 14.1.
- Sodium ( $\text{Na}^+$ ) and chloride ( $\text{Cl}^-$ ) are the important electrolytes in the ECF compartment.
- Potassium ( $\text{K}^+$ ) and phosphate are the important electrolytes in the intracellular fluid (ICF) compartment.
- **Osmolarity:** It is number of osmoles per liter of solution. It depends on

the volume of various solutes and temperature of the solution.

- **Osmolality:** It represents the solute or particle concentration of a fluid. It indicates the number of osmoles per kg of the solvent and it does not depend on the temperature or the solutes. It is expressed as milliosmoles per kilogram of water (mOsm/kg):

$$\text{Osmolality of plasma} = 2 \times \text{Na}^+ (\text{mEq/L}) + \text{glucose} (\text{mg/dL})/18 + \text{blood urea} (\text{mg/dL})/6.$$

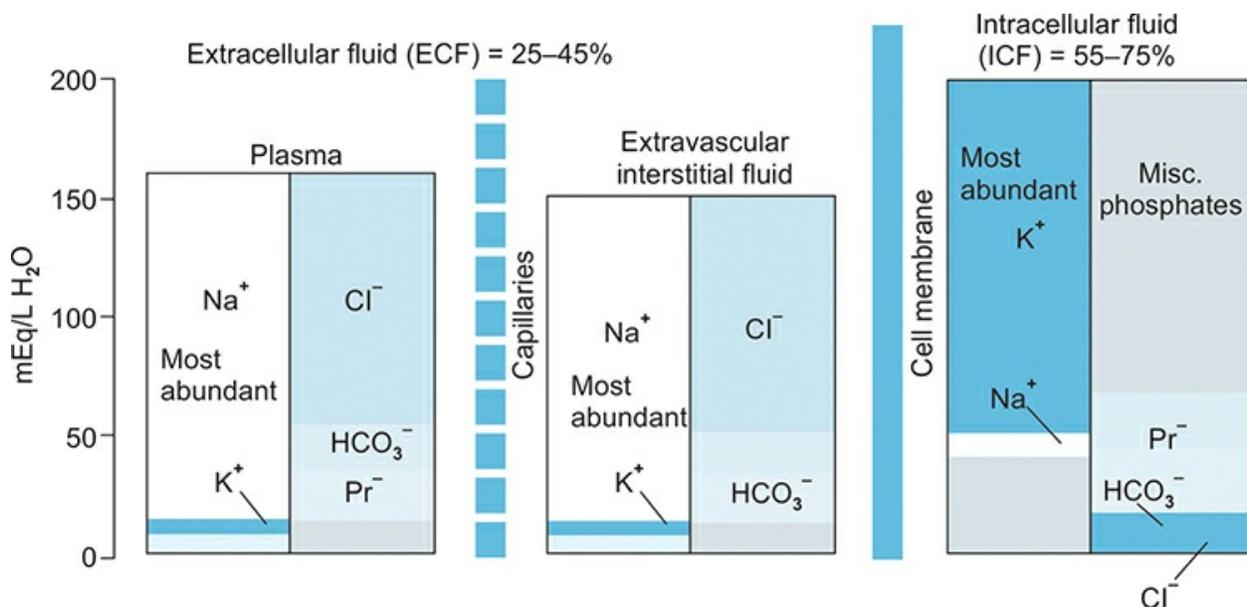

Fig. 14.1: Normal distribution of water and electrolytes in the body.

**Table 14.1:** Normal range of various electrolytes, pH and osmolality of blood.

Component	Normal range	Component	Normal range
Sodium (Serum)	136–145 mmol/L	Calcium (Plasma)	9–10.5 mg/dL
Potassium (Serum)	3.5–5.0 mmol/L	pH of blood	7.35–7.45
Chloride (Serum)	98–106 mmol/L	Bicarbonate (Blood)	21–28 mmol/L
Magnesium (Serum)	2–3 mg/dL	Osmolality (Serum)	285–295 mOsm/kg water
Phosphorus (Serum)	3–4.5 mg/dL		

## VOLUME DEPLETION (HYPOVOLEMIA)

**Q.** Describe the causes, clinical features, laboratory features and

### treatment of volume depletion.

- Volume depletion or hypovolemia generally refers to combined salt and water loss leading to contraction of the extracellular fluid volume (ECFV).
- Dehydration is defined as **relatively pure water deficit** (hypernatremia).

### Causes (Table 14.2)

**Table 14.2: Causes of volume depletion (hypovolemia).**

<i>Extrarenal losses</i>	<i>Renal losses</i>
<ul style="list-style-type: none"> <li>• <i>Gastrointestinal losses:</i> <ul style="list-style-type: none"> <li>– Diarrhea</li> <li>– Vomiting</li> </ul> </li> <li>• <i>Sequestration in the abdomen:</i> <ul style="list-style-type: none"> <li>– Peritonitis</li> </ul> </li> <li>• <i>Loss from skin:</i> <ul style="list-style-type: none"> <li>– Excessive sweating</li> <li>– Burns</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <i>Excessive use of diuretics:</i> <ul style="list-style-type: none"> <li>– Osmotic diuresis</li> <li>– Glycosuria in uncontrolled diabetes</li> <li>– Excessive use of mannitol</li> </ul> </li> <li>• <i>Renal disease:</i> <ul style="list-style-type: none"> <li>– Salt-wasting tubular diseases</li> <li>– Diuretic phase of acute renal failure</li> <li>– Chronic renal failure</li> </ul> </li> <li>• <i>Deficiency of mineralocorticoids:</i> <ul style="list-style-type: none"> <li>– Addison’s disease</li> </ul> </li> </ul>

### Clinical Features

- **Features of volume depletion (Table 14.3):** Dry skin and mucous membranes, reduced skin turgor, reduced or absent tears, tachycardia, shock, depressed fontanelle (in infants) and altered mental status.
- **Features due to extrarenal losses:** Decreased urine output.

**Table 14.3: Signs of dehydration depending on the degree of dehydration.**

<i>Features</i>	<i>Degree of dehydration</i>		
	<i>Mild</i>	<i>Moderate</i>	<i>Severe</i>
Peripheral pulses	Normal	Slightly decreased	Difficult to palpate
Heart rate	Normal	Slightly increased	Significant increased with tachycardia
Capillary refill	Normal	About 2 seconds	> 3 seconds
Mucus membranes and skin	Normal	Dry	Extremely dry
Eyes	Normal	Normal	Shrunken
Production of tears	Normal	Decreased	Absent
Amount of urine	Normal	Decreased	Little or none

excreted			
Fontanelle (in infants)	Flat	Soft	Shrunken

## Laboratory Features

- **Sodium concentration:** Normal, reduced or elevated depending on the proportion of loss between water and sodium.
- **Blood urea nitrogen (BUN) and creatinine:** Often raised, especially in severe volume depletion.
- **Urinary sodium:** Helps in differentiating between renal from extrarenal losses. In renal causes, urinary sodium is usually more than 20 mEq/L, and it is less than 10 mEq/L in extrarenal losses.

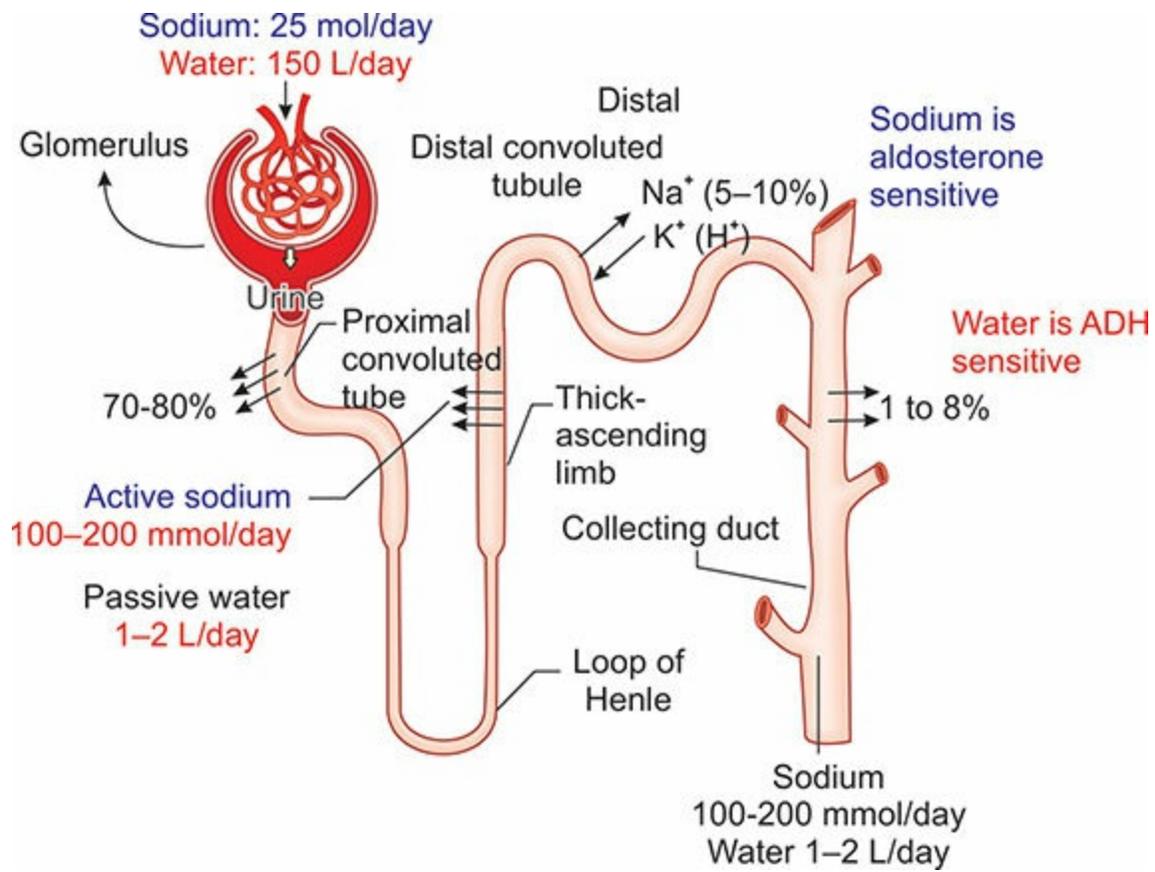

### Treatment

- Mild-to-moderate volume depletion (often due to gastroenteritis) should be corrected by increasing oral intake of sodium and water by an oral rehydration solution.
- In severe volume depletion, administer intravenous fluids (normal saline or Ringer's lactate).

## DISORDERS OF SODIUM BALANCE

### Sodium (Na<sup>+</sup>)

Majority of the body's sodium is in the ECF (where it is by far the most abundant cation); total body sodium is the main determinant of ECF volume. Regulation of sodium excretion by the kidney is crucially important in maintaining normal ECF volume, and plasma volume (Fig. 14.2).

**Fig. 14.2:** Regulation of sodium excretion by kidney.

**Sodium intake:** It is recommended that people over the age of one year eat between 1000–1500 mg sodium per day.

**Absorption** of sodium from intestine is via two mechanisms, first by being freely permeable across the interstitial cell and secondly by import with glucose and amino acids.

**Sodium excretion:** The regulation of sodium excretion is the major determinant of sodium balance. Mainly Na<sup>+</sup> is absorbed at three main regions in the nephron.

1. *Proximal convoluted tubule (PCT):* ~65% of Na<sup>+</sup> reabsorbed.
2. *The loop of Henle:* About 25–30% is reabsorbed via apical Na<sup>+</sup> K<sup>+</sup> 2Cl<sup>-</sup> transporter.
3. *Distal convoluted tubule (DCT):* About 5% by thiazide sensitive Na<sup>+</sup> Cl<sup>-</sup> cotransporter. Finally, Na<sup>+</sup> reabsorption also occurs in cortical and medullary collecting ducts.

**Sodium excretion is regulated at four major steps:**

1. *Circulating levels of aldosterone:* It primarily acts on cortical collecting ducts especially T-cell to increase ENaCs (Epithelial sodium channels) in apical membrane.
2. *Circulating number of ANP and other natriuretic hormones:* ANP causes increase cGMP and this inhibits transport via ENAC.
3. *Amount of angiotensin II, prostaglandins levels in kidney:* They cause increase reabsorption of  $\text{Na}^+$  and  $\text{HCO}_3^-$  by action on PCT. PGE<sub>2</sub> causes natriuresis by inhibition of sodium transport via ENaCs.
4. *Rate of tubular secretion of  $\text{K}^+$  and  $\text{H}^+$ :*  $\text{Na}^+$  reabsorption is coupled with  $\text{H}^+$  and  $\text{K}^+$  secretion in tubules and play important role in acid-base metabolism.

## Hyponatremia

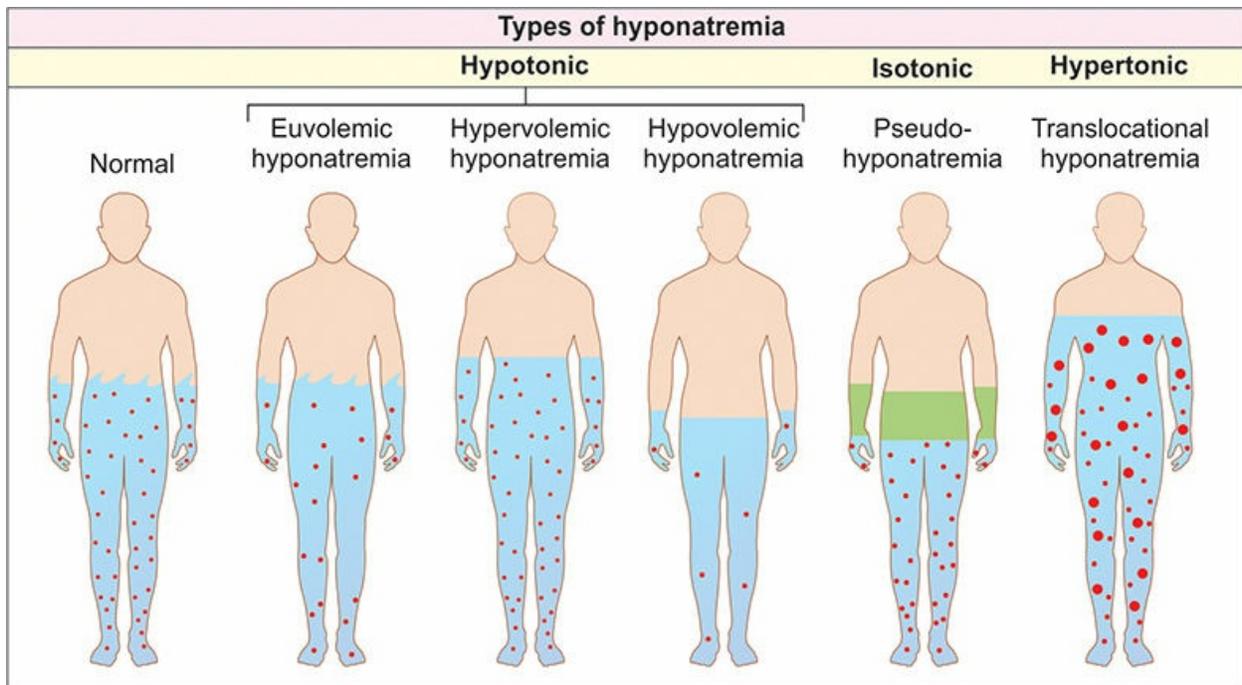

**Q.** Write short essay/note on definition, pathophysiology, causes, clinical features and treatment of hyponatremia.

**Definition:** Hyponatremia is defined as a condition in which the plasma concentration of sodium is  $<135$  mEq/L (**mild 130 to 134 mEq/L/moderate 120 to 129 mEq/L/severe  $<120$  mEq/L**).

- Generally, considered a disorder of water as opposed to disorder of salt, i.e. it usually results from increased water retention.
- Hyponatremia is the most common electrolyte disorder in hospitalized patients (seen in 15–22% patients at admission).
- Normal physiologic measures allow a person to excrete up to 10 liters of water per day which protects against hyponatremia. Thus, in most cases, some impairment of renal excretion of water is present.

## Pathophysiology

- Mechanism of hyponatremia is almost always the result of an **increase in circulating arginine vasopressin (AVP) and/or increase in renal sensitivity to arginine vasopressin**, combined with any intake of free water.
- Depending on clinical history and volume status, hyponatremia is subdivided into three groups, namely: **(1) hypovolemic type I; (2) euvolemic type IIa, IIb; and (3) hypervolemic type III (Fig. 14.3)**.

**Fig. 14.3:** Types of hyponatremia.

### *Hypovolemic hyponatremia*

- Hypovolemic hyponatremia is characterized by sodium deficit with a relatively smaller water deficit.
- Hypovolemia → causes neurohumoral activation → increasing level of AVP → increase AVP leads to BP preservation via vascular and baroreceptors  $V_{1a}$  receptors and increase water reabsorption via renal  $V_2$  receptors. Activation of  $V_2$  receptor can lead to hyponatremia in setting of increased free water intake.

### *Causes of hypovolemic hyponatremia (Table 14.4)*

**Table 14.4:** Causes of hypovolemic hyponatremia.

<i>Renal (urinary sodium is more than 20 mmol/L)</i>	<i>Extrarenal (urinary sodium is less than 20 mmol/L)</i>
<ul style="list-style-type: none"> <li>• Renal losses, excess diuretics</li> <li>• Mineralocorticoid deficiency (Addison)</li> <li>• Salt losing deficiency</li> <li>• Bicarbonaturia with renal tubular acidosis and metabolic alkalosis</li> <li>• Osmotic diuresis</li> <li>• Cerebral salt wasting syndrome</li> </ul>	<ul style="list-style-type: none"> <li>• Diarrhea</li> <li>• Vomiting</li> <li>• Third space loss</li> <li>• Burn</li> <li>• Pancreatitis</li> <li>• Trauma</li> </ul>

### *Hypervolemic hyponatremia*

- Hypervolemic hyponatremia characterized by disproportionate excess of sodium with relatively less water retention.
- It leads to increase in body water as compared to total body sodium, leading to a reduced plasma Na concentration.

### *Causes (Table 14.5)*

**Table 14.5: Causes of hypervolemic hyponatremia.**

<i>Urine Na is less than 20 mEq</i>	<i>Urine Na is more than 20 mEq</i>
<ul style="list-style-type: none"><li>• Nephrotic syndrome</li><li>• Cirrhosis</li><li>• Cardiac failure</li></ul>	<ul style="list-style-type: none"><li>• Acute or chronic renal failure</li></ul>

### *Euvolemic hyponatremia*

Normovolemic/euvolemic is characterized by pure water deficit.

### *Causes (Table 14.6)*

**Table 14.6: Causes of euvolemic hyponatremia**

<ul style="list-style-type: none"><li>• Primary polydipsia</li><li>• Decreased solute intake (e.g. beer potomania)</li><li>• SIADH</li><li>• Glucocorticoid deficiency</li><li>• Hypothyroidism</li><li>• Pain, stress, nausea, psychosis (stimulates ADH)</li><li>• Positive pressure ventilation</li><li>• Porphyrria</li></ul>	<ul style="list-style-type: none"><li>• <i>Drugs:</i> ADH, nicotine, sulfonylureas, morphine, barbiturates, NSAIDs, acetaminophen, carbamazepine, phenothiazines, tricyclic antidepressants, colchicine, clofibrate, cyclophosphamide, isoproterenol, tolbutamide, vincristine, monoamine oxidase inhibitor</li><li>• Essential (reset osmostat or sick cell syndrome—usually in the elderly)</li></ul>
---	---

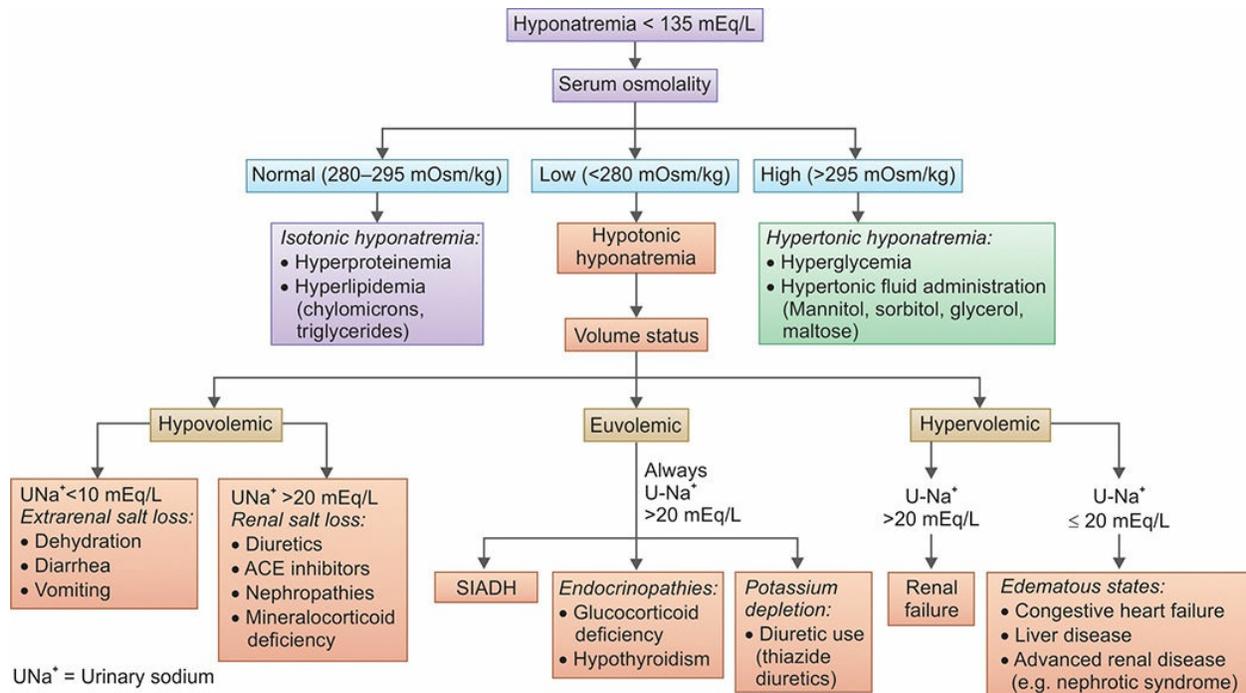

### *Pseudohyponatremia*

Characterized by spuriously low plasma sodium concentration.

### *Causes (Table 14.7)*

### ***Clinical Features***

- Depends on rate of development, age of the patient and severity.
- Symptoms universal, if  $\text{Na} < 120$  is acute.
- Chronic hyponatremia is less likely to be symptomatic.

**Fig. 14.4:** Algorithm for types and causes of hyponatremia.

Types and causes of hyponatremia are shown in Figure 14.4.

### *Effect of hyponatremia on brain*

Hyponatremia induces generalized cellular swelling due to entry of water from ECF to ICF. The symptoms of hyponatremia are primarily neurological and are due to the development of cerebral edema within a rigid skull.

- **Swelling and reduced osmolality:** Within minutes of hyponatremia, water enters the brain → causes swelling and reduced osmolality.
- **Rapid adaptation:** Brain volume is partially restored within a few hours due to loss of electrolytes (major intracellular ions  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Cl}^-$ ) from the brain cells due to rapid adaptation.
- **Slow adaptation:** Within next several days, the brain volume is normalized due to loss of organic compounds (creatine, betaine, glutamate, myoinositol, and taurine) from the brain cells and is due to slow adaptation. This response reduces intracellular osmolality and the osmotic gradient favoring water entry.

- **Slow versus rapid correction of correction of hypotonicity:** Loss of solutes the brain osmolality is low. Slow correction of hypotonicity causes gradual rise in brain osmolality without any damage. However, rapid correction of hyponatremia causes loss of brain water leading to brain damage.

**Table 14.7:** Causes of pseudohyponatremia.

<i>Normal plasma osmolality</i>	<i>Increased plasma osmolality</i>
<ul style="list-style-type: none"> <li>• Hyperlipidemia</li> <li>• Hyperproteinemia</li> <li>• Post-transurethral resection of prostate/bladder tumor</li> </ul>	<ul style="list-style-type: none"> <li>• Hyperglycemia</li> <li>• Mannitol</li> </ul>

### *Signs and symptoms of hyponatremia*

- **Acute:**
  - *Sodium level 121–130 mEq/L:* Nausea, hiccoughs, malaise, headache, lethargy, muscle cramps, disorientation, restlessness.
  - *Sodium level <120 mEq/L:* Obtundation, seizures, respiratory arrest, coma, death.
- **Chronic (developed over days):**
  - Usually asymptomatic/non-specific.
  - Nausea, gait disturbance, forgetfulness, muscle cramps, confusion, lethargy, fatigue.

### **Investigations (Table 14.8)**

Differences between various types of hyponatremia is indicated in Table 14.9.

**Table 14.8:** Investigations in hyponatremia.

<i>Serum sodium PLUS 4 mandatory laboratory tests</i>	<i>Additional labs depending on clinical suspicion</i>
<ul style="list-style-type: none"> <li>• Serum osmolality</li> <li>• Urine osmolality</li> <li>• Urine specific gravity</li> <li>• Urine sodium concentration</li> </ul>	<ul style="list-style-type: none"> <li>• TSH, cortisol (hypothyroidism or adrenal insufficiency)</li> <li>• Albumin, triglycerides, glucose (pseudohyponatremia, cirrhosis)</li> <li>• Plasma urea, creatinine and uric acid</li> <li>• Acid-base balance</li> </ul>

**Table 14.9: Differences between various types of hyponatremia.**

<i>Clinical findings</i>	<i>Type I, Hypovolemic</i>	<i>Type IIA, Euvolemic</i>	<i>Type IIB, Euvolemic (SIAD)</i>	<i>Type III, Hypervolemic</i>
History				
CHF, cirrhosis, or nephrotic syndrome	No	No	No	Yes
Salt and water loss	Yes	No	No	No
Physical examination				
ACTH–cortisol deficiency and/or nausea and vomiting	No	Yes	No	No
Generalized edema, ascites	No	No	No	Yes
Postural hypotension	May be	May be	No	May be
Laboratory				
BUN, creatinine	High-normal	Low-normal	Low-normal	High-normal
Uric acid	High-normal	Low-normal	Low-normal	High-normal
Serum potassium	Low-normal	Normal	Normal	Low-normal
Serum albumin	High-normal	Normal	Normal	Low-normal
Serum cortisol	Normal-high	Low	Normal	Normal-high
Plasma renin activity	High	Low	Low	High
Urinary sodium	Low	High	High	Low

## Management

### Step 1 (V) Volume status

First assess volume status (extracellular fluid volume) namely hypovolemic, euvolemic and hypervolemic hyponatremia.

### Step 2: (O) Osmolality approach to hyponatremia is listed in Box 14.1

- Second assess osmolality (hyper, iso, or hypo).
- Hypotonic hyponatremia = warrants further workup, especially when there is no obvious fluid overload or depletion.
- **Serum osmolality:** Lab value or calculation in mOsm/kg.
- **Hypertonic**—> 295: Hyperglycemia, mannitol, glycerol.
- **Isotonic**—280–295: Pseudo-hyponatremia from elevated lipids or protein.
- **Hypotonic**—< 280: Excess fluid intake, low solute intake, renal disease, SIADH, hypothyroidism, adrenal insufficiency, CHF, cirrhosis, etc.

### Step 3: (U) Urine studies

- For euvolemic hyponatremia, check urine osmolality.
  - Urine osmolality < 100—excess water intake: Primary polydipsia, tap water enemas, and post-TURP.
  - Urine osmolality > 100—impaired renal concentration: SIADH, hypothyroidism, cortisol deficiency.
- Check urine sodium and calculate FeNa%.
  - A low urine sodium (< 10) and low FeNa (< 1%) implies the kidneys are appropriately reabsorbing sodium.
  - A high urine sodium (> 20) and high FeNa (> 1%) implies the kidneys are not functioning properly.

#### Box 14.1: Approach to hyponatremia.

- *First:* Assess **V**olume status, is the patient volume overloaded, depleted, or euvolemic?
  - *Second:* Assess **O**smolality (hyper- iso- or hypo-), is the blood concentrated? For hypotonic hyponatremia, continue to 3rd step:
  - *Third:* Assess **U**rinary sodium excretion and FeNa%, is the urine concentrated?
- (\*Remember **VOU**—volume status, osmolality, and urine studies)

**Aquaretics** (e.g. Vaptans) is a class of drug that is used to promote the excretion of water without electrolyte loss. Strictly speaking they are not diuretics and is preferable to diuresis in the treatment of hyponatremia.

#### **Q. Write short note on VAPTANS.**

Vasopressin V<sub>2</sub>-receptor antagonists (VAPTANS)

- Vasopressin receptor antagonists (VRA)
- Nonselective (mixed V1A/V2)
- *Conivaptan. Intravenous:*
  - *V1A selective (V1RA):* Relcovaptan.
  - *V1B selective (V3RA):* Nelivaptan,
  - *V2 selective (V2RA):* Lixivaptan, Moxavaptan, Satavaptan, Tolvaptan. can cause an electrolyte-free aquaresis, reduce urine osmolality and raise serum Na. Their mechanism of action is presented in Figure 14.5.
- Use in euvolemic/hypervolemic hyponatremia (heart failure, cirrhosis).
- Contraindicated in hypovolemic hyponatremia.
- Vaptans are not suitable for hyponatremia due to cerebral salt wasting and psychogenic polydipsia where the ADH level is appropriate.

#### **Adverse effects:**

- Thirst 8–16%; dry mouth 4–13%.
- Hypernatremia develops in 5%.
- Contraindicated in pregnancy and severe liver dysfunction.

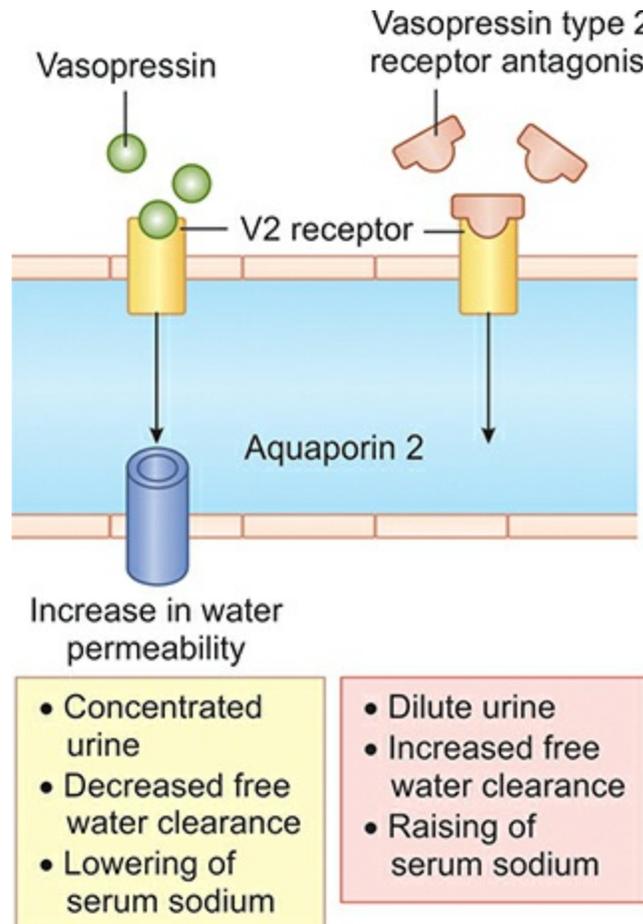

#### **Other uses of Vaptans:**

- **Polycystic kidney disease**

- Polycystin defects may promote cyst development b/c they → increase intracellular cAMP (a second messenger for AVP acting at the V2R) → therefore, V2R antagonists may reduce cyst volume.

- **Congenital nephrogenic diabetes insipidus.**

- Type 2 V2R mutations cause misfolding and interfere with trafficking of the receptor from the endoplasmic reticulum to the cell membrane—VRA can bind to misfolded intracellular V2R and improve transport to the cell membrane.

**Fig. 14.5:** Mechanism of action of vaptans.

## ***Treatment of Hyponatremia (Tables 14.10 and 14.11)***

### **Table 14.10: Treatment of hyponatremia.**

#### **GOALS OF THERAPY**

- Prevent a further decline in serum sodium
- Prevent brain herniation
- Relieve symptoms of hyponatremia
- Avoid overcorrection

#### **ACUTE HYPONATREMIA**

Generally symptomatic. The risk of brain herniation is high and rapid correction is needed

### CHRONIC HYPONATREMIA

It is generally asymptomatic or has mild symptoms. However; it may present with seizures, if hyponatremia is very severe

#### Mild-to-moderate symptoms:

In patients at low risk for herniation: 3% NaCl infused at 0.5–2 mL/kg/hour

Reassess using serum and urinary electrolytes every 4–6 hours

#### Severe symptoms:

100 mL of 3% NaCl infused intravenously over one hour

Can be repeated based on clinical assessment hourly

(100 mL of 3% hypertonic saline, the serum sodium concentration will increase by approximately 2 mmol/L)

#### Hypovolemic hyponatremia:

- isotonic saline to patients who are hypovolemic to replace the contracted intravascular volume

#### Hypervolemic hyponatremia:

- Salt and fluid restriction, plus loop diuretics
- Correction of the underlying condition.
- Use of a V2 receptor antagonist

#### Normovolemic (euvolemic) asymptomatic hyponatremia:

- Free water restriction (<1 L/day)
- Vaptans

#### Overtly symptomatic euvolemic hyponatremia

- Hypertonic (3%) saline
- Intravenous normal saline and diuresis with a loop diuretic

**Total Body [Na<sup>+</sup>] Deficit** = (desired plasma [Na<sup>+</sup>] – measured plasma [Na<sup>+</sup>]) × total body water (TBW)

- TBW is 0.6 × body weight in kg in men and 0.5 × body weights in kg in women

**Example:** The amount of Na needed to raise the Na from 106 to 112 in a 70-kg man can be calculated as follows: (112 mEq/L – 106 mEq/L) × (0.6 L/kg × 70 kg) = 252 mEq

**Water deprivation /Fluid restriction** is the main stay of treatment for chronic hyponatremia and hypervolemic hyponatremia

This can be calculated by **urine: plasma electrolyte ratio (urinary [Na] + [K] / Plasma [Na]**

If it is more than 1, then the fluid can be aggressively restricted up to less than 500 mL/day

For approx, 1 then the fluid can be restrict up to 500–700 mL

For ratio less than 1, fluids can be restricted up to 1 liters

#### Be CAUTIOUS with correction.

- 0.5 mEq/L increase per every hour initially.
- Do not increase Na more than 10 mEq/L in 24 hours or 18 mEq/L in 48 hours.

Sodium content of various intravenous fluid is mentioned in Table 14.11.

**Table 14.11:** Sodium content of various intravenous fluid.

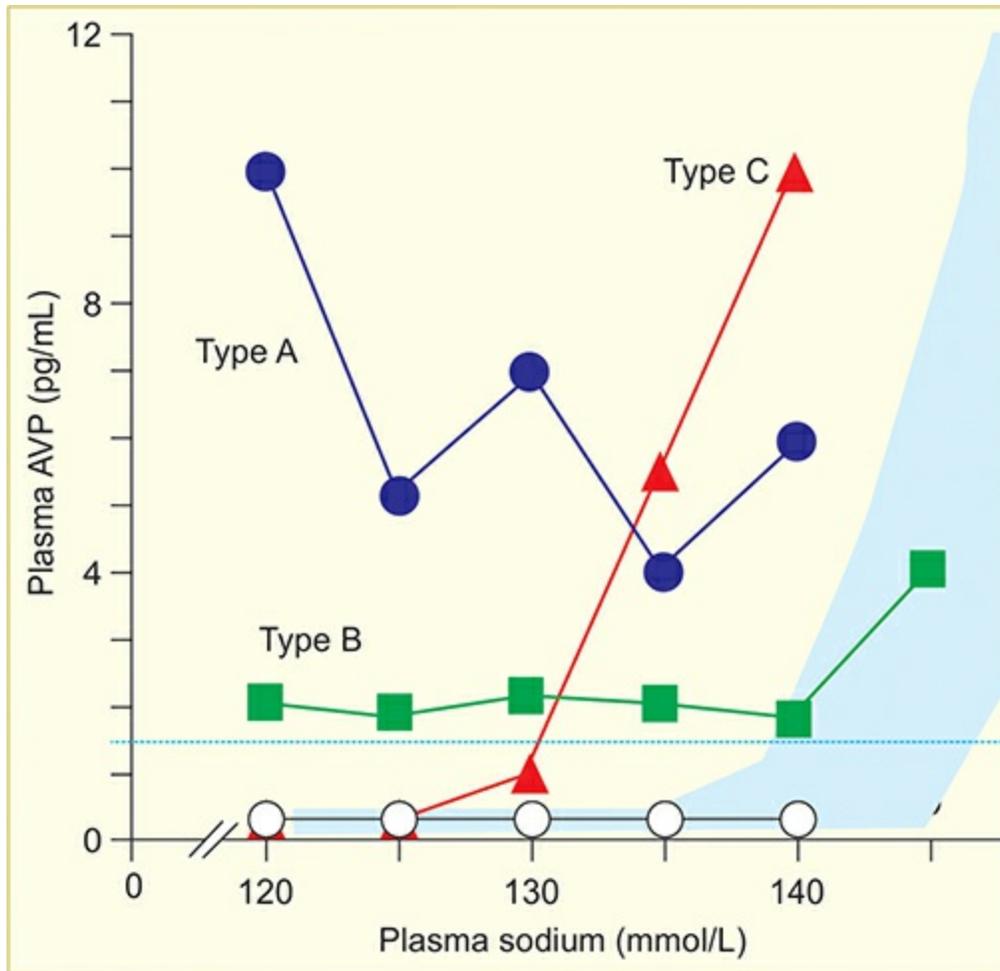

<i>Intravenous fluid</i>	<i>Sodium content</i>
• 7.5% NaHCO <sub>3</sub>	• 900 mEq/L
• 3% NaCl	• 512 mEq/L
• 0.9% NaCl Normal saline	• 514 mEq/L
• Ringer Lactate	• 130 mEq/L
• 0.45% NaCl Half NS	• 77 mEq/L
• Isolyte G	• 65 mEq/L
• Isolyte M	• 40 mEq/L
• 5% Dextrose	• Nil

## Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH/SIAD)

**Q. Write short note on syndrome of inappropriate antidiuretic hormone secretion.**

Normally, hypotonicity of the ECF stops the secretion of antidiuretic hormone (ADH) (Box 14.2). In syndrome of inappropriate antidiuresis (SIAD), the secretion of ADH continues ‘inappropriately’ in spite of hypotonicity of the ECF.

Plasma levels of arginine vasopressin (AVP) in various types of SIADH are shown in Figure 14.6 and Box 14.3.

**Fig. 14.6:** Types of SIADH (syndrome of inappropriate antidiuretic hormone).

(AVP: arginine vasopressin)

**Box 14.2:** Bartter's criteria for diagnosis of syndrome of inappropriate antidiuretic hormone secretion.

- Hyponatremia and true hypo-osmolality by definition
- Euvolemia clinical
- Urine less than maximally dilute (urinary osmolality usually  $> 200$  mOsm/kg of  $H_2O$ )
- Normal renal, cardiac, hepatic, adrenal, pituitary, and thyroid function
- No history of antidiuretic drugs
- No emotional or physical stress
- Urinary sodium  $>20$  mEq/L (Urinary sodium may be  $<20$  mEq/L if the patient is volume depleted or on low sodium intake)

**Box 14.3:** Four types of SIADH.

*Type A:* Characterized by unregulated secretion of vasopressin

Type B: Elevated basal secretion of vasopressin despite normal regulation by osmolality

Type C: A 'reset osmostat'

Type D: Undetectable vasopressin (AVP) levels (these patients may have a gain of function mutation of the V<sub>2</sub>-receptor)

## Etiology (Box 14.4)

### Box 14.4: Various causes of SIADH.

- *Neoplasm*: Carcinomas of lungs (small cell carcinoma), duodenum, ovary, bladder
- *Infection*: Abscess, cavitation, pneumonias, TB, AIDS, meningitis
- *Vascular*: CVA, cavernous sinus thrombosis
- *Neurological*: GBS, multiple sclerosis (MS), amyotrophic lateral sclerosis (ALS) and hydrocephalus
- *Respiratory*: (Positive pressure ventilation) (PPV), pneumothorax, asthma
- *Drugs*: Chlorpropamide, SSRI, MAOI, oxytocin, vasopressin, desmopressin, carbamazepine, cyclophosphamide, vincristine

## Clinical Features

Nausea, hiccoughs, irritability, confusion, seizures and coma. **No edema** observed. Differentiating features of diabetic insipidus, SIADH and cerebral salt wasting are presented in Table 14.12.

### Treatment

- Treat the underlying cause.
- Restrict the fluid intake to 500–1000 mL/day. Oral salt tablets can be advocated.
- In severe hyponatremia, there may be need of slow infusion of hypertonic saline and furosemide.
- Vasopressin-2 receptor antagonists (aquaretics: tolvaptan, conivaptan)
- Demeclocycline, urea and lithium have been used for treatment of SIADH.

**Table 14.12:** Differentiating features of diabetic insipidus, syndrome of inappropriate antidiuretic hormone secretion (SIADH) and cerebral salt wasting (CSW).

	<i>Diabetic insipidus</i>	<i>SIADH</i>	<i>CSW</i>
Urine output	Polyuric	Decreased	Polyuric
Serum Na	High	Low	Low
Urine Na	Low	High	High
Serum osmolality	High	Low	Can be low or normal
Urine osmolality	Low	High	Can be low or normal
CVP	Can be normal or low	High	Low

## Cerebral Salt Wasting

**Causes:** CNS damage due to closed head injury, CNS surgery, CNS tumors, CNS infections, meningitis.

**Signs/Symptoms:** Polyuria, weight loss, dehydration/hypovolemia, hypotension, low CVP.

### Lab Values

- Hyponatremia due to excessive renal Na loss
- High urine Na >20 mmol/L
- Increased plasma ANP (atrial natriuretic peptide), because of low volume status
- Inappropriately normal or low aldosterone and ADH levels despite high ANP.

### Treatment

- Volume for volume replacement of urine Na losses.
- Salt supplementation to the diet.

## Table 14.13: Causes of primary Na<sup>+</sup> gain/primary water deficit.

### 1. Extrarenal:

- Skin and respiratory tract (insensible water loss) due to evaporation
- *GI loss:* Diarrheas
  - i. *Osmotic:* Lactulose, sorbitol, malabsorption, viral gastroenteritis—in all these conditions, water loss > Na<sup>+</sup> loss—hypernatremia.
  - ii. *Secretory:* Cholera, carcinoid syndromes, VIPomas. In these conditions fecal osmolality is almost same as plasma osmolality. Thus, plasma Na<sup>+</sup> concentration remains same or decreases with ECV contraction.

### 2. Renal loss: Most common cause of hypernatremias.

- *Drug induced:* Loop diuretics produces iso-osmotic, solute diuresis
- *Osmotic diuresis:* The presence of nonreabsorbed organic solutes in the tubular lumen in osmotic diuresis water loss > Na<sup>+</sup> K<sup>+</sup> loss, e.g. hyperglycemia, IV mannitol increased urea in body.

## Primary Water Depletion (Hypernatremia)

**Q.** Write short note on primary water depletion or hypernatremia or

## dehydration.

**Definition:** It is defined as plasma Na<sup>+</sup> concentration >145 mmol/L.

Hypernatremia is generally mild unless thirst mechanism is abnormal or access to water is limited, e.g. infants, physically challenged, impaired mental status, postoperative patient, intubated patients in ICU.

### Causes (Table 14.13)

Clinical features and investigations in hypernatremia are presented in Table 14.14.

**Table 14.14:** Clinical features and investigations in hypernatremia.

Clinical features	Investigations
<ul style="list-style-type: none"><li>• Marked thirst</li><li>• Muscle weakness, rigidity</li><li>• Dry mouth</li><li>• Mental confusion, coma</li><li>• Intracranial hemorrhage (in acute hypernatremia)</li><li>• Tachycardia and low systolic blood pressure</li></ul>	<ul style="list-style-type: none"><li>• Hematocrit usually 50%</li><li>• Raised blood urea levels</li><li>• Raised plasma sodium</li><li>• Polyuria and urine specific gravity &lt; 1.010 in diabetes insipidus</li></ul>

### Diagnosis and Management of Hypernatremia

- Complete history and physical examination often provide clues to the underlying cause of hypernatremia.
- Measurement of urine volume and osmolality.
- *Calculation:*

$$\text{Water deficit} = \frac{\text{Plasma Na}^+ \text{ concentration} - 140}{140} \times \text{Total body water}$$

- Rapid correction of hypernatremia is dangerous because sudden decrease in osmolality can cause rapid shift of water into the cells resulting in swelling of brain cells.
- Treatment of hypovolemic hypernatremia is listed in Box 14.5.

**Box 14.5:** Treatment of hypovolemic hypernatremia.

- Treatment of hypovolemic hypernatremia is by restoring volume by intravenous normal saline
- Treatment of hypervolemic hypernatremia is by removing sodium excess by diuresis
- In cases of euvoletic patients D-5%, DNS are given as preferred solutions for free water correction

### Treatment of diabetes insipidus

- In the treatment of central diabetes insipidus (CDI) desmopressin intranasally plays important

role. It can be given 1–2 µg qd or bid injection or 10–20 µg by BID or TID by nasal spray.

- Besides chlorpropamide, clofibrate, carbamazepine can also be given for treatment of CDI. Thiazide diuretic and low Na<sup>+</sup> diet is given for management of nephrogenic diabetes insipidus (NDI).
- Besides in the management of NDI—NSAIDs, amiloride and lithium can also be given in selected patients.

Requirement of fluids depending on degree of depletion is presented in Table 14.15.

**Table 14.15:** Requirement of fluids depending on degree of depletion.

<i>Degree of depletion</i>	<i>Type of fluid and route of administration</i>	<i>Quantity and time for replacement</i>
Mild (1–2 L deficit)	Water by mouth or 5% glucose IV	2 L, over 6–12 hours
Moderate (2–4 L deficit)	5% glucose IV	2–4 L, over 24 hours
Severe (4–10 L deficit)	0.9% NaCl IV	1 L, over 1 hour
	5% dextrose IV	3 L, over 2 hours
	5% dextrose IV	4 L, over 24–48 hours

**Indicators of adequate correction:** Relief of thirst, urine output of more than 1500 mL/24 hours and normal plasma sodium levels.

## Diabetes Insipidus (Discussed on pages 37-39)

## Osmotic Demyelination Syndrome or Central Pontine Myelinolysis

### **Q. Write short note on osmotic demyelination.**

- First described by Adams et al. in 1959.
- *Risk factors:* Alcoholism, chronically ill patients, elderly/malnourished, cirrhosis predisposes to demyelination (due to depletion of intracellular organic solutes).
- Hypokalemia is a strong predictor
- Demyelination can be diffuse and not involve the pons. Extrapontine areas include cerebellar and neocortical white/gray junctional areas, thalamus, subthalamus, amygdale, globus pallidus, putamen, caudate and lateral geniculate bodies.
- Rate of correction over 24 hours more important than rate of correction in

any one particular hour.

- More common, if sodium increases by more than 20 mEq/L in 24 hours
- Very uncommon, if sodium increases by 12 mEq/L or less in 24 hours
- Symptoms generally occur 2–6 days after elevation of sodium and usually either irreversible or only partially reversible.

### ***Clinical Features***

Dysarthria, dysphagia, Parkinsonism, catatonia, locked-in syndrome, lethargy and coma, seizures, nystagmus, ataxia, emotional lability, akinetic mutism, gait disturbance, myoclonus, behavioral disturbances, paraparesis or quadriparesis. MRI with diffusion-weighted imaging will be helpful in early detection.

#### **Treatment**

No effective therapy. Changes are permanent. Mortality is very high. Case reports of improvement with aggressive plasmapheresis immediately after diagnosis. Case reports of treatment with thyrotropin-releasing hormone. Infusion of myoinositol (a major osmolyte lost in the adaptation to hyponatremia) protects against mortality and myelinolysis from rapid correction of hyponatremia.

## **DISORDERS OF POTASSIUM BALANCE**

### **Potassium**

**Q. Write short note on the normal physiology of potassium in the body.**

- Potassium is the major intracellular cation. Potassium is essential for a number of normal body functions of tissue such as nerve, muscle and heart.
- *Distribution of potassium:* Normal plasma level of potassium is 3.5–5.0 mmol/L (mEq/L) whereas inside the cells (Potassium is the principle intracellular cation, i.e. ICF) it is about 150 mmol/L. The extra cellular intracellular ratio being 1:38. Therefore, the amount of  $K^+$  in ECF (30–70 mmol) constitutes less than 2% of total body  $K^+$  content (2500–4500 mmol).

### ***Physiology***

- The concentration gradient between ECF and ICF is maintained by the  $Na^+ K^+$  stimulated ATPase system.

- Total dietary intake of  $K^+$  is 40–120 mmol/day or 1.5 mmol/kg/day. About 90% of it is absorbed in GI tract.
- Sudden rise in plasma  $K^+$  is prevented by: (i) shift of  $K^+$  into the cell by insulin and (ii) excess  $K^+$  excreted in urine.
- Excretion through kidney is the major route of elimination of dietary and other sources of excess  $K^+$ .
- About 90% of filtered potassium is absorbed in proximal convoluted tubule. It is absorbed passively with sodium and water.

## Hypokalemia

### Q. Write short note on:

- **Normal serum potassium level and causes of hypokalemia**
- **Hypokalemia.**

An abnormally low level ( $<3.5$  mmol/L) of plasma potassium ( $K^+$ ) is called hypokalemia.

### Causes (Table 14.16)

**Table 14.16: Various causes of hypokalemia.**

<p>1. <b>Decreased intake</b></p> <p>a. Starvation</p> <p>b. Clay ingestion (geophagia): It binds dietary <math>K^+</math> and iron.</p> <p>2. <b>Redistribution into cell</b></p> <p>a. <i>Metabolic alkalosis</i>: Due to <math>K^+</math> redistribution into the cell as well as increased <math>K^+</math> loss (renal)</p> <p>b. Hormonal</p> <p>i. Insulin</p> <p>ii. <math>\beta_2</math> adrenergic agonist: it causes <math>K^+</math> influx into the cell as well as stimulates insulin release</p> <p>iii. <math>\alpha</math>-adrenergic antagonist</p> <p>c. <i>Anabolic states</i>:</p> <p>i. Vitamin B<sub>12</sub> or folic acid (red blood cell production)</p> <p>ii. Granulocyte macrophage colony</p>	<p>b. <i>Renal</i>: Increased distal flow</p> <p>i. Diuretic</p> <p>ii. Osmotic diuretic</p> <p>iii. Salt-wasting nephropathy</p> <p>c. <i>Increased renal secretion of <math>K^+</math></i></p> <p>i. Mineralocorticoid excess</p> <p>ii. <i>Primary hyperaldosteronism</i>: Adenoma (Conn's syndrome), hyperplasia, carcinoma</p> <p>iii. Secondary hyperaldosteronism</p> <p>iv. Malignant hypertension</p> <p>v. Hypovolemia</p> <p>vi. Renal artery stenosis</p> <p>d. <i>Apparent mineralocorticoid excess</i>:</p> <p>i. Tobacco chewing, liquorice consumption</p> <p>ii. Congenital adrenal hyperplasia</p> <p>iii. Cushing's syndrome</p> <p>iv. Bartter's syndrome</p>
---	---

<ul style="list-style-type: none"> <li>stimulating factor</li> <li>iii. Total parenteral nutrition</li> <li>d. <i>Others</i>: <ul style="list-style-type: none"> <li>i. Pseudohypokalemia</li> <li>ii. Barium toxicity</li> <li>iii. Hypothermia</li> <li>iv. Hypokalemic periodic paralysis.</li> </ul> </li> <li>3. <b>Increased loss</b> <ul style="list-style-type: none"> <li>a. <i>Nonrenal</i>: <ul style="list-style-type: none"> <li>i. <i>Gastrointestinal</i>: Diarrhea, vomiting</li> <li>ii. <i>Integumentary</i></li> </ul> </li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>e. <i>Distal delivery of nonreabsorbed anion</i>: <ul style="list-style-type: none"> <li>i. Vomiting, nasogastric suction, type 2 (proximal) RTA, toluene abuse, penicillin derivatives</li> <li>ii. <i>Others</i>: Amphotericin B, Liddle's syndrome, hypomagnesemia</li> </ul> </li> </ul>
---	---

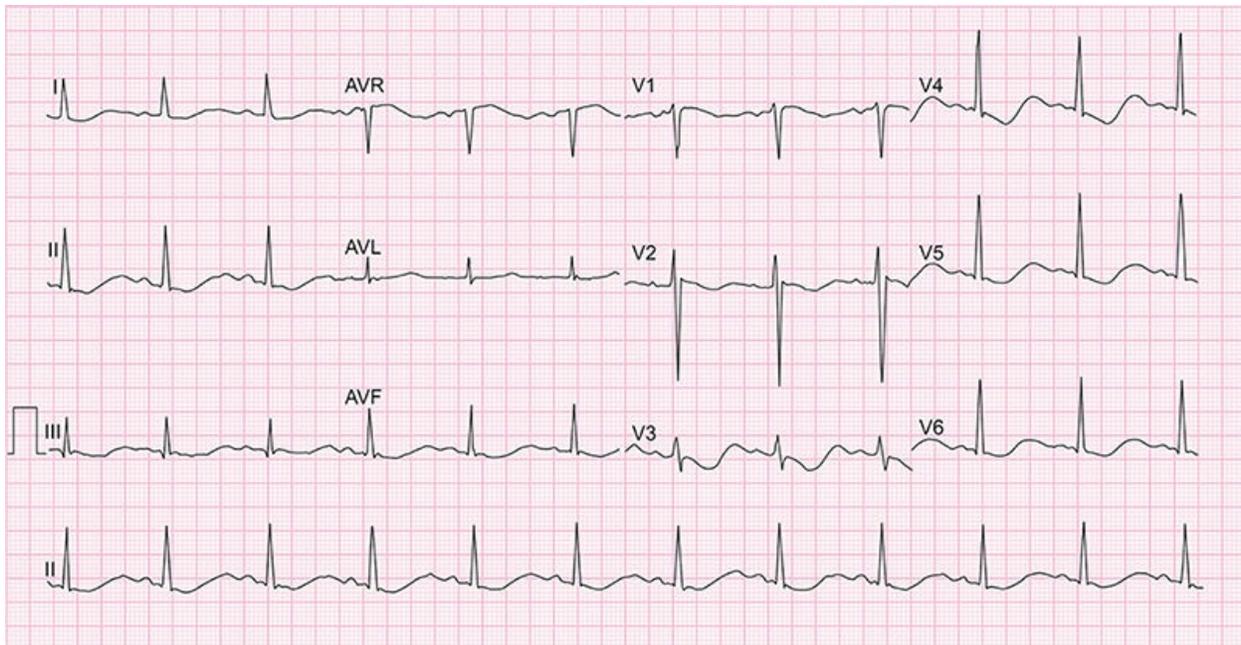

## ***Clinical Features of Potassium Depletion (Table 14.17)***

**Table 14.17: Clinical manifestations of potassium depletion.**

<ul style="list-style-type: none"> <li>1. <i>Neuromuscular</i>: <ul style="list-style-type: none"> <li>• Skeletal muscle weakness, fatigue, myalgia, muscular weakness in extremities—quadripareisis (<b>Periodic Paralysis</b>)</li> <li>• Smooth muscles—paralytic ileus.</li> <li>• Respiratory muscle weakness—hypoventilation</li> <li>• Tetany</li> <li>• Rhabdomyolysis</li> </ul> </li> <li>2. <i>Renal</i>: <ul style="list-style-type: none"> <li>• Polyuria (Nephrogenic) diabetic insipidus.</li> <li>• Increased ammonia production.</li> <li>• Increased bicarbonate reabsorption.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>3. <i>Hormonal</i>: <ul style="list-style-type: none"> <li>• Decreased insulin secretion</li> <li>• Decreased aldosterone secretion</li> <li>• Insulin resistance</li> </ul> </li> <li>4. <i>Metabolic</i>: <ul style="list-style-type: none"> <li>• Negative nitrogen balance</li> <li>• Encephalopathy in patients with liver disease.</li> </ul> </li> <li>5. <i>Cardiovascular</i>: <ul style="list-style-type: none"> <li>• ECG changes/dysrhythmia</li> <li>• Myocardial dysfunction</li> </ul> </li> </ul>
---	--

### ***Investigations***

- Measurement of plasma electrolytes, bicarbonate, urine potassium, plasma calcium and magnesium.
- **ECG changes (Fig. 14.7 and Table 14.18)**: The electrocardiographic changes of hypokalemia are due to delayed ventricular, repolarization and do not correlate well with plasma-potassium concentration.

**Fig. 14.7:** Various ECG changes depending on plasma potassium levels.

**Table 14.18:** Electrocardiographic changes in hypokalemia.

<i>Early changes</i>	<i>Changes due to severe potassium depletion</i>
<ul style="list-style-type: none"> <li>• Flattening or inversion of the T wave</li> <li>• Prominent U wave</li> <li>• ST segment depression</li> <li>• Prolonged QU interval</li> </ul>	<ul style="list-style-type: none"> <li>• Prolonged PR interval</li> <li>• Decreased voltage and widening of the QRS complex</li> <li>• An increased risk of ventricular, arrhythmias especially in patients with myocardial ischemia or left ventricular hypertrophy.</li> </ul>

### Management

- Careful history, e.g. diuretic and laxative abuse, vomiting.
- Exclude pseudohypokalemia, e.g. with marked leukocytosis (AML) and normokalemia patients with low plasma  $K^+$  (It is due to WBC uptake of  $K^+$  at room temperature).
- Eliminate decrease intake (e.g. starvation, geophagia) and intracellular cause (e.g. metabolic alkalosis, insulin therapy, beta 2 agonist administration stress, hypokalemic periodic paralysis, anabolic states, and massive transfusion).
- Assess urinary excretion (to clarify source of  $K^+$  loss).

### Transtubular potassium gradient or TTKG (Box 14.6):

- Rule out **magnesium deficiency**, if hypokalemia not getting corrected.

**Therapeutic goals:** To correct the potassium deficit and to minimize the ongoing losses.

- It is generally safer to correct hypokalemia via oral route.
- **A decrement of 1 mmol/L in the plasma-potassium concentration (from 4.0 to 3.0 mmol/L) may represent a total body potassium deficit of 200 to 400 mmol.**

- For every 1 mmol/L potassium depletion—A potassium deficiency is 10% of total body potassium stores (2500–4500 mmol).
- Patients with plasma levels under <3 mmol often require in excess of 600 mmol of potassium to correct the deficit.

#### Oral therapy:

- Potassium chloride (15 mL = 20 mEq) is **preferred agent**. Especially useful in Cl-responsive metabolic alkalosis.
- Potassium phosphate useful when coexistent phosphorus deficiency.
- Potassium bicarbonate, acetate, gluconate, or citrate useful in metabolic acidosis.

#### IV therapy:

- Patients with severe hypokalemia or those unable to take anything by mouth require intravenous replacement therapy with KCl (Potassium chloride).
- IV 15% **potassium chloride** 1 mL = 2 mEq/L, 10 mL = 20 mEq/L.
- The maximum concentration of administered potassium should be no more than 40 mmol/L via a peripheral vein or 60 mmol/L via central vein.
- The rate of infusion should not exceed 20 mmol/hour unless paralysis or malignant ventricular arrhythmia is present.
- **Do not give more than** 10–20 mEq/hr or 40 mEq/L or 240 mEq/L/day.

#### Box 14.6: Transtubular potassium gradient or TTKG.

- This is ratio of  $K^+$  concentration in lumen of cortical collecting duct (CCD) to that of potassium concentration in plasma.
- $TTKG = \text{Urinary } K^+ \times \text{Plasma osm} / \text{Serum } K^+ \times \text{Urinary osm}$
- **Significance of TTKG:** During hypokalemia—TTKG should fall < 3—indicating appropriately reduced urinary excretion of K. TTKG > 4— indicates renal K loss is due to increased distal K secretion.

## Hyperkalemia

### Q. Write short essay/note on:

- **Causes and treatment of hyperkalemia**
- **ECG changes in hyperkalemia**
- **Clinical features, diagnosis and treatment/management of hyperkalemia**
- **Drugs used to treat hyperkalemia.**

**Definition:** Hyperkalemia is defined as plasma **potassium greater than 5.0 mmol/L** occurs as a result of either potassium release from cells or decreased renal loss.

### *Causes of Hyperkalemia (Table 14.19)*

Pseudohyperkalemia (factitious, spurious) represents an artificially elevated plasma-potassium concentration.

**Table 14.19: Causes of hyperkalemia.**

<ul style="list-style-type: none"> <li>• Renal failure</li> <li>• Decreased distal flow (i.e. decreased effective circulatory arterial volume).</li> <li>• <i>Decrease K<sup>+</sup> potassium secretion:</i> <ul style="list-style-type: none"> <li>A. <i>Impaired Na<sup>+</sup> reabsorption:</i> <ol style="list-style-type: none"> <li>1. Primary hypoaldosteronism               <ul style="list-style-type: none"> <li>• Adrenal insufficiency</li> <li>• Adrenal enzyme deficiency: 21-hydroxylase, 3 β-hydroxysteroid dehydrogenase, corticosteronemethyl oxidase.</li> </ul> </li> <li>2. Secondary hypoaldosteronism Hyporeninemia Drugs (ACE inhibitors, NSAIDs, Heparin)</li> <li>3. Resistance to aldosterone Pseudohypoaldosteronism Drugs (K<sup>+</sup> sparing diuretics, trimethoprim, pentamidine)</li> </ol> </li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>B. <i>Enhanced BCl<sup>-</sup> reabsorption:</i> <ol style="list-style-type: none"> <li>1. Gordon's syndrome</li> <li>2. Cyclosporine</li> <li>3. Type IV RTA</li> </ol> </li> <li>C. <i>Shift of potassium out of cell:</i> <ol style="list-style-type: none"> <li>1. Tissue damage (ischemia or shock) severe exercise.</li> <li>2. Metabolic acidosis.</li> <li>3. Uncontrolled diabetes due to insulin deficiency.</li> <li>4. Aldosterone deficiency.</li> <li>5. Hyperkalemic periodic paralysis, succinyl choline.</li> </ol> </li> <li>D. <i>Tissue breakdown:</i> <ol style="list-style-type: none"> <li>1. Bleeding into soft tissue, GI tract or body cavities.</li> <li>2. Hemolysis, rhabdomyolysis</li> <li>3. Catabolic state</li> </ol> </li> </ul>
---	--

### ***Clinical Features***

- Hyperkalemia is **often asymptomatic** until plasma K<sup>+</sup> concentration is greater than 6.5 to 7.0 mEq/L and may lead to fatal cardiac arrhythmia, hence it is called as **silent killer**.
- **Vague muscular weakness** is usually first symptom of hyperkalemia.
- Severe hyperkalemia can lead to hyporeflexia, gradual paralysis effecting initially legs, then trunk and arms and at last face and respiratory muscle (Periodic paralysis).
- Paralysis usually spares the muscles supplied by cranial nerves and patients remain alert and apprehensive until cardiac arrest and death occurs.
- The most serious effect of hyperkalemia is cardiac toxicity, which does not correlate well with plasma potassium concentration. Various approaches of hyperkalemia is listed in Box 14.7.

## Investigations

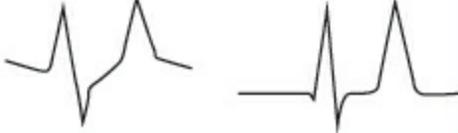

- Measurement of electrolytes, creatinine and bicarbonate.
- **ECG changes (Figs. 14.8 and 14.9):** The earliest electrocardiographic changes: increased T-wave, amplitude or peaked T-wave.

### Treatment

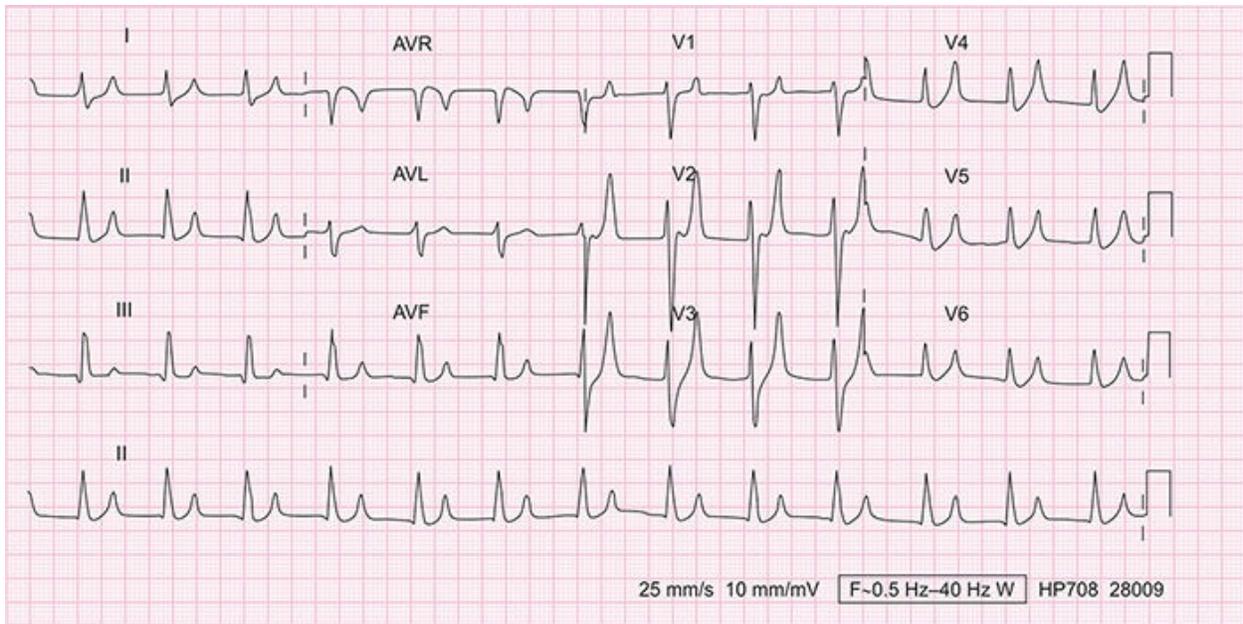

- The urgency and aggressiveness of treatment of hyperkalemia depends on its degree clinical status.
  - **Emergency treatment (Table 14.20)**
- Potentially fatal hyperkalemia (serum potassium > 7.5 mmol/L).
- Profound weakness, absence of P wave, QRS widening or ventricular arrhythmia on ECG needs urgent treatment.

### Box 14.7: Approach to hyperkalemia.

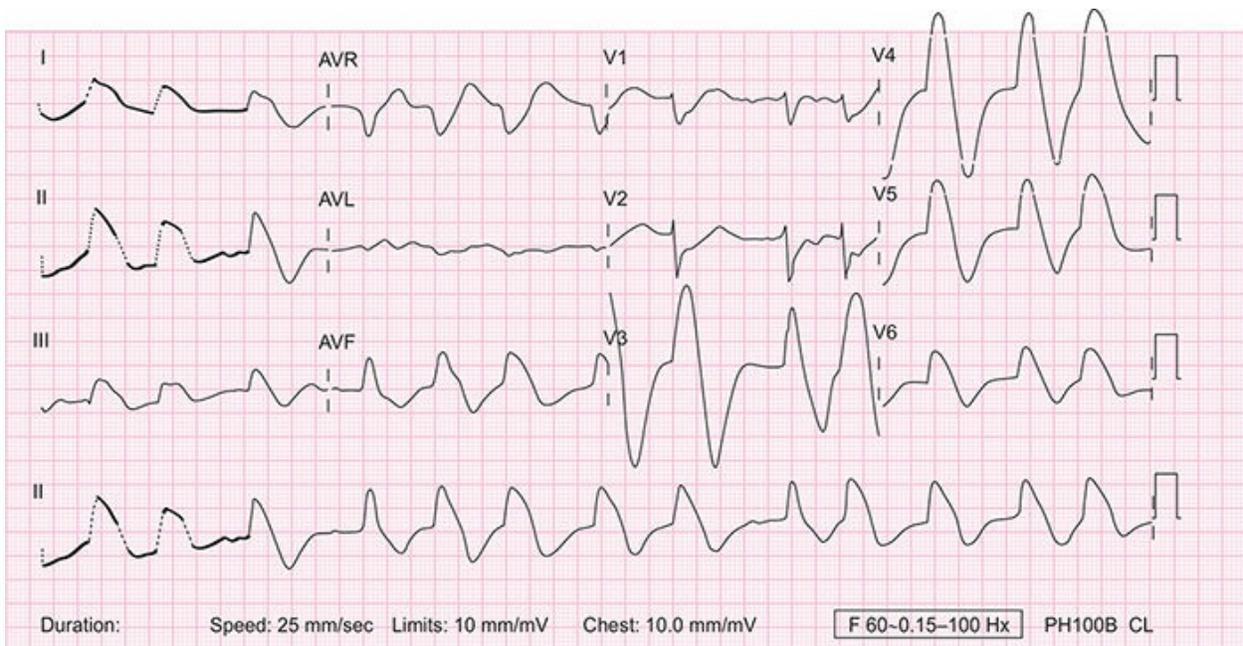

- Exclude pseudohyperkalemia.
- Exclude transcellular K<sup>+</sup> shift.
- Exclude oliguric renal failure.
- Stop NSAIDs and ACE inhibitors.

Serum K <sup>+</sup>	ECG findings
6–7 mEq/L	Tall peaked T-waves 
7–8 mEq/L	Loss of P-waves and progressive widening of QRS complex 
8–10 mEq/L	QRS merges with T-waves forming <b>sine waves</b> 
> 9 mEq/L	Atrioventricular dissociation, ventricular tachycardia or fibrillation or asystole.

**Fig. 14.8:** ECG changes in hyperkalemia in relation to serum potassium.

**Fig. 14.9A:** ECG changes in hyperkalemia in relation to serum potassium (increased T-wave, amplitude or peaked T-wave).

**Fig. 14.9B:** ECG of severe hyperkalemia showing sine wave pattern.

## ACID-BASE BALANCE

**Q.** Write short essay/note on:

- **Physiology of acid-base balance.**

- **Different terminologies used in assessment of acid-base status of a patient.**

## Definitions

- **Acid:** Any compound which forms  $H^+$  ions in solution (proton donors), e.g. carbonic acid releases  $H^+$  ions.
- **Base:** Any compound which combines with  $H^+$  ions in solution (proton acceptors), e.g. bicarbonate ( $HCO_3^-$ ) accepts  $H^+$  ions.

**Table 14.20: Drugs used in the treatment of hyperkalemia.**

<i>Therapeutic goal</i>	<i>Intervention</i>	<i>Dose and method of administration</i>
Myocardial membrane stabilization, if ECG changes are +ve)	Calcium chloride or	<ul style="list-style-type: none"> <li>• 1 g IV over 10 minutes non-emergent setting</li> </ul>
	Calcium gluconate	<ul style="list-style-type: none"> <li>• 1 g IV push in cardiac arrest or significant dysrhythmia</li> </ul>
Intracellular potassium shifting	Dextrose/Insulin	<ul style="list-style-type: none"> <li>• Dextrose 50 g IVP (intravenous push)</li> <li>• Insulin (regular) 10 units IVP</li> </ul>
	Sodium bicarbonate	<ul style="list-style-type: none"> <li>• 1 mEq/kg ideal body weight</li> <li>• IV over 10–20 minutes non-emergent setting</li> <li>• IVP in cardiac arrest or significant dysrhythmia</li> </ul>
	Magnesium sulfate	<ul style="list-style-type: none"> <li>• 1–2 g IV over 10 minutes non-emergent setting</li> <li>• IVP in cardiac arrest or significant dysrhythmia</li> </ul>
	Sympathomimetic agents	<ul style="list-style-type: none"> <li>• Albuterol-standard metered ‘respiratory dose’ via nebulizer non-emergent/emergent (significant dysrhythmia) setting</li> <li>• Epinephrine-<b>cardiac arrest only:</b> 1 mg IVP (1:10,000 concentration)</li> </ul>
Potassium removal from body (excretion from the body)	Sodium polystyrene	<ul style="list-style-type: none"> <li>• 30–60 g PO or PR</li> </ul>
	Normal saline	<ul style="list-style-type: none"> <li>• Volume determined by clinical setting</li> </ul>
	Furosemide	<ul style="list-style-type: none"> <li>• 20 g IV for furosemide-naïve patients</li> </ul>
	Hemodialysis	<ul style="list-style-type: none"> <li>• Best way of removal</li> </ul>

## Regulation of Acid-Base Balance

- Maintenance of blood pH is an important homeostatic mechanism of the body. The pH of the blood is maintained between 7.35 and 7.45.
- Normal pH and its variation is indicated in Box 14.8.

## Maintenance of Acid-Base Balance/pH

Many physiological mechanisms maintain pH of the ECF within narrow limits (Box 14.9).

### Box 14.8: Normal pH and its variation.

- *Normal pH*: 7.35–7.45
- *Acidosis*: Physiological state resulting from abnormally low plasma pH.
- *Alkalosis*: Physiological state resulting from abnormally high plasma pH.
- *Acidemia*: Plasma pH <7.35
- *Alkalemia*: Plasma pH >7.45

### Box 14.9: Response of the body to acid base challenge.

1. *Buffering*: Two most common chemical buffer groups
  - a. Bicarbonate
  - b. Nonbicarbonate (Hemoglobin, protein, phosphate)
    - ◆ Blood buffer systems act instantaneously
    - ◆ Regulate pH by binding or releasing H<sup>+</sup>
2. Respiratory acid-base control mechanisms
3. Renal acid-base control mechanisms

## Classification of Acid-Base Disorders (Table 14.21)

**Table 14.21:** Classification of acid-base disorders.

<i>Disorder</i>	<i>pH</i>	<i>[H<sup>+</sup>]</i>	<i>Primary disturbance</i>	<i>Secondary response</i>
Metabolic acidosis	↓	↑	↓ [HCO <sub>3</sub> <sup>-</sup> ]	↓ pCO <sub>2</sub>
Metabolic alkalosis	↑	↓	↑ [HCO <sub>3</sub> <sup>-</sup> ]	↑ pCO <sub>2</sub>
Respiratory acidosis	↓	↑	↑ pCO <sub>2</sub>	↑ [HCO <sub>3</sub> <sup>-</sup> ]
Respiratory alkalosis	↑	↓	↓ pCO <sub>2</sub>	↓ [HCO <sub>3</sub> <sup>-</sup> ]

## Anion Gap

**Q. What is anion gap? Enumerate conditions associated with increased anion gap.**

- Anion gap denotes the concentration of the unmeasured anions in the plasma, namely—phosphates, sulfates, organic acids and protein anions.
- Anionic gap =  $\{[Na^+] + [K^+]\} - \{[HCO_3^-] + [Cl^-]\}$ 
  - Normal cations in plasma:  $Na^+$ ,  $K^+$ ,  $Ca^{2+}$ ,  $Mg^{2+}$ .
  - Normal anions in plasma are  $Cl^-$ ,  $HCO_3^-$ , negative charges present on albumin, phosphate, sulfate, lactate, and other organic acids.
  - The sums of the positive and negative charges are equal.
- Calculation of the anion gap helps to decide whether metabolic acidosis due to:
  - Loss of bicarbonate
  - Accumulation of non-volatile acids
- It is an index of the relative concentration of plasma anions other than chloride, bicarbonate  $[serum Na^+ - (serum Cl^- + serum HCO_3^-)]$ .
  - Unmeasured anions—unmeasured cations
  - Normal anionic gap is 8–16 mEq/L (in new techniques it is 5–11).
  - Mostly represent **albumin**.
- **Increased anionic gap:** Usually found in some forms of metabolic acidosis (Box 14.10).
- **Reduced anionic gap:** Lithium and bromide intoxication, multiple myeloma marked hyperlipidemia.

**Box 14.10:** Causes of high anion gap metabolic acidosis (HAGMA).

<b>Lactic acidosis</b> <b>Ketoacidosis</b> <ul style="list-style-type: none"> <li>• Diabetic</li> <li>• Alcoholic</li> <li>• Starvation</li> </ul> <b>Renal failure</b> (acute and chronic)	<b>Toxins</b> <ul style="list-style-type: none"> <li>• Ethylene glycol</li> <li>• Methanol</li> <li>• Salicylates</li> <li>• Propylene glycol</li> </ul>
--	--

***Causes of Metabolic Acidosis (Box 14.10)***

**(High anion gap metabolic acidosis, HAGMA) → (Normochloremic)**

Causes of normal anion gap metabolic acidosis are listed in Table 14.22.

**Table 14.22: Normal anion gap metabolic acidosis—NAGMA (Hyperchloremic).**

<p><b>Gastrointestinal bicarbonate loss</b></p> <ul style="list-style-type: none"> <li>• Diarrhea</li> <li>• External pancreatic or small-bowel drainage</li> <li>• Ureterosigmoidostomy, jejunal loop, ileal loop</li> <li>• <i>Drugs:</i> <ol style="list-style-type: none"> <li>1. Calcium chloride (acidifying agent)</li> <li>2. Magnesium sulfate (diarrhea)</li> <li>3. Cholestyramine (bile acid diarrhea)</li> </ol> </li> </ul> <p><b>Renal acidosis</b></p> <ul style="list-style-type: none"> <li>• Hypokalemia           <ul style="list-style-type: none"> <li>– Proximal RTA (type 2)</li> <li>– Distal (classic) RTA (type 1)</li> </ul> </li> <li>• Hyperkalemia</li> </ul>	<p><b>Drug-induced hyperkalemia (with renal insufficiency)</b></p> <ul style="list-style-type: none"> <li>• Potassium-sparing diuretics (amiloride, triamterene, spironolactone)</li> <li>• Trimethoprim</li> <li>• Pentamidine</li> <li>• ACE-Is and ARBs</li> <li>• Nonsteroidal anti-inflammatory drugs</li> <li>• Cyclosporine and tacrolimus</li> </ul> <p><b>Others</b></p> <ul style="list-style-type: none"> <li>• Acid loads (ammonium chloride, hyperalimentation)</li> <li>• Loss of potential bicarbonate: Ketosis with ketone excretion</li> <li>• Expansion acidosis (rapid saline administration)</li> </ul>
--	---

**Combined elevated anion gap and hyperchloremic acidoses:** Diarrhea, ketoacidosis and progression of kidney disease,

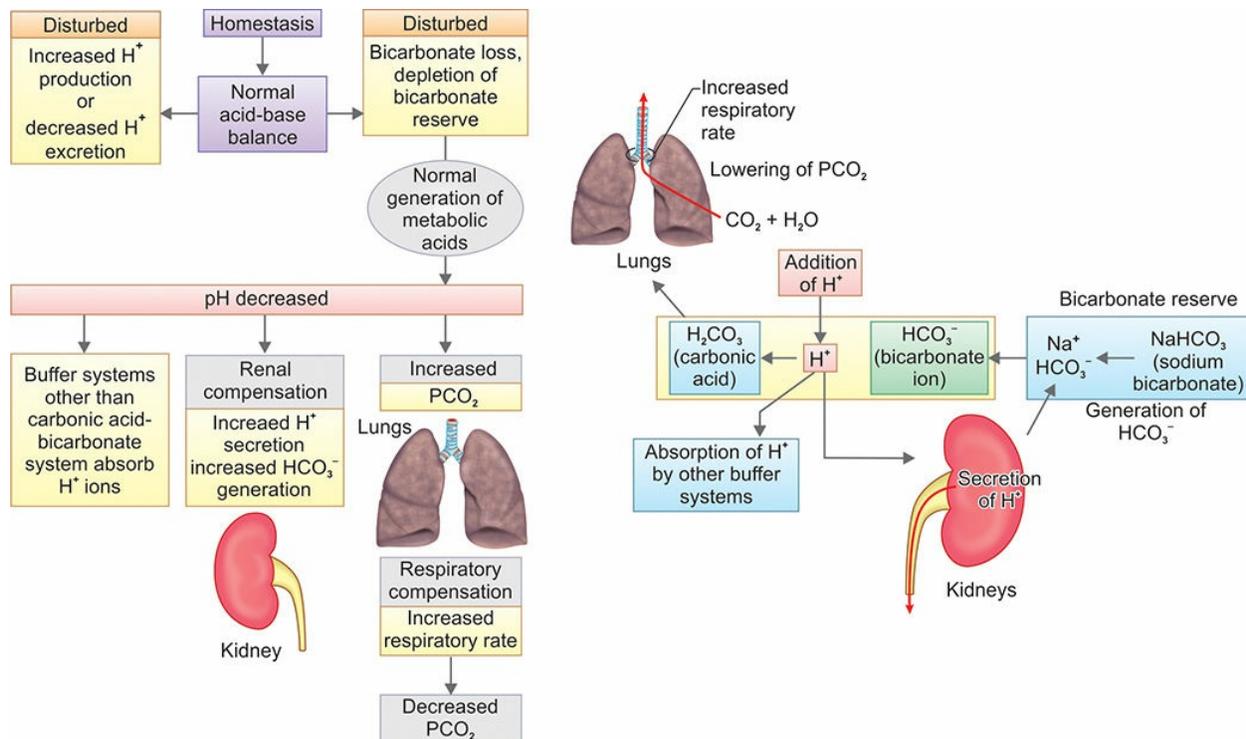

### Urine Net Charge/UAG

- Distinguish between hyperchloremic acidosis due to diarrhea and renal tubular acidosis (RTA)
- **UAG (in mEq/L or mmol/L) = Urine (Na + K - Cl)**
- Provides an estimate of urinary  $\text{NH}_4^+$  production
- Normal UAG = -25 to -50
- Negative UAG – Diarrhea (Hyperchloremic acidosis)
- Positive UAG – RTA

### ‘Delta Ratio’/‘GAP-GAP’

- Ratio between  $\uparrow$  in anionic gap (AG) and  $\downarrow$  in bicarbonate
- Used in the assessment of elevated anion gap metabolic acidosis to determine, if a mixed acid-base disorder (metabolic acidosis) is present.
- **Equation for calculating**

$$\text{Delta ratio} = \frac{(\text{AG} - 12)}{(24 - [\text{HCO}_3^-])}$$

**Fig. 14.10:** Mechanism and response to acidosis.

## Metabolic Acidosis

### Q. Write short note on:

- **Causes of metabolic acidosis.**
- **Clinical features and management of metabolic acidosis.**
- Metabolic acidosis is a primary acid-base disorder characterized by fall in both pH of blood ( $\downarrow$  pH) and bicarbonate level in the plasma ( $\downarrow$   $\text{HCO}_3^-$ ).
- Metabolic acidosis can develop when there is an imbalance between net acid production and net acid excretion (Fig. 14.10). Metabolic acidosis occurs when an acid other than carbonic acid (due to  $\text{CO}_2$  retention) accumulates in the body, leading to fall in the plasma bicarbonate. Thus, it is due to gain of strong acid or loss of base ( $\text{HCO}_3^-$ ).

### Clinical features (Box 14.11)

Symptoms are specific and a result of the underlying pathology.

#### Treatment

- Correct the underlying disorder.
- Sodium bicarbonate may be administered in severe acidosis.

- Tromethamine (tris-hydroxymethyl aminomethane; THAM) is an alternative to  $\text{NaHCO}_3$ .
- Dialysis may be necessary in renal failure with metabolic acidosis.

### Box 14.11: Clinical features of metabolic acidosis.

**Respiratory effects:** Hyperventilation. In severe cases, there is deep sighing respiration (Kussmaul's breathing or 'air hunger').

**CVS:** ↓ myocardial contractility, sympathetic over activity, resistant to catecholamines

**CNS:** Lethargy, disorientation, stupor, muscle twitching, coma, cranial nerve palsies

**Others:** Hyperkalemia

## Metabolic Alkalosis

### Q. Write short note on metabolic alkalosis.

Metabolic alkalosis is characterized by rise in both plasma bicarbonate level and plasma pH. The primary event is elevation of pH due to raised plasma bicarbonate concentration ( $\text{HCO}_3^-$ ) or decreased acid (Fig. 14.11).

**Types:** Metabolic alkalosis may be hypovolemic or normovolemic. Causes of metabolic alkalosis are listed in Table 14.23.

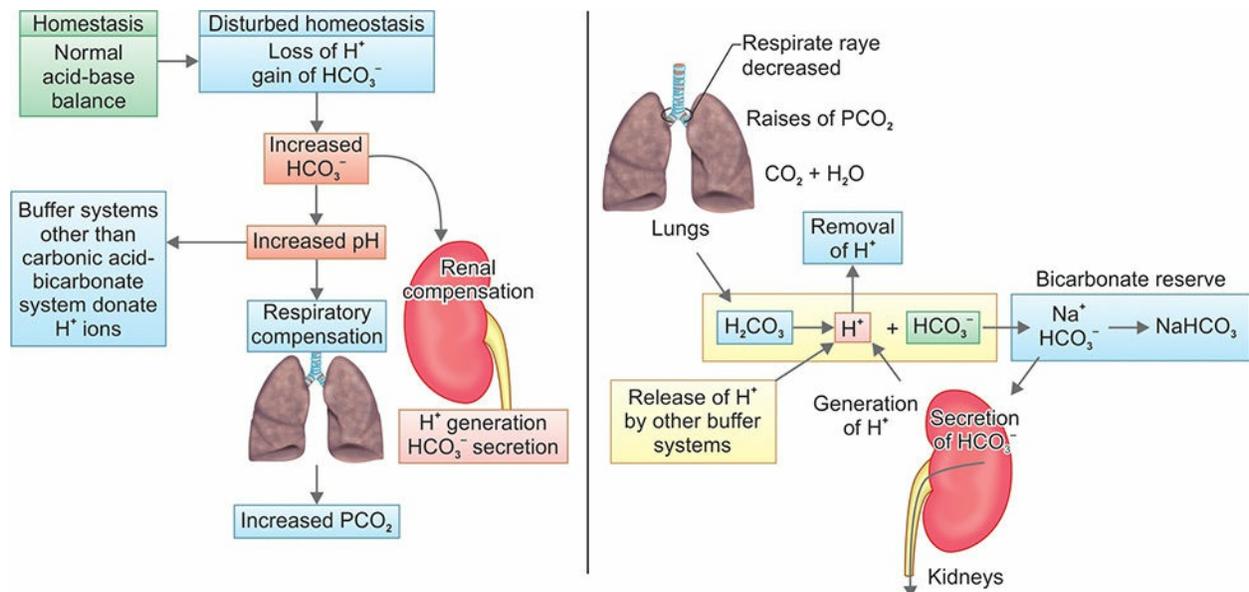

Fig. 14.11: Mechanism and response to alkalosis.

### Table 14.23: Causes of metabolic alkalosis.

- Exogenous  $\text{HCO}_3^-$  loads:
  - Acute alkali administration

#### Chloride-responsive alkalosis

- Low urinary chloride concentration (<15 mEq/L)

<ul style="list-style-type: none"> <li>- Milk-alkali syndrome</li> <li>• <i>Gastrointestinal origin:</i> <ul style="list-style-type: none"> <li>- Vomiting</li> <li>- Gastric aspiration</li> <li>- Congenital chloridorrhea</li> <li>- Villous adenoma</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>- Gastric acid loss</li> <li>- Diuretic therapy</li> <li>- Volume depletion</li> <li>- Renal compensation for hypercapnea</li> </ul>
<ul style="list-style-type: none"> <li>• <i>Renal origin:</i> <ul style="list-style-type: none"> <li>- Diuretics</li> <li>- Posthypercapnic state</li> <li>- Hypercalcemia/hypoparathyroidism</li> <li>- Recovery from lactic acidosis or ketoacidosis</li> <li>- Non reabsorbable anions including penicillin, carbenicillin</li> <li>- Mg<sup>2+</sup> deficiency</li> <li>- K<sup>+</sup> depletion</li> </ul> </li> </ul>	<p><b>Chloride-resistant alkalosis</b></p> <ul style="list-style-type: none"> <li>• <b>Elevated urinary chloride</b> (&gt;25 mEq/L) <ul style="list-style-type: none"> <li>- 1° mineralocorticoid excess</li> <li>- Severe potassium depletion</li> </ul> </li> <li>• <b>Associated with volume expansion</b></li> </ul>

### Clinical features (Table 14.24)

#### Management

- *Metabolic alkalosis with hypovolemia:* Corrected by intravenous infusions of 0.9% saline with potassium supplements. This reverses the secondary hyperaldosteronism and the kidney excretes the excess alkali in the urine.
- *Metabolic alkalosis with normal or increased volume:* Treatment of the underlying endocrine cause.

## Respiratory Acidosis

### Q. Write short note on respiratory acidosis.

Respiratory acidosis is a primary acid-base disorder characterized by ↑ PCO<sub>2</sub>  
→ ↓pH.

- Acute (<24 hours)
- Chronic (>24 hours)

### Causes of respiratory acidosis (Table 14.25)

#### Table 14.24: Clinical features of metabolic alkalosis.

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• Decreased myocardial contractility</li> <li>• Arrhythmias</li> <li>• ↓ cerebral blood flow</li> </ul> | <ul style="list-style-type: none"> <li>• Mental obtundation</li> <li>• Neuromuscular excitability</li> <li>• Hypoventilation</li> </ul> |
|--|---|

- Confusion

- Pulmonary microatelectasis

**Table 14.25: Causes of respiratory acidosis.**

<p><b>CNS depression</b></p> <ul style="list-style-type: none"> <li>• <i>Drugs:</i> Opiates, sedatives, anesthetics</li> <li>• Obesity hypoventilation syndrome</li> <li>• Stroke</li> </ul>	<p><b>Chest wall restriction</b></p> <ul style="list-style-type: none"> <li>• <i>Pleural:</i> Effusions, empyema, pneumothorax, fibrothorax</li> <li>• <i>Chest wall:</i> Kyphoscoliosis, scleroderma, ankylosing spondylitis, obesity</li> </ul>
<p><b>Neuromuscular disorders</b></p> <ul style="list-style-type: none"> <li>• <i>Neurologic:</i> Multiple sclerosis, polio, GBS, tetanus, botulism, high cord lesions</li> <li>• <i>End plate:</i> Myasthenia gravis, OP poisoning, aminoglycoside toxicity</li> <li>• <i>Muscle:</i> Hypokalemia, hypophosphatemia, muscular dystrophy</li> </ul> <p><b>Airway obstruction</b></p> <ul style="list-style-type: none"> <li>• COPD, acute aspiration, laryngospasm</li> </ul>	<p><b>Severe pulmonary restrictive disorders</b></p> <ul style="list-style-type: none"> <li>• Pulmonary fibrosis</li> <li>• <i>Parenchymal infiltration:</i> Pneumonia, edema</li> </ul> <p><b>Abnormal blood CO<sub>2</sub> transport</b></p> <ul style="list-style-type: none"> <li>• <i>Decreased perfusion:</i> Heart failure, cardiac arrest, pulmonary embolism</li> <li>• Severe anemia</li> <li>• Acetazolamide-Ca inhibition</li> <li>• Red cell anion exchange: Loop diuretics, salicylates, NSAID</li> </ul>

### *Clinical features (Box 14.12)*

**Treatment:** The underlying causes should be corrected. Rapid infusion of alkali is justified only in prolonged cardiopulmonary arrest.

## **Respiratory Alkalosis**

**Q. Write short note on respiratory alkalosis and its causes.**

- Most common acid-base abnormality in critically ill characterized by  $\downarrow\text{PCO}_2 \rightarrow \uparrow\text{pH}$ .
- Primary process: **Hyperventilation**
  - **Acute:**  $\text{PaCO}_2 \downarrow$ , pH-alkalemic
  - **Chronic:**  $\text{PaCO}_2 \downarrow$ , pH normal/near normal

**Box 14.12:** Clinical features of respiratory acidosis.

- **RS (Respiratory system)**
  - Stimulation of ventilation (tachypnea)
  - Dyspnea
- **CNS (Central nervous system)**
  - $\uparrow$  cerebral blood flow  $\rightarrow \uparrow$  ICT, papilledema

- CO<sub>2</sub> NARCOSIS (Disorientation, confusion, headache, lethargy)
- COMA (arterial hypoxemia, ↑ ICT, anesthetic effect of ↑ PCO<sub>2</sub> >100 mm Hg)
- **CVS:** Tachycardia, bounding pulse
- **Others:** Peripheral vasodilatation (warm, flushed, sweaty)

## ***Causes of respiratory alkalosis (Table 14.26)***

**Table 14.26:** Causes of respiratory alkalosis.

<p><b>A. Central nervous system stimulation:</b></p> <ol style="list-style-type: none"> <li>1. Pain</li> <li>2. Anxiety, psychosis</li> <li>3. Fever</li> <li>4. Cerebrovascular accident</li> <li>5. Meningitis, encephalitis</li> <li>6. Tumor</li> <li>7. Trauma</li> </ol> <p><b>B. Hypoxemia or tissue hypoxia:</b></p> <ol style="list-style-type: none"> <li>1. High altitude</li> <li>2. Septicemia</li> </ol>	<ol style="list-style-type: none"> <li>3. Hypotension</li> <li>4. Severe anemia</li> </ol> <p><b>C. Drugs or hormones:</b></p> <ol style="list-style-type: none"> <li>1. Pregnancy, progesterone</li> <li>2. Salicylates</li> <li>3. Cardiac failure</li> </ol> <p><b>D. Stimulation of chest receptors:</b></p> <ol style="list-style-type: none"> <li>1. Hemothorax</li> <li>2. Flail chest</li> <li>3. Cardiac failure</li> <li>4. Pulmonary embolism</li> </ol>	<p><b>E. Miscellaneous:</b></p> <ol style="list-style-type: none"> <li>1. Septicemia</li> <li>2. Hepatic failure</li> <li>3. Mechanical ventilation</li> <li>4. Heat exposure</li> <li>5. Recovery from metabolic acidosis</li> </ol>
--	---	---

## ***Clinical features of respiratory alkalosis (Table 14.27)***

### **Treatment**

- Elimination of the underlying disorder.
- In acute hyperventilation syndrome, sedation and re-breathing into a bag may terminate the attack.

**Table 14.27:** Clinical features of respiratory alkalosis.

<ul style="list-style-type: none"> <li>• <b>CNS</b> <ul style="list-style-type: none"> <li>- ↑ neuromuscular irritability (tingling, circumoral numbness)</li> <li>- Tetany</li> <li>- ↓ ICT</li> <li>- Light headedness, confusion</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>CVS</b> <ul style="list-style-type: none"> <li>- CO and SBP ↑ (↑ SVR, HR)</li> <li>- Arrhythmias</li> <li>- ↓ myocardial contractility</li> </ul> </li> <li>• <b>Others</b> <ul style="list-style-type: none"> <li>- Hypokalemia, hypophosphatemia</li> <li>- ↓ Free serum calcium—tetany</li> <li>- Hyponatremia, hypochloremia</li> </ul> </li> </ul>

## **Primary and Compensatory Responses in Various Acid-base**

## Disorders (Tables 14.28)

**Table 14.28:** Primary and compensatory responses in various acid-base disorders.

<i>Disorder</i>	<i>pH</i>	<i>Primary response</i>	<i>Compensatory response</i>
Metabolic acidosis	Decreased	Decreased HCO <sub>3</sub>	Decreased pCO <sub>2</sub>
Metabolic alkalosis	Increased	Increased HCO <sub>3</sub>	Increased pCO <sub>2</sub>
Respiratory acidosis	Decreased	Increased CO <sub>2</sub>	Increased HCO <sub>3</sub>
Respiratory alkalosis	Increased	Decreased CO <sub>2</sub>	Decreased HCO <sub>3</sub>

**Q. What are primary and compensatory responses to various acid-base disturbances?**

## Compensatory Responses in Acid-base Disorders (Tables 14.29)

**Table 14.29:** Compensation in various acute or chronic acid-base disorders.

### Respiratory Acidosis

- *Acute:* for every 10 increase in pCO<sub>2</sub> → HCO<sub>3</sub> increases by 1 and there is a decrease of 0.08 in pH
- *Chronic:* for every 10 increase in pCO<sub>2</sub> → HCO<sub>3</sub> increases by 4 and there is a decrease of 0.03 in pH

### Respiratory Alkalosis

- *Acute:* for every 10 decrease in pCO<sub>2</sub> → HCO<sub>3</sub> decreases by 2 and there is an increase of 0.08 in pH
- *Chronic:* for every 10 decrease in pCO<sub>2</sub> → HCO<sub>3</sub> decreases by 5 and there is an increase of 0.03 in pH

### Metabolic Acidosis

- *Winter's formula:*  $p\text{CO}_2 = 1.5[\text{HCO}_3] + 8 \pm 2$
- If serum pCO<sub>2</sub> > expected pCO<sub>2</sub> → additional respiratory acidosis

### Metabolic Alkalosis

- For every 10 increase in HCO<sub>3</sub> → pCO<sub>2</sub> increases by 6

## EDEMA

**Q. What are the common causes of generalized edema?**

**Q. Discuss the mechanism of edema formation. How will you differentiate between cardiac, renal and hepatic edema.**

## Definition

An abnormal (increased) accumulation of fluid in the interstitial space within tissues.

Special forms of edema are listed in Table 14.30.

**Table 14.30: Special forms of edema.**

<i>Terminology</i>	<i>Body cavity involved</i>
Hydrothorax	Pleural cavity
Hydropericardium	Pericardial cavity
Hydroperitoneum (ascites)	Peritoneal cavity

- **Anasarca:** Severe and generalized edema with profound subcutaneous tissue swelling and fluid in the body cavities.

## Causes of Pitting Dependent Edema (Table 14.31)

Pathogenesis of systemic edema from congestive heart failure, renal failure, or reduced plasma osmotic pressure is shown in Figure 14.12.

Pitting edema may be divided into two categories:

1. **Rapid pitting** recovery within <40 seconds and is due to hypoproteinemia
2. **Slow pitting edema** (>40 seconds) and is due to normal albumin level (normoalbuminemia) (Fig. 14.13).

**Table 14.31: Causes of pitting dependent edema.**

<i>Mechanism</i>	<i>Causes</i>
Increased hydrostatic/systemic venous pressure	<b>Systemic venous hypertension</b> <ul style="list-style-type: none"> <li>• Congestive heart failure</li> <li>• Pericardial diseases, constrictive pericarditis, tricuspid valve disease</li> </ul>
	<b>Regional venous hypertension</b> <ul style="list-style-type: none"> <li>• Inferior vena cava syndrome</li> <li>• Obstruction (e.g. venous thrombosis) or compression of veins (e.g. external mass)</li> <li>• Lower extremity venous insufficiency</li> </ul>

Decreased plasma osmotic pressure (decreased serum protein/hypoproteinemia)	<p><b>Impaired protein synthesis</b></p> <ul style="list-style-type: none"> <li>• <i>Decreased protein intake:</i> Starvation, kwashiorkor, malnutrition</li> <li>• <i>Decreased absorption of proteins:</i> Malabsorption</li> <li>• Impaired hepatic synthesis due to liver disease</li> </ul> <p><b>Increased loss of protein</b></p> <ul style="list-style-type: none"> <li>• <i>Skin loss:</i> Burns, weeping skin diseases</li> <li>• <i>Urinary loss:</i> Nephrotic syndrome</li> <li>• <i>Fecal loss:</i> Bowel disease, malabsorption, protein-losing gastroenteropathy</li> </ul>
Inflammation	Acute* and chronic inflammation*
Increased capillary permeability	Vasculitis*, idiopathic cyclic edema of women (varies with menstrual cycle) and postanoxic encephalopathy
Sodium retention	Excessive salt intake with renal insufficiency Increased tubular reabsorption of sodium, e.g. increased renin-angiotensin-aldosterone secretion

\* Causes of painful edema

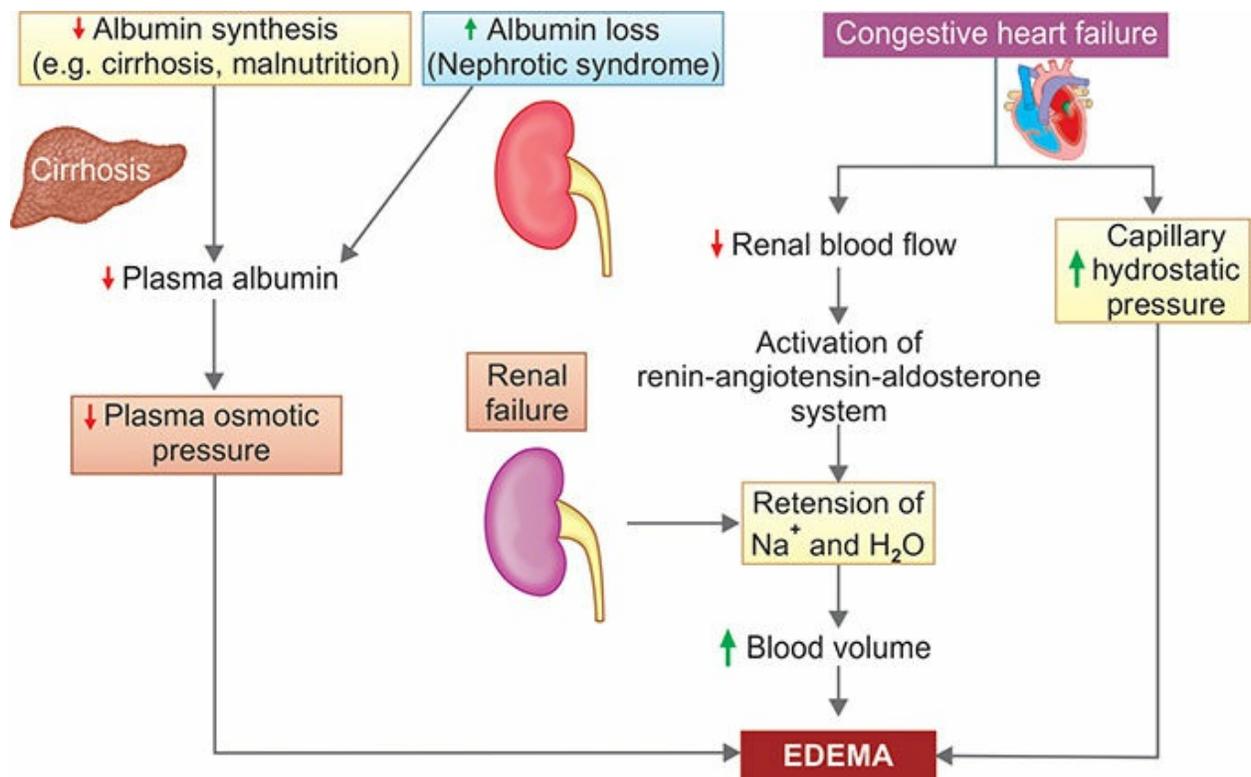

Fig. 14.12: Pathogenesis of systemic edema from congestive heart failure, renal failure, or reduced

plasma osmotic pressure.

**Fig. 14.13:** Pitting edema in congestive heart failure.

## Treatment (Box 14.13)

### Box 14.13: Treatment of pitting edema.

#### *Rapid/Fast-recovering Pitting edema*

- *Treatment the cause of hypoalbuminemia:*
  - Treat underlying disease
  - Treat malnutrition
  - Treat protein loss
    - ◆ *Urinary loss:* Angiotensin-converting enzyme inhibitor
  - Treat underlying cause of malabsorption
  - Treatment of edema due to cirrhosis.
- Judicious use of diuretics and aldosterone antagonist can alleviate edema

#### *Slow Pitting Edema*

- *Treat congestive heart failure:*
  - Bed rest and elevation of legs useful for acute edema
  - Loop diuretics, digoxin, angiotensin-converting enzyme inhibitor, beta-blocker, if tolerated
- *Treat venous insufficiency:*
  - Diuretics, compression, leg-elevating exercises.
- *Treat underlying obstruction of veins:*
  - Anticoagulants, leg elevation for thrombosis

## Lymphedema: Nonpitting Edema

**Characteristics:** Nontender, painless and does not vary much during the day. Ulceration rare and skin shows hyperkeratosis and thickening (Fig. 14.14).

## Causes (Table 14.32)

**Table 14.32: Causes of lymphedema.**

- *Upper extremity:*
  - Breast cancer or surgery/radiation for breast cancer
  - Newborn baby, Turner’s syndrome (X0)
- *Lower extremity:*
  - *Idiopathic:* Aplasia/dysplasia of lymphatics
    - ◆ 3 types: Congenital, praecox, form tarde
    - ◆ Associated with yellow nails, pleural effusions
  - *Secondary:*
    - ◆ *Inflammatory:*
      - ◇ *Tropical:* Filariasis + recurrent streptococcal infection
      - ◇ *Nontropical:* Recurrent streptococcal cellulitis
- ◆ *Obstructive:* Unilateral in 95%
  - ◇ *Usually due to malignancy:*
    - ◇ Prostate cancer most common in men
    - ◇ Lymphoma most common in women
  - ◇ Any pelvic tumor or major pelvic surgery/irradiation

**Fig. 14.14:** Massive nonpitting edema with elephantiasis caused by filariasis of the leg.

## Complications of Lymphedema

- *Infection*: Recurrent cellulitis, lymphangitis
- Lymphangiosarcoma (**Stewart-Treves syndrome**).

## Treatment (Box 14.14)

**Box 14.14:** Treatment of nonpitting edema.

- *Fluid mobilization*:
  - Diuretics
  - Elevation
  - Exercise
  - Compressive, elastic stockings
  - Massage
- *Control of infection*:
  - Treatment of dermatophytes
  - Prophylaxis against streptococcal infections: Amoxicillin, amoxicillin/clavulanate
- *Other therapies*:
  - Coumadin
  - Flavonoids, water soluble vitamin
- *Surgery*: Liposuction

## Medication That Causes Edema (Table 14.33)

**Table 14.33:** Medication that causes bilateral swollen extremities.

<i>Type of medication</i>	<i>Class of medication</i>
Antihypertensive medications	Calcium-channel blockers (Nifedipine, felodipine, amlodipine, verapamil) Direct vasodilators (hydralazine, diazoxide) Antiadrenergics (clonidine, reserpine, methyl dopa)
Chemotherapy	Gemcitabine, docetaxel
Diabetic medications	Thiazolidinediones (rosiglitazone)
Hormones	Estrogen, progesterone, testosterone,

	corticosteroid
Pain relief medications	NSAIDs Nonselective cyclo-oxygenase inhibitor Selective cyclo-oxygenase-2 inhibitor
Psychiatric medications	Monoamine oxidase inhibitors Antipsychotics (olanzapine)
Immunological/Immunosuppressant	Cyclosporine, interleukin 2, OKT3 monoclonal antibody

## Localized Edema (Box 14.15)

**Box 14.15:** Various type of localized edema.

- *Facial edema:* Trichinosis, hypothyroidism, allergies, nephrotic syndrome, angioedema
- *Pretibial myxedema:* Graves' thyrotoxicosis
- *Neurogenic edema:* Secondary to autonomic dysfunction
- *Lipedema:* Adiposity of the legs
- *Pseudothrombophlebitis:* It is unilateral edema with raised venous pressure caused by a popliteal cyst

# Neurology

# CHAPTER 15

## INTRODUCTION AND SYMPTOMATOLOGY

### WEAKNESS AND PARALYSIS

#### Categories

- **Upper motor neurons:** Consist of corticospinal interneurons which arise from the motor cortex and descend to the spinal cord where they activate the lower motor neurons (anterior horn cells) through synapses.
- **Lower motor neurons:** The term ‘motor neuron’ is usually used only to the efferent neurons that actually innervate muscles (the lower motor neurons). A motor neuron consists of nerve cell (neuron) which is located in the anterior horn cell of the spinal cord and its fibers (axon) projects outside the spinal cord to directly or indirectly control effector organs, mainly muscles and glands. Motor neuron axons are efferent nerve fibers and carry signals from the spinal cord to the effectors to produce effects.

#### *Signs of Upper and Lower Motor Neuron Disease (Table 15.1)*

**Table 15.1:** Signs of upper and lower motor neuron disease.

<i>Sign</i>	<i>Upper motor neuron</i>	<i>Lower motor neuron</i>
Atrophy	None (rarely disuse atrophy)	Severe wasting
Fasciculations	None	Common
Tone	Hypertonia-rigidity/spasticity	Decreased (hypotonia)
Distribution of weakness	Distal predominant/regional	Predominantly proximal (except neuropathy)/ segmental
Tendon reflexes	Exaggerated/ hyperactive	Hypoactive/lost
Babinski sign	Present	Absent

Flexor spasms, clonus	Present	Absent
-----------------------	---------	--------

**Q. Write a short note on:**

- **Signs of upper motor neuron lesion/disease.**
- **Signs of lower motor neuron lesion/disease.**

**Tone**

- Muscle tone is a partial state of contraction of a skeletal muscle to maintain its optimal length during resting condition, even when a force is applied to elongate the muscle. It is accomplished by the asynchronous discharge of nervous impulse in the motor neurons in the anterior gray horn of the spinal cord.
- Clinically, it may be defined as the resistance that is encountered when the joint of relaxed muscle is moved passively.
- Increased tone: Associated with disease of upper motor neurons due to loss of inhibition of  $\gamma$ -motor neurons above the site of lesion.
- Hypotonia: Causes of hypotonia is listed in Table 15.2.

**Q. Write a short note on causes of hypotonia.**

**Table 15.2: Causes of hypotonia.**

<ul style="list-style-type: none"> <li>• Lesions of the motor side of the reflex arc: Poliomyelitis, polyneuritis, peripheral nerve injuries</li> <li>• Lesions of the sensory side of the reflex arc: Tabes dorsalis, herpes-zoster, carcinomatous neuropathy</li> <li>• Combined motor and sensory lesion: Syringomyelia, cord or root compression, gross cord destruction</li> <li>• Lesions of the muscle (myopathies), NMJ (myasthenia)</li> </ul>	<ul style="list-style-type: none"> <li>• State of neuronal shock in upper motor neuron lesion</li> <li>• Cerebellar lesions</li> <li>• Chorea</li> <li>• Periodic paralysis</li> <li>• REM (rapid eye movement) sleep</li> <li>• Benzodiazepine overdose, neuromuscular blockers</li> </ul>
---	---

**Q. Write a short note on differences between spasticity and rigidity.**

***Differences between Spasticity and Rigidity (Table 15.3)***

**Table 15.3: Differences between spasticity and rigidity.**

--	--	--

	<b>Spasticity</b>	<b>Rigidity</b>
Lesion	Pyramidal tract lesion	Extrapyramidal tract lesion
Tone	Tone is more in the antigravity group of muscles than in the gravity assisted group of muscles	Tone is equally raised in the gravity assisted and antigravity group of muscles
Character	Clasp knife type of spasticity	Lead pipe or cog wheel type of rigidity
Relation to velocity	Velocity dependent, better appreciated when passive movement of the joint is carried out rapidly	Rigidity is not velocity dependent
Abdominal reflexes	Lost	Preserved
Plantar reflex	Plantar is extensor	Plantar is flexor
Deep tendon reflexes	Brisk or exaggerated	Normal or decreased
Clonus	May be associated sustained clonus	Clonus is absent
Features in limbs	The limb does tend to return toward a particular fixed posture or extreme joint angle	The limb does not tend to return toward a particular fixed posture or extreme joint angle
Reason	Increased gamma motor activity	Increased alpha and gamma motor activity

**Other causes of hypertonia:** Tetanus, seizure (tonic phase), tetany, catatonia, paratonia (*Gegenhalten*, *Mitgehen*).

## ***Fasciculation and Fibrillation***

### **Q. What is fasciculation and fibrillation?**

When a motor unit (group of muscle fibers) becomes diseased, especially in anterior horn cell diseases, it may discharge spontaneously, producing **fasciculations** that may be seen or felt clinically or recorded by electromyography (EMG). Fasciculations are visible, fine and fast, sometimes vermicular contractions of fine muscle fibers that occur spontaneously and intermittently.

When motor neurons or their axons degenerate, the denervated muscle fibers also may discharge spontaneously. These single muscle fiber discharges, or **fibrillation** potentials, cannot be seen or felt but can be recorded with EMG.

**Causes of fasciculation:** Amyotrophic lateral sclerosis, progressive spinal muscular atrophy, post-polio syndrome, hyperthyroidism,

organophosphorous poisoning, drugs (e.g. atropine, lithium), mercury, benign fasciculation.

## **Myotonia**

### **Q. What is myotonia?**

- Myotonia is characterized by continued, involuntary muscle contraction even after cessation of voluntary effort (i.e. muscle contraction continues beyond the period of time required for a particular movement to be made and there is failure of normal muscle relaxation).
- It is best seen in the face and hand muscle. When the patient is asked to smile and then relax his facial muscle, a delay in relaxation of the muscle is noted and the smile remains fixed for a longer duration (transverse smile). Similarly when the patient is asked to grip the examiner's fingers and then let go immediately, a delay in the relaxation of the grip is noted.
- **Myokymia** is a vermicular or continuous rippling movement of a group of muscle fibers that can be seen in neuropathies (GBS), plexopathies, Isaac syndrome.

## **Causes of myotonia (Box 15.1)**

### **Box 15.1:** Causes of myotonia.

- Myotonic dystrophy type 1
- Myotonic dystrophy type 2/proximal myotonic myopathy
- Myotonia congenital
- Paramyotonia congenita
- Hyperkalemic periodic paralysis

## **Ataxia**

### **Q. Write a short note on causes of ataxia.**

Ataxia is a disorder characterized unsteadiness and impaired coordination of regulating body posture and the rate, range, force and direction of movement. Types of ataxia are listed in Table 15.4.

### **Table 15.4:** Types of ataxia.

- Cerebellar: vasculitis, multiple sclerosis,
- Vestibular

## Reflexes

### *Plantar Response/Reflex*

**Q. Write a short note on plantar reflex and extensor plantar reflex/Babinski sign.**

Plantar response/reflex is nociceptive, superficial reflex. Its segmental innervation is S<sub>1</sub> segment of the spinal cord. First described by Babinski.

#### *Technique*

- Position the patient in supine with hip and knee extended.
- Fix the ankle joint by holding it and stroke (gentle but firm pressure) the outer aspect of sole with a blunt point (tip of a key). The stroke is directed forwards and then curves inwards along the metatarsophalangeal joints from the little to the big toe and stopped short of the base of great toe (root value S<sub>1</sub>).

#### *Interpretation*

Normal response is great toe will flex at the metatarsophalangeal joint accompanied by flexion of other toes. Normal response should not be termed 'negative Babinski's sign'.

#### *Abnormal responses*

- Absent: No response is seen. Plantar response/reflex may be absent when there is loss of sensation of the sole (L<sub>5</sub>-S<sub>1</sub>), thick sole, paralysis of the extensor hallucis and lesions of reflex arc.
- Extensor: Extension (dorsiflexion) of the great toe with or without fanning of others toes (abduction) is known as **Babinski's sign (mediated by L5)**. Fanning of toes without great toe extension has no significance. When fully developed it is accompanied by dorsiflexion of ankle, flexion of hip and knee joint and slight abduction of thigh with contraction of the tensor fascia lata. Its causes are:
  - Physiological: It may be normally extensor in infants below 6 months,

during deep sleep, under general anesthesia.

- Pathological: Lesion of corticospinal (pyramidal) tract above S<sub>1</sub> segment, deep coma, transiently after seizure, alcohol intoxication, hypoglycemia and metabolic encephalopathy.

*Alternative ways to elicit Babinski's sign*

Chaddock's (lateral malleolus), Gordon's (Calf), Oppenheim's (anterior tibia), Schaffer's (Achilles Tendon), Gonda's (press down 4th toe), Stransky's (adduct little toe), Bing's (pinprick on dorsolateral foot).

**Deep Tendon Reflex (Table 15.5)**

**Table 15.5: Commonly elicited superficial releases and deep tendon reflexes.**

<i>Superficial reflexes</i>	<i>Deep tendon reflexes</i>
<ul style="list-style-type: none"> <li>• Corneal (Cranial nerve V &amp; VII)</li> <li>• Abdominal               <ul style="list-style-type: none"> <li>Epigastric (T6-T9)</li> <li>Mid abdominal (T9-T11)</li> <li>Hypogastric (T11-L1)</li> </ul> </li> <li>• Cremasteric (L1, L2)</li> <li>• Anal reflex (S2, S3)</li> <li>• Plantar reflex               <ul style="list-style-type: none"> <li>Reflexogenic zone-S1</li> <li>Afferent nerve- tibial nerve</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Jaw jerk (afferent and efferent both 5th nerve center mid pons)</li> <li>• Biceps (C5, C6)</li> <li>• Brachiradial/supinator/radial periosteal (C5, C6)</li> <li>• Triceps (C6, C7, C8)</li> <li>• Knee jerk/quadriceps/patellar reflex (L2, L3, L4)</li> <li>• Ankle jerk (L5, S1, S2)</li> </ul> <p><b>Latent reflexes</b> (suggest pyramidal lesion if present unilaterally)</p> <ul style="list-style-type: none"> <li>• Tromner's/finger flexor reflex/Hoffman's sign</li> <li>• Wartenberg's sign</li> </ul>

**VERTIGO**

**Q. Write a short note on causes of vertigo.**

- **Definition:** Vertigo is defined as an abnormal perception (hallucination/illusion) of movement (a sensation of rotation or tipping) of either the environment or self (body or part of it). The individual feels that the surroundings are spinning or moving.
- The perceived movement may be falling down, or rotating or there is a sensation of spinning of the outside world. It is often accompanied by

nausea or vomiting.

- Mechanism: It develops because of conflicting visual, proprioceptive and vestibular information about a person's position in space. Lesions causing vertigo are listed in Table 15.6.

**Table 15.6:** Lesions causing vertigo— The most common cause is Benign paroxysmal positional vertigo (BPPV).

<i>Site of lesion</i>	<i>Example</i>
Labyrinth	Ménière's disease
VIII cranial nerve	Acoustic neuroma
Vestibular neurons	Vertebral artery ischemia, vestibulitis, drugs
Cerebellum/brainstem	Tumor, infarct, multiple sclerosis, drugs, toxins
Temporal lobe	Epilepsy, tumor
Others	Migraine, epilepsy, neurodegenerative diseases

## Gait

Observation to be noted while the patient walks: (1) Posture of the body while walking, (2) the regularity of the movement, (3) the position and movement of the arms, (4) the relative ease and smoothness of the movement of the legs, (5) the distance between the feet both in forward and lateral directions, (6) the ability to maintain a straight course, (7) the ease of turning (8) stopping and (9) position of feet and posture just before initiation of gait.

### ***Abnormalities of Gait (Fig. 15.1)***

**Q. Write a short note on gait abnormalities with examples.**

Neurogenic gait disorders should be differentiated from those due to skeletal abnormalities (characterized by pain producing an antalgic gait, or limp). Gait abnormalities incompatible with any anatomical or physiological deficit may be due to functional disorders.

#### *Pyramidal (circumduction/hemiplegic) gait*

- Lesions of the upper motor neuron lesions produce characteristic extension of the affected leg. There is tendency for the toes to strike the ground on walking and outward throwing/swing of lower limbs. This movement occurring at the hip joint is called circumduction. There is leaning towards the opposite normal side. The arm of the affected side is

adducted at the shoulder and flexed at the elbow, wrist and fingers.

- In hemiplegia/hemiparesis, there is a clear asymmetry between affected and normal sides on walking, but in paraparesis both lower legs swing slowly from the hips in extension and are stiffly dragged over the ground (walking in mud).

#### *Foot drop (high stepping/slapping gait)*

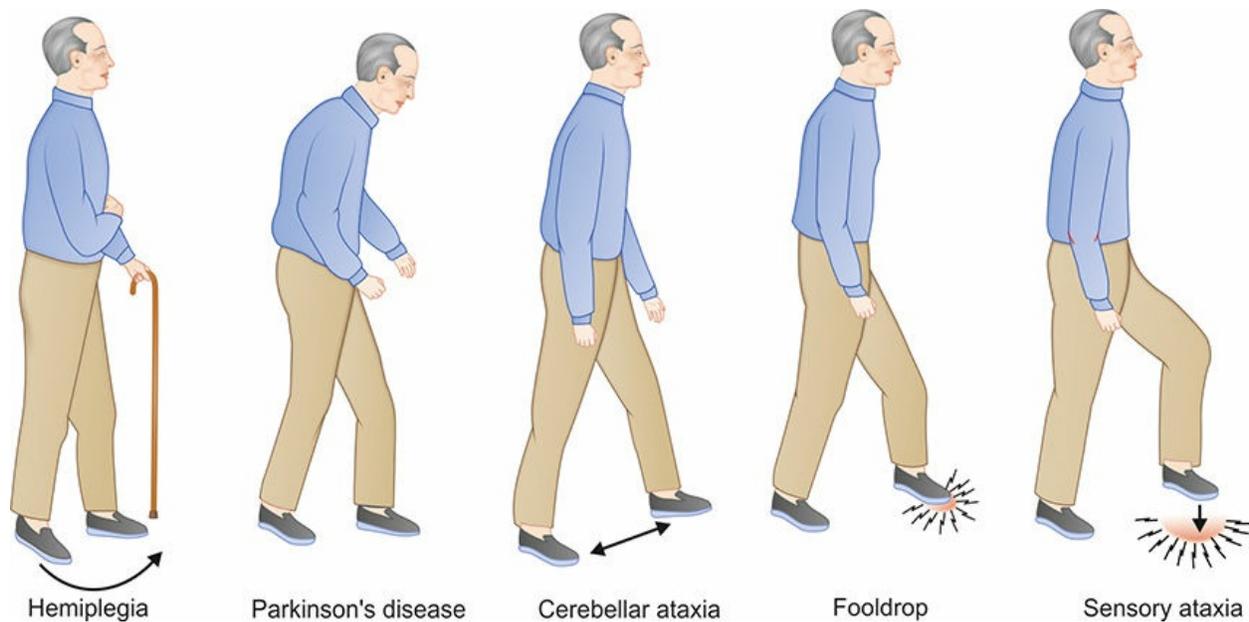

In normal walking, the heel is the first part of the foot to hit the ground. A lower motor neuron lesion affecting the leg will cause weakness of ankle dorsiflexion, resulting in a less controlled descent of the foot, which makes slapping noise as it hits the ground. In severe cases, the foot will have to be lifted higher at the knee to allow room for the inadequately dorsiflexed foot to swing through, resulting in a high-stepping gait. Cause: e.g. common peroneal nerve palsy.

#### *Myopathic gait/waddling gait (primary muscle disease)*

- During walking, alternating transfer of the body's weight through each leg, needs adequate hip abduction.
- Causes:
  - Weakness of proximal lower limb muscles (e.g. polymyositis, muscular dystrophy) causes difficulty rising from sitting. The hips are not properly fixed by these muscles and trunk movements are exaggerated, and walking becomes a *waddle or rolling*. The pelvis is poorly supported by each leg. This may be seen with bilateral congenital dislocation of hip (Trendelenburg gait). The patient walks on a broad base with exaggerated lumbar lordosis.

#### *Ataxic gait (cerebellar ataxia: broad-based gait)*

- In this type of gait, the patient, unstable, tremulous and reels in any direction (including backwards) and walks on a broad base. Ataxia describes this incoordination. The patient finds difficulty in executing tandem walking.
- Causes: Lesions of the cerebellum, vestibular apparatus or peripheral nerves. When walking, the patient tends to veer to the side of the affected cerebellar lobe. When the disease involves cerebellar vermis, the trunk becomes unsteady without limb ataxia, with a tendency to fall backwards or sideways and is termed truncal ataxia.

**Fig. 15.1: Abnormal gait.**

### *Apraxic gait*

- In an apraxic gait, the acquired walking skills become disorganized. On examination of the legs the power, cerebellar function and proprioception are normal. Leg movement is normal when sitting or lying and the patient can carry out complex motor tasks (e.g. bicycling motion). But patient cannot initiation and organization the motor act of walking. The feet appear stuck to the floor and the patient cannot walk.
- Causes: Diffuse bilateral hemisphere disease or diffuse frontal lobe disease (e.g. tumor, hydrocephalus, infarction).

### *Marche à petits pas*

- It is characterized by small, slow steps and marked instability. In contrast to the festination found in Parkinson's disease, it lacks increasing pace and freezing.
- Cause: Small-vessel cerebrovascular disease, and accompanying bilateral upper motor neuron signs.

### *Extrapyramidal gait (shuffling gait) Festinant gait*

- It is characterized by stooped posture and gait difficulties with problems initiating walking and controlling the pace of the gait. Patients make a series of small, flat footed shuffles and become stuck while trying to start walking or when walking through doorways ('freezing'). The center of

gravity will be moved forwards to aid propulsion and difficulty stopping. It is characterized by muscular rigidity throughout extensors and flexors. Power is preserved, pace is shortened and slows to a shuffle, and its base remains narrow. There is a stoop and diminished arm swinging and gait becomes festinant (hurried) with short rapid steps. Patient will be having difficulty in turning quickly and initiating movement. Retropulsion, i.e. small backward steps are taken involuntarily when a patient halts.

- Cause: Parkinsonism.

### *Scissoring gait*

Seen classically with cerebral palsy due to bilateral spasticity.

### *Sensory ataxia: Stomping gait*

- It is characterized by broad based, high stepping, stamping gait and ataxia due to loss of *proprioception* (position sense). This type of ataxia become more prominent by removal of sensory input (e.g. walks with eyes closed) and become worse in the dark. Romberg's test is positive.
- Cause: Peripheral sensory (large fiber) lesions (e.g. polyneuropathy), posterior column lesion (vitamin B<sub>12</sub> deficiency or tabes dorsalis).

### *Choreiform gait (hyperkinetic gait)*

- The patient will display irregular, jerky, involuntary movements in all extremities. Walking may accentuate their baseline movement disorder.
- Cause: Sydenham's chorea, Huntington's Disease and other forms of chorea, athetosis or dystonia.

## **ABNORMAL SPEECH AND LANGUAGE**

### ***Definitions***

- **Phonation:** It is the production of vocal sounds without word formation.
- **Speech:** It consists of words which are articulate vocal sounds that symbolize and communicate ideas. Speech is the articulation and phonation of language sounds.
- **Language:** refers to the selection and serial ordering of words according to learned rules by which a person can use spoken or written modalities to communicate with others and to express cerebral activities involved with

thinking and learning. It can be by speech (auditory symbols), writing (graphic symbols), or by gestures and pantomime (motor symbols).

## Aphasias

### **Q. Write a short note on aphasia.**

- Aphasia is loss or defective language content of speech resulting from damage to the speech centers within the dominant (usually left in 97%) hemisphere. A language disturbance occurring after a right hemisphere lesion in a right hander is known as crossed aphasia.
- It includes defect in or loss of the power of expression by speech, writing or gestures or a defect in or loss of the ability to comprehend spoken or written language or to interpret gestures.
- Aphasia may be categorized according to whether the speech output is fluent or nonfluent.
  - **Fluent aphasias** (receptive aphasias) are impairments mostly due to the input or reception of language, with difficulties either in auditory verbal comprehension or in the repetition of words, phrases or sentences spoken by others. For example, Wernicke's aphasia.
  - **Nonfluent aphasias** (expressive aphasias) are difficulties in articulating, with relatively good auditory, verbal comprehension. For example, Broca's aphasia.

### ***Categories/Varieties of Aphasia (Table 15.7)***

#### *Definitions*

- **Alexia:** It is the impairment of visual word recognition, in the context of intact auditory word recognition and writing ability.
- **Agraphia:** It is the inability to write, as a language disorder resulting from brain damage.
- **Anomia:** In this, word approximates the correct answer but it phonetically inaccurate (plentil for pencil)—phonemic paraphasia. When the patient cannot say the appropriate name when an object is shown but can point the object when the name is provided is known as one way or retrieval based naming deficit.

**Table 15.7:** Types of aphasias.

Type of aphasia	Site of lesion	Comprehension	Fluency	Repetition	Reading	Writing	Naming
Wernickes/sensory/receptive/posterior	Infarction of inferior division of middle cerebral artery	Absent	Preserved	Absent	—	—	—
Broca's/ motor/ expressive/anterior	Infarction of superior frontal branch of middle cerebral artery	Preserved	Absent	Absent	—	—	—
Global	Dominant frontal, parietal and superior temporal lobe	Absent	Absent	Absent	—	—	—
Conduction/arcuate	Arcuate fascicle	Preserved	Preserved	Absent	—	—	—
Transcortical sensory	Posterior watershed zone	Absent	Preserved	Preserved	—	—	—
Transcortical motor	Anterior watershed zone	Preserved	Absent	Preserved	—	—	—
Alexia without agraphia	Occipitotemporal region	Preserved	Preserved	Preserved	Lost	Preserved	—
Alexia with agraphia	Left angular gyrus	Preserved	Preserved	Preserved	Lost	Lost	—
Nominal/anomic/amnesic	Temporoparietal	Preserved	Preserved	Preserved	Preserved	Preserved	Absent

## APRAXIA

### Q. Write a short note on apraxia.

Apraxia is impaired ability (inability) to carry out (perform) skilled, complex, organized motor activities in the presence of normal basic motor, sensory and cerebellar function. Examples of complex motor activities: dressing, using cutlery and geographical orientation.

### Types

- **Ideomotor apraxia:** Most common. It is the inability to perform a specific motor command/act (e.g. cough, lighting a cigarette with a matchstick) in the absence of motor weakness, incoordination, sensory loss or aphasia. Site of lesion is bilateral parietal lobe. Buccofacial apraxia involves apraxic deficits in movements of the face and mouth. Limb apraxia encompasses apraxic deficits in movements of the arms and legs.
- **Dressing apraxia:** Site of lesion is non-dominant parietal lobe. It is inability to wear his/her dress.
- **Constructional apraxia:** It is inability to copy simple diagrams or build simple blocks. Site of lesion is non-dominant parietal lobe.
- **Ideational apraxia:** It is a deficit in the execution of a goal-directed sequence of movements even with real object. (e.g. asked to pick up a pen and write, the sequence of uncapping the pen, placing the cap at the opposite end). This is commonly associated with confusion and dementia rather than focal lesions associated with aphasic conditions.
- **Gait apraxia (Bruns ataxia):** Seen in normal pressure hydrocephalus

(NPH).

- **Gaze apraxia:** Part of Balint syndrome.
- **Other apraxias:** Speech apraxia, conceptual apraxia, and conduction apraxia.
- **Gerstmann's syndrome:** The combination of acalculia (impairment of simple arithmetic), dysgraphia (impaired writing), finger anomia (an inability to name individual fingers such as the index or thumb), and right-left confusion (an inability to tell whether a hand, foot, or arm of the patient or examiner is one the right or left side of the body) is known as Gerstmann's syndrome.  
**Site of lesion:** Inferior parietal lobule (especially the angular gyrus) in the left (dominant) hemisphere.

## AGNOSIA

### Q. Write a short note on agnosia.

Agnosia is failure to recognize objects (e.g. places, clothing, persons, sounds, shapes or smells), despite the presence of intact sensory system.

**Site of lesion:** Contralateral parietal lobe.

- **Visual agnosia:** Failure to recognize what is seen with eyes despite the presence of intact visual pathways. The individual can describe the shape, color and size without naming it. Site of lesion is in the posterior occipital or temporal lobes.
- **Prosopagnosia:** A type of visual agnosia in which patient cannot identify familiar faces, sometimes the reflection of his or her own face in the mirror even including their own. Site of lesion is parieto-occipital lobe.
- **Simultanagnosia** is inability to perceive more than one object at a time.
- **Autotopagnosia** is a form of agnosia, characterized by an inability to localize and orient different parts of the body.

## Anosognosia

### Q. Write a short note on anosognosia.

Anosognosia is an inability or refusal to recognize a defect or disorder that is clinically evident. Site of lesion is predominantly in non-dominant (right) parietal lesions.

## DYSARTHRIAS

Dysarthrias involve the abnormal articulation of sounds or phonemes. Types of dysarthria are listed in Table 15.8.

**Table 15.8:** Types of dysarthria.

<i>Type</i>	<i>Cause</i>
Flaccid (lingual, buccal, guttural)	LMN weakness of facial, lingual or pharyngeal muscles. <ul style="list-style-type: none"> <li>• Facial paralysis causes difficulty with labials such as b p m w.</li> <li>• Tongue paralysis affects a large number sounds, particularly l, d, n, s, t, x.</li> <li>• Palatal paralysis produces a nasal twang in speech</li> </ul>
Spastic (hot potato voice)	UMN weakness (bilateral) e.g. pseudobulbar palsy
Ataxic (staccato speech)	Cerebellar
Hypokinetic	Extrapyramidal (Parkinsonism)
Myasthenic dysarthria	Voice is normal in the beginning but becomes weak as sentences progress

## Functions of Cerebral Hemispheres

**Q. Write a short note on normal functions of different cortical lobes and their abnormalities.**

**Q. Write a short note on functions of parietal lobe.**

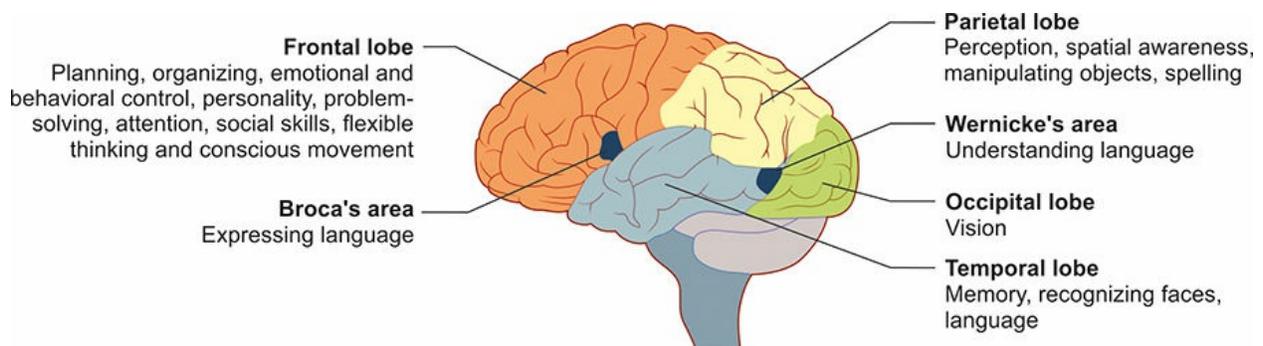

Cerebral dominance aligns limb dominance with language function. Right-handed individuals almost always (>95%) have the dominant left hemisphere, and about 7% of left handers have a dominant right hemisphere.

Functions and effects of damage to various lobes of cerebral hemispheres are listed in Table 15.9 (Fig. 15.2).

**Table 15.9:** Functions and effects of damage to various lobes of cerebral hemispheres.

<i>Lobe</i>	<i>Function</i>	<i>Cognitive/behavioral effects of damage</i>
Frontal Please <b>SMILE</b> (MNEMONIC)	Personality	Disinhibition
	Social behavior	Lack of initiation
	Micturition	Antisocial behavior

	Intelligence	Impaired memory
	Language	Expressive dysphasia
	Emotional response	Incontinence
Parietal: Dominant side	Language	Dysphasia, dyslexia,
	Calculation	Acalculia
	Others	Apraxia, agnosia
Parietal: Nondominant side	Spatial orientation	Spatial disorientation, neglect of contralateral side
	Constructional skills	Constructional apraxia, dressing apraxia
Temporal: Dominant side	Auditory perception	Receptive aphasia
	Language	Dyslexia
	Verbal memory	Impaired verbal memory
	Smell	
	Balance	
Temporal: Nondominant side	Auditory perception	Impaired non-verbal memory
	Melody/pitch perception	Impaired musical skills(tonal perception)
	Non-verbal memory	
	Smell	
	Balance	
Occipital	Visual processing	Visual inattention, visual loss, visual agnosia (Anton–Babinski syndrome)

**Fig. 15.2:** Functions of various lobes of cerebral hemispheres.

## HEADACHE

Headache is among the most common reasons patients seek medical attention.

## Classification of Headache (Table 15.10 and Fig. 15.3)

- Primary headaches: Benign, recurrent, no organic disease as their cause. It affects the quality of life of the patient.
- Secondary headaches: Underlying organic disease.

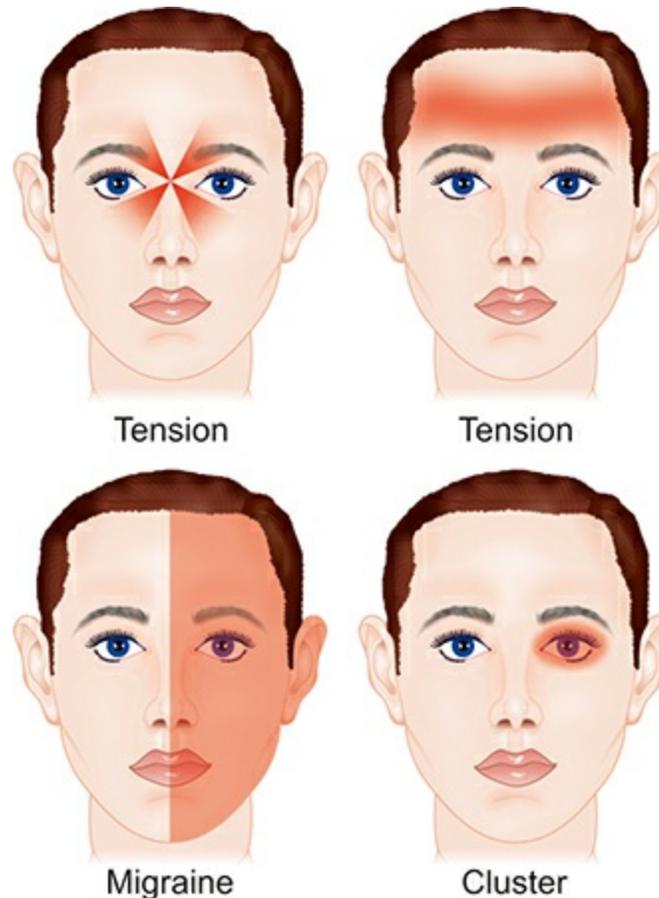

Fig. 15.3: Headache types.

## Migraine

**Q.** Write a short essay/note on classification, pathogenesis, clinical features and management of migraine.

Migraine is a **neurovascular disease** caused by neurogenic inflammation and characterized by **severe, recurring headaches**.

- It is the second most common cause of headache. It usually characterized by an episodic severe pain on one side of the head (headache) and usually associated with certain features such as sensitivity to light, sound or movement; nausea and vomiting often accompany the headache.

- Gender: F:M ratio is 5:1.

### Classification

- **Migraine without aura or common migraine:** Does not give any warning signs before the onset of headache. It occurs in about 70–80% of migraine patients.
- **Migraine with aura or classical migraine:** Gives some warning signs called ‘aura’ before the actual headache begins. About, 20–30% migraine patients experience aura. The most common aura is visual and may include both positive and negative (visual field defects) features.

**Table 15.10: Classification of headache.**

Primary headache		Secondary headache	
Type	%	Type	%
• Tension-type	69	• Systemic infection, meningitis, encephalitis	63
• Migraine	16	• Head injury–post traumatic	4
• Idiopathic stabbing	2	• Vascular disorders, e.g. giant cell arteritis	1
• Exertional	1	• Subarachnoid hemorrhage	<1
• Cluster	0.1	• Brain tumor	0.1
• Other primary headache		Other secondary causes	
• Paroxysmal hemicrania		Associated with metabolic disorders	
• SUNCT (Short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing)		• Hypoxia	
		• Hypercapnia	
		• Dialysis	
		Associated with substance use or withdrawal venous thrombosis	

- **Retinal migraine:** It involves attacks of monocular scotoma or even blindness of one eye for less than an hour and associated with headache.
- **Childhood periodic syndromes:** It involve cyclical vomiting (occasional intense periods of vomiting), abdominal migraine (abdominal pain, usually accompanied by nausea), and benign paroxysmal vertigo of childhood (occasional attacks of vertigo). They may be precursors or associated with migraine.
- **Complicated migraine:** Describes migraine headaches and/or auras that are unusually long or unusually frequent, or associated with a seizure or brain lesion.
- **Basilar migraine:** Occipital headache, preceded by vertigo, diplopia and dysarthria, ±visual and sensory symptoms (brainstem symptoms).
- **Hemiplegic migraine:** Rare autosomal dominant disorder characterized by prolonged headache lasting hours or days, followed by hemiparesis and/or coma that recovers slowly over days.
- **Ophthalmoplegic migraine:** Migraine associated with transient 3rd nerve palsy with/without

involvement of pupil; sometimes also affect 4th and 6th nerve.

- **Vestibular migraine** (also called migrainous vertigo) associated vertigo.
- **Catamenial migraine:** Migraine associated with menstruation associated migraine.

## ***Pathogenesis***

- Cause of migraine is not known.
- **Genetic factors:** Play a role in causing the neuronal hyperexcitability. Migraine is usually polygenic. Rarely, familial migraine is associated with mutations in the  $\alpha 1$  subunit of the P/Q type voltage gated calcium channel or neuronal sodium channel (SCN1A), and a **dominant** loss of function mutation in a potassium channel gene (TRESK). Migraine is frequently associated with positive family history, and similar phenomena occur in disorders such as CADASIL. Mutations involving the Cav2.1 (P/Q)-type voltage-gated calcium channel (CACNA1A gene) are now known to cause familial hemiplegic migraine.
- **Hormonal influences:** Female preponderance and the frequency of migraine attacks at certain points in the menstrual cycle due to hormonal fluctuations. Estrogen-containing oral contraception can exacerbate migraine in few patients.
- **Right-to-left cardiac shunt:** Migraine with aura has been associated with patent foramen ovale (PFO), atrial septal defect (ASD) and pulmonary arteriovenous malformations in hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu syndrome).

**Several theories** have been proposed for the pathogenesis of migraine.

- **Vascular theory:** Constriction of intracerebral blood vessel produces aura. Vasodilatation of intracranial/extracranial blood vessel produces headache phase.
- **Serotonin theory:** Decreased serotonin levels linked with migraine and specific serotonin receptors found in blood vessels of brain.
- **Neurogenic theory:** The aura (see clinical features below) is thought to be due to spreading cortical depression wave of neuronal depolarization followed by depressed activity spreading slowly anteriorly across the cerebral cortex from the occipital region. This spreading process occurs at a rate of about 3 mm/minute. Dysfunction of activation of cells in the trigeminal nucleus releases vasoactive neuropeptides [e.g. calcitonin gene-related peptide (CGRP), substance P and other vasoactive peptides

including 5HT] by activated trigeminovascular neurons. They produce painful meningeal inflammation and vasodilation.

- Dopamine plays a role and most migraine symptoms can be induced by dopaminergic stimulation. There is dopamine receptor hypersensitivity in patients with migraine.

**Precipitating factors:** Anything can initiate or precipitate or amplify an attack. Common triggers are: excess stress, glare, exposure to bright light, loud noises/sounds, smoke or strong scents, menstruation, lack or excess of sleep, cheese, caffeine, alcohol, chocolate, citrus fruit, food additives such as monosodium glutamate, vasodilators, hunger, physical exertion, stormy weather or barometric pressure changes and contraceptive pills, etc.

## ***Clinical Features***

**Headache** is usually hemicranial, throbbing, and associated with nausea and vomiting.

- **Migraine without aura** (previously called ‘common’ migraine).
  - About 70–80% of patients with migraine have characteristic headache but without aura.
  - Typically attacks are episodic and start at puberty and prevalence increases in 4th decade. May show variable degree of spontaneous remissions.
  - The scalp may be tender to touch during episodes (allodynia is production of pain from normally non-painful stimuli) and the patient prefer to be still in a dark and quiet environment.
  - Other symptoms associated with migraine headache are listed in Table 15.11.
- **Migraine with aura** (previously known as classical migraine)
  - Migraine aura: About 20–30% of patient with migraine experience malaise, irritability, behavioral change or focal neurological symptoms for some hours or days immediately preceding the headache phase.

**Table 15.11:** Symptom associated with migraine headache.

<b><i>Nausea</i></b>	<b><i>Vomiting</i></b>
Photophobia, prostration	Visual disturbances
Lightheadedness	Paresthesias
Scalp tenderness/cutaneous allodynia	Vertigo

- Type of aura: (1) visual aura (2) sensory aura or (3) language aura.
  - ◆ **Visual aura:** It is most common type characterized by positive visual symptoms such as shimmering, teichopsia (silvery zigzag lines also called **fortification spectra**) flashing lights or fragmentation of the image (like looking through a pane of broken glass) or scintillating spots across the visual fields for up to 40 minutes. Sometimes there may be temporary patchy visual field loss which may move across the visual field (scotomas) and even evolve into hemianopia or tunnel vision.
  - ◆ **Sensory aura:** It consists of positive sensory symptoms such as tingling followed by numbness, spreading over 20–30 minutes, from one part of the body to another.
  - ◆ **Language aura:** Dominant hemisphere involvement may cause transient speech disturbance.
  - ◆ Motor aura-transient weakness.
- **Duration of aura:** Usually evolves over 5–20 minutes with symptoms changing as the wave of spreading neuronal depression moves across the surface of the cortex. It rarely lasts for more than 60 minutes and is followed immediately by the headache phase.

### **Diagnostic Criteria (Table 15.12)**

**Table 15.12: Simplified diagnostic criteria for migraine.**

<b>Repeated attacks of headache lasting 4–72 hours (untreated) with</b>	
At least 2 of the following features:	Plus at least 1 of the following features:
• Unilateral pain	• Nausea/vomiting
• Throbbing pain	• Photophobia and phonophobia
• Motion sensitivity (headache aggravated with head movement or physical activity)	• Normal physical examination, no other reasonable cause for the headache
• Moderate or severe intensity	

### **Complications of Migraine**

**Status migrainosus** is a debilitating migraine attack lasting for more than 72 hours.

**Persistent aura without infarction** is defined by aura symptoms persisting for one week or more with no evidence of infarction on neuroimaging.

- **Migrainosus infarction:** Migraine attack, occurring in a patient with migraine with aura, in which one or more aura symptoms persist for more than one hour and neuroimaging shows an infarction in a relevant brain area.
- **Migraine aura-triggered seizure** is a seizure triggered by an attack of

migraine with aura.

*RED flags of headache (Box 15.2)*

**Q. Write a short essay/note on management of migraine in young adults. Mention three drugs used and write short note on prophylactic therapy.**

**Box 15.2:** RED flags of headache.

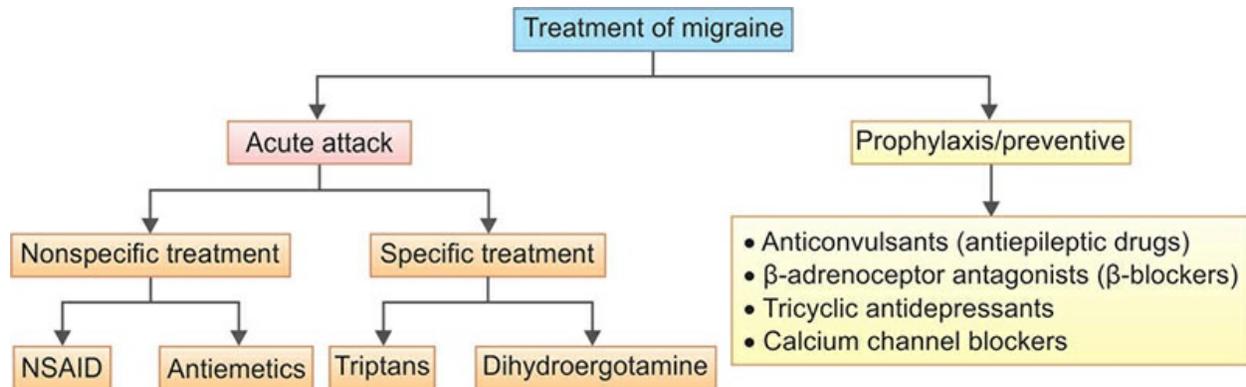

- “Worst” headache ever
- First severe headache
- Subacute worsening over days or weeks
- Altered level of sensorium/consciousness
- Abnormal neurologic examination
- Fever or unexplained systemic signs
- Significant weight loss
- Vomiting that precedes headache
- Pain induced by bending, lifting, cough, Worsens with Valsalva maneuvers
- Pain which disturbs sleep or presents immediately upon awakening
- Known systemic illness, history of trauma, cancer or HIV
- New onset headache in a patient >50 years of age
- Focal neurologic deficits, jaw claudication
- Morning headache associated with nausea and vomiting
- Pain associated with local tenderness (e.g. region of temporal artery)

**Management (Flowchart 15.1)**

***Nonpharmacological treatment (General measures)***

- Explanation that migraine has no grave prognosis.
- Identification of triggers and avoidance of identified triggers or exacerbating factors to prevent attacks. Women with aura should avoid estrogen treatment (oral contraception or hormone replacement). Lifestyle modification wherever possible.
- Other measures: Meditation, relax techniques, psychotherapy.

**Flowchart 15.1:** Treatment of migraine.

### Pharmacological treatment

- Abortive treatment-treatment of acute attack.
- Preventive treatment: Drug prophylaxis.

#### *Treatment of an acute attack*

- Analgesic: Simple analgesia such as aspirin, paracetamol or nonsteroidal anti-inflammatory agents.
- Nausea may be treated by an antiemetic (metoclopramide or domperidone).
- Severe attacks: If there is previously no relief with an NSAID, use 'triptans'.
- **Triptans:** (e.g. sumatriptan, almotriptan, eletriptan, frovatriptan, naratriptan, rizatriptan and zolmitriptan).
  - **Mode of action:** Potent 5HT<sub>1B/1D</sub> agonists, inhibit release of CGRP and substance P, inhibit activation of the trigeminal nerve and inhibit vasodilation in the meninges.
  - **Administration triptans are** available as oral preparations, nasal spray and subcutaneous injections.
  - **Contraindications:** Ischemic heart disease or stroke, high-risk for coronary artery disease, pregnancy, hemiplegic or basilar migraine and use with ergots.
- CGRP (calcitonin gene-related peptide) antagonists (e.g. **telcagepant**) are very effective for acute treatment of migraine.
- **Lasmiditan**, a selective serotonin 1F receptor agonist has been tried.
- Single-pulse **transcranial magnetic stimulation** (TMS) has shown good benefits.

#### *Drug prophylaxis*

- Indications for drug prophylaxis in migraine are listed in Box 15.3. Various drugs can be used and the most frequently used are:
  - Anticonvulsants (antiepileptic drugs): Valproate (800 mg) or topiramate (100–200 mg daily) are the most effective options.
  - beta-adrenoceptor antagonists (beta-blockers), e.g. propranolol slow release 80– 160 mg daily.
  - Tricyclic antidepressants, e.g. amitriptyline 10 mg increasing weekly in 10 mg steps to 50–60 mg or Dosulepin (10–200 mg at night).
  - Methysergide 1-2 mg TID in resistant cases (prolonged use may produce retroperitoneal and mediastinal fibrosis).
  - Botulinum toxin has been tried as a treatment for chronic migraine.
  - Vasoactive drugs and calcium channel blockers: These include flunarizine (5–10 mg OD at bed time), verapamil (80 to 160 mg 3 times a day) and methysergide and are used in refractory cases. Pizotifen is rarely used.

- Butterbur, coenzyme Q10, fever few, magnesium, melatonin, riboflavin have been tried.

**Box 15.3:** Indications for drug prophylaxis in migraine.

- Patients who have very frequent headaches (more than 2–3 week)
- Attack duration > 48 hours
- Headache extremely severe
- Migraine accompanied by severe aura
- Contraindication to acute treatment
- Unacceptable adverse effects with acute migraine treatment
- Patients preference

## Cluster Headache

**Q.** Write a short note on cluster headache.

Cluster headache (migrainous neuralgia) is distinct from migraine and is much less common than migraine.

- Age and gender: Usually occurs in young adult in the third decade (20 and 40 years) with male predominance (M: F = 5:1).

### *Pathophysiology*

- Cause and precise mechanism is unknown.
- It differs from migraine in its character, absence of genetic predisposition, lack of triggering dietary factors, male predominance and different drug effect.
- Abnormal hypothalamic activity is observed on functional imaging studies during an attack. Patients are often smokers and consume more than average alcohol.

### *Clinical Features*

- Cluster headache is **periodic with recurrent bouts** of identical headaches beginning at the **same hour for weeks at a time** (the eponymous ‘cluster’). Patients may develop either one or several attacks within a 24-hour period.
- Cluster headache causes **severe (excruciating) and worst, stabbing/boring, unilateral periorbital/retro-orbital pain with parasympathetic autonomic features** in the same eye (e.g. unilateral lacrimation, nasal congestion and conjunctival redness/injection or even a

transient Horner's syndrome). The pain is so severe that they may commit suicide.

- **Circadian periodicity:** Usually cluster period lasts for few weeks and followed by remission for months to years. They typically recur a year or more later often at the same time of year

**Table 15.13:** Diagnostic criteria for cluster headache.

At least five attacks fulfilling following:

- Severe or very severe unilateral orbital, supraorbital and/or temporal pain lasting 15 to 180 minutes if untreated.
- Headache is accompanied by at least one of the following.
  - Autonomic features: Unilateral
    - ◆ Conjunctival redness/ injection and/or lacrimation or
    - ◆ Nasal congestion and/or rhinorrhea or
    - ◆ Edema of eyelid
    - ◆ Sweating on the forehead and face or
    - ◆ Miosis and/or ptosis or
  - Restlessness or agitation
- Frequency of attacks: From one every other day to eight/day

## ***Diagnostic Criteria for Cluster Headache (Table 15.13)***

### **Management of cluster headache**

- **Acute attacks:** Analgesics are not useful and acute attacks are usually halted by:
  - **Subcutaneous injection of sumatriptan** (6 mg) is the drug of choice for acute treatment. It works quickly and usually shortens an attack to 10–15 minutes. There is no evidence of tachyphylaxis. Oral sumatriptan is not effective. Sumatriptan (20 mg) and zolmitriptan (5 mg) nasal sprays are also effective or
  - **Inhalation of 100% oxygen** at 10–12 L/min for 15–20 min. Many respond very well.
  - The brevity of the attack probably prevents other migraine therapies from being effective. **Octreotide** is effective in the treatment of acute cluster headaches.
- **Most prophylactic migraine drugs are often ineffective.** Attacks can be prevented in some patients by sodium valproate, lithium, verapamil, methysergide and/or a short course of **oral corticosteroids**.

## **Tension-Type Headache**

**Q. Write short note on tension headache.**

Most common type of headache.

**Pathophysiology** is incompletely understood, and few consider this as a

milder version of migraine.

**Clinical features:** Characteristic features of headache (Fig. 15.3) are:

- Pain is ‘dull’, ‘tight’ or like a ‘pressure’, and it may be accompanied by a sensation of a band round the head or pressure at the vertex.
- It is of constant character and generalized, but often radiates forwards from the occipital region. It may be episodic or persistent.
- Severity may vary, and is not associated vomiting or photophobia. The pain often progresses throughout the day.
- Tenderness may be present over the skull vault or in the occiput.

#### Management

- Carefully assess, followed by discussion of likely precipitants and reassurance that the prognosis is good.
- Physiotherapy (with muscle relaxation and stress management) may be helpful.
- Low-dose amitriptyline may be beneficial. Investigation is rarely required.

Differences between most common primary headache is presented in Table 15.14.

**Table 15.14:** Comparison of most common primary headaches.

<i>Characteristic</i>	<i>Migraine</i>	<i>Tension</i>	<i>Cluster</i>
Age of onset	25–55 years	30–50 years	20–40 years
Location	Unilateral (but may be bilateral)	Bilateral	Unilateral, orbital, supraorbital, temporal
Duration of episode	4–72 hours	30 min–7 days	15–180 minutes
Severity	Moderate to severe	Mild to moderate	Extremely severe
Type	Pulsating, throbbing	Pressing, tightening but not pulsating	Boring, searing
Pattern	1 to 2 attacks per month	<180 attacks per year (or <15 attacks per month)	1 to 8 attacks per day separated by pain-free periods
Associated symptoms	Nausea, vomiting, photophobia, phonophobia (2 of these)	Either photophobia or phonophobia, but not both, no nausea or vomiting	Conjunctival injection, Lacrimation Forehead/ facial swelling, nasal congestion, rhinorrhea, ptosis,

## STROKE AND CEREBROVASCULAR DISEASE

- Q. Describe the predisposing factors, clinical features, investigations, and management of a patient with right middle cerebral artery occlusion.**
- Q. Describe clinical features, diagnosis of the cerebral stroke in young and its management.**
- Q. Describe the etiology, clinical features and treatment of cerebral thrombosis.**
- Q. Write a short essay/note on cerebrovascular accidents/stroke.**

### Stroke

- **A stroke (cerebrovascular accident is a vague term which should be avoided)** is defined as a syndrome of rapid (**abrupt**) **onset of a neurologic deficit** that is attributable to a focal vascular cause.
- **World Health Organization (WHO) definition:** Stroke is a '**rapidly developing clinical signs of focal (or global) disturbance of cerebral function, with symptoms lasting for 24 hours or longer or leading to death, with no apparent cause other than of vascular origin**'.
- **Progressing stroke (or stroke in evolution):** It is a stroke in which the focal neurological deficit worsens after the patient first presents. It may be due to increasing volume of infarction, secondary hemorrhage in the infarcted area or increasing cerebral edema.
- **Complete stroke:** Rapid onset with persistent focal neurological deficit which does not progress beyond 96 hours.
- **Evolving stroke:** Gradual stepwise development of neurological deficits.

Focal cerebral deficits that develop slowly (over weeks to months) are unlikely to be due to stroke and are more suggestive of tumor or inflammatory or degenerative disease.

### *Terminologies*

Several terms are used to classify strokes, mainly based on the duration and evolution of symptoms.

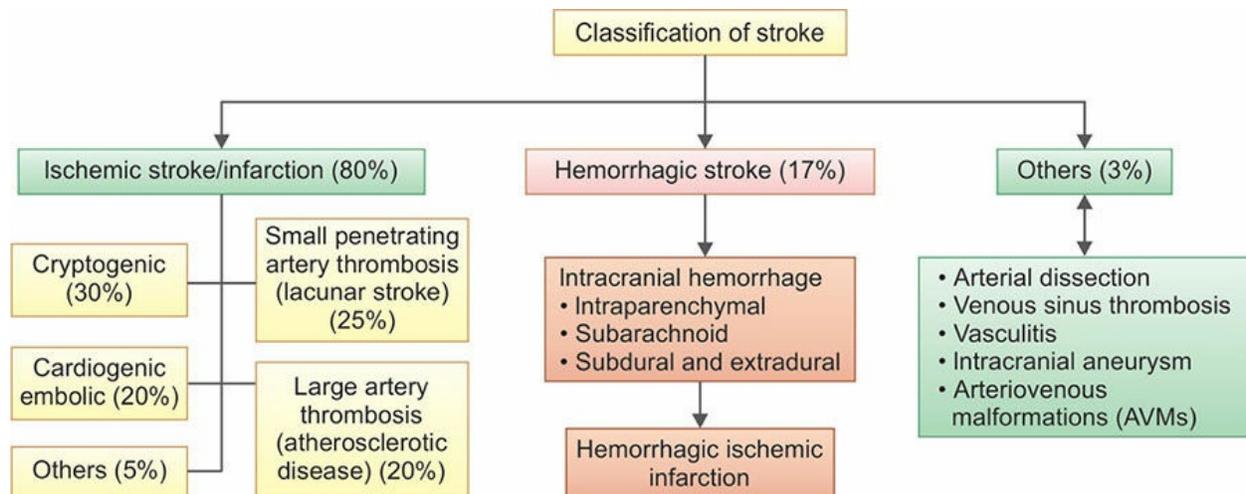

- **Transient ischemic attack (TIA):** Described later (refer page 960)
- **Reversible ischemic neurological deficit (RIND):** In some cases, deficits last for longer than 24 hours but resolve completely or almost completely within a few days.
- **Stuttering hemiplegia:** Internal carotid lesions are characterized by repeated episodes of TIA followed by fully evolved stroke.

### ***Types of Stroke (Flowchart 15.2)***

About 80% of patients develop **cerebral infarction** due to inadequate blood flow to part of the brain, and most of the remainder develops an **intracerebral hemorrhage**.

- **Ischemic stroke: Cerebral infarction is most commonly caused by thromboembolic disease** secondary to atherosclerosis in the major extracranial arteries (carotid artery and aortic arch). About 20% of infarctions are caused by emboli from the heart, and about 20% are caused by thrombosis in situ caused by intrinsic disease of small perforating vessels (lenticulostriate arteries), producing lacunar infarctions.
- **Hemorrhagic stroke: Intracranial hemorrhage** is caused by bleeding directly into or around the brain. Neurological symptoms are produced by compression, toxic effects or raised intracranial pressure.
- **Cerebrovascular anomalies** such as intracranial aneurysm and arteriovenous malformations (AVMs).

**Flowchart 15.2:** Classification of stroke.

## Risk (Predisposing) Factors for Stroke (Table 15.15)

**Q. Write a short essay/note on risk factors for stroke.**

**Table 15.15: Risk factors for stroke.**

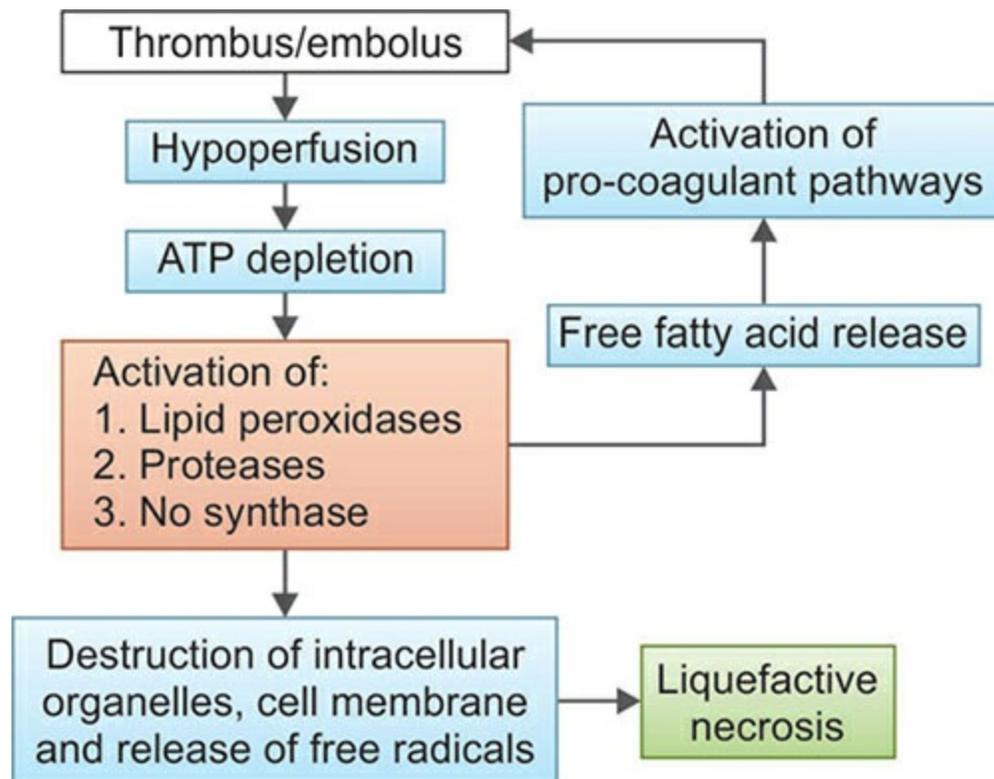

<i>Risk factors in patients of all age groups</i>		<b>High-risk</b>
<ul style="list-style-type: none"> <li>• Hypertension (including isolated systolic)</li> <li>• Smoking</li> <li>• Diabetes mellitus</li> <li>• Atrial fibrillation</li> <li>• Drugs: Cocaine, amphetamine</li> <li>• Dilated cardiomyopathy</li> <li>• Endocarditis</li> </ul>	<ul style="list-style-type: none"> <li>• High cholesterol</li> <li>• Obesity</li> <li>• Vasculitis: Systemic vasculitides (e.g. polyarteritis nodosa-PAN), granulomatosis with polyangiitis (Wegener's) etc.), primary CNS vasculitis, meningitis (syphilis, tuberculosis, fungal, bacterial, zoster)</li> </ul>	
<b>Low-risk</b>		
<ul style="list-style-type: none"> <li>• Migraine</li> <li>• Oral contraceptives or alcohol</li> <li>• Patent foramen ovale</li> </ul>	<ul style="list-style-type: none"> <li>• Recent myocardial infarction</li> <li>• Prosthetic valve</li> <li>• Sleep apnea</li> </ul>	
<b>Additional risk factors that are more common in young patients</b>		
<b>Hypercoagulable disorders</b>		
<ul style="list-style-type: none"> <li>• Protein C and S deficiencies</li> <li>• Antithrombin III deficiency</li> <li>• Antiphospholipid syndrome</li> <li>• Factor V Leiden mutation</li> <li>• Prothrombin G20210A heterozygous mutation</li> </ul>	<ul style="list-style-type: none"> <li>• Sickle-cell anemia</li> <li>• Hyperhomocysteinemia</li> <li>• Thrombotic thrombocytopenic purpura</li> <li>• Arterial dissection</li> <li>• Infections (e.g. syphilis, HIV)</li> <li>• Systemic malignancy</li> </ul>	

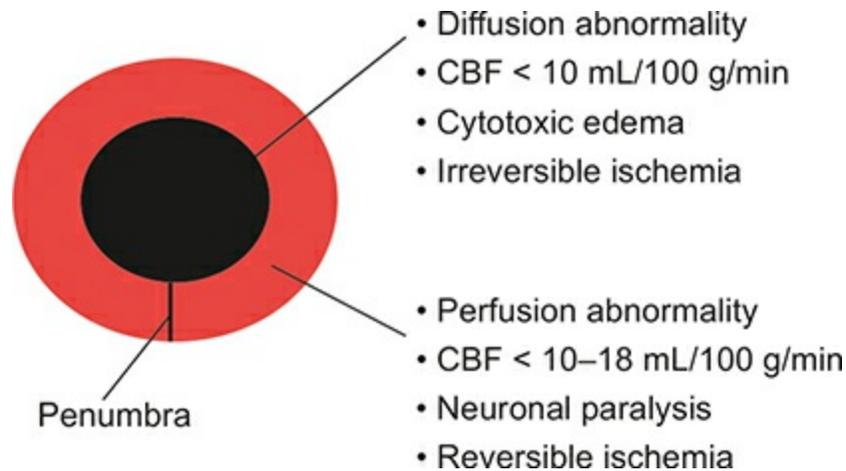

## Ischemic Stroke

### Pathophysiology (Flowchart 15.3)

- Complete stop of cerebral blood flow causes death of brain tissue within 4–10 minutes. The cerebral blood flow (CBF) to the **ischemic core** is <10 mL/100 g/min.
- **Ischemic penumbra (Fig. 15.4)** is the region surrounding the central core. The tissue of the penumbra is functionally impaired and is at risk of infarction. CBF is 10–18 mL/100 g/min. It has the potential to be salvaged by revascularization. The damage of the penumbra is coupled by inflammation and excitotoxicity mediated by glutamine and sodium. Also hyperglycemia and fever worsen the penumbra, so need to be controlled.

Flowchart 15.3: Pathophysiology of ischemic stroke.

**Fig. 15.4:** Ischemic penumbra and ischemic core (black center).

(DWI: diffusion weighted image; PWI: perfusion weighted image; CBF: cerebral blood flow)

## ***Etiology of Ischemic Stroke (Table 15.16)***

### ***Embolic occlusion***

**Q. Write a short essay/note on embolic stroke, its causes and management.**

#### *Artery-to-artery embolic stroke*

- **Any vessel** may be the source of emboli, including the aortic arch, common and internal carotid, vertebral and basilar arteries.
- **Atherosclerosis within the carotid artery:** Carotid bifurcation atherosclerosis is the most common source of artery-to-artery embolus.
- **In young (age <60 years) patients:** Intracranial atherosclerosis, dissection of the internal carotid or vertebral arteries or even vessels beyond the circle of Willis is a common source of embolic stroke.

#### *Cardioembolic stroke*

- Heart is a common source of emboli. Emboli from the heart **most often lodge in the middle cerebral artery (MCA)**, the **posterior cerebral artery (PCA)**, or one of their branches. Infrequently, the anterior cerebral artery (ACA) territory is involved.
- **Non-rheumatic atrial fibrillation** (and other arrhythmias) causing thrombosis in a dilated left atrium is the **most common cause of cerebral embolism**. Other causes include cardiac valvular disease such as congenital valve disorders, infective vegetations; rheumatic and degenerative calcific changes may cause embolization.
- Simultaneous infarcts in different vascular territories are suggestive that heart or aorta is the source of emboli.

#### **Paradoxical embolus**

Atrial septal defect or patent foramen ovale (PFO) may occasionally allow passage of fragments of thromboemboli (e.g. from a lower limb DVT) from the right atrium to the left. This is believed to be the most common cause of cryptogenic strokes.

*Other embolism like fat embolism, air embolism, amniotic fluid embolism, tumor embolism are rarely associated with neurological deficits.*

**Table 15.16:** Etiology of ischemic stroke.

**Thrombotic occlusion**

- Small vessel (lacunar) stroke
- Large vessel thrombosis

**Embolic occlusion**

- **Artery-to-artery:** Carotid bifurcation, aortic arch, arterial dissection
- **Cardioembolic:** Atrial fibrillation, mural thrombus, myocardial infarction, dilated cardiomyopathy, valvular lesions, mitral stenosis, mechanical valve, bacterial endocarditis
- **Paradoxical embolus:** Atrial septal defect, patent foramen ovale

**Venous sinus thrombosis**

**Subarachnoid hemorrhage** due to vasospasm

*Thrombosis occlusion*

*Large vessel thrombosis*

Thrombosis developing at the site of ruptured mural atheromatous plaque may produce occlusion of involved vessel or may be a source of artery to artery embolism.

**Small Vessel (Lacunar) Stroke**

**Q. Write a short essay/note on lacunar infarct.**

- Small penetrating arterial branches of 200–800  $\mu\text{m}$  in diameter, supply the deep brain parenchyma. Each of these small branches can be occluded either by atherothrombotic disease at its origin or by the development of occlusive vasculopathy—lipohyalinotic thickening (consequence of hypertension).
- Thrombosis of these vessels causes small infarcts that are referred to as lacunes. These infarcts range in size from **0.2 to 15 mm** in diameter.
- Risk factors: Include hypertension and age.
- Small-vessel strokes account for 20% of all strokes.
- Symptoms (Table 15.17): Lacunar strokes present with fluctuating symptoms ‘capsular warning syndrome’.

**Table 15.17: Signs and symptoms of lacunar stroke depending on location of lesion.**

<i>Syndrome</i>	<i>Signs/Symptoms</i>	<i>Localization</i>	<i>Vascular supply</i>
Pure motor	Contralateral hemiparesis or hemiplegia. Affects face, arm and leg equally	<ul style="list-style-type: none"> <li>• Posterior limb of internal capsule</li> <li>• Corona radiata-Basis pontis</li> </ul>	Lenticulostriate branches of the middle cerebral artery (MCA) or perforating arteries from basilar artery
Pure sensory	Contralateral hemisensory loss. Persistent or transient numbness and/or tingling on one side of the body	<ul style="list-style-type: none"> <li>• VPL (ventral posterolateral) nucleus of thalamus</li> </ul>	Lenticulostriate branches of MCA. Small thalamoperforators of PCA (posterior cerebral artery)
Mixed sensorimotor	Contralateral weakness and numbness. Hemiparesis or hemiplegia with ipsilateral sensory impairment	Thalamus and adjacent posterior limb of internal capsule	Lenticulostriate branches of MCA
Dysarthria- clumsy hand	Slurred speech and weakness of contralateral hand (fine motor)	Basis pontis	Basilar artery perforators
Ataxia- hemiparesis	Combination of cerebellar and motor symptoms. Contralateral hemiparesis and ataxia out of proportion to weakness	<ul style="list-style-type: none"> <li>• Internal capsule-posterior limb</li> <li>• Basis pontis</li> <li>• Corona radiata</li> </ul>	<ul style="list-style-type: none"> <li>• Lenticulostriate branches of MCA</li> <li>• Perforating arteries of basilar artery</li> </ul>
Hemiballismus/ hemichorea	Contralesional limb flailing/dyskinesia	Subthalamic nucleus	Perforating arteries of anterior choroidal or PCOM (posterior communicating artery)

***Clinicoanatomic Correlation (Table 15.18 and Flowchart 15.2)***

**Table 15.18: Features of cerebral ischemia depending on the neuroanatomic basis.**

<i>Vascular territory</i>	<i>Signs and symptoms</i>
Internal carotid artery	<ul style="list-style-type: none"> <li>• Combined ACA (anterior cerebral artery) + MCA (middle cerebral artery)</li> <li>• Ipsilateral monocular visual loss (amaurosis)</li> </ul>

	secondary to CRAO
Left anterior cerebral artery (ACA)	<ul style="list-style-type: none"> <li>• Right leg numbness and weakness</li> <li>• Transcortical motor aphasia</li> <li>• Ideomotor apraxia</li> </ul>
Right anterior cerebral artery (ACA)	<ul style="list-style-type: none"> <li>• Left leg numbness and weakness</li> <li>• Motor neglect</li> <li>• Possibly ideomotor apraxia</li> </ul>
Left middle cerebral artery (MCA)	<ul style="list-style-type: none"> <li>• Right face/arm &gt; leg numbness and weakness</li> <li>• Aphasia</li> <li>• Left gaze preference</li> </ul>
Right middle cerebral artery (MCA)	<ul style="list-style-type: none"> <li>• Left face/arm &gt; leg numbness and weakness</li> <li>• Left hemispatial neglect</li> <li>• Right gaze preference</li> <li>• Agraphesthesia/astereognosia</li> </ul>

### Stroke Localization—Clinical Features (Table 15.19 and Fig. 15.5)

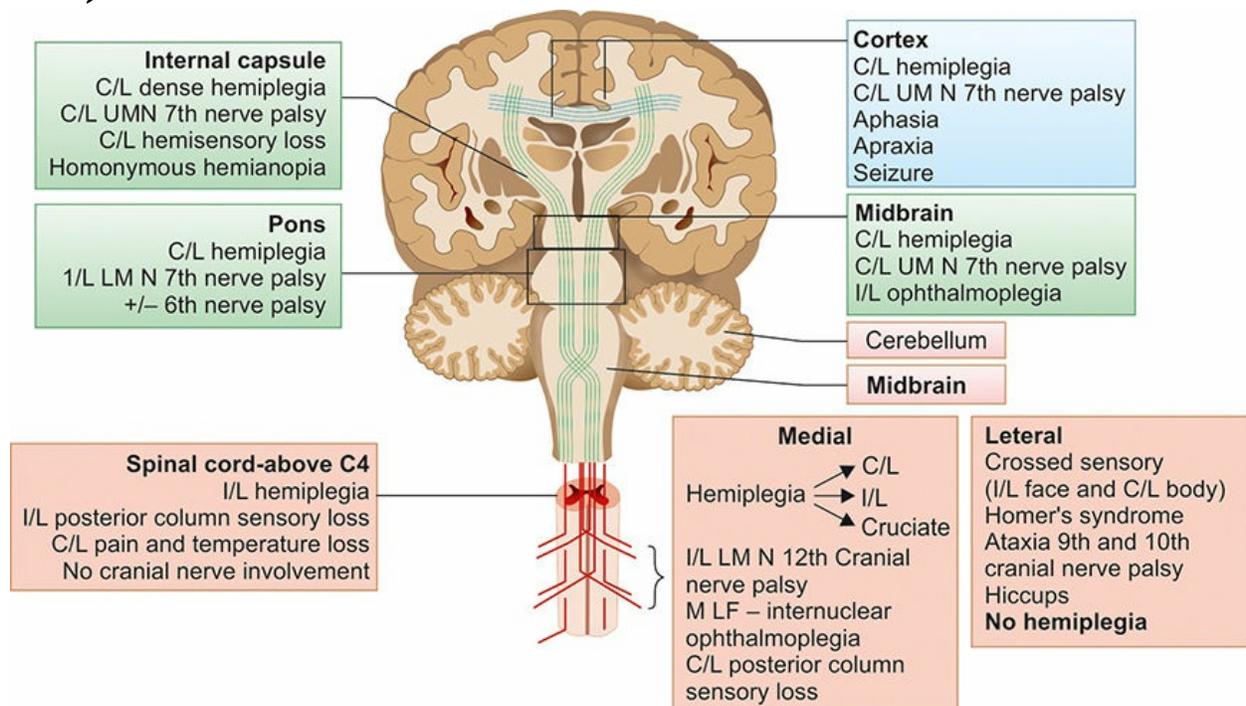

Fig. 15.5: Localization of lesion in hemiplegia. (I/L: ipsilateral; C/L: contralateral)

**Table 15.19: Clinical features of stroke depending on localization.**

Syndrome	Clinical features	Localization
Middle cerebral artery (M1)	Produces pure motor or sensory	Internal capsule,

syndrome	motor stroke contralateral to the side of lesion. If ischemia of putamen, pallidus- predominantly parkinsonian features	caudate nucleus, putamen and outer pallidus
Middle cerebral artery (M2) syndrome	Brachial syndrome: Weakness of hand and arm Frontal opercular syndrome: Broca's aphasia with facial weakness with or without arm weakness	Superior division of MCA-M2 involved
	If dominant hemisphere: Wernicke's aphasia without weakness with contralateral homonymous superior quadrantanopia If non-dominant hemisphere: Hemispatial neglect, spatial agnosia without weakness	Inferior division of MCA-M2 involved
Complete MCA syndrome	Contralateral hemiplegia, contralateral hemianesthesia, contralateral homonymous hemianopia, gaze preference to the ipsilateral side. If dominant hemisphere involved-global aphasia. If non-dominant hemisphere involved-hemispatial neglect, anosognosia and constructional apraxia	
Unpaired ACA syndrome	Profound abulia and bilateral pyramidal signs with paraparesis or quadriparesis and urinary incontinence	Frontal lobe, entire medial part of cerebral hemispheres
Anterior choroidal artery occlusion syndrome	Contralateral (c/l) hemiplegia, c/l hemianesthesia, c/l homonymous hemianopia	Posterior limb of internal capsule, retrolentiform and sublenticular parts
Claude's syndrome	3rd nerve palsy + contralateral ataxia	Red nucleus/cerebral peduncle
Weber's syndrome	3rd nerve palsy + contralateral hemiplegia	Medial midbrain/cerebral peduncle
Benedict's syndrome	Weber's + tremors + ataxia	Red nucleus/medial midbrain
Dejerine-Roussy syndrome	Contralateral hemisensory loss and agonizing pain	Thalamus
Parinaud's syndrome	Loss of up gaze, convergence-retraction nystagmus on attempted	Dorsal midbrain

	up gaze, downward ocular deviation ('setting sun' sign), lid retraction nystagmus (Collier's sign), mydriasis	
Marie-Foix syndrome	Ipsilateral ataxia—arm and leg Contralateral hemiparesis and hemisensory loss	Lateral pontine (middle cerebellar peduncle, corticospinal tract and spinothalamic tract)
Raymond-Cestan syndrome	Ipsilateral lateral gaze palsy (VI nerve), contralateral hemiparesis	Ventral pons
Millard-Gubler syndrome	Ipsilateral lateral gaze palsy (VI nerve) and LMN facial palsy, contralateral hemiparesis	Ventral pons
Medial medullary syndrome (Dejerine syndrome)	Ipsilateral XII nerve palsy, contralateral hemiparesis, Internuclear ophthalmoplegia (involvement of medial longitudinal fascicle), loss of posterior column sensation	Medial medulla
Hemimedullary syndrome (Babinski–Negolette)	Lateral medullary syndrome + contralateral hemiparesis	Involve both lateral and medial medulla
Top of basilar syndrome	Parinauds syndrome features+ oculomotor palsy, behavioral features, abulia	Basilar artery occlusion Involves thalamus, midbrain, occipital lobes, cerebellum (superior cerebellar artery)

## Lateral medullary syndrome

**Q.** Write short note on lateral medullary syndrome.

Also called as Wallenberg's syndrome and is due to occlusion of the **posterior inferior cerebellar artery**. Localization/structures involved and associated symptoms are presented in Table 15.20.

**Table 15.20:** Localization/structures involved and associated symptoms of LMS.

<i>Localization/structures involved</i>	<i>Symptoms</i>
<ul style="list-style-type: none"> <li>• Vestibular nuclei and connections</li> <li>• Inferior cerebellar peduncle (Restiform body)</li> </ul>	<ul style="list-style-type: none"> <li>• Dizziness and imbalance</li> <li>• Hypotonia ipsilateral side</li> <li>• Diplopia/ oscillopsia</li> <li>• Nystagmus, limb ataxia</li> </ul>

<ul style="list-style-type: none"> <li>• Spinal nucleus of CNV</li> <li>• Spinothalamic tract</li> </ul>	<ul style="list-style-type: none"> <li>• Loss of pain and temperature sensation in ipsilateral face</li> <li>• Loss of pain and temperature contralateral trunk (crossed sensory loss)</li> </ul>
<ul style="list-style-type: none"> <li>• Nucleus ambiguus (CN 9 and 10)</li> </ul>	<ul style="list-style-type: none"> <li>• Ipsilateral paralysis palate, pharynx, and larynx</li> <li>• Absent gag reflex</li> </ul>
<ul style="list-style-type: none"> <li>• Descending sympathetic fibers</li> <li>• Dorsomotor nucleus of Vagus</li> </ul>	<ul style="list-style-type: none"> <li>• Ipsilateral Horner's syndrome</li> <li>• Autonomic signs—labile BP/tachycardia/sweating/arrhythmias</li> </ul>
<ul style="list-style-type: none"> <li>• Ventrolateral medullary tegmentum and the medullary reticular zone (Respiratory centers)</li> </ul>	<ul style="list-style-type: none"> <li>• Failure of automatic respirations</li> <li>• Hiccoughs</li> </ul>
<ul style="list-style-type: none"> <li>• <b>Corticospinal tracts, Medial lemniscus NOT involved</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>No pyramidal tract signs. Posterior column sensations preserved</b></li> </ul>

TOAST (The Trial of ORG 10172 in Acute Stroke Treatment) classification of subtypes of acute ischemic stroke is presented in Box 15.4.

### Hypoperfusion and its consequences

- A **generalized reduction in cerebral blood flow due to systemic hypotension** (e.g. cardiac arrhythmia, cardiac arrest, myocardial infarction, or hemorrhagic shock) usually **produces syncope**.
- If low cerebral blood flow persists for a longer duration, then **infarction in the border zones** (watershed areas) between the major and posterior cerebral artery distributions may develop (particularly if there is severe stenosis of proximal carotid vessels).
- In **more severe instances, global hypoxia-ischemia causes** widespread brain injury, the constellation of cognitive sequelae that ensues is called **hypoxic-ischemic encephalopathy**.
- **Focal ischemia or infarction**, conversely, is usually by thrombosis of the cerebral vessels themselves or by emboli from a proximal arterial source of the heart.

### Carotid and vertebral artery dissection

- About 20% of cases of young (below the age 40 years) stroke is due to dissection of carotid or vertebral artery.
- It may develop sometimes as a **sequel of trivial neck trauma or hyperextension** (e.g. after whiplash, hair washing in a salon, or exercise). Predisposing factor include subtle collagen disorders (e.g. partial forms of

Marfan's syndrome).

- **Most dissections occur in large extracranial neck vessels** and are characterized by **penetration of blood into the subintimal region of vessel wall** and forms false lumen. However, it is the thrombosis within the true lumen due to tissue thromboplastin release which results in embolization from the site of dissection. This type of stroke sometimes develops days after the initial event.
- Symptoms: Pain in the neck or face is the clue for diagnosis.

**Box 15.4:** TOAST classification of subtypes of acute ischemic stroke.

- Large-artery atherosclerosis
- Cardioembolism
- Small-vessel occlusion
- Stroke of other determined etiology
- Stroke of undetermined etiology

### *Venous stroke*

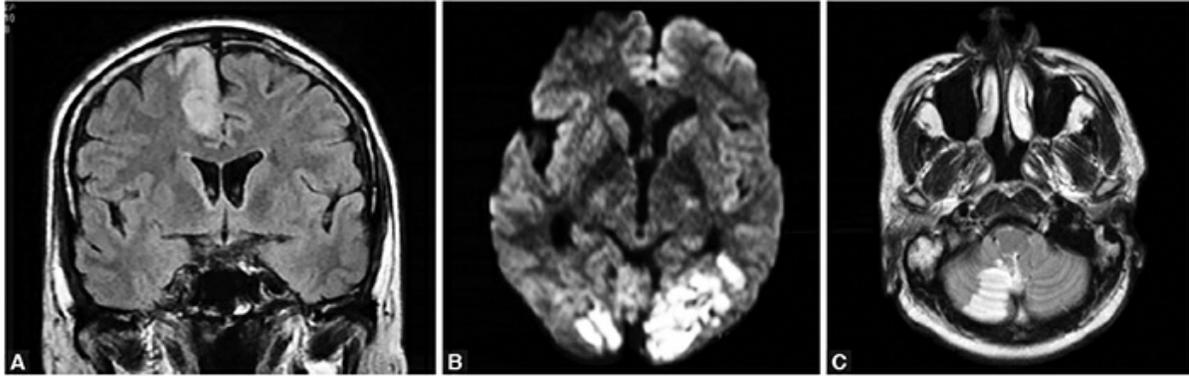

- Only 1% of strokes are due to venous thrombosis (within intracranial venous sinuses).
- **Predisposing factors:** It may occur in **pregnancy, hypercoagulable states** and thrombotic disorders or with dehydration or malignancy.
- **Consequences:** Cortical infarction, seizures and raised intracranial pressure.

### ***Investigations/Diagnosis***

**Q. Write a short essay/note on computerized tomography (CT) in stroke.**

#### *Neuroimaging (Figs. 15.6A to C)*

- CT scans: To identify or exclude hemorrhage as the cause of stroke.
  - They **identify extraparenchymal hemorrhage**, neoplasms, abscesses, and other conditions mimicking as stroke.
  - Brain CT scans in the first several hours after an infarction generally does not show any abnormality, and the infarct may not be detected reliably for 24–48 hours.

**Figs. 15.6A to C:** Neuroimaging in stroke: (A) Acute right anterior cerebral artery (ACA) infarct; (B) Acute bilateral posterior cerebral artery (PCA) infarct—Anton syndrome; (C) Right lateral medullary syndrome.

- CT may fail to show small ischemic strokes in the posterior fossa because of bone artifact; small infarcts on the cortical surface may also be missed.
- MRI: reliably documents the extent and location of infarction in all areas of the brain, including the posterior fossa and cortical surface. MRI is less sensitive than CT in detecting acute bleeding.
- **Diffusion-weighted imaging and FLAIR** (fluid-attenuated inversion recovery) imaging is more sensitive for early brain infarction than standard MR sequences or CT. It can identify ischemic penumbra and patients showing large regions of mismatch may be better candidates for acute revascularization.

### *Vascular imaging*

- Many ischemic strokes are due to atherosclerotic thromboembolic disease of the major extracranial vessels. Detection of extracranial vascular disease can establish the diagnosis of ischemic stroke and, it may also help for specific treatments (e.g. carotid endarterectomy to reduce the risk of further stroke).
- Extracranial arterial disease can be non-invasively detected by duplex ultrasound, MRA or CT angiography, or occasionally intra-arterial contrast radiography.

### *Cardiac investigations*

- Cardioembolism is responsible for 20% of ischemic strokes. The source of emboli includes atrial fibrillation, prosthetic heart valves, other valvular abnormalities and recent myocardial infarction.

- Clinical examination and ECG helps in identifying the source of cardiac emboli. However, it may be necessary to perform a transthoracic or transesophageal echocardiogram to confirm the cardiac source or for detecting an unsuspected source (e.g. endocarditis, atrial myxoma, intracardiac thrombus or patent foramen ovale). Such findings will help in providing specific cardiac treatment.

Paramedical personnel and general public are taught how to make the diagnosis of stroke on a simple history and examination—**FAST** (Box 15.5).

Complications of acute stroke (Box 15.6).

### Box 15.5: Diagnosis of stroke on a simple history and examination—FAST.

- **Face:** Sudden weakness of the face
- **Arm:** Sudden weakness of one or both arms
- **Speech:** Difficulty in speaking, slurred speech
- **Time:** Sooner the starting of treatment, better the outcome

### Box 15.6: Complications of acute stroke.

- Cerebral edema
- Cardiac arrhythmias, myocardial infarction, and neurogenic cardiac injury
- Chest infection
- Seizures
- Deep venous thrombosis/ pulmonary embolism
- Pressure sores
- Urinary infection
- **GI bleed:** Stress ulcers, drug induced
- Constipation
- Painful shoulder/contractures
- Depression and anxiety

**Q. Write a short essay/note on complications of stroke.**

## Differential Diagnosis of Stroke (Table 15.21)

### *Treatment of Ischemic Stroke—'Time is brain'*

Treatments designed to reverse or lessen the amount of tissue infarction and improve clinical outcome fall into six categories: (1) IV thrombolysis, (2) endovascular techniques, (3) antithrombotic treatment, (4) medical support, (5) neuroprotection, and (6) stroke centers and rehabilitation.

**Table 15.21: Differential diagnosis of stroke.**

<b>Structural stroke mimickers</b>	
• Tumors: Primary and metastatic cerebral tumors	• Demyelinating disorders: Multiple sclerosis
• Subdural hematoma	• Peripheral nerve lesions (vascular or compressive)
• Cerebral abscess	
<b>Functional stroke mimickers</b>	
• Seizure and postictal state	• Ménière's disease/other vestibular disorders
• Focal seizures	• Encephalitis
• Syncope	• Wernicke encephalopathy
• Hypoglycemia	• Transient global amnesia
• Migrainous aura	• Metabolic encephalopathy
• Conversion disorders and other psychiatric disorders	

- Intravenous thrombolysis**
  - Intravenous administration for recombinant t-PA within three hours of the onset of symptoms reduces disability and mortality from ischemic stroke.  
Indications and contraindications for r-tPA (Table 15.22)
  - Administration
    - Administer at the rate of 0.9 mg/kg intravenously (maximum 90 mg) as 10% of total dose as an intravenous bolus and remainder of dose as a continuous intravenous infusion over 60 minutes.
    - No other antithrombotic treatment for 24 hours.
    - Avoid urethral catheterization for 2 hours.
  - For decline in neurologic status or uncontrolled blood pressure, stop infusion, give cryoprecipitate, and reimage brain emergently.
- Endovascular mechanical thrombectomy:** It an alternative or adjunctive treatment of acute stroke in patients who are ineligible for, or have contraindications to, thrombolytics or in those who have failed to have vascular recanalization with IV thrombolytics.
- Antiplatelet therapy**
  - Platelet inhibition: Aspirin 150 mg PLUS clopidogrel 75 mg daily.  
**Note:** Glycoprotein IIb/IIIa receptor inhibitor abciximab causes excess intracranial hemorrhage and should be avoided in acute stroke.
  - Randomized studies of unfractionated heparin, low-molecular-weight heparins, or heparinoids have shown no proven benefits in the reduction of stroke-related mortality, stroke-related morbidity, early stroke recurrence, or stroke prognosis except in the case of cerebral venous thrombosis.
- Anticoagulation for acute ischemic stroke Routine use of anticoagulation for acute ischemic stroke is not recommended.** Only indications for anticoagulants are:
  - Conditions with potential high risk of early cardiogenic re-embolization (e.g. atrial fibrillation)
  - Symptomatic arteriosclerotic stenosis with crescendo TIAs

- Known hypercoagulable states
- Cerebral venous sinus thrombosis

#### 5. Medical support

- **Prevention of the common complications** of bedridden patients:
  - ◆ Infections (pneumonia, urinary and skin): Prophylactic antibiotic.
  - ◆ Deep venous thrombosis (DVT) with pulmonary embolism: Subcutaneous heparin and pneumatic compression stockings to prevent DVT.
  - ◆ Others: Catheterization, Ryle's tube (RT) feeding, maintenance of hygiene etc.
- **Maintenance of blood pressure:** Collateral blood flow within the ischemic brain is dependent on the blood pressure; hence it is to be maintained. Blood pressure should be lowered if there is malignant hypertension or concomitant myocardial ischemia or if blood pressure is >185/110 mm Hg and thrombolytic therapy is anticipated.
- **Fever:** It is detrimental and should be treated with antipyretics and surface cooling.
- **Serum glucose** should be monitored and kept at <6.1 mmol/L (110 mg/dL) using an insulin infusion if necessary.
- **Decreasing intracranial tension (ICT):** By water restriction and IV mannitol, oral glycerol, head end elevation.
- **Hemicraniectomy** (craniotomy and temporary removal of part of the skull) markedly reduces mortality.
- **Control of intracranial pressure (ICP):** In cerebellar strokes, even small amounts of cerebellar edema can acutely increase ICP or directly compress the brainstem. Prophylactic suboccipital decompression of large cerebellar infarcts before brainstem compression is very useful.

#### 6. Statins: Atorvastatin, rosuvastatin—10–20 mg

7. **Neuroprotection:** Drugs that block the excitatory amino acid pathways (nimodipine, **magnesium lubeluzole**, basic fibroblast growth factor, and citicoline) protect neurons and glia in animals, but they have not yet been proven to be beneficial in humans.

#### 8. Rehabilitation:

- Proper rehabilitation of the stroke patient includes **early physical, occupational and speech therapy**. It is directed toward educating the patient and family about the patients' neurologic deficit, preventing the complications of immobility (e.g. pneumonia, DVT and pulmonary embolism, pressure sores of the skin, and muscle contractures), and providing encouragement and instructions in overcoming the deficit.
- **Goal of rehabilitation:** It is to **return the patient to home and to maximize recovery**. The use of **restrain therapy** (immobilizing the unaffected side) has been shown to improve hemiparesis following stroke, even years following the stroke.

**Table 15.22: Indications and contraindications for r-tPA.**

#### *Indications for r-tPA*

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• Clinical diagnosis of stroke</li> <li>• Onset of symptom to time of drug administration less than or equal to 3 hours (time window: 3–4.5 hours)</li> <li>• Age more than or equal to 18 years</li> </ul> | <ul style="list-style-type: none"> <li>• CT scan showing no hemorrhage or infarct size more than one-third of the MCA territory</li> <li>• Consent by patient or surrogate</li> </ul> |
|--|---|

### **Contraindications for r-tPA**

- Sustained BP > 185/110 mm of Hg despite treatment
- Platelets < 100,000/ $\mu$ L
- Hematocrit < 25%
- Glucose < 50 or > 400 mg%
- Use of heparin/warfarin within 48 hours and prolonged APTT or INR
- Prior intracranial hemorrhage
- Prior stroke or head injury within 3 months
- Major surgery in preceding 14 days
- Minor stroke symptoms
- GI bleed in preceding 21 days
- Recent MI (myocardial infarction within 3 months)
- Coma or stupor
- Pregnancy
- Age > 80 years

## **Secondary Prevention of Stroke and TIA**

**ABCD<sup>2</sup> score** can help in identifying the stroke risk. A score of <4 is associated with a minimal risk whereas >6 is high-risk for a stroke (Table 15.23).

### **Treatment of Atherosclerosis**

- **Risk factors:** Treatment of hypertension, diabetes, dyslipidemia and cessation of smoking. Patients with higher risk scores need to be on anticoagulation while those with lower scores antiplatelet agents would suffice.
- **Atorvastatin:** In the dose of 80 mg/day useful both in secondary and primary prevention even with normal lipid levels.
- **Antiplatelet agents:** Aspirin, clopidogrel or dipyridamole are used.
- **Anticoagulation therapy** for embolic stroke: Anticoagulation (INR range, 2–3) in patients with chronic nonvalvular (nonrheumatic) atrial fibrillation prevents cerebral embolism and is safe. Warfarin, apixaban, dabigatran, rivaroxaban, edoxaban are equally effective.
- **Calculation of CHADS<sup>2</sup> score:** *One point for age > 75 years, one point for hypertension, one point for congestive heart failure, one point for diabetes, and two points for stroke or TIA; sum of points is the total CHADS2 score.*

### **Treatment of Carotid Atherosclerosis**

- **High-grade stenosis of carotid artery:** Patient with recent symptomatic (within 2 weeks of symptoms) hemisphere ischemia, high grade, stenosis (>70%) in the appropriate internal carotid artery, and an institutional perioperative morbidity and mortality rate of 6% generally should undergo carotid endarterectomy.
- **Low-grade stenosis of carotid artery:** For asymptomatic stenosis and symptomatic low-grade stenosis (50–70%), medical therapy for reduction of atherosclerosis risk factors, including cholesterol-lowering agents and antiplatelet medications, is generally recommended.
- **Endovascular therapy:** Balloon angioplasty coupled with stenting to open stenotic carotid arteries and maintain their patency.

### **Treatment of Intracranial Atherosclerosis**

- Symptomatic lesions with intracranial angioplasty and stenting.
- Dural sinus thrombosis: By short-term anticoagulants, regardless of the presence of intracranial hemorrhage, for venous infarction following sinus thrombosis.

**Table 15.23:** Features and ABCD2 score useful in assessing the stroke risk.

<i>Clinical feature</i>	<i>Score</i>
<b>A:</b> Age > 60 years	1
<b>B:</b> BP systolic > 140 mm Hg or diastolic BP > 90 mm Hg	1
<b>C:</b> Clinical symptoms	
• Unilateral weakness	2
• Speech disturbance without weakness	1
<b>D:</b> Duration of symptoms	
• > 60 minutes	2
• 10–59 minutes	1
<b>D:</b> Diabetes (oral medications or insulin)	1
ABCD <sup>2</sup> total score	Sum each category

## Young Stroke (Table 15.24)

**Q.** Write a short essay/note on etiology of stroke in a young.

The term ‘young stroke’ is used to denote stroke in individuals less than 45 years of age.

**Table 15.24:** Causes for young stroke.

<ul style="list-style-type: none"> <li>• <b>Cardiac</b> <ul style="list-style-type: none"> <li>– Congenital heart disease, patent foramen ovale</li> <li>– Atrial myxoma</li> <li>– Atrial fibrillation and other arrhythmia</li> <li>– Cardiomyopathy, myocarditis, myocardial infarction</li> <li>– Cardiac surgery, cardiac catheterization</li> <li>– Endocarditis, rheumatic heart disease</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• <b>Vascular</b> <ul style="list-style-type: none"> <li>– <b>Noninflammatory</b> <ul style="list-style-type: none"> <li>◆ Arterial dissection</li> <li>◆ Secondary to connective tissue disease (Ehlers-Danlos, Marfan)</li> <li>◆ Moyamoya disease</li> <li>◆ Hypertension</li> <li>◆ Radiation vasculopathy</li> </ul> </li> </ul> </li> </ul>
--	--

- Prosthetic valve
- **Hematologic**
  - Sickle cell disease, iron deficiency anemias, polycythemia vera
- **Hypercoagulable states**
  - Inherited prothrombotic states, protein C and S deficiency, antithrombin III deficiency, factor V Leiden gene mutation, prothrombin gene mutation
  - Antiphospholipid syndrome
  - Hyperhomocysteinemia
  - Myeloproliferative disorders (e.g. leukemia, lymphoma)
  - Pregnancy exposure to hormonal treatments such as anabolic steroids and erythropoietin, nephrotic syndrome
- Vasculitis and postinfectious vasculopathy
- Migraine
- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) Fibromuscular dysplasia, Susac's syndrome, Sneddon's syndrome, Fabry's disease
- **Inflammatory**
  - Takayasu arteritis
  - Giant cell arteritis
  - Kawasaki disease
  - Polyarteritis nodosa
  - Human immunodeficiency virus (HIV)
  - Bacterial meningitis

## Intracranial Hemorrhage (ICH)

**Q. Describe the risk factors, etiopathogenesis, clinical features, investigations, diagnosis and management of cerebral/intracerebral hemorrhage.**

**Q. Describe the etiology, clinical features, investigations and management of hemorrhagic stroke.**

- This includes: (1) intracerebral (Fig. 15.7) and cerebellar hemorrhage, (2) subarachnoid hemorrhage (SAH), and (3) subdural and extradural hemorrhage/hematoma.
- It causes about 10% of acute stroke events. It usually due to rupture of a blood vessel within the brain parenchyma but may also occur in association with an SAH if the artery ruptures into the brain substance as well as into the subarachnoid space.
- **Hypertensive intraparenchymal hemorrhage** (hypertensive hemorrhage or hypertensive intracerebral hemorrhage) usually results from spontaneous rupture of a small penetrating artery deep in the brain. The most common sites are the **basal ganglia (especially the putamen), thalamus, cerebellum, and pons. Cortical bleeds are rare.**
- **Pontine hemorrhages:** 3 Ps namely pinpoint pupil, hyperpyrexia, paralysis (quadriplegia). There is prominent decerebrate rigidity and

‘pinpoint’ (1 mm) pupils that react to light. There is impairment of reflex horizontal eye movements evoked by head turning (doll’s head or oculocephalic maneuver) or by irrigation of the ears with ice water.

- **Primary versus secondary hemorrhage** (Hemorrhage that frequently occurs also into an area of brain infarction)—may be difficult to distinguish from primary intracerebral hemorrhage both clinically and radiologically.

**Fig. 15.7:** CT showing hemorrhage in internal

### ***Consequences of Hemorrhage***

- **Immediate cessation of function:** The sudden entry of blood into the brain parenchyma causes immediate cessation of function in that area as neurons are structurally disrupted with splitting of white-matter fiber tracts.
- **Mass effect:** The **hemorrhage may expand** over the first minutes or hours, or it may produce a rim of **cerebral edema**. Progression of neurological deficit occurs due to the mass effect. If large, they can cause shift of the intracranial contents, producing transtentorial coning and sometimes rapid death.
- **Resorption of hematoma:** If the patient survives, the hematoma is

gradually absorbed, and produces a hemosiderin-lined slit in the brain parenchyma.

### ***Causes of Intracranial Hemorrhage (Table 15.25)***

**Table 15.25: Causes of intracranial hemorrhage and its location.**

<b><i>Cause</i></b>	<b><i>Location</i></b>	<b><i>Comments</i></b>
Head trauma	Intraparenchymal: Frontal lobes, anterior temporal lobes, subarachnoid	Coup and countercoup injury during brain deceleration
Hypertensive hemorrhage	Putamen (most common), globus pallidus, thalamus, cerebellar hemisphere, pons	Chronic hypertension produces hemorrhage from small (100 μm) vessels in these regions
Metastatic brain tumor	Lobar	Primary tumors in lung, choriocarcinoma, melanoma
Coagulopathy	Any	Uncommon cause: Often associated with prior stroke or underlying vascular anomaly
Drug	Lobar, subarachnoid	Cocaine, amphetamine, phenylpropanolamine
Arteriovenous malformation	Lobar, intraventricular, subarachnoid	Risk is 2–4% per year for bleeding
Aneurysm	Subarachnoid, intraparenchymal, rarely subdural	Mycotic and nonmycotic forms of aneurysms
Cerebral amyloid angiopathy	Lobar	Most common cause for recurrent lobar hemorrhage in elderly

### ***Clinical Features***

- **Clinical presentation depends upon which arterial territory is involved and the size of the lesion.**
- **Rapid-onset:** Occurs over minutes.
- **Most common presentation:** Weakness of the face or arm, or disturbance of speech.
- **Focal deficit of brain function:** Affects an identifiable area of the brain and is ‘negative’ in character (i.e. abrupt loss of function without positive features such as abnormal movement). Features which suggest the location of lesion are:
  - **Lesion in the cerebral hemisphere:** Usually characterized by

unilateral motor deficit, a higher cerebral function deficit such as aphasia or neglect, or a visual field defects.

- **Lesion in the brainstem or cerebellum:** Ataxia, diplopia, vertigo and/or bilateral weakness.
- **Intracerebral hemorrhage:** Combination of severe headache and vomiting at the onset of the focal deficit.

### **Management/Treatment**

- Any identified coagulopathy should be reversed as soon as possible.
- For patients taking VKAs (vitamin K antagonists), rapid reversal of coagulopathy can be achieved by infusing prothrombin complex concentrates which can be administered quickly, followed by fresh-frozen plasma and vitamin K.
- When ICH is associated with thrombocytopenia (platelet count  $<50,000/\mu\text{L}$ ), transfusion of fresh platelets is indicated.

### **Control of BP**

- BP  $>185/110$  increases the size of hematoma by more bleeding. Hence, maintain a mean arterial pressure (MAP)  $<130$  mm Hg, unless an increase in ICP (intracranial pressure) is suspected.
- In patients who have ICP monitors in place, keep the cerebral perfusion pressure (MAP-ICP) above 60 mm Hg (i.e. one should lower MAP to this target if blood pressure is elevated).
- Blood pressure should be lowered with nonvasodilating IV drugs such as nicardipine, labetalol, or esmolol.

### **Hyperosmolar therapy**

- Mannitol: Bolus of 0.25 g/kg to 1 g/kg body weight.
- Hypertonic saline, concentrations ranging from 3% to 23.4%.

**Hyperventilation** decreases  $\text{PaCO}_2$ , which can induce constriction of cerebral arteries by alkalinizing the CSF.

### **Barbiturate coma**

- Pentobarbital is given in a loading dose of 10 mg/kg body weight followed by 5 mg/kg body weight each hour for 3 doses.

### **Hypothermia**

**Steroids** are used for primary and metastatic brain tumors, to decrease vasogenic cerebral edema.

### **Treatment of raised intracranial tension**

- If the hematoma causes marked midline shift of structures with consequent obtundation, coma or hydrocephalus, osmotic agents coupled with induced hyperventilation can be instituted to lower ICP.
- Once ICP is recorded, further hyperventilation and osmotic therapy can be tailored to the individual patient to keep cerebral perfusion pressure (MAP-ICP) above 60 mm Hg.
- If ICP is still found to be high, CSF can be drained from the ventricular space and osmotic therapy continued.
- Persistent or progressive elevation in ICP may prompt surgical evacuation of the clot.
- Glucocorticoids are not helpful for the edema from intracerebral hematoma.
- Most cerebellar hematomas  $> 3$  cm in diameter will require surgical evacuation.

## Transient Ischemic Attacks

**Q. Write a short essay/note on transient ischemic attack (TIA) including its definition.**

Transient ischemic attack (TIA) is characterized by a brief episode of neurological dysfunction (sudden loss of function) in which symptoms and signs resolve completely after a brief period within 24 hours (usually within 30 minutes).

- Transient ischemic attack is defined as a transient episode of neurologic dysfunction caused by focal brain, spinal cord, or retinal ischemia, **without acute infarction**. However, TIAs may herald a stroke.
- Newly proposed definition classifies those with new brain infarction as ischemic strokes regardless of whether symptoms persist.

**Clinical features:** Hemiparesis and aphasia are most common. Other features include amaurosis fugax (sudden transient loss of vision in one eye), hemisensory loss, hemianopic visual loss, diplopia, vertigo, vomiting, choking and dysarthria, ataxia, etc.

Types of TIA (transient ischemic attack) (Box 15.7).

**Diagnosis of TIA** often depends on its description. There may be clinical evidence of a source of embolus (e.g. carotid arterial bruit/stenosis, atrial fibrillation or other dysrhythmia, valvular heart disease/endocarditis, recent myocardial infarction).

- An underlying **risk factor**/condition may be present. These include atheroma, hypertension, postural hypotension, bradycardia or low cardiac output, diabetes mellitus, etc.

**Box 15.7:** Types of TIA (transient ischemic attack).

- Large artery low-flow TIA—recurrent, short lasting episodes of stereotyped symptoms (shotgun TIA/ thrombotic TIA)
- Embolic TIA—longer lasting less frequent episodes with varied symptoms, changing territories
- Lacunar TIA

### Treatment

Medical therapy and surgical treatment if appropriate. If patients have ABCD<sup>2</sup> (refer Table 15.23) score >4, or have had two recent TIAs (especially within the same vascular territory), they should be investigated and advised for secondary prevention of stroke.

## Subarachnoid Hemorrhage

**Q. Discuss the clinical manifestations and treatment of primary subarachnoid hemorrhage (SAH).**

**Q. Write a short essay/note on subarachnoid hemorrhage.**

Subarachnoid hemorrhage (SAH) is a pathologic condition in which the **blood enters the subarachnoid space**.

SAH is less common than ischemic stroke or intracerebral hemorrhage. It accounts for about 5% of strokes.

### *Etiology (Table 15.26)*

- **Most common cause of SAH is trauma.**
- **Most common cause of spontaneous SAH is an aneurysmal (saccular or ‘berry’ aneurysms) bleed (65–80%).**
- SAH causes intense reductions in CBF (cerebral blood flow), reduced cerebral autoregulation and acute cerebral ischemia.
- The overall case fatality varied from 32–67%.

Risk factors for subarachnoid hemorrhage (Table 15.27).

**Table 15.26:** Causes of subarachnoid hemorrhage.

Category	Causes
Trauma	Closed, penetrating, electric, etc.
Vascular	Aneurysms (berry aneurysm), atherosclerosis, arteriovenous malformations (AVM), vasculitides
Idiopathic	Benign perimesencephalic subarachnoid hemorrhage
Blood dyscrasias	Leukemia, hemophilia, thrombocytopenia
Infections	Dengue, leptospirosis, bacterial meningitis
Toxins	Amphetamines, cocaine, nicotine, anticoagulants
Neoplasms	Gliomas, meningiomas, hemangioblastoma, etc.

**Table 15.27:** Risk factors for subarachnoid hemorrhage.

- |  |  |
|--|--|
| <ul style="list-style-type: none"><li>• Hypertension</li><li>• Cigarette smoking</li></ul> | <ul style="list-style-type: none"><li>• Slight increased risk with advancing age</li><li>• Alcohol consumption (debatable)</li></ul> |
|--|--|

- Oral contraceptives
- Diurnal variations in blood pressure
- Pregnancy and parturition
- Slight increased risk during lumbar puncture and/or cerebral angiography in patient with cerebral aneurysm
- Following cocaine abuse
- Increased incidence of polycystic kidneys, fibromuscular dysplasia of extracranial arteries, Ehler-Danlos syndrome, moyamoya, AV malformations and coarctation of aorta

## Circle of Willis

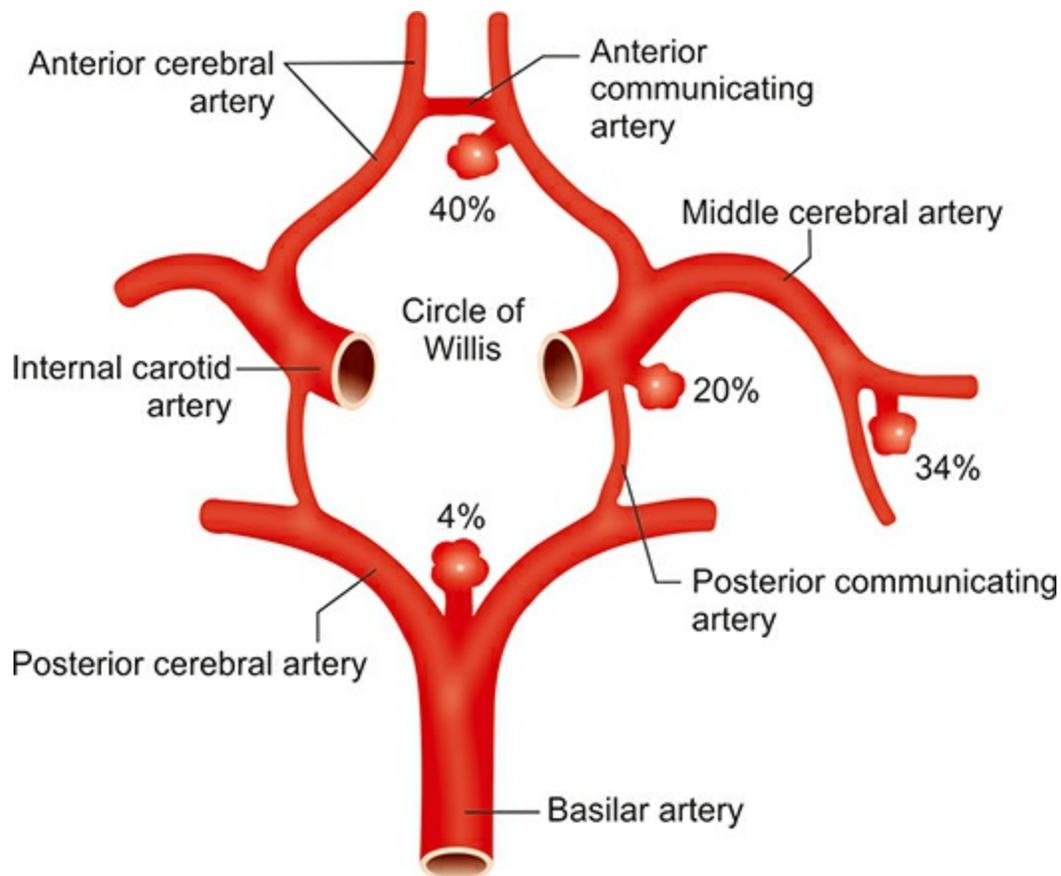

### **Q. Write a short note on circle of Willis.**

- Circle of Willis is a circulatory anastomosis that supplies blood to the brain and surrounding structures. This anastomotic pathway is important for the preservation of brain function when major blood flow is disrupted in one of the major feeding vessels.
- Constituents arteries of circle of Willis (Fig. 15.8 and Box 15.8):

The middle cerebral arteries, supplying the brain, do not form the part of the circle of Willis.

#### *Saccular ('berry') aneurysm*

- Saccular aneurysms develop within the circle of Willis and adjacent arteries. Three most common locations are—(1) the terminal internal carotid artery, (2) middle cerebral artery (MCA) bifurcation, and (3) top of the basilar artery.
- It can undergo spontaneous rupture and cause subarachnoid hemorrhage. If the patient survives, but the aneurysm is not obliterated, the rate of rebleeding is about 20% in the first 2 weeks, 30% in the first month, and about 3% per year afterwards.
- The annual risk of rupture for aneurysms <10 mm in size is 0.1%, and for aneurysms >10 mm in size is 0.5–1%.

**Fig. 15.8:** Blood supply to the brain and circle of Willis with common sites of saccular (berry) aneurysms.

### **Box 15.8:** Constituents arteries of circle of Willis.

- Two internal carotid arteries (left and right)
- Anterior cerebral artery (left and right)
- Anterior communicating artery
- Posterior cerebral artery (left and right)
- Posterior communicating artery (left and right)
- Basilar artery formed by joining of two vertebral arteries

### ***Clinical Features of Subarachnoid Hemorrhage (SAH)***

- **Headache:** Most common symptom (97%). Usually severe (the worst headache of my life) and sudden (**thunderclap**) in onset. Few patients may have milder warning headaches (sentinel headaches) in 2–8 weeks preceding the major hemorrhage. Headache may pulsate towards the occiput and sometimes may be felt as neck pain. Occipital and posterior cervical pain may signal a posterior inferior cerebellar artery (PICA) or

anterior inferior cerebellar artery aneurysm. If there is expanding middle cerebral artery aneurysm, pain may be observed in or behind the eye and in the low temple. Headache commonly occurs on physical exertion, straining and sexual excitement.

- **Vomiting** may be present.
- **Other symptoms:** Decreased consciousness and alertness, seizure (10%) and stiff neck, etc.
- **Rerupture/rebleed:** The rerupture of an untreated aneurysm in the first month following SAH is ~30%, with the peak in the first 7 days.

### *Physical examination*

- Patient is usually distressed and irritable, with photophobia.
- Neck stiffness (and a positive Kernig's sign) due to subarachnoid blood may be present but this may take few hours to develop. Focal hemisphere signs, e.g. intracerebral hematoma may cause hemiparesis or aphasia.
- Rarely, third nerve palsy may be developing due to local pressure from an aneurysm of the posterior communicating artery.
- Fundoscopy: May show **subhyaloid hemorrhage** (canoe shaped) produced due to tracking of blood along the subarachnoid space around the optic nerve.

### **Investigations**

**CT scan:** It shows blood in the subarachnoid space (if performed in the first few days), intracerebral hematoma, hydrocephalus, associated brain ischemia and occasionally aneurysmal location.

### **Q. Write a short essay/note on CSF findings in subarachnoid hemorrhage.**

- **Lumbar puncture:** It should be performed when clinical suspicion of SAH is high, CT scan does not reveal subarachnoid blood, and there is no mass effect. In the initial few hours CSF will be uniformly blood stained. **Xanthochromia** appears within 6 hours of SAH and persists for nearly 2 weeks. Naked inspection of supernatant CSF is usually sufficiently reliable for diagnosis of SAH. Spectrophotometry to estimate bilirubin in the CSF released from lysed cells confirm the diagnosis.
- **Angiography:** It is required to locate the site of bled aneurysm and details

that are needed to ligate the aneurysm by the neurosurgeon. It should be done in all patients fit for surgery (i.e. age <65 years and who are not in coma).

- **MR angiography (MRA):** It will accurately identify aneurysms >5 mm in size.
- **CT angiography:** It is a rapid readily available, less invasive alternative to catheter angiography. It is equivalent to conventional angiography for detecting large aneurysms.
- **ECG changes:** Prolonged QRS complex, increased QT interval, and prominent 'peaked' or deeply inverted symmetric T waves are usually secondary to the intracranial hemorrhage (**cerebral T waves**).

### ***Differential Diagnosis of Subarachnoid Hemorrhage (Box 15.9)***

#### ***Complications***

- **Obstructive hydrocephalus:** Due to blood in the subarachnoid space. It may be asymptomatic but may cause deteriorating consciousness following SAH. Shunting may be required.
- **Arterial spasm (cause of coma or hemiparesis):** It is a serious complication and is a poor prognostic feature.
- **Hyponatremia.**

#### **Box 15.9:** Differential diagnosis of subarachnoid hemorrhage.

- Migraine
- Acute bacterial meningitis
- Cervical arterial dissection

#### **Q. Write a short essay/note on treatment of subarachnoid hemorrhage.**

##### **Management**

- Immediate treatment is absolute **bed rest** (for 4 weeks) and **supportive measures**. These include protecting the airway, managing blood pressure and raised ICP, pain management, and sedation. It should be discussed urgently with a neurosurgical team. Patient is advised to gradually resumption of physical activities after recovery.
- **Control of hypertension:** In conscious patients without raised ICP, active treatment of hypertension is necessary. A target mean arterial pressure of 130 mm Hg is recommended. Drugs include labetalol, esmolol or nicardipine. Sodium nitroprusside should be avoided because may cause increase of ICP.
- **Avoid strictly:** *Hypovolemia, hypotension, hyperthermia, hyperglycemia and hyponatremia* are important to prevent delayed cerebral ischemia.

- **Calcium channel blocker:** Nimodipine (30–60 mg IV for 5–14 days, followed by 360 mg orally for a further 7 days) provides a modest but significant improvement in outcome by reducing cerebral arterial vasospasm. It is given for 3 weeks to prevent delayed ischemia in the acute phase and decreases mortality.
- **Prophylactic anticonvulsants**
- **Interventional management:** Early aneurysm repair prevents rerupture/rebleeding and improve blood flow. An aneurysm can be 'clipped' by a neurosurgeon or 'coiled' by an endovascular surgeon.
  - **Insertion of platinum coils into an aneurysm:** If angiography shows an aneurysm (most common cause of SAH), endovascular treatment by inserting a platinum coils via a catheter in the aneurysm sac to promote thrombosis and ablation of the aneurysm, is the first line treatment. Surgical clipping of the aneurysm neck also helps in reducing the risk of recurrence (both early and late). Endovascular coiling has fewer perioperative complications and better outcomes than surgery. For unruptured aneurysms larger than 8 mm in diameter the risk of treatment is less than the risk of hemorrhage if not treated.
- **Treatment of complications:** Managing delayed cerebral ischemia due to vasospasm (may be treated with vasodilators), treating obstructive hydrocephalus (may require drainage via a shunt), treating hyponatremia (managed by fluid restriction) and systemic complications associated with immobility, such as chest infection venous thrombosis and preventing pulmonary embolus.

## Differences between hemorrhagic, thrombotic and embolic strokes (Table 15.28).

**Q. Mention the differences between hemorrhagic, thrombotic and embolic strokes.**

**Table 15.28:** Differences between hemorrhagic, thrombotic and embolic strokes.

Feature	Hemorrhagic stroke (Intracerebral or subarachnoid hemorrhage)	Ischemic stroke	
		Thrombotic	Embolic
Time of onset of stroke	During activity	Suddenly and often during sleep or in the early morning (4 AM)	Any time
Rapidity of onset and progression	Over minutes and hours	On waking up or over hours	Rapid within seconds deficit maximum at onset
Transient ischemic attacks (TIAs)	Absent	Precedes stroke	Precedes stroke
Vomiting	Recurrent	Absent or occasional	Absent or occasional
Headache	Severe and prominent	Mild or absent	Mild or absent
Early resolution (within	Unusual	Variable	Possible

minutes or days)			
Meningeal irritation	May be present	Absent	Absent
Carotid bruit and absence of pulse	Not observed	Highly supports the diagnosis	Possible
Valvular heart disease and atrial fibrillation	Not found	Unusual	Highly supports the diagnosis
CT scan findings	Hemorrhage	Early stage: Normal Later: Pale infarct	Early stage: Normal Later: Pale infarct

*Note:* It may not be possible always to differentiate stroke of different type with absolute certainty.

## Cerebral Venous Thrombosis

**Q. Write a short note of cerebral venous thrombosis (CVT).**

It is the thrombosis of the draining venous sinuses of the cerebral cortex and the least common of all other types of cerebrovascular accidents (1–2% of strokes in young adults).

Thrombosis most commonly involves superior sagittal sinus and it may extend into transverse and sigmoid sinuses.

Thrombosis of deep venous system (e.g. internal cerebral veins, vein of Galen or straight sinus) is less common.

Age and gender: It frequently affects young adults and children. More common in women than men with an F: M ratio of 3:1. It may be due to the presence of gender specific risk factors such as pregnancy, puerperium and oral contraceptive pills and hormone replacement therapy (HRT). One of the leading causes of maternal mortality and morbidity with cases of puerperal CVT occurring 10–12 times more frequently in India than the west.

### ***Causes of Cerebral Venous Thrombosis (Table 15.29)***

**Table 15.29:** Causes of cerebral venous thrombosis.

<i>Local causes</i>	<i>Systemic causes</i>
<ul style="list-style-type: none"> <li>• Trauma to the dural sinuses</li> <li>• Infection of structures adjacent to the dural sinuses: Otitis media, mastoiditis, sinusitis, tonsillitis</li> <li>• Invasion or compression of venous sinuses by</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Hypercoagulable states</b>, e.g. inherited prothrombotic states, protein C /S deficiency, antithrombin III deficiency, factor V Leiden gene mutation, prothrombin gene mutation, presence of lupus anticoagulant, oral</li> </ul>

## ***Pathophysiology***

Two basic mechanisms are responsible for the development of the clinical features in CVT.

1. Thrombosis of cerebral veins or sinuses leading to cerebral parenchymal lesions or dysfunctions.
2. Occlusion of dural venous sinus causes reduced absorption of CSF and raised intracranial pressure.

Obstruction of venous structures → increased venous pressure → decreased capillary perfusion → increased cerebral blood volume → disruption of blood brain barrier → plasma leakage into interstitial space → cerebral edema, parenchymal changes and venous hemorrhage.

## ***Clinical Features***

The clinical presentation of CVT is highly variable and it may present as acute/subacute/chronic.

**Symptoms and signs:** Depends on the sinuses involved, the place of occlusion, and involvement of cortical veins and presence of collaterals, parenchymal changes and the patient's age. Symptoms are grouped under three major clinical syndromes:

1. **Isolated intracranial hypertension syndrome** (headache with or without vomiting, papilledema, and visual problems)
2. **Focal syndrome** (focal deficits or seizures or both)
3. **Encephalopathy** (multifocal signs, mental status changes, stupor or coma)

## ***Diagnosis***

- **CT or MR venography:** Direct signs of CVT in CT include:
  - **Dense triangle sign** seen as hyperdensity with triangular shape at the posterior end of superior sagittal sinus caused by venous thrombus.
  - **Empty delta sign** seen in head CT with contrast as a triangular pattern of contrast enhancement surrounding a central region lacking contrast enhancement.
  - **Cord sign** as linear or curvilinear hyperdensity over the cerebral cortex

caused by thrombosed cerebral veins.

- **CT or MRI** to detect secondary parenchymal lesions.
- **CSF examination:** To rule out meningitis or SAH.
- Workup for prothrombotic state.

#### Treatment

Treatment should be started as soon as the diagnosis is confirmed and consists of:

- Treatment of the underlying cause when known.
- Control of seizures and intracranial hypertension.

- **Antithrombotic therapy**

The main treatment option to achieve these goals is anticoagulation using heparin or LMWH (IV/SC). It is recommended that anticoagulant therapy with warfarin should be given for a minimum of 3 months after acute CVT aiming at an INR target of 2.5(2–3).

## DEMYELINATING DISEASES

### DEMYELINATING DISEASES

**Q. What are the common demyelinating diseases? (refer Table 15.30)**

**Table 15.30:** Example of demyelinating diseases.

<i>Central nervous system</i>	<i>Peripheral nervous system</i>

### Multiple Sclerosis (MS)

**Q. Write short essay on multiple sclerosis and its clinical features.**

- Chronic autoimmune T-cell mediated inflammatory disorder with selective destruction of myelin of the central nervous system (CNS). It has

a **relapsing-remitting** or progressive course. The neurological deficits are disseminated in time and space.

- It is termed multiple sclerosis because of the multiple scarred areas (well demarcated gray areas termed **plaques**) of demyelination throughout the brain and spinal cord observed on macroscopic examination. The plaques are crucial for diagnosis. The peripheral nervous system (PNS) is generally spared.

### ***Epidemiology***

- **Gender:** Female preponderance and female to male ratio is 2:1.
- **Age:** Usually present between 20 and 40 years of age and is rare after 60 years of age.

### ***Pathophysiology***

Both genetic and environmental factors play a causative role.

- **Genetic factors:** Risk of familial recurrence in MS is 15%, with highest risk in first-degree relatives. Multiple genes interact and it has a complex polygenic inheritance pattern. HLA DR2 association. Other autoimmune disorders occur in patients with MS and their relatives, indicating a genetic predisposition to autoimmunity.
- **Environmental factors:** Epidemiologic evidence supports the role of an environment exposure in MS but these factors are still largely unknown. For example, sunlight exposure, vitamin D and exposure to Epstein–Barr virus (EBV). Viral infections can precipitate MS relapses in genetically susceptible individuals.

### ***Etiology and Pathogenesis***

- Etiology is not known.
- It is probably a T-cell mediated autoimmune disease causing an inflammatory process within the white matter of the brain and spinal cord. MS risk correlates with high socioeconomic status, which may reflect improved sanitation and delayed initial exposures to infectious agents.

### ***Clinical Manifestations***

- No single group of signs or symptoms is diagnostic of MS (Table 15.31).
- **Onset:** May be abrupt/insidious, vary from trivial to severe form.

- Presentation varies and depends on the anatomical site of lesions and severity. It has been called as the modern ‘great imitator’. MS commonly involve **pyramidal tract, optic nerve, posterior cord, cerebellum and MLF (medial longitudinal fascicle)**.
- **Common symptoms in MS (Box 15.10):** Disability and neurological impairments gradually accumulate over the years.

**Box 15.10:** Common presentations of multiple sclerosis.

- Optic neuropathy (neuritis)
- Relapsing/remitting sensory symptoms, e. g. **Lhermitte sign** (barber chair phenomenon, is an electrical sensation that runs down the back and into the limb on neck flexion)
- Subacute painless spinal cord lesion
- Acute brainstem syndrome: Sudden diplopia, and vertigo with nystagmus
- Subacute loss of function of upper limb (dorsal column deficit): Clumsy/useless hand or limb
- Fatigue, cognitive impairment
- Sixth cranial nerve palsy, wall-eyed bilateral internuclear ophthalmoplegia (**WEBINO**)
- Unsteadiness or ataxia. **Charcot triad** of dysarthria, ataxia, and tremor
- Urinary symptoms—bladder hyperreflexia
- Neuropathic pain, fatigue, spasticity, depression, sexual dysfunction
- **Uhthoff’s phenomenon:** Worsening of neurologic symptoms (especially vision) when the body gets overheated

**Clinical course:** Main clinical patterns are:

- **Relapsing remitting MS (RRMS)** (85–90%): Discrete attack and complete recovery.
- **Secondary progressive MS (SPMS):** Begin as RRMS, clinical steady deterioration at some stage.
- **Primary progressive MS (PPMS)** (10–15%): Steady function decline from onset.
- **Progressive relapsing MS (PRMS)**
- **Malignant MS/Aggressive MS** refers to disease with a rapid progressive course, leading to significant disability in multiple neurologic systems in a relatively short time after disease onset.
- **Tumefactive MS** is an acute tumor-like MS variant in which some patients with demyelinating disease present with large (>2 cm) acute lesions, often associated with edema or ring enhancement.

**Diagnosis**

The diagnosis of MS is usually easily made in a young adult with relapsing and remitting symptoms referable to different areas of CNS white matter. No single diagnostic test for definitive diagnosis of MS.

### **MRI (Fig. 15.9)**

- Characteristic abnormalities are found in >95% of patients.
- Lesion appears as focal area of hyperintensity on T2-weighted.
- Typical lesions are oval up to 2 cm in diameter, and frequently orientated perpendicular to the lateral ventricular surface, corresponding to the pathologic pattern of perivenous demyelination (Dawson's fingers).
- Lesions are multifocal (periventricular, juxtacortical, infratentorial, or spinal cord).

**Evoked potential (EP)** or evoked responses: Assesses function in afferent (visual, auditory and somatosensory) or efferent (motor) CNS pathways, Abnormalities on one or more EP modalities occur in 80–90% of MS patients. However, they are less important than MRI.

### **CSF examination**

- CSF cell count may be raised (5–60 mononuclear cells/mm)—mononuclear cell pleocytosis.
- Increased IgG, total CSF protein, CSF IgG index.
- Protein electrophoresis: Oligoclonal IgG bands detected by agarose gel, but these are not specific.

Mc Donald criteria for multiple sclerosis is presented in Table 15.31.

**Fig. 15.9:** MRI of multiple sclerosis.

**Table 15.31:** Mc Donald criteria for MS.

<b>Attack</b>	<b>Lesions</b>	<b>Additional criteria for diagnosis MS</b>
2 or more	2 or more	Non-clinical evidence alone will suffice
2 or more	1 lesion	<b>Dissemination in space of MR</b> (or await further clinical attack implicating a different CNS site)
1 attack	2 lesion	<b>Dissemination in time on MR</b> (or await further clinical attack implicating a different CNS site)
1 attack	1 lesion	<b>Dissemination in space and time</b> (or await further clinical attack implicating a different CNS site)
0 attack <b>progression from onset</b>		One year of disease progression (Retrospective or prospective) and at least 2 out of 3 criteria <ul style="list-style-type: none"> <li>• Dissemination in space in the brain</li> <li>• Dissemination in space in the spinal cord based on 2 or more T2 lesions</li> <li>• Positive CSF</li> </ul>

## Treatment multiple sclerosis

### • Treatment of acute attack

- **Intravenous methyl prednisolone** 500–1,000 mg/day for 3–5 days, followed by a course of oral prednisone beginning at a dose 60–80 mg/day and gradually tapered over 2 weeks. High-dose cyclophosphamide has been used for induction therapy to stabilize aggressive MS.
- **Plasma exchange:** 5–7 changes are done with 40–60 mL/kg per exchange alternate days for 14 days for cases that are unresponsive to glucocorticoids.

• **Disease modifying drugs:** For prophylaxis of RRMS and SPMS after acute stage has passed. No effective treatment for PPMS. These include IFN  $\beta$  (1a-1b), glatiramer acetate, natalizumab, mitoxantrone hydrochloride, rituximab, siponimod, fingolimod, and cladribine.

• **Ocrelizumab**, a recombinant human anti-CD20 monoclonal antibody designed to optimize B cell depletion, is the first drug to significantly reduce the risk of disability progression among patients with primary progressive MS (PPMS).

### • Symptomatic therapy

- **Weakness (heat induced):** K<sup>+</sup> channel blockers-4 aminopyridine, 3-4 diaminopyridine
- **Spasticity/spasm:** Physiotherapy, avoid trigger factors. Drugs like baclofen, diazepam, tizanidine, dantrolene can be used
- **Pain:**
  - ◆ Anticonvulsant: Carbamazepine, phenytoin, gabapentin, pregabalin
  - ◆ Antidepressant: Amitriptyline/nortriptyline, desipramine, venlafaxine
  - ◆ Antiarrhythmic: Mexiletine
- Bladder care

Differences between multiple sclerosis (MS) and neuromyelitis optica (NMO) are listed in Table 15.32. It is important to differentiate as IFN is contraindicated in NMO.

**Table 15.32:** Differences between multiple sclerosis (MS) and neuromyelitis optica (NMO).

<i>Features</i>	<i>Devic's disease (NMO)</i>	<i>Multiple sclerosis</i>
Age	Adults	Young adults
F:M	>3:1	<3:1
Distribution of signs and symptoms	Restricted to optic nerves and spinal cord	Any white matter
Attack severity	Usually severe	Usually mild
Brain MRI	Usually normal (rarely lesion around area postrema +)	Multiple periventricular white matter lesions
Cord MRI	Longitudinally extensive transverse myelitis (LETM) central necrotic lesions, 3 or more spinal cord segments	Multiple small peripheral lesions

	involved	
CSF cells	Pleocytosis during attack	Rarely >25 cells
Oligoclonal bands	Usually absent	Usually present
Antibodies	Anti NMO antibody (46%), antiQP4 (aquaporin) (85%) present	No antibodies
Coexisting autoimmunity	Frequent (30–40%) (Sjogren's syndrome)	Less common
Recurrence rate	Higher (90%)	Lower
Recurrence interval	Shorter	Longer

## SEIZURES AND EPILEPSY

**Q.** Classify seizure/epilepsy. Discuss the evaluation of adult seizures and management of seizures.

**Q.** Describe the types, etiology, clinical features, investigations (evaluation) and management of epilepsy. Enumerate antiepileptic agents.

**Q.** Classify epilepsy. Describe the clinical features and treatment of grand mal (generalized tonic clonic) epilepsy.

**Q.** Write a short essay/note on:

- Enumerate the causes and investigation of a seizure. Mention drugs used to treat grand mal epilepsy.
  - Temporal lobe epilepsy.
  - Management of complex partial seizures.
  - Complications of status epilepticus.
  - Causes of convulsion.
  - Primary epileptic disorders.
  - Complications of seizures.
  - Define complex partial seizure.
- **Seizure:** It is a **paroxysmal event due to abnormal, excessive, hypersynchronous discharges from an aggregate of central nervous system (CNS) neurons.**
  - **Epilepsy:** It is a condition in which an individual has **recurrent seizures due to a chronic, underlying process.**
  - An individual with a single seizure or recurrent seizures due to correctable or avoidable circumstances does not necessarily have epilepsy.

### Classification of Seizures (Tables 15.33 and 15.34)

**Q.** Classify seizure/epilepsy.

- Seizures are classified as **'simple'** if there is **no impairment of consciousness** or as **'complex'** if an **alteration in consciousness** occurs.

**Seizures may be either focal or generalized.**

- **Focal seizures:** They originate within networks limited to one cerebral hemisphere across both cerebral hemispheres. They are usually associated with structural abnormalities of the brain.
- **Generalized seizures:** In contrast to focal, they may result from cellular, biochemical, or structural abnormalities that have a more widespread distribution. However, there are clear exceptions in both cases.
- Most seizures last seconds to minutes.
- **Status epilepticus** (refer pages 972-5).

**Table 15.33:** New classification of seizures.

**Focal seizures:** It can be further described as having motor, sensory, autonomic, cognitive, or other features

**Generalized seizures**

- |  |  |
|--|--|
| <ul style="list-style-type: none"> <li>• Absence (typical/atypical)</li> <li>• Tonic clonic (in any combination)</li> <li>• Clonic</li> <li>• Tonic</li> </ul> | <ul style="list-style-type: none"> <li>• Atonic</li> <li>• Myoclonic</li> <li>• May be focal, generalized, or unclear</li> </ul> |
|--|--|

**Unknown:** Epileptic spasms

**Focal Seizures**

***Focal Seizures without Dyscognitive Features***

- In this type, **consciousness is fully preserved during the seizure** and the clinical manifestation is relatively simple.
- Focal seizures can cause motor, sensory, autonomic, or psychic symptoms without an obvious alteration in consciousness.
- A focal motor seizure arising from the right primary motor cortex near the area controlling hand movement will note the onset of involuntary movements of the contralateral, left hand.
- Three additional features of this seizures are:

**Table 15.34:** International League Against Epilepsy (ILAE) classification of seizure types 2017.

***Generalized onset seizures***

<ul style="list-style-type: none"> <li>• Tonic-clonic</li> <li>• Clonic</li> <li>• Tonic</li> <li>• Myoclonic</li> <li>• Myoclonic-tonic-clonic</li> <li>• Myoclonic-atonic</li> <li>• Atonic</li> <li>• Epileptic spasms</li> </ul>	<ul style="list-style-type: none"> <li>• Typical</li> <li>• Atypical</li> <li>• Myoclonic</li> <li>• Eyelid myoclonia</li> </ul>
<b><i>Focal onset seizures</i></b>	
Motor onset	Nonmotor onset
<ul style="list-style-type: none"> <li>• Aware</li> <li>• Impaired awareness</li> <li>• Unknown awareness</li> </ul>	<ul style="list-style-type: none"> <li>• Aware</li> <li>• Impaired awareness</li> <li>• Unknown awareness</li> </ul>
<ul style="list-style-type: none"> <li>• Automatisms</li> <li>• Atonic</li> <li>• Clonic</li> <li>• Epileptic spasms</li> <li>• Hyperkinetic</li> <li>• Myoclonic</li> <li>• Tonic</li> </ul>	<ul style="list-style-type: none"> <li>• Autonomic</li> <li>• Behavior arrest</li> <li>• Cognitive</li> <li>• Emotional</li> <li>• Sensory</li> </ul>
<ul style="list-style-type: none"> <li>• Focal to bilateral tonic-clonic</li> </ul>	<ul style="list-style-type: none"> <li>• Focal to bilateral tonic-clonic</li> </ul>
<b><i>Unknown onset seizures</i></b>	
Motor	Nonmotor
<ul style="list-style-type: none"> <li>• Tonic-clonic</li> <li>• Epileptic spasms</li> </ul>	<ul style="list-style-type: none"> <li>• Behavior arrest</li> </ul>
<b><i>Unclassified seizures</i></b>	

**Q. Write a short note on Jacksonian epilepsy.**

1. **Jacksonian march:** Representing the **spread of seizure activity over a progressively larger region of motor cortex**. In Jacksonian seizures, march of symptoms occur where if it is motor, clonic jerking starts at a point. For example it may start at face, and spreads to upper limb, then to lower limb and then on to opposite side to become a generalized fit. This denotes the path of spread of the epileptic activity and is called Jacksonian spread/march.

**Q. Write a short note on Todd's paralysis.**

2. **Todd's paralysis** or the **localized paresis:** It is a condition characterized by brief, temporary paralysis that follows a seizure. It may occur **for minutes to hours in the involved region following** the

seizure.

- 3. Epilepsia partialis continua:** Analogous to partial status epilepticus. It is often quite refractory to medical therapy.

#### *Other manifestations*

Changes in somatic sensation (e.g. paresthesia), vision (flashing lights or formed hallucinations), equilibrium (sensation of ailing or vertigo), and autonomic function (flushing, sweating, piloerection).

### ***Focal Seizures with Dyscognitive Features***

- Focal seizure activity may be accompanied by a transient impairment of the patient's ability to maintain normal contact with the environment.
- Patient is **unable to respond to visual or verbal commands** during the seizure and has impaired recollection or awareness of the ictal phase.
- The seizures **frequently begin with an aura** (i.e. focal seizures without dyscognitive features) that is stereotypic for the patient.
- The start of the ictal phase is often a **sudden behavioral arrest or motionless stare**, and this marks the onset of the event for which the patient will be amnesic.
- The behavioral arrest is usually accompanied by oromandibular or hand automatisms, which are involuntary, automatic behaviors that have a wide range of manifestations.
- **Automatisms** may consist of very basic behaviors such as chewing, lip smacking, swallowing or picking movements of the hands or more elaborate behaviors such as a display of emotion or running.

#### **Complex partial seizures (temporal lobe seizures)**

Focal seizures arising from the temporal or frontal cortex may also cause alterations in hearing, olfaction or higher cortical function (psychic symptoms-like to sensation of unusual intense odors (e.g. burning rubber or kerosene) or sounds (crude or highly complex sounds) or illusions that objects are growing (metamorphopsia) smaller (micropsia) or larger (macropsia). When such symptoms precede focal seizures with dyscognitive features or secondarily generalized seizure, these seizures serve as a warning, or aura.

### **Generalized Seizures**

- Generalized seizures **arise from both cerebral hemispheres simultaneously.**
- It may be practically defined as **bilateral clinical and electrographic**

**events without any detectable focal onset.**

- Though they arise at some point of the brain they rapidly engage neuronal networks in both cerebral hemispheres.

### **Absence Seizures (Petit Mal)**

- Sudden, brief lapses of **consciousness without loss of postural control.**
- **It lasts for only a few seconds and consciousness returns rapidly** and there is no postictal confusion.
- Usually accompanied by subtle, bilateral motor signs such as rapid blinking of the eyelids, chewing movements, or small-amplitude, clonic movements of the hands. Absence seizures can be typical or atypical.
- Onset usually in childhood (ages 4–8 years) or early adolescence and are the main seizure type in 15–20% of children with epilepsy.
- May occur hundreds of times in a day without the knowledge of parents or the child.
- First clue may be often unexplained ‘daydreaming’ and a decline in school performance recognized by a teacher.
- **EEG:** Generalized, symmetric, 3-Hz spike-and-wave discharge that begins and ends suddenly, superimposed on a normal EEG background which can be provoked by hyperventilation.

### **Generalized, Tonic-Clonic Seizures (GTCS) (Grand Mal)**

**Q. Write short essay/note on clinical features and treatment of grand mal (generalized tonic clonic) epilepsy.**

- Main type of seizure in 10% of all individuals with epilepsy.
- Usually **begins abruptly without warning.** Some may develop vague premonitory symptoms which are distinct from the stereotypic auras associated with focal seizures that generalize.
- **Initially,** there is **tonic contraction of muscles throughout the body** leading to **loud moan or ictal cry, cyanosis,** biting of the tongue, etc.
- Marked enhancement of sympathetic tone leads to increases in heart rate, blood pressure, and pupillary size.
- **After 10–20 seconds, clonic phase starts with superimposed relaxation** which progressively increases until the end of ictal period.
- **Postictal phase** is characterized by **unresponsiveness, muscular**

**flaccidity, and excessive salivation, bladder or bowel incontinence.**

- Patients **gradually regain consciousness** over **minutes to hours** with accompanying postictal confusion, headache and muscle ache.
- **EEG:** Generalized high-amplitude, polyspike discharges in tonic phases which in the clonic phase typically interrupted by slow waves to create a spike-and-wave pattern.
- **Other variants** include pure tonic and pure clonic type.

### ***Atonic Seizures***

- Characterized by **sudden loss of postural muscle tone** lasting **1–2 seconds**.
- **Consciousness is briefly impaired**, but there is usually **no postictal confusion**.
- May cause only a quick head drop or nodding movement, while a longer seizure will cause the patient to collapse.
- They **are rarely seen in isolation** and are usually seen in association with known epileptic syndromes.
- **EEG:** Brief, generalized spike-and-wave discharges followed immediately by diffuse slow waves that correlate with the loss of muscle tone.

### ***Myoclonic Seizures***

- **Sudden, brief jerky muscle contraction** that may involve **one part of the body or the entire body**.
- Normal, common physiologic forms of myoclonus are the sudden jerking movement observed while falling asleep and hiccups.
- Most pathologic myoclonus commonly seen in association with metabolic disorders, degenerative CNS diseases, or anoxic brain injury.
- Myoclonic seizures are the predominant feature of juvenile myoclonic epilepsy.
- **EEG:** May show bilaterally synchronous spike-and-wave discharges synchronized with the myoclonus.

## **Epilepsy Syndromes**

Epilepsy syndromes are disorders in which **epilepsy is a predominant feature**, and there is sufficient evidence to suggest a common underlying

mechanism.

### ***Juvenile Myoclonic Epilepsy***

- Juvenile myoclonic epilepsy (JME) is a **generalized seizure** disorder of **unknown cause** that appears in **early adolescence** and is usually characterized by **bilateral myoclonic jerks** that may be single or repetitive.
- The myoclonic seizures are **most frequent in the morning** after awakening and can be provoked by sleep deprivation.
- Unless severe **consciousness is preserved**.
- Many patients also experience generalized tonic-clonic seizures, and up to one-third have absence seizures.
- The condition is otherwise benign, and although complete remission is uncommon, the seizures respond well to appropriate anticonvulsant medication.
- Lifelong treatment is necessary and **sodium valproate** is the drug of choice.

### ***Lennox-Gastaut Syndrome***

Lennox-Gastaut syndrome is seen in children between the age of 1 to 8 and is characterized by the following triad.

1. **Multiple seizure types** (usually including generalized tonic-clonic, atonic and atypical absence seizures).
2. **EEG:** Shows **slow (<3 Hz) spike and wave discharges** and a variety of other abnormalities.
3. **Impaired cognitive function** in most but not all patients.

Lennox-Gastaut syndrome is an epileptic encephalopathy **associated with CNS disease or dysfunction** from a variety of causes, including developmental abnormalities, perinatal hypoxia/ischemia, trauma, infection and other acquired lesions.

- The multifactorial nature of this syndrome suggests that it is a nonspecific response of the brain to diffuse neural injury.
- A similar syndrome in infancy that often evolves into Lennox-Gastaut syndrome is **West syndrome**, characterized by infantile spasms, Salaam attacks, other findings of cerebral dysfunction, and abnormal EEG pattern

(Hypsarrhythmia).

### ***Mesial Temporal Lobe Epilepsy Syndrome***

- Mesial temporal lobe epilepsy (MTLE) is the **most common syndrome** associated with complex partial seizures and is an example of symptomatic, partial epilepsy.
- Characteristic **hippocampal sclerosis** on MRI is an essential element in the pathophysiology of MTLE for many patients.
- Recognition of this syndrome is especially important because it tends to be **refractory to treatment with anticonvulsants but responds extremely well to surgical intervention.**

### ***Febrile Seizure***

- Usually occur between **3 months and 5 years of age** and have a peak incidence between 18 and 24 months.
- It is **generalized, tonic-clonic seizure** in child **during a febrile illness** in the setting of a common childhood infections.
- The seizure is likely to occur during the rising phase of the temperature curve (i.e. during the first day)
- A **simple febrile seizure** is a **single, isolated** event, brief and symmetric in appearance. **Complex febrile seizures** are characterized by **repeated seizure activity**, duration >15 minutes, or by focal features.
- Simple febrile seizures are not associated with an increase in the risk of developing epilepsy; while complex febrile seizures have a risk of 2–5%. Other risk factors include the presence of pre-existing neurologic deficits and a family history of nonfebrile seizures.

### **Causes of Seizures According to Age (Box 15.11)**

#### **Evaluation of the Patient with a Seizure**

- When a patient is seen shortly after a seizure, the first priorities are **attention to vital signs, respiratory and cardiovascular support, and treatment of seizures if they resume.**
- When the patient is not acutely ill, the evaluation will initially focus on whether or not there is a history of earlier seizures.

**Box 15.11:** Causes of seizures according to age.

---

### **Neonates (<1 month)**

- Perinatal hypoxia and ischemia
- Intracranial hemorrhage and trauma
- CNS infections
- Metabolic

### **Infants and children(>1 month and <12 years)**

- Febrile seizures
- Genetic disorders (metabolic, degenerative, primary epilepsy syndromes)
- CNS infections

### **Adolescents (12–18 years)**

- Trauma
- Genetic disorders
- Infection

### **Young adults (18–35 years)**

- Trauma
- Alcohol withdrawal

### **Older adults (>35 years)**

- Cerebrovascular disease
- Trauma (including subdural hematoma)
- Brain tumor
- Alcohol withdrawal
- Degenerative diseases

---

## ***First Seizure***

If this is the patient's first seizure, then the emphasis will be to **establish whether** the reported **episode was a seizure** rather than another paroxysmal event.

In case of **generalized, tonic-clonic seizures (GTCS)**, features supporting organicity are postictal confusion, tongue bite, history of fall or having sustained injury, etc.

- **Determine the cause of the seizure** by identifying risk factors and precipitating events. Precipitating factors such as sleep deprivation, systemic diseases, electrolyte or metabolic derangements (like hypoglycemia, hyper and hypocalcemia, hyponatremia hypomagnesemia) acute infection, drugs that lower the seizure (like penicillins, quinolones, antipsychotics, lithium, amphetamine, barbiturates, cocaine) threshold or alcohol or illicit drug use should be identified.
- **General physical examination:** Look for signs of system illnesses or infection. Careful examination of the skin may reveal signs of

neurocutaneous disorders such as tuberous sclerosis or neurofibromatosis, or chronic liver or renal disease. Organomegaly may indicate a metabolic storage disease, and limb asymmetry may provide a clue to brain injury early in development.

- Finally **decide whether anticonvulsant therapy is required** in addition to treatment for any underlying illness. It is usually not required in case of metabolic or electrolyte derangements and seizures due to alcohol withdrawal.
- If no metabolic or infectious causes found, then look for
- Focal features of seizure
- Any focal neurological deficits
- Any other neurological dysfunction/mental retardation
- Unusual features such as, prolonged duration of seizures (>6 hours), more than six seizures, status epilepticus, or a prolonged postictal state.
  - If present, usually antiepileptic therapy is required. Then MRI and EEG are done to find any mass lesion/stroke/degenerative lesion. Treatment of underlying cause besides antiepileptic therapy.
  - If absent, it is idiopathic epilepsy and antiepileptic therapy continued.

### ***Recurrence of a Seizure***

In the patient with prior seizures or a known history of epilepsy, the evaluation is directed toward:

- **Identification of the underlying cause and precipitating factors.** Common precipitating factors are: sleep deprivation, fever, hypoglycemia, and alcohol.
- **Determination of the adequacy of the patient's current therapy.**
  - If no precipitating factors found, measure the plasma concentration of antiepileptic drug.
  - If subtherapeutic concentration: Appropriate increase in drug dosage is done.
  - If therapeutic concentration is normal: Either drug increased to maximum tolerated dose or alternate therapy is started with gradually tapering the first drug.

### **Laboratory Studies**

- **Routine investigations:** These include serum glucose, calcium, electrolytes, renal and hepatic functions.
- **Lumbar puncture:** If indicated.
- **EEG:** May help establish the diagnosis of epilepsy, classify the seizure type, and provide evidence for the existence of a particular epilepsy syndrome.
  - The presence of electrographic seizure activity, i.e. of abnormal, repetitive, rhythmic activity having an abrupt onset and termination, clearly establishes the diagnosis.
  - The EEG findings may also be helpful in the inter-ictal period by showing certain abnormalities that are strongly supportive of an epilepsy. Such epileptiform activity consists of bursts of abnormal discharges containing spikes or sharp waves.
  - EEG is normal in 40% of epileptic patients.
- Neuroimaging studies (MRI preferred over CT).

**Differences between seizures and syncope are listed in Table 15.35.**

**Table 15.35: Differences between seizures and syncope.**

<i>Features</i>	<i>Seizures</i>	<i>Syncope</i>
Immediate precipitating factor	Usually none	Emotional stress, Valsalva, orthostatic hypotension, cardiac etiologies
Premonitory symptoms	None or aura (e.g. odd odor)	Tiredness, nausea, diaphoresis, tunneling of vision
Posture at onset	Variable	Usually erect
Transition to unconsciousness	Often immediate	Gradual over seconds
Duration of unconsciousness	Minutes	Seconds
Duration of tonic or clonic movements	30–60 seconds	Never more than 15 seconds
Facial appearance during event	Cyanosis, frothing at mouth	Pallor
Disorientation and sleepiness after event	Many minutes to hours	<5 minutes
Headache, muscle pain, tongue bite incontinence	Often, tongue bite—lateral	Rarely, tongue bite—tip

### **Treatment**

***Indications to initiate antiepileptic drug therapy***

Antiepileptic drug therapy should be **started in any patient with recurrent seizures of unknown etiology** or a **known cause that cannot be reversed with in short time**. Risk factors associated with recurrent seizures are listed in Box 15.12.

Selection of antiepileptic drugs (Table 15.36). Certain AEDs like phenytoin and carbamazepine can worsen myoclonic seizure. Hence proper AED for proper seizure must be given.

**Treatment modification**

- If a treatment is modified recently, one should wait for at least four half-lives of the drug before further modifying dosage.
- If one drug is unable to control seizures then another drug should be considered when either maximum dose of the first drug is reached or the patient starts showing intolerable side effects.
- Whenever a new drug is added, the first drug is continued till the second drug controls seizures. Only after achieving adequate seizure control the first drug should be gradually withdrawn.

**Box 15.12:** Risk factors associated with recurrent seizures.

- An abnormal neurologic examination
- Seizures presenting as status epilepticus
- Post-ictal Todd’s paralysis
- Strong family history of seizures
- An abnormal EEG
- Abnormal CT or MRI

**Table 15.36:** Selection of antiepileptic drugs in seizures.

<b>Seizure types</b>	<b>1st choice</b>	<b>2nd choice</b>
Monotherapy for generalized-onset tonic-clonic seizures	Valproate, topiramate	Zonisamide, levetiracetam, lamotrigine, phenytoin, carbamazepine
Absence seizure	Ethosuximide, valproate	Zonisamide, levetiracetam, topiramate, felbamate, clonazepam
Monotherapy for partial seizures	Carbamazepine, oxcarbazepine, phenytoin, topiramate	Lamotrigine, gabapentin, levetiracetam
Myoclonic	Valproate, levetiracetam, clonazepam	Zonisamide, Topiramate
Status epilepticus	Diazepam, Lorazepam	Phenytoin IV, Phosphenytoin IV

Febrile convulsions	Diazepam rectal 0.5 mg/kg	
Infantile spasms	Corticotropin Corticosteroids Zonisamide	Clonazepam, nitrazepam, vigabatrin, phenobarbital

#### **Indications for discontinue therapy**

- Complete medical control of seizures for 1–5 years.
- Single seizure type, either focal or generalized.
- Normal neurologic examination (including intelligence)
- Normal EEG

In most cases, it is preferable to reduce the dose of the drug gradually over 2–3 months.

Most recurrences occur in the first 3 months after discontinuing therapy, and patients should be advised to avoid potentially dangerous situations such as driving or swimming during this period.

#### **Treatment of refractory epilepsy**

- Therapy combines first line drugs, i.e. carbamazepine, phenytoin, valproic acid and lamotrigine.
- If these drugs are unsuccessful, then the addition of a newer drug such as levetiracetam and topiramate is indicated.
- Patients with myoclonic seizures resistant to valproic acid may respond to a combination of valproic acid and ethosuximide.

#### **Surgical treatment of refractory epilepsy**

- About 20–30% of patients with epilepsy are resistant to medical therapy. **ketogenic diet**—has been advised to decrease seizure recurrence. Low carbohydrate, adequate protein, high fat has been advised.
- **Anteromedial temporal lobe** (temporal lobectomy) or a **more limited removal of the underlying hippocampus and amygdala** (amygdalohippocampectomy).
- Focal seizures arising from extratemporal regions may be abolished by a focal neocortical resection with precise removal of an identified lesion (lesionectomy).
- **Others:** Hemispherectomy, corpus callosotomy, etc.
- **Vagus nerve stimulation (VNS)** may be used—some of these cases, although the benefit for most patients seem to very limited.

### **Antiepileptic drugs for chronic use (Tables 15.37 and 15.38).**

**Q. Write a short essay/note on drugs used in epilepsy/antiepileptic/anticonvulsant drugs.**

**Q. Write short note on (1) phenytoin (2) sodium valproate.**

**Newer antiepileptic drugs (Third Generation AEDs):** Carisbamate, eslicarbazepine, brivaracetam, carabersat, ganaxalone, huperzine, lacosamide, losigamone, remacemide, retigabine, rufinamide, safinamide, perampanel.

## Status Epilepticus

**Q. Write short essay/note on definition, complications of status epilepticus and its emergency management.**

Status epilepticus (SE) refers to **continuous seizures or repetitive, discrete seizures with impaired consciousness** in the interictal period.

Status epilepticus is an epileptic seizure of greater than five minutes or more than one seizure within a five-minute period without the patient returning to normal between them. Previous definitions used a 30-minute time limit.

### Subtypes

- **Generalized convulsive status epilepticus (GCSE)**, e.g. persistent, generalized electrographic seizures, coma and tonic- clonic movements.
- **Nonconvulsive status epilepticus**, e.g. persistent absence seizures or focal seizures, confusion or partially impaired consciousness, and minimal motor abnormalities.

**Table 15.37: Antiepileptic drugs for chronic use.**

Type of drug		Examples
Na <sup>+</sup> channel blockers		Phenytoin, carbamazepine, oxcarbazepine, primidone, valproic acid, lamotrigine, topiramate, zonisamide, phenobarbital, gabapentin, felbamate
Ca <sup>2+</sup> channel blockers		Ethosuximide, phenobarbital, zonisamide
Drugs that potentiate GABA	Increase opening time of channel	Phenobarbital
	Increase frequency of openings of channel	Diazepam, lorazepam, clonazepam
	Increase GABA in synapse	Valproic acid
	Increase GABA metabolism	Gabapentin
	Increase GABA release	Gabapentin
	Block GABA transaminase	Vigabatrin
	Block GABA transporter (GAT-1)	Valproic acid Tiagabine
	Facilitate GAD (Glutamic acid decarboxylase)	Valproic acid

	Increase GABA synthesis	
	Synaptic vesicle protein 2A binding	Levetiracetam (inhibits presynaptic calcium channels)
	AMPA agonist	Perampanel

**Table 15.38:** Antiepileptic drugs and their mechanism of action, adverse reactions and uses.

<i>Drug and mechanism of action</i>	<i>Adverse reactions</i>	<i>Uses</i>
<p><b>Phenytoin:</b> Oldest nonsedative antiepileptic drug. It alters <math>\text{Na}^+</math>, <math>\text{Ca}^{2+}</math> and <math>\text{K}^+</math> conductances</p>	Ataxia and nystagmus, cognitive impairment, hirsutism, gingival hyperplasia, coarsening of facial features, dose-dependent zero order kinetics, exacerbates absence seizures, 'Fetal hydantoin syndrome'	Partial seizure, generalized (including tonic-clonic) seizures, contraindicated in absence seizures. <b>Nonseizure indications</b> include trigeminal neuralgia, manic-depressive disorders
<p><b>Carbamazepine:</b> Tricyclic, antidepressant (bipolar) Mechanism of action, similar to phenytoin. Inhibits high frequency repetitive firing (<math>\text{Na}^{++}</math>)</p>	Auto induction of metabolism, nausea and visual disturbances, granulocyte suppression, aplastic anemia, exacerbates absence seizures	Partial seizure (including tonic-clonic) seizures. <b>Contraindicated in absence seizures.</b> <b>Nonseizure indications</b> include trigeminal neuralgia, manic-depressive disorders
<p><b>Oxcarbazepine:</b> Related to carbamazepine. With improved toxicity profile. Less potent than carbamazepine. Active metabolite</p>	Hyponatremia, less hypersensitivity and induction of hepatic enzymes than with carbamazepine	
<p><b>Phenobarbital:</b> It is the oldest antiepileptic drug. Although considered one of the safest drugs, it has sedative effects. Prolongs opening of <math>\text{Cl}^-</math> channels. Blocks excitatory GLU (AMPA) responses. Blocks <math>\text{Ca}^{2+}</math> currents (L, N)</p>	Sedation, cognitive impairment, behavioral changes, induction of liver enzymes, may worsen absence and atonic seizures	Useful for partial, generalized tonic-clonic seizures, and febrile seizures
<p><b>Primidone:</b> Metabolized to phenobarbital and phenylethylmalonamide (PEMA), both active metabolites.</p>	Same as phenobarbital Sedation occurs early. Gastrointestinal disturbances	Effective against partial and generalized tonic-clonic seizures

<p><b>Valproate:</b> Mechanism of action, similar to phenytoin. Increases levels of GABA in brain. May facilitate glutamic acid decarboxylase (GAD). Inhibits GAT-1</p>	<p>Elevated liver enzymes, nausea and vomiting, abdominal pain, heartburn, tremor, hair loss, syncratic, hepatotoxicity, teratogen (spina bifida)</p>	<p>A broad spectrum anti-seizure drug t most partial and generalized seizures, including myoclonic and absence seizures).</p> <p><b>Nonseizure indications include:</b> Migraine (prophylaxis), bipolar disorder</p>
<p><b>Ethosuximide:</b> Reducing low-threshold <math>Ca^{2+}</math> channel current (T-type channel) in thalamus</p>	<p>Gastric distress, including, pain, nausea and vomiting, lethargy and fatigue, headache, hiccups, euphoria, skin rashes</p>	<p>Drug of choice for absence seizures</p>
<p><b>Clonazepam:</b> One of the most potent antiepileptic agents known</p>	<p>Sedation is prominent. Ataxia, behavior disorders</p>	<p>Long-acting drug with efficacy for absence seizures. Also effective in some cases of myoclonic seizures. Has been tried in infantile spasms</p>
<p><b>Lamotrigine:</b> Suppresses sustained rapid firing of neurons and produces a voltage and use-dependent inactivation of sodium channels, thus its efficacy in partial seizures</p>	<p>Dizziness, headache, diplopia, nausea, somnolence, rash</p>	<p>Presently use as add-on therapy with valproic acid. Also effective in generalized and myoclonic seizures in childhood and absence seizures preferred in elderly</p>
<p><b>Topiramate:</b> Potentiates inhibitory effects of GABA (acting at a site different from BDZs and BARBs)</p>	<p>Somnolence, fatigue, dizziness, cognitive slowing, paresthesia, nervousness, confusion, urolithiasis</p>	<p>Myoclonic seizures, migraine</p>
<p><b>Zonisamide:</b> Sulfonamide derivative</p>	<p>Drowsiness, cognitive impairment, high incidence of renal stones</p>	<p>Effective against partial and generalized tonic-clonic seizures</p>
<p>Felbamate</p>	<p>Aplastic anemia, severe hepatitis</p>	<p>Third-line drug used only for refractory partial seizure cases</p>
<p><b>Vigabatrin (g-vinyl-GABA):</b> Irreversible inhibitor of GABA-aminotransferase</p>	<p>Drowsiness, dizziness, weight gain, agitation, confusion, psychosis</p>	<p>Use for infantile spasms, partial seizures and contraindicated if pre-existing mental illness is present</p>
<p><b>Tiagabine:</b> GABA uptake inhibitor GAT-1</p>	<p>Dizziness, nervousness, tremor, difficulty</p>	<p>Effective against partial and generalized tonic-clonic seizures</p>

	concentrating, depression, asthenia, emotional liability, psychosis, skin rash	
<b>Gabapentin:</b> Analog of GABA that does not act on GABA receptors. Low potency	Somnolence, dizziness, ataxia, headache, tremor	Used as an adjunct in partial and generalized tonic-clonic seizures. Neuropathy
Levetiracetam	Somnolence, incoordination, irritability, mood swings, psychosis	Effective for GTCS, JME. Preferred in elderly.

## ***Etiology of Status Epilepticus (Box 15.13)***

### **Box 15.13:** Etiology of status epilepticus.

- Stroke, including hemorrhagic
- Low AED levels
- Alcohol withdrawal
- Anoxic brain injury
- Metabolic disturbances
- Remote brain injury/congenital malformations
- Infections
- Brain neoplasms
- Idiopathic

### ***Clinical Features***

- Self-perpetuating, generalized tonic-clonic seizure or
- Series of generalized tonic-clonic seizures
- Without return to consciousness in between seizures.

### **Phases**

- **Initial compensatory phase:** Sympathetic overdrive, increased CO, increased BP.
- **Decompensation** → homeostatic failure
  - Reduced → CO/sugar/lactate/O<sub>2</sub> levels leading to
    - ◆ Cardiorespiratory collapse
    - ◆ Electrolyte imbalance
    - ◆ Rhabdomyolysis and delayed tubular necrosis
    - ◆ Hyperthermia

- ◆ MOF (multiorgan failure)
- ◆ Raised ICP and cerebral edema.

## Complications

These include aspiration, hypotension, cardiac arrhythmias and renal or hepatic failure.

## Diagnosis

- **Diagnosis of nonconvulsive status epilepticus in critically ill patients.**
- Correlate with poorer outcome.
- EEG patterns are difficult to interpret (equivocal patterns)—criteria are **not** validated.
- A trial of rapidly acting IV AED is used to observe improvement in both clinical → EEG by several hours.

**Management of Status Epilepticus (Table 15.39): Convulsive/nonconvulsive.**

**Table 15.39: Management of status epilepticus.**

### First 5 minutes

- Check emergency ABC's
- Give O<sub>2</sub>
- Obtain IV access
- Begin ECG monitoring
- Check finger stick glucose
- Draw blood for serum electrolytes. RFT, magnesium, calcium, phosphate, CBC, LFTs, AED levels, ABG, troponin
- Toxicology screen (urine and blood)

### 6–10 minutes

- Thiamine 100 mg IV; 50 mL of D50 IV unless adequate glucose known
- Lorazepam 4 mg IV over 2 minutes; if still seizing, repeat × 1 in 5 minutes
- If no rapid IV access give diazepam 20 mg PR or midazolam 10 mg intranasally, buccally or IM

### 10–20 minutes

- If seizures persist, begin fosphenytoin 20 mg/kg IV at 150 mg/min, with blood pressure and ECG monitoring. OR
- Phenytoin 15–20 mg/kg at 30–50 mg/min

*Reasonable to bypass this step, or perform subsequent step simultaneous with fosphenytoin loading*

**10–60 minutes:** One (or more) of the following 4 options (intubation usually necessary except for valproate):

1. Continuous IV midazolam: Load: 0.2 mg/kg; repeat 0.2–0.4 mg/kg boluses every 5 minutes until seizures stop, up to a maximum total loading dose of 2 mg/kg. Initial rate: 0.1 mg/kg/hr.

Continuous IV dose range: 0.05 – 2.9 mg/kg/hr.

OR

2. Continuous IV propofol: Load: 1 mg/kg; repeat 1–2 mg/kg boluses every 3–5 minutes until seizures stop, up to maximum total loading dose of 10 mg/kg. Initial continuous IV rate: 2 mg/kg/h. Continuous IV dose range: 1–15 mg/kg/hr. Avoid >48 hrs of >5 mg/kg/h (increased risk of propofol infusion syndrome).

OR

3. IV valproate: 40 mg/kg over ∞10 minutes. If still seizing, additional 20 mg/kg over ∞5 minutes.

OR

4. IV phenobarbital: 20 mg/kg IV at 50–100 mg/min.

### 60 minutes

- Continuous IV pentobarbital. Load: 5 mg/kg at up to 50 mg/min; repeat 5 mg/kg boluses until seizures stop. Initial continuous IV rate: 1 mg/kg/hr. Continuous IV-dose range: 0.5–10 mg/kg/hr; traditionally titrated to suppression-burst on EEG.

Perform neuroimaging when convulsive activity is controlled.

- Begin continuous EEG, if patient does not awaken rapidly or if continuous IV Rx is used.
- Treat metabolic abnormalities and hypothermia.
- Lumbar puncture and antibiotics can be considered if infection is suspected.

SE not controlled even with anesthetic agents is called **super refractory SE**, for which IV Ig/pulse steroid can be tried as last resort.

- Other available modalities
  - Brain imaging (perfusion/metabolic imaging)
  - Intracranial monitoring with intracortical EEG.
  - Brain tissue O<sub>2</sub> monitoring.
  - Cerebral microdialysis.

## Pregnancy and Epilepsy

- In approximately 50% epileptic women, the frequency of epilepsy remain the same. In about 30% it increases and in about 20% it decreases in frequency.
- Uncontrolled seizures in mother causes harm to both mother and fetus greater than the teratogenic effects of antiepileptic drugs. Hence, pregnant women should be maintained on effective drug therapy.
- Due to the numerous side effects phenytoin is not used in pregnancy. Neural tube defects are associated with valproic acid and carbamazepine.
- Carbamazepine is considered relatively safe in pregnancy, because of its low teratogenic potential. **Levetiracetam is safest drug.**
- If mother is on phenobarbital, she should be given oral vitamin K (20 mg

daily) in the last 2 weeks of pregnancy, and the infant should be given an intramuscular injection of vitamin K (1 mg) at birth. This is because phenobarbital may cause a transient and reversible deficiency of vitamin K- dependent clotting factors in up to 50% of newborn infants.

## NEUROINFECTIONS

**Q. Write a short essay/note on classify meningitis and enumerate its causes.**

### Classifications of Meningitis (Table 15.40)

**Table 15.40: Classifications of meningitis.**

<b>Infective</b>	
<p><b>1. Bacterial meningitis</b></p> <ul style="list-style-type: none"> <li>– Common organisms: <i>Streptococcus pneumoniae</i>, <i>Neisseria meningitidis</i>, <i>Haemophilus influenzae</i></li> <li>– Uncommon organisms: <i>Staphylococcus aureus</i>, <i>Staphylococcus epidermidis</i>, Group B streptococci, <i>E.coli</i>, <i>Klebsiella</i>, <i>Proteus</i> spp, <i>Listeria monocytogenes</i>.</li> <li>– Rare organisms: <i>Salmonella</i>, <i>Shigella</i>, <i>Clostridium perfringens</i>, <i>Neisseria gonorrhoeae</i></li> </ul>	<p><b>3. Viral meningitis (aseptic meningitis)</b></p> <ul style="list-style-type: none"> <li>– Enteroviruses (Coxsackie, poliovirus)</li> <li>– Mumps virus</li> <li>– Arboviruses</li> <li>– HIV</li> <li>– Herpes simplex-2</li> </ul>
<p><b>2. Tuberculous meningitis (TBM):</b> <i>Mycobacterium tuberculosis</i></p>	<p><b>4. Spirochetal:</b> Leptospirosis, Lyme disease, syphilis</p> <p><b>5. Rickettsial:</b> Typhus fever</p> <p><b>6. Protozoal:</b> Cysticerci, amoeba, <i>Naegleria</i></p> <p><b>7. Fungal:</b> <i>Cryptococcus neoformans</i>, <i>Candida</i>, <i>Histoplasma</i>, <i>Blastomyces</i>, <i>Coccidioides</i>, <i>Sporothrix</i></p>
<b>Noninfective ('sterile')</b>	
<p><b>1. Malignant disease</b></p> <ul style="list-style-type: none"> <li>– Breast cancer</li> <li>– Bronchial cancer</li> <li>– Leukemia (leukemic meningitis)</li> <li>– Lymphoma</li> </ul> <p><b>2. Subarachnoid hemorrhage (SAH) (causes meningismus)</b></p>	<p><b>3. Inflammatory disease (may be recurrent)</b></p> <ul style="list-style-type: none"> <li>– Sarcoidosis</li> <li>– Systemic lupus erythematosus, rheumatoid arthritis</li> <li>– Behçet's disease</li> <li>– Vasculitis</li> </ul>

## Neurosyphilis

**Q. Write a short essay on the clinical features and management of neurosyphilis.**

- *Treponema pallidum* invades nervous system within 3 to 18 months (may take years to develop) after primary infection.
- **Neurosyphilis** may be asymptomatic or symptomatic. Initial event is usually in the form of asymptomatic meningitis. Later it may produce more damage. All forms of neurosyphilis have meningitis of variable severity. Secondary to meningitis, the blood vessels show endarteritis obliterans.

### ***Asymptomatic Neurosyphilis***

- Asymptomatic invasion of CNS by treponema is common and occur within few months of primary infection by *Treponema pallidum*.
- Neurosyphilis may develop in 25% cases of latent syphilis. Many of them may develop symptomatic neurosyphilis.
- Cerebrospinal fluid (CSF) shows lymphocytosis with increased protein and low glucose. Antibodies in the CSF, is the most specific test for neurosyphilis. Venereal disease research laboratory test is positive.
- Treatment: Penicillin.

### ***Symptomatic Neurosyphilis***

It takes one of several forms, although mixed features are common (Box 15.14).

### ***Meningeal syphilis***

- Symptoms of meningitis may develop at any time after infection, but usually occur within 2 years after primary infection.
- Symptoms:
  - These include headache, neck stiffness, seizures, altered sensorium and cranial nerve palsies. It may show skin rash on palms and soles.
  - Papilledema with symptoms of increased intracranial pressure (ICP) may develop.
  - Patient is afebrile and CSF is abnormal.

### Box 15.14: Major categories of symptomatic neurosyphilis.

- Meningeal syphilis
- Chronic meningovascular disease
- Parenchymatous syphilis
  - General paresis of insane
  - Tabes dorsalis

#### *Meningovascular syphilis*

- Chronic meningitis involves base of the brain, cerebral convexities and spinal leptomeninges.
- Usually presents 6–7 years after primary infection. However, it can develop as early as 6 months and as late as 10–12 years.
- It should be suspected when a young patient develops stroke (generally subacute) which results in hemiparesis, aphasia, visual loss, etc. Other features include headache, vertigo, insomnia and psychological abnormalities.

#### *CSF findings (Table 15.41)*

**Note:** Gold standard test for diagnosis is VDRL from CSF. This is highly specific but only 30–70% sensitive for neurosyphilis. CSF FTA-ABS is more sensitive but not specific because false positives are common.

#### *General paralysis of insane*

- It develops about 20 years after primary infection.
- Shows generalized/diffuse brain parenchymal disease with **dementia**; hence called as general paresis of insane.
- Clinical manifestation includes personality changes, illusions, delusions, hallucinations, dementia (reduced memory), hyperactive reflexes and Argyll Robertson pupils.

#### *Tabes dorsalis*

- Tabes dorsalis is the parenchymal form of neurosyphilis characterized by **demyelination of posterior column, dorsal root and dorsal root ganglia** in the spinal cord.
- Usually develops 20–25 years after primary infection.
- **Symptoms:** Severe lightning pains in trunk and extremities, ataxia and

urinary incontinence.

- **Signs:** Patchy tactile sensory loss and severe impairment of proprioception with sensory ataxia. Muscular strength is normal and tendon jerks are absent. Complications include trophic lesions such as perforating ulcers of feet and Charcot joints. Argyll Robertson pupils may also be observed in tabes dorsalis.
- **Visceral crisis:** It consists of sudden epigastric pain with vomiting that Abadie's sign (Pinching of, or the application of firm pressure to, the Achilles tendon does not result in pain) lasts for hours. Barium studies show pylorospasm (gastric crisis). Other crisis includes intestinal crisis with diarrhea, rectal crisis with tenesmus, genitourinary crisis with strangury and pharyngeal-laryngeal crisis with gulping movements and dyspnea.
- CSF findings: (refer Table 15.41).

**Table 15.41:** CSF findings in neurosyphilis.

<i>Parameter</i>	<i>Findings</i>
Pressure	Normal or raised
CSF fluid	Clear
Protein	Raised (100–200 mg%)
Glucose	Normal
Cell count	Mildly elevated and cells are lymphocytes
Gamma globulin levels	Raised
Venereal disease research laboratory (VDRL)	Positive
FTA-ABS (fluorescent treponemal antibody absorption)	Positive

#### **Treatment**

- Penicillin: Drug of choice and given in the dose of 18–24 million units/day for 15–20 days.
- If patient is sensitive to penicillin: Erythromycin and tetracycline 0.5 g 6 hourly for 20–30 days.

#### **Follow-up**

- Re-examine the patient every 3 months and CSF examination at 6 months interval.
- If CSF is normal and VDRL titers are reduced, no further treatment is necessary. However, if CSF remains abnormal, patient should be treated by another full course of penicillin.

## **Cerebrospinal Fluid (CSF)**

- CSF is formed within the ventricles and circulates in the subarachnoid

space (between arachnoid and pia matter) and in the ventricles. The total volume of CSF in adults ranges from 90 to 150 mL. It is a medium for transfer of substances from brain and spinal cord into the blood.

- **Importance of CSF examination:** Analysis of the CSF is of diagnostic importance in conditions like meningitis or primary/metastatic tumor of CNS with CSF involvement.
- **Collection of CSF:** CSF is usually obtained by lumbar puncture (LP) using an LP needle under strict aseptic conditions.

**Fig. 15.10:** Procedure of lumbar puncture.

### ***Lumbar Puncture (LP)***

**Q. Write a short essay on the procedure indications, contraindications and complications of lumbar puncture.**

- Lumbar puncture is the technique (Fig. 15.10) done to obtain CSF sample and also provides an indirect measure of intracranial pressure (ICP).
- After local anesthetic injection, a lumbar puncture needle is inserted in the midline between lumbar spinous processes usually between L3 and L4 (3rd **lumbar space**) through the dura and into the spinal canal. In children, it is collected from the 4th lumbar space.

- Intracranial pressure can be assessed (if patients are lying on their side) and CSF obtained for analysis.
- CSF pressure is important in the diagnosis and monitoring of idiopathic intracranial hypertension.

### Indications and contraindication for lumbar puncture (Box 15.15).

#### *Complications of Lumbar Puncture*

- Most common complication is **post spinal headache**. Herniation of cerebellum through the foramen magnum due to raised intracranial pressure.
- Hematoma, either extradural or subdural.
- Introduction of infection by the LP needle through the infected skin or subcutaneous tissue.

Normal CSF findings are presented in Table 15.42.

- CSF osmolality and sodium level is same as that of serum
- Constituents that are in higher concentration in CSF than in blood include magnesium, chloride, H<sup>+</sup> concentration and lactate.

**Table 15.42:** Normal CSF findings.

<i>Constituent</i>	<i>Normal value</i>
CSF volume	150 mL
CSF pressure	90–180 mm of water
Cell count	<5 cells, all lymphocytes, no neutrophils
CSF proteins	15–45
CSF sugar	60–80% of blood glucose

### Box 15.15: Indications and contraindication for lumbar puncture.

#### Indications for lumbar puncture

- **Diagnostic indications**
  - **Infection:**
    - ◆ **Meningeal infection:** Bacterial (pyogenic, tuberculosis, syphilitic (to differentiate general paresis of insane, tabes dorsalis and meningeal syphilis), viral, fungal)
    - ◆ **Encephalitis**
  - **Subarachnoid hemorrhage**
  - **Primary or metastatic malignancy** (e.g. acute leukemia, lymphoma)
  - **Demyelinating diseases:** Multiple sclerosis and subacute sclerosing panencephalitis (SSPE)

- **Guillain-Barré syndrome**
  - **Spinal canal blockage** leading to elevated intracranial tension (spinal cord tumors)
  - **Injecting the radio-opaque dye for myelography**
  - **Therapeutic indications**
    - Spinal anesthesia, epidural analgesia
    - **Intrathecal injection of chemotherapeutic drugs** for CNS prophylaxis/relapse of ALL, lymphomas
    - Therapeutic CSF drainage in cases of normal pressure hydrocephalus
- Contraindications for lumbar puncture**
- Raised intracranial pressure, coagulopathy
  - Local infective lesion
  - Bony deformities at site of puncture

### Box 15.16: Causes of elevated CSF proteins.

- Meningitis
- Brain abscess
- Brain or spinal cord tumors
- Multiple sclerosis
- Guillain-Barré syndrome
- Syphilis
- Hemorrhage
- Froin's syndrome

Causes of low sugar in CSF: Pyogenic, tuberculous, fungal and carcinomatous meningitis.

Causes of elevated protein in CSF (Box 15.16).

**Q. Write a short note on causes of elevated CSF proteins.**

### *Xanthochromia*

**Q. Write a short note on xanthochromia in CSF analysis.**

Xanthochromia is the yellowish appearance of cerebrospinal fluid (CSF).

**Causes:** Xanthochromia is always pathological and conditions associated with it are:

- **Old subarachnoid hemorrhage:** The yellow appearance is due to RBCs which may leak into the cerebrospinal fluid during the hemorrhage. RBCs are breakdown and liberate hemoglobin which is converted into yellow bilirubin.

- Other causes are high protein in the CSF, jaundice and Froin's syndrome (refer page 984).

## Meningitis and Encephalitis

**Q. What are the causes of meningitis? Discuss the clinical features, investigations, diagnosis, complications and management of acute pyogenic (bacterial/meningococcal) meningitis.**

### *Acute Bacterial (Pyogenic/ Purulent) Meningitis*

**Q. Write a short essay/note on the common organisms causing pyogenic meningitis.**

Relative frequency of various bacterial species causing meningitis varies with age.

- **Neonatal period:** Major causative agents include gram-negative bacilli (principally *Escherichia coli*), *Listeria monocytogenes*, and group B streptococci.
- **Infants and children:** Major causes in children beyond 1 month of age are *Haemophilus influenzae* and *Neisseria meningitidis*.
- **Adolescents and in young adults:** **Meningococcus** (*Neisseria meningitides*) is the most common pathogen.
- **Extremes of life:** *Streptococcus pneumoniae* and *Listeria monocytogenes*.

**Causes of community acquired bacterial meningitis:** Important causes are:

- *Streptococcus pneumoniae* (50%): Most common
- *Neisseria meningitides* (25%): Is the only major cause of epidemics of bacterial meningitis.
- Group B streptococci (15%) and
- *Listeria monocytogenes* (10%)
- *Haemophilus influenzae* (10%)

### *Predisposing conditions*

- **For Pneumococci:** Other Pneumococcal infections (pneumonia, sinusitis, otitis media), splenectomy, hypogammaglobulinemia, complement deficiency.
- **For *Neisseria meningitides*:** Complement deficiency (including properdin), B-serotype (not protected by vaccine is responsible for one-third of cases). Usually associated with petechial or purpuric skin lesions.
- ***Listeria monocytogenes*:** Important cause in neonates (<1 month), pregnant women, >60 years and immunocompromised persons.

### *Clinical manifestations*

**Q. Write a short essay/note on physical signs of meningitis.**

- **Classic triad:** (1) Fever, (2) headache, and (3) nuchal rigidity.

- **Consciousness:** Vary from lethargy to coma (>75%).
- Nausea, vomiting and photophobia are common
- **Seizure/convulsions** (especially in children) may be initial presentation or present during course (20–40%).
  - **Focal:** Due to arterial ischemia, infarction, cortical venous thrombosis or focal edema.
  - **Generalized or status:** Due to hyponatremia, cerebral anoxia or toxic effects of antimicrobial drugs.
- **Classic signs of meningitis (Box 15.17).**
- **Occasionally cranial nerve palsies**, with focal neurologic deficits such as visual field defects, dysphasia, and hemiparesis may occur.
- **In meningococcus: Rash** begin as diffuse erythematous maculopapular that become petechial, found on trunk, lower limbs, mucous membrane, conjunctiva and rarely on palm and sole.
- **Raised ICP:** One of the complications of bacterial meningitis and CSF pressure may be raised to 180–400 mm H<sub>2</sub>O. Disastrous complication of ICP is cerebral herniation.
  - Other signs: Reduced level of consciousness, papilledema, dilated poorly reactive pupil, VIth cranial palsy, decerebrate posture, Cushing reflex (bradycardia, hypertension, and irregular respiration).

#### Box 15.17: Classical sign of meningitis.

- Cervical rigidity/neck stiffness
- Kernig sign: Knee pain with hip flexion
- Brudzinski sign: Knee/hip flexion when the neck is flexed

#### Box 15.18: Complications of bacterial meningitis.

- Obstructive hydrocephalus
- Thrombophlebitis of leptomeningeal veins may lead to venous thrombosis, cerebral infarction, focal infection of the underlying brain parenchyma
- Chronic adhesive arachnoiditis
- Cerebral abscess
- Subdural empyema
- Focal neurologic deficits (e.g. cranial nerve palsy, hemiparesis)
- Sensorineural hearing loss
- Vasculitis of cranial vessel
- Epilepsy

- Waterhouse-Friderichsen syndrome: It results from meningitis-associated septicemia with hemorrhagic infarction of the adrenal glands and cutaneous petechiae. It occurs most often with meningococcal and pneumococcal meningitis

## Complications of bacterial meningitis (Box 15.18)

### Diagnosis

- **By examination of the CSF:** It is usually obtained by lumbar puncture. Lumbar puncture should be postponed if there is papilledema and or focal neurologic findings suggestive of an intracranial mass lesion. It can be done only after ruling out the same by computed tomography (CT) or magnetic resonance imaging (MRI).
- **Blood culture:** If meningitis seems likely, blood should be sent for culture and sensitivity and empirical antimicrobial therapy should be started while the neuroimaging study is being carried out.

### CSF findings in bacterial meningitis (refer Table 15.46)

**Q. Write a short essay/note on CSF findings pyogenic/bacterial meningitis.**

**Q. Write a short essay/note on treatment of pyogenic meningitis.**

### Treatment

Antibiotics used in empirical therapy of bacterial meningitis and focal CNS infections.

#### A. Empirical therapy (Table 15.43)

*S. pneumoniae* and *Neisseria meningitides* are common organisms. Due to emergence of penicillin and cephalosporin resistant of

*S. pneumoniae* a combination therapy of 3rd or 4th generation cephalosporin (ceftriaxone, cefotaxime, cefepime) and vancomycin, plus acyclovir (HSV is a differential diagnosis) and doxycycline (tick infection) is given as empirical therapy.

#### B. Specific antimicrobial therapy

- *Neisseria meningitides*

- **Penicillin sensitive:** Penicillin G-250,000–300,000 U /kg/day in divided doses, Ampicillin (3 g intravenous TID/QID)
- **Penicillin resistant:** Ceftriaxone 2 g intravenous BID/Cefotaxime 2 g intravenous BID
- 7 days IV dose are adequate.
- All close contacts should be given chemoprophylaxis with rifampicin for 2 days or azithromycin (500 mg once) or one IM ceftriaxone (250 mg).

- *Streptococcus pneumonia*

- Should be tested for penicillin and cephalosporin sensitivity
- **Penicillin sensitive:** Penicillin G

- **Penicillin-intermediate:** Ceftriaxone/cefotaxime/cefepime
- **Penicillin-resistant:** Ceftriaxone/cefotaxime/cefepime+vancomycin
- 2 weeks IV is adequate.
- Lumbar puncture is to be repeated 24-36 hours after initiation to see the response
- Intraventricular vancomycin may be more effective than IV or intrathecal.
- **Gram-ve bacilli (except *Pseudomonas*):** Ceftriaxone/cefotaxime for 3 weeks
- ***Pseudomonas aeruginosa*:** Ceftazidime/cefepime/meropenem
- **Staphylococci spp:**
  - **Methicillin sensitive:** Nafcillin
  - **Methicillin resistant:** Vancomycin (1 g intravenous TID) (IV or intraventricular)
- ***Listeria monocytogenes*:** Ampicillin for 3 weeks. Gentamicin may be added in critical ill cases. Trimethoprim and sulfamethoxazole is alternative
- ***H. influenzae*-intermediate:** Ceftriaxone/cefotaxime/ cefepime
- ***Streptococcus Agalactiae*:** Penicillin G/ampicillin
- ***Bacteroides fragilis*:** Metronidazole
- ***Fusobacterium spp*:** Metronidazole

C. **Adjunctive therapy**

- **Dexamethasone** inhibits synthesis of IL-1 $\beta$  and TNF- $\alpha$ , decrease CSF out flow resistance and stabilize blood brain barrier (BBB).
- It is to be given 20 minutes before antimicrobial therapy. It is less effective if given 6 hours after antibiotic therapy.

D. **Treatment of raised ICP**

- Elevation of head end of the bed to 30 to 45°, hyperventilation, and administration of mannitol.
- Duration of therapy: 7 days for *N. meningitides*, 7–10 days for *H. influenzae*, 10–14 days for *S. pneumoniae* and 3 weeks for gram-negative bacilli.

**Table 15.43:** Empirical therapy for bacterial meningitis depending on the age group/predisposing factors.

<b>Age group/predisposing factors</b>	<b>Drug used</b>
Infants <1 month	Ampicillin + cefotaxime
Infants 1–3 months	Ampicillin + cefotaxime/ceftriaxone
Infants >3 months and adults <55 years	Cefotaxime/ceftriaxone/cefepime + vancomycin
Adults >55 years or adult with alcohol or debilitating conditions	Ampicillin + cefotaxime/ceftriaxone/cefepime + vancomycin
Hospital acquired, posttraumatic, post neurosurgery, neutropenic patients or impaired cell mediated immunity	Ampicillin + ceftazidime/meropenem + vancomycin

## **Tubercular Meningitis**

**Q. Describe the pathology, clinical features, investigation, complications**

## **and treatment/management of tuberculous meningitis.**

In India tubercular meningitis (TBM) remains the most common form of meningitis.

- **Risk factors**

- Previous history of exposure to tuberculosis or illness.
- Immunocompromised state of AIDS
- Young children.

### *Pathology*

- Main neuropathologic finding is **basal meningeal exudates** containing mainly mononuclear cells.
- **Tubercles may** be seen on the meninges and on the surfaces of the brain.
- The **ventricles may be dilated** as a result of hydrocephalus, and the ependymal surface may be covered by **exudates**.
- **Hydrocephalus** is common in children and most develop symptoms in 2–3 weeks.
  - **Communicating type:** Common, due to blockage of basal cistern by exudates in acute phase or adhesive leptomeningitis in chronic phase.
  - **Obstructive type:** Less common, due to narrowing or occlusion of aqueduct by ependymal inflammation, tuberculomas, or obstruction of outlet of IVth ventricle.
- Arteritis can cause cerebral infarction, and basal inflammation; and fibrosis can compress cranial nerves.

### *Clinical features*

- **Onset:** Usually subacute/chronic. Acute: children—50%, adult—14%.
- **Past history of TB:** Children—50%, adult—10%.
- **Prodromal symptoms:** Two to three weeks, vague ill health, apathy, irritability, anorexia, changes in behavior.
- **Features of meningitis:** Headache, vomiting, fever and focal neurological deficit.
- Features of raised **intracranial pressure (ICP)**
  - **Convulsions** (focal/generalized—20–30%).
  - **Cranial nerve palsy:** 20–30% (6th cranial nerve).
  - **Loss of vision:** Partial/complete. Due to opticochiasmatic exudate, and

arteritis.

- **Other presentation:** Hemiplegia, facial nerve palsy, optic atrophy, abnormal movement, oculomotor palsy, choroid tubercle, etc.
- **In untreated cases:** Consciousness deteriorates, pupillary abnormality, pyramidal signs due to hydrocephalus and tentorial herniation.

*Complications of tubercular meningitis (Table 15.44)*

*Investigations*

**Q. Write a short essay/note on laboratory diagnosis and CSF findings in tuberculous meningitis.**

### 1. CSF study

– *Cytological study*

- ◆ **Leukocyte count:** 100–500 cells/ $\mu$ L, rarely  $>1000$ /cells/ $\mu$ L.
- ◆ **Cell type: Lymphocytes** predominant, polymorphonuclear cells in acute stag. Hemorrhagic due to fibrinoid necrosis of vessels. No malignant cells seen.

– *Biochemical study*

- ◆ **Protein:** Usually 100–200 mg/100 mL. In spinal block  $>1$  g/100 mL and xanthochromic.
- ◆ **On standing a pellicle/cobweb formed** indicating fibrinogen—high suggestion of TBM.
- ◆ **Glucose:** Reduced to 20–50 mg/100 mL. In most cases  $<40\%$  of corresponding blood sugar, but unlike pyogenic never undetectable.
- ◆ **Chloride:** Low value 450–600 mg/100 mL and is nonspecific indicating hypochloremia. It may be seen in bacterial, viral meningitis also.
- ◆ **Adenosine deaminase (ADA)** produced by T-lymphocytes elevated in CSF (60–100%).

– *Microbiological study*

- ◆ Negative with Gram stain, Indian ink stain and culture is sterile.
- ◆ Acid-fast bacilli (AFB): AFB in smear and culture-confirmatory but number of bacteria should be  $>10^4$ /ML. Stained by Ziehl-Neelsen and auramine (4–40% positive).

- **Centrifuged CSF:** The thick smear from pellicle and repeated culture enhance detection.
- **CSF culture:** In Lowenstein-Jensen media in 4–8 weeks. It may be enhanced by liquid media like septi-check AFB system or Middlebrook 7H9. Isolation is better from cisternal/ventricular CSF.

## 2. Radiological investigations

- Chest X-ray: It may reveal miliary mottling in the lung.
- CT scan:
  - Thickening of meninges in basal cistern (60%)
  - Hydrocephalus in 50–80% depending on duration
  - Cerebral infarct (28%) in MCA, edema (periventricular), tuberculoma (10%).

## 3. Immunological methods

- **Antibody detection:** CSF shows antibodies against various antigens that are sensitive and are detected by ELISA and RIA.
- Antigen detection: More specific. Antigen is detected by Latex agglutination, ELISA, etc.
- **Molecular methods:** Amplification of specific DNA sequence by PCR used for rapid diagnosis. PCR is confirmatory and not affected by other organisms.

### Table 15.44: Complications of tubercular meningitis.

- Raised intracranial pressure (ICP), cerebral edema
- Basal meningitis with cranial nerve palsy—II, III, IV, VI and VII
- Focal neurologic deficit and seizure
- Hydrocephalus
- Tuberculoma
- Opticochiasmatic pachymeningitis: Visual loss
- Endocrine abnormality: Growth hormone and gonadotropin
- Hypothalamic disorder: Loss of control of blood pressure (BP) and temperature, delayed or precocious sexual development
- Diabetes insipidus, syndrome of inappropriate ADH secretion (SIADH)

### Management

- Antituberculous treatment (ATT) for one and a half year in uncomplicated cases is usually sufficient.
- Steroids: It is recommended to give steroids during initial 6 weeks to decrease the possibility of

adhesion formation. Steroids prevent complications. There is no definite duration for which treatment might be continued, but should be judged on the basis of neuroimaging findings.

- Surgical intervention: If hydrocephalus, tuberculoma, or abscess develops. Tubercular abscess needs drainage.

## Viral Meningitis/Aseptic Meningitis

- Viral infections of the meninges (meningitis) or brain parenchyma (encephalitis) often present as acute confusional states.
- Children and young adults are frequently affected.

### *Etiology*

**Common viruses** include:

- **Enteroviruses** (most common, i.e. coxsackie viruses, echoviruses, and human enteroviruses): At least **two-thirds** of the cases of CSF culture-negative aseptic meningitis are due to enteroviruses.
- **Herpes simplex virus-2 (HSV-2) meningitis:** It may occur during the initial episode of genital herpes. Most cases of benign recurrent lymphocytic meningitis (previously called as Mollaret's meningitis) appear to be due to HSV.
- **Arthropod-borne viruses:** These are transmitted through infected insect vectors.
- **HIV: Aseptic meningitis** is a common manifestation of primary exposure to **HIV**. **Cranial nerve palsies**, most commonly involving cranial nerves V, VII and VIII are more common in HIV meningitis than in other viral infections.
- **Mumps** can also cause meningitis.

### *Clinical Manifestations*

Fever, headache, and meningeal irritation. Other features include malaise, myalgia, anorexia, nausea and vomiting, abdominal pain, and/or diarrhea.

### *Laboratory Diagnosis*

**Q. Write short answer on CSF changes in viral meningitis.**

- CSF examination:
  - Reveals lymphocytosis, mildly elevated protein and normal glucose.

- As a rule, a **lymphocytic pleocytosis with a low glucose level** (<25 mg/dL) should **suggest** the presence of **fungal, listerial or tuberculous meningitis** or of **noninfectious disorders** (e.g. neoplastic meningitis)
- **Polymerase chain reaction (PCR):** Amplification of viral-specific DNA or RNA from CSF by polymerase chain reaction (PCR) important method for the diagnosis of CNS viral infection.

#### Management

- **Symptomatic** and hospitalization is not required.
- **Oral or intravenous acyclovir** may be of benefit in patients with meningitis caused by **HSV-1 or 2** and in cases of severe **EBV or VZV** infection.
- Patients with **HIV** should receive highly **active retroviral therapy**.

## Mollaret's Meningitis

**Q.** Write short note on Mollaret's meningitis.

**Definition:** It is a syndrome characterized by recurrent aseptic, self-limiting meningitis and presence of large typical monocytes (Mollaret cells) in the CSF.

- **Cause:** Not known, but may be due to some virus infections. Herpes simplex-2 infection must be excluded in these patients.
- **Clinical features:** Repeated self-limiting episodes of fever, meningismus and severe headache (of 2–5 days duration) separated by symptom-free intervals.

Noninfective causes of meningitis are listed in Table 15.45.

**Table 15.45:** Noninfective ('sterile') causes of meningitis.

<i>Type of noninfectious meningitis</i>	<i>Causes</i>
Carcinomatous	Leukemia, lymphoma, myeloma, melanoma, breast and lung cancer
Connective tissue disorders	Behets, SLE, sarcoid, rheumatoid, Sjogrens
Drugs	Azathioprine, cyclosporine, sulfasalazine
Substances injected into the subarachnoid space	Anesthetics, antibiotics, chemotherapy drugs, radiopaque contrast agents

## CSF Findings in Meningitis (Table 15.46)

**Q.** Write a short note on compare the CSF findings of pyogenic, aseptic, and tuberculous meningitis.

**Table 15.46:** CSF findings in meningitis.

	<i>Normal</i>	<i>Acute pyogenic</i>	<i>Acute viral (aseptic)</i>	<i>Tuberculous</i>
Physical examination	Clear and colorless	Turbid and forms coagulum	Clear	Clear and colorless, forms cobweb on standing due to coagulation of fibrinogen
CSF pressure	60–150 mm of H <sub>2</sub> O	Raised above 180 mm of H <sub>2</sub> O	Raised above 250 mm of H <sub>2</sub> O	Raised above 300 mm of H <sub>2</sub> O
Total protein	20–40 mg/100 mL (<0.45 g/L)	<50–200 mg/100 mL	<40 mg/100 mL	50–150 mg/100 mL
Glucose	45–80 mg/100 mL (>50–60% of blood level)	0–20 mg/100 mL (Usually ≤40 mg/dL)	Normal	Decreased: May be <45 mg/100 mL
Chlorides	720–750 mg/100 mL	600–700 mg/100 mL	Normal	450–600 mg/100 mL
<b>Cells</b>				
Polymorphs	Usually absent	1000–5000/μL	Absent	0–5 cells/μL
Lymphocytes	0–5 cells/μL	5–50 cells/μL	10–2000 cells/μL	50–5000 cells/μL
Gram stain/ZN stain	-	Bacteria +	-	AFB + (Ziehl–Neelsen/auramine stain) or tuberculosis culture positive

### ***Causes of Neck Stiffness (Box 15.19)***

**Box 15.19:** Causes of neck stiffness.

- Meningitis (including leukemic meningitis) and meningism
- Subarachnoid hemorrhage, posterior fossa tumors
- Cervical spondylosis
- Trauma to the neck: Fracture, dislocation of cervical spine, sprain, rupture of ligament
- Rupture of cerebral abscess into subarachnoid space
- Tetanus
- Elderly individuals

**Q.** List the causes of neck stiffness.

## ENCEPHALITIS

### *Viral Encephalitis*

- In meningitis, the infectious process and associated inflammatory response is limited largely to the meninges, whereas in encephalitis, the brain parenchyma is also involved.
- Encephalitis is characterized by nonsuppurative inflammation of brain by an inflammatory process.

*Etiology (Box 15.20)*

**Box 15.20:** Viruses causing encephalitis.

- Epidemics of encephalitis are caused by arboviruses
- Acute encephalitis
- Herpesvirus
  - Herpes simplex virus I (MC)
  - Varicella zoster virus
  - Epstein–Barr virus
- Arthropod-borne viruses
- West Nile virus
- Japanese encephalitis Colorado tick fever
- Others: Rabies, enteroviruses, mumps, cytomegalovirus

### *Clinical manifestations*

- Acute febrile illness with evidence of meningitis and encephalitis.
- Altered level of consciousness (ranging from mild lethargy to coma), an abnormal mental state, and evidence of either focal or diffuse neurologic signs or symptoms.
- It may have hallucinations, agitation, personality change, behavioral disorders and at times a frankly psychotic state.
- Focal or generalized seizures occur in many patients with encephalitis.
- Most common focal neurological findings: Aphasia, ataxia, upper or lower motor neuron patterns of weakness, involuntary movements (e.g. myoclonic jerks, tremor), and cranial nerve deficits (e.g. ocular palsies, facial weakness).

- Involvement of the hypothalamic pituitary axis may result in temperature dysregulation, diabetes insipidus, or the development of the syndrome of inappropriate secretion of antidiuretic hormone (SIADH).

### ***Laboratory diagnosis***

#### 1. CSF

- **CSF examination:** Indistinguishable from that of viral meningitis and typically consists of lymphocytic pleocytosis, a mildly elevated protein concentration, and a normal glucose concentration.
- **CSF PCR:** Primary diagnostic test for CNS infections caused by CMV, EBV, HHV-6 and enteroviruses.
- **CSF culture:** Limited utility.

#### 2. Serologic studies and antigen detection: Demonstration of antibodies or antigens.

#### 3. Brain biopsy: Reserved for patients in whom CSF PCR studies fail to lead to a specific diagnosis, who have focal abnormalities on MRI, and who continue to show progressive clinical deterioration despite treatment with acyclovir and supportive therapy.

#### 4. MRI, CT and EEG

##### **Management**

- **General measures:** Care of the unconscious patient. Anticonvulsants may be needed. Brain edema is managed with dexamethasone 4 mg 6 hourly.
- **Herpes simplex encephalitis:** Acyclovir (10 mg/kg IV 8 hourly for 14–21 days), if instituted early.

### ***Froin's Syndrome***

#### **Q. Write a short note on Froin's syndrome.**

- Froin's syndrome describes the CSF findings in cases of complete spinal (subarachnoid) block (below the block).
- **CSF below the block** shows following features:
  - **CSF pressure:** Reduced
  - **Queckenstedt's test:** It is an outdated clinical test, formerly used for diagnosing spinal block.
  - **Physical examination:** Yellowish discoloration (xanthochromia)

coagulum may form due to high protein content.

- **Chemical examination:** Very much elevation of protein levels, sugar levels are normal or occasionally reduced if the obstruction is due to tuberculous meningitis.
- Cytology: Normal cell count. Increased cells if the obstruction is due to tuberculous meningitis.
- **Causes of total block:**
  - Intraspinous tumors.
  - Vertebral diseases with compression.
  - Chronic spinal arachnoiditis.

## DISEASES OF THE SPINAL CORD

### Features Suggestive of Involvement of Spinal Cord (Box 15.21)

### Patterns of Spinal Cord Disease (Box 15.22)

**Box 15.21:** Features suggestive of spinal cord involvement.

- Presence of sensory deficit and/or motor weakness in both lower limbs and/or upper limbs
- Bladder and bowel involvement
- Brown-Sequard type of clinical picture
- Presence of definite sensory level

**Box 15.22:** Patterns of spinal cord disease.

- Complete cord transection syndrome
- Brown-Sequard syndrome (bullet injury, multiple sclerosis)
- Central cord syndrome (syringomyelia), Friedreich's ataxia, HIV myelopathy
- Posterior column syndrome (tabes dorsalis), Friedreich's ataxia, HIV myelopathy
- Posterolateral cord syndrome subacute combined degeneration of the cord (SACDC)
- Combined AHC—pyramidal tract syndrome amyotrophic lateral sclerosis (ALS)
- Anterior horn cell (AHC) syndrome (polio)
- Anterior cord syndrome (anterior spinal artery occlusion)
- Conus medullaris and cauda equina syndrome

### Causes and Clinical Features of Complete Cord Transection (Table 15.47)

**Table 15.47: Causes and clinical features of complete cord transection.**

<i>Causes</i>	<i>Clinical features</i>		
	<i>Sensory</i>	<i>Motor</i>	<i>Autonomic</i>
<ul style="list-style-type: none"> <li>• Trauma</li> <li>• Metastatic carcinoma</li> <li>• Multiple sclerosis</li> <li>• Spinal epidural hematoma</li> <li>• Autoimmune disorders</li> <li>• Postvaccinal syndromes</li> </ul>	<ul style="list-style-type: none"> <li>• All sensations are affected</li> <li>• Sensory level is usually 2 segments below the level of lesion</li> <li>• Segmental paresthesia occurs at the level of lesion</li> </ul>	<ul style="list-style-type: none"> <li>• Paraplegia due to corticospinal tract involvement</li> <li>• First spinal shock followed by hypertonic hyperreflexic paraplegia</li> <li>• Loss of abdominal and cremasteric reflexes</li> <li>• At the level of lesion lower motor neuron (LMN signs) occur</li> </ul>	<ul style="list-style-type: none"> <li>• Urinary retention and constipation</li> <li>• Anhidrosis, trophic skin changes, vasomotor instability below the level of lesion</li> <li>• Sexual dysfunction can occur</li> </ul>

**Differentiation between compressive and noncompressive myelopathy (Table 15.48).**

**Table 15.48: Differences between compressive and noncompressive myelopathy.**

<i>Features</i>	<i>Compressive</i>	<i>Noncompressive</i>
• Bony deformity	+	–
• Bony tenderness	+	–
• Girdle like sensation	+	–
• Upper level of sensory loss	+	–
• Zone of hyperesthesia	+	–
• Root pain	+	–
• Onset and progress	Gradual	May be acute
• Symmetry	Symmetrical	Majority are asymmetrical
• Flexor spasm	Common	Usually absent
• Pattern of neurodeficit	U-shaped (Elsberg phenomenon)	Bilaterally symmetrical
• Bladder and bowel movement	Late	Early (acute transverse myelitis)
• Classical example	Caries spine	Acute transverse myelitis, motor neuron

**Differences between extramedullary and intramedullary lesions of the spinal cord (Table 15.49).**

**Q. Write a short essay on differences between extramedullary and intramedullary lesions of the spinal cord.**

**Table 15.49:** Differences between extramedullary and intramedullary lesions of the spinal cord.

<i>Features</i>	<i>Extramedullary</i>	<i>Intramedullary</i>
• Root pain	Early and common	Rare, pain is burning in type and poorly localized
• Secondary deficit	No dissociation of sensation, contralateral loss of pain and temperature, with ipsilateral loss or proprioception	Dissociation of sensation common, suspended sensory loss
• Sacral sensation	Lost (early)	Sacral sparing
• Lower motor neuron (LMN) involvement	Segmental	Marked with wide spread atrophy, fasciculation seen
• Upper motor neuron (UMN) involvement	Early and prominent. Ascending pattern of weakness (sacral?lumbar? thoracic ?cervical)	Less pronounced, late feature, descending pattern
• Reflexes	Brisk early feature	Less brisk, later feature
• Autonomic involvement (bladder and bowel)	Late	Early
• Trophic changes	Usually not marked	Common
• Vertebral tenderness	May be sensitive to local pressure	No bony tenderness in vertebrae
• Changes in CSF	Frequent	Rare

**Differences between presentation of intradural and extradural lesion is presented in Table 15.50.**

**Q. Write short note on differentiation between extradural, intradural extramedullary and intradural intramedullary myelopathies.**

**Table 15.50:** Differences between presentation of intradural and extradural

lesion.		
<i>Features</i>	<i>Extradural</i>	<i>Intradural</i>
Mode of onset	Usually symmetrical	Asymmetrical
Root pain	Less common	More common
Spinal tenderness	Common	Uncommon
Spinal deformity	Present	Absent

## Causes of Compressive Myelopathies (Table 15.51)

**Q. Write short note on common causes of compressive myelopathies.**

**Table 15.51: Causes of compressive myelopathies.**

<i>Extradural</i>	<i>Intradural</i>	<i>Intramedullary</i>
<ul style="list-style-type: none"> <li>• Spondylosis</li> <li>• Disk prolapse</li> <li>• Trauma</li> <li>• Tumor: Metastasis, multiple myeloma</li> </ul>	<ul style="list-style-type: none"> <li>• Tumor: Neurofibroma, meningioma, lipoma, sarcoma</li> <li>• metastasis</li> <li>• Arachnoiditis</li> </ul>	<ul style="list-style-type: none"> <li>• Syring</li> <li>• Tumor: Ependymoma, astrocytoma, hemangioblastoma, hematomyelia</li> </ul>
<ul style="list-style-type: none"> <li>• CVJ anomalies</li> <li>• Fluorosis</li> <li>• TB spine</li> <li>• Epidural abscess</li> <li>• Epidural hematoma</li> </ul>	<ul style="list-style-type: none"> <li>• Sarcoidosis</li> <li>• Cervical meningitis</li> <li>• Arteriovenous malformation</li> <li>• Leukemic infiltration</li> <li>• Arachnoid cyst</li> </ul>	

### Localization of the level of lesion in a compressive myelopathy

- **Distribution root pain:** Ask for specific dermatomes involved.
- **Upper border of sensory loss:** Examine the patient from below upwards for demonstration of upper border of sensory loss (spinothalamic tract).
- **Girdle like sensation or sense or constriction** at the level of lesion (involvement of posterior column).
- **Zone of hyperesthesia or hyperalgesia** (zone of hyperesthesia is present just above the level of girdle like sensation, and is due to compression of posterior nerve roots).
- **Analysis of abdominal reflex:** If upper abdominal reflex is intact with loss of middle and lower one, the site of lesion is probably at T10 spinal segment.
- **Atrophy of the muscles in a segmental distribution** (due to anterior

horn cells).

- **Loss of deep reflexes:** If the particular segment is involved. The reflexes will be brisk below the involved segment.
- Deformity or any swelling in the vertebra
- Tenderness in the vertebra
- The area of sweating may help (lack of sweating below the level) in localizing the level of lesion.
- The level can also be localized by X-ray of the spine, myelography, CT scan or MRI.

- **Analysis of Beevor's sign:** It is medical sign seen in the selective weakness of the lower abdominal muscles. Rectus abdominis is innervated by the terminal branches lower six or seven thoracic spinal nerves via the lower intercostal and subcostal nerves. If a lesion lies above T6, entire rectus abdominis is weak so there is no contraction of muscle. If it is at or below T10, the upper abdominal muscular function is preserved, whereas the lower abdominal muscles are weak. Therefore, when the head is flexed against resistance (patient supine), the intact upper abdominal muscles pull the umbilicus upward and shift of umbilicus 3 cm when head flexed is considered significant.
- **Causes of Beevor's sign:**
  - Amyotrophic lateral sclerosis
  - Facioscapulohumeral muscular dystrophy (FSHD)
  - Adult form of acid maltase deficiency disease
  - Spinal cord injury
  - Myopathy

**Difference between paraplegia in flexion and paraplegia in extension (Table 15.52).**

**Q. Write a short note on paraplegia in flexion, paraplegia in extension.**

**Table 15.52: Difference between paraplegia in flexion and paraplegia in extension.**

<i>Feature</i>	<i>Paraplegia in extension</i>	<i>Paraplegia in flexion</i>
Definition	Lower limb take an extension attitude and extensor muscles are spastic	Lower limb muscles take an attitude of flexion
Pathology	Only pyramidal tract involved	Both pyramidal and extrapyramidal tract involved. Occurs in late stage of paraplegia or progressive lesion and spinal arc is

		dominant
Evolution	Early	Late
Position of lower limbs	Extended	Flexed
Deep tendon reflexes	Exaggerated	Less exaggerated
Clonus	Present	Absent
Mass reflex	Absent	Present
Bladder	Precipitancy	Automatic bladder

**Note:** Pierre Marie Foix test is done by firm passive plantar flexing of the toes and foot. This will result in spontaneous “withdrawal reflex” i.e. spontaneous flexion of the hip, knee and dorsiflexion of the ankle if the paraplegia is passing from extension to flexion.

## Flexor Spasms

- After recovery from spinal shock, many types of innocuous or noxious cutaneous or muscle stimuli to the lower limb can elicit a prolonged, coordinated pattern of hip flexion and ankle dorsiflexion, similar to flexion withdrawal. It is attributed to increased hyperexcitability of spinal cord circuitry and lead to flexor spasms.
- Spinal cord lesions are associated with flexor spasms except for incomplete and high spinal cord lesion that usually have dominant extensor tone.

## Acute and Subacute Spinal Cord Diseases

### *Spinal Cord Compression*

**Q. Write a short note on causes of extramedullary spinal cord compression.**

- Spinal cord compression is one of the common neurological emergencies in clinical practice.
- **Mechanism of damage:** A space-occupying lesion within the spinal cord may damage nerve tissue either by **direct pressure** or indirectly by **interfering with blood supply**. Edema due to venous obstruction impairs neuronal function, and ischemia due to arterial obstruction may causes necrosis of the spinal cord.
- **Consequences:** During early stages, the damage is reversible but severely damaged neurons cannot recover. Hence, it is important to diagnose and treat early.

- Various causes of spinal cord compression are listed in Box 15.23.

**Box 15.23:** Causes of spinal cord compression.

**Vertebral (80%)**

- Vertebral body destruction by bone metastases, e.g. breast, prostate, bronchus, myeloma
- Disk and vertebral lesions: Trauma (extradural), chronic degenerative and acute central (intervertebral) disk prolapse
- Inflammatory: Tuberculosis, *Staph. aureus*, Melioidosis

**Meninges (intradural, extramedullary) (15%)**

- Tumors (e.g. meningioma, neurofibroma, ependymoma, metastasis, lymphoma, leukemia)
- Inflammatory: Epidural abscess, epidural hemorrhage/hematoma

**Spinal cord (intradural, intramedullary) tumors (5%)**

- Extramedullary, e.g. meningioma or neurofibroma, metastasis
- Intramedullary, e.g. glioma or ependymoma

**Symptoms and signs of spinal cord compression (Table 15.53).**

**Investigations**

Patients with acute or subacute spinal cord syndrome should be investigated urgently.

- MRI of spine: MRI is the investigation of choice. MRI can define the extent of compression and associated abnormality in the soft-tissue.
- Plain X-rays of spine: It may show destruction of bone and soft-tissue abnormalities.
- Chest X-ray: It may show evidence of systemic disease
- Myelography
- CSF: If there is complete spinal block, CSF shows a normal cell count with a raised protein causing yellow discoloration of the fluid (Froin's syndrome).
- Serum vitamin B<sub>12</sub>
- Biopsy: If a secondary tumor is causing the cord compression, needle biopsy may be establish diagnosis.

**Table 15.53:** Symptoms and signs of spinal cord compression.

**Symptoms of spinal cord compression**

**Pain:** Occurs early. Localized over the spine or in a root distribution. Maybe aggravated by coughing, sneezing or straining.

**Sensory:** Occurs early. Paresthesia, numbness or cold sensations (especially in the lower limbs), spread proximally to a level on the trunk

**Motor:** Occurs late. Weakness, heaviness or stiffness of the limbs (commonly legs)

**Sphincters:** Occurs late. Urgency or hesitancy of micturition, and retention of urine

**Signs of spinal cord compression:** Vary according to the level of the cord compression and the structures involved.

**Cervical, above C5:** Frequently life threatening

- Upper motor neuron signs and sensory loss in all four limbs (quadriplegia)
- Weakness of diaphragm (phrenic nerve)

**Cervical C4-C5**

- Quadriplegia with preserved respiratory function

**Cervical, C5–T1**

- Lower motor neuron (LMN) signs and segmental sensory loss in the arms; upper motor neuron (UMN) signs in the legs
- Weakness of respiratory (intercostal) muscle

**Thoracic cord**

- Spastic paraplegia with a sensory level on the trunk
- Weakness of legs, sacral loss of sensation and extensor plantar responses
- Midline back pain is a useful localizing sign

**Lumbar cord and Cauda equina**

- Spinal cord ends at the T12/L1 spinal level. Spinal lesions below this level can cause only lower motor neuron signs by affecting the cauda equina
- L1-L2 - cremasteric reflex is a cutaneous reflex useful in localization of lumbar cord disease
- L2-L4 paralyzes flexion and abduction of the thigh, weakens leg extension at the knee, and abolishes the patellar reflex
- L5-S1 paralyze movements of the foot and ankle, flexion at the knee, and extension of the thigh, and abolish the ankle jerk (S1).

**Management**

- Treatment depends on the underlying lesion.
- Benign tumors should be surgically excised.
- Extradural compression due to malignancy has a poor prognosis. Useful function can be regained if treatment (e.g. radiotherapy), is started within 24 hours of the onset of severe weakness or sphincter dysfunction.
- Spinal cord compression due to tuberculosis may require surgical treatment and antituberculous chemotherapy.
- Traumatic lesions of the vertebral column needed treatment by neurosurgeon

## Brown-Séquard Syndrome

**Q. Write a short note on the causes and clinical manifestations of Brown-Séquard syndrome.**

It refers to findings seen when the damage is confined to one side (lateral

half) of the spinal cord. With compressive lesions, there is a band of pain at the level of the lesion in the distribution of the nerve roots involved by compression.

**Causes:** Due to extramedullary lesions, usually caused by penetrating (Gun shot) or tumor.

### ***Clinical Features***

- Sensory
  - Ipsilateral loss of proprioception due to posterior column involvement
  - Contralateral loss of pain and temperature due to involvement of lateral spinothalamic tract
- Motor
  - Ipsilateral spastic weakness due to descending corticospinal tract involvement
  - LMN signs at the level of lesion.

## **Chronic Myelopathies**

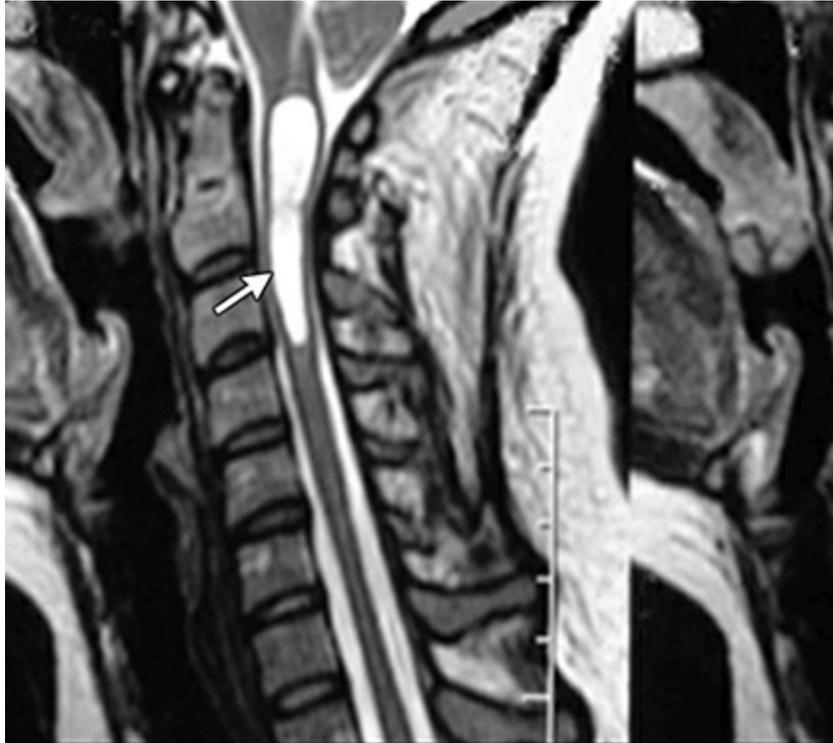

### ***Syringomyelia***

**Q. Write a short essay on the pathogenesis of syringomyelia.**

- A syrinx is a fluid-filled cavity within the spinal cord. Syringomyelia is a **cavitary expansion of the spinal cord**. Syrinxes commonly develop in the lower cervical and high thoracic regions or in the high cervical region. They may extend proximally to the medulla or pons (syringobulbia).
- Pathogenesis: More than 50% are associated with Arnold-Chiari type I malformation characterized by herniation of cerebellar tonsils through the foramen magnum. This abnormality at the foramen magnum probably allows normal pulsatile CSF pressure waves to be transmitted to fragile tissues of the cervical cord and brainstem. This results in secondary cavity formation. There is gradually destruction of spinothalamic neurons, anterior horn cells and lateral corticospinal tracts. It leads to progressive myelopathy.
- **Classic presentation** is a central cord syndrome with dissociated sensory loss and areflexic weakness in the upper limbs.
- **Sensory loss:** Most cases begin asymmetrically with unilateral sensory

loss. The sensory loss has a distribution that is ‘suspended’ over the nape of the neck, shoulders, and upper arms (cape distribution) or in the hands.

- Neurogenic arthropathies (**Charcot joint**): Most common in shoulder. Thoracic kyphoscoliosis is common.
- **La Main succulente of syringomyelia** (subcutaneous thickening and swollen fingers)
- **Morvan’s syndrome**: Progressive loss of pain sensation, ulceration, loss of soft tissues and resorption of phalanges.
- **MRI scans (Fig. 15.11)**: Accurately identify syrinx cavities and associated spinal cord enlargement.
- **Treatment is surgery**: Posterior decompression of Arnold-Chiari malformation and the coperitoneal shunt to drain syrinx cavity.

**Fig. 15.11:** MRI showing cervical syringomyelia.

### ***Syringobulbia***

It is characterized by dysphagia, nystagmus, pharyngeal and palatal weakness, asymmetric weakness and atrophy of the tongue, and loss of pain, temperature in the distribution of the trigeminal nerve (facial sensory loss resembling in distribution a **balaclava helmet**), involving the outer parts of

the face but sparing the nose and mouth. This pattern of facial sensory impairment also be known as onion peel or onion skin pattern.

### ***Subacute Combined Degeneration (SACD) of Cord***

**Q. Write a short essay on etiology, clinical features/neurological signs and management of subacute combined degeneration.**

It is myelopathy that develops due to nutritional deficiency of vitamin B<sub>12</sub> deficiency, including pernicious anemia.

- This treatable myelopathy presents with paresthesia in the hand and feet, early loss of vibration and position sensation, and a progressive spastic and ataxic weakness.
- Loss of reflexes due to a superimposed peripheral neuropathy in a patient who also has Babinski signs is an important diagnostic clue.
- The myelopathy of subacute combined degeneration tends to be diffuse rather than focal; signs are generally symmetric and reflect predominant involvement of the posterior and lateral tracts.
- Optic atrophy and irritability prominent in advanced cases.
- **Low vitamin B<sub>12</sub> levels confirm the diagnosis.**
- **MRI spinal cord:** Inverted V sign or rabbit ear sign due to T2 hyper intensity along posterolateral column of spinal cord.

**Treatment** is by replacement therapy, beginning with 100 mg of intramuscular vitamin B12 repeated at regular intervals or by subsequent oral treatment.

### ***Causes of posterior column disease (Box 15.24)***

**Q. Write a short essay on diseases affecting posterior column. Explain clinical features of any one of them.**

Refer respective diseases.

### **Paraplegia**

**Q. Write a short note on causes and differential diagnosis of spastic paraplegia.**

Paraplegia is weakness or paralysis of both lower limbs, sparing the upper

limbs.

**Causes:** It can occur in disorders of cerebrum, spinal cord, spinal roots, peripheral nerves or muscles. It is usually due to disorders of spinal cord.

### ***Spastic Paraplegia***

Spasticity is due to an upper motor neuron lesion. It is usually produced to subacute or chronic lesion. Acute lesions usually cause flaccid paralysis.

**Box 15.24:** Causes of posterolateral column disease.

- Vitamin B<sub>12</sub> deficiency
- AIDS
- HTLV associated myelopathy
- Cervical spondylosis, hypocupremia, vitamin E deficiency

### ***Causes of spastic paraplegia (Table 15.54)***

**Table 15.54:** Causes of spastic paraplegia (Upper motor neuron (UMN) type lesion).

<i>A. Gradual onset</i>	<i>B. Sudden onset</i>
<b><i>Cerebral causes</i></b>	
<ul style="list-style-type: none"> <li>• Parasagittal meningioma</li> <li>• Hydrocephalus</li> </ul>	<ul style="list-style-type: none"> <li>• Thrombosis of unpaired anterior cerebral artery or superior sagittal sinus</li> </ul>
<b><i>Spinal causes</i></b>	
<p><b>Compressive or transverse lesion in the spinal cord:</b> Cord compression</p> <p><b>Non-compressive or longitudinal lesion or systemic disease of the spinal cord</b></p> <ul style="list-style-type: none"> <li>• Motor neuron disease (MND) e.g. amyotrophic lateral sclerosis</li> <li>• Multiple sclerosis, Friedreich’s ataxia</li> <li>• Subacute combined degeneration (i.e. from vitamin B<sub>12</sub> deficiency)</li> <li>• Lathyrism, syringomyelia, Erb’s spastic paraplegia, tropical spastic paraplegia</li> <li>• Radiation myelopathy</li> </ul>	<p><b>Compressive causes</b></p> <ul style="list-style-type: none"> <li>• Injury to the spinal cord (fracture-dislocation or collapse of the vertebra)</li> <li>• Intervertebral disc prolapse</li> <li>• Spinal epidural abscess or hematoma</li> </ul> <p><b>Non-compressive causes</b></p> <ul style="list-style-type: none"> <li>• Acute transverse myelitis</li> <li>• Thrombosis of anterior spinal artery</li> <li>• Hematomyelia (from arteriovenous malformation, angiomas, or endarteritis)</li> </ul>

### ***Cauda Equina Syndrome***

The **epiconus** comprises the cord segment between L4 and S1, corresponding

to the T12 and L1 vertebrae. The most distal bulbous part of the spinal cord (L1-L2) is called the conus medullaris. The **conus medullaris** consists of the cord segment between S2 and S5 as well as coccygeal segments. Distal to this end of the spinal cord is a collection of nerve roots (L2-3 onwards to coccygeal), which are horsetail-like in appearance called the **cauda equina** (Table 15.55).

**Q. Write a short note on differences between conus medullaris lesions and cauda equina lesions.**

**Table 15.55: Differences between conus medullaris and cauda equina syndromes.**

<i>Features</i>	<i>Conus medullaris syndrome</i>	<i>Cauda equina syndrome</i>
Presentation	Sudden and bilateral	Gradual and unilateral
Reflexes	Knee jerks preserved but ankle jerks affected	Both knee and ankle jerks affected
Radicular pain	Less severe	More severe
Low back pain	More	Less
Sensory symptoms and signs	Numbness in symmetrical and bilateral, sensory dissociation occurs. Saddle anesthesia present	Numbness is asymmetrical, may be unilateral, no necessary dissociation
Motor strength	Typically symmetric, hyperreflexic distal paresis of lower limbs	Asymmetric areflexic paraplegia
Impotence	Frequent	Less frequent
Sphincter dysfunction	Overflow urinary incontinence and fecal incontinence, tend to present early in course of disease	Urinary retention, tends to present late in course of disease

### ***Complications of Paraplegia (Box 15.25)***

#### **Management of Paraplegia**

- **Skin care:** Prevention of pressure sores. They develop due to loss of sensation and reduced blood supply. Following measures will be helpful.
  - Turn the patient every 2-4 hour to avoid pressure over bony prominences.
  - Keep the skin dry and clean.
  - Specially designed mattress like water or air-cushioned bed will be useful.
  - The patient should be prevented from lying on the side of the pressure sores. Needs aseptic care and may require skin grafting.
- **Bladder**

- Aseptic intermittent catheterization. Indwelling catheter is not advisable as it predisposes to infection, reduces bladder capacity and promotes calculus formation.
- Prompt treatment of urinary infections and maintenance of adequate fluid intake
- **Bowel:** Laxative to prevent constipation. If fecal matter becomes hard, manual evacuation is done.
- **Paralysis**
  - Spasticity can lead to contractures and flexor spasms. Hence, regular passive movements of the limbs should be encouraged.
  - Posture should be such that flexion is prevented at joints.
  - Drug treatment of spasticity: Baclofen, diazepam and tizanidine. In severe spasticity, intrathecal baclofen via a pump or sectioning of the anterior roots (rhizotomy).
- **Rehabilitation:** Use a caliper or wheel chair and physiotherapy

**Box 15.25:** Complications of paraplegia.

- Pressure/bed sore
- Urinary infection and renal stones
- Fecal impaction with intestinal obstruction
- Contracture of limbs
- It may lead to death.

## Spinal Pain

**Q. Write a short note on different types of spinal pain.**

- **Radicular pain:**
  - It is **unilateral, lancinating, dermatomal** pain often exacerbated by cough, sneeze, or Valsalva maneuver.
  - Common with **extradural growths** (e.g. neurilemmoma which is intradural extramedullary) and rare with intramedullary lesions.
- **Vertebral pain**
  - It is an **aching pain localized to the point of the spine involved** in the compressive process and often accompanied by point tenderness.
  - Common with **neoplastic or inflammatory extradural lesions** and infrequent with intramedullary or intradural- extramedullary lesions.
- **Funicular (central) pain**
  - It is **deep, ill-defined painful dysesthesia**, usually distant from the affected spinal cord level (and therefore of poor localizing value), probably related to dysfunction of the spinothalamic tract or posterior columns.
  - It is common with **intramedullary lesions** and very unusual with extradural lesions.
- With dysfunction of the posterior columns in the cervical region, neck flexion may elicit a sudden 'electric-like' sensation down the back or into the arms (**Lhermitte's sign or Barber's chair syndrome**).
- More reliable band-like radicular pain or segmental paresthesia may occur at the level of the lesion and may be of localizing value for the appropriate spinal level.

## Causes of Flaccid Paraplegia (LMN type)

- **UMN lesion in shock stage:** i.e. sudden onset or history of long duration as in extradural transverse myelitis and spinal injury
- **Lesion involving anterior horn cells**
  - Acute anterior poliomyelitis
  - Progressive muscular atrophy (a variety of motor neuron disease)
- **Diseases affecting nerve root:** tabes dorsalis, radiculitis, GB syndrome
- **Diseases affecting peripheral nerves**
  - Acute infective polyneuropathy (GB syndrome)
  - High cauda equina syndrome
  - Disease of peripheral nerves involving both the lower limbs
  - Lumbar plexus injury (psoas abscess or hematoma)
- **Diseases affecting myoneural junction**
  - Myasthenia gravis, Lambert-Eaton syndrome
  - Periodic paralysis due to hypo- or hyperkalemia
- **Diseases affecting muscles:** Myopathy.

**Table 15.56:** Causes of quadriplegia.

<i>UMN causes</i>	<i>LMN causes</i>
<ul style="list-style-type: none"> <li>• Cerebral palsy</li> <li>• Bilateral brainstem lesion (glioma)</li> <li>• Craniovertebral anomaly</li> <li>• High cervical cord compression</li> <li>• Multiple sclerosis</li> <li>• Motor neuron disease</li> </ul>	<ul style="list-style-type: none"> <li>• Acute anterior poliomyelitis</li> <li>• GB syndrome</li> <li>• Peripheral neuropathy</li> <li>• Myopathy or polymyositis</li> <li>• Myasthenia gravis and crisis</li> <li>• Periodic paralysis</li> <li>• Snake bite, organophosphorous poisoning, etc.</li> </ul>

### Box 15.26: Causes of pure motor paraplegia.

- Hereditary spastic paraplegia
- Lathyrism
- GB syndrome
- Amyotrophic lateral sclerosis (MND)
- Fluorosis
- Erb's spastic paraplegia (syphilitic)

### *Causes of Pure Motor Paraplegia (Box 15.26)*

### *Causes of Quadriplegia (Table 15.56)*

Weakness of all the 4 limbs can occur in the lesions from cortex to C5 level

of spinal cord and various lower motor neuron (LMN) lesion affecting anterior horn cells, roots, peripheral nerve, neuromuscular junction and muscles.

## Craniovertebral Junction (CVJ) Anomalies

**Q. Discuss craniovertebral junction anomalies.**

- **Abnormal general physical appearance:** Head may be cocked to one side, short neck and scoliosis.
- **Neurological:** Most common posterior occipital headache that worsens with neck flexion or extension. Others include myelopathy and brainstem and lower cranial nerve deficits.
- **Vascular symptoms:** Intermittent attacks of altered consciousness, confusion, transient loss of visual fields and vertigo.

**Classification of craniovertebral junction anomalies (Table 15.57).**

## Hemiplegia

**Q. Discuss hemiplegia in an elderly male. Give the differential diagnosis, investigations and its treatment.**

Hemiplegia is paralysis of one side of the body. Hemiparesis is the weakness of one side of body.

For differential diagnosis, investigations and its treatment, refer individual diseases.

**Table 15.57: Craniovertebral junction anomalies.**

<i>Skeletal anomalies</i>	<i>Neuraxial anomalies</i>
<ul style="list-style-type: none"> <li>• Platybasia</li> <li>• Basilar invagination (10/20)</li> <li>• Klippel-Feil anomaly</li> <li>• Occipitalization of atlas</li> <li>• Atlanto-axial dislocation</li> </ul>	<ul style="list-style-type: none"> <li>• Arnold-Chiari malformation</li> <li>• Dandy-Walker syndrome</li> <li>• Occipitocervical myelomeningocele</li> <li>• Posterior fossa cysts</li> </ul>

## *Causes of Hemiplegia (Table 15.58)*

**Table 15.58: Causes of hemiplegia.**

<i>Onset</i>	<i>Cause</i>

Acute	
• Stroke	Cerebral infarct (thrombotic/embolic-most common cause in elderly), intracerebral hemorrhage (hypertensive), subarachnoid hemorrhage (SAH) with intracerebral hemorrhage
• Trauma	Hematoma (epidural or subdural), cerebral contusion
• Others Subacute Chronic	Meningitis, encephalitis, postseizure (Todd's paralysis) Cerebral metastasis, subdural hematoma, granulomas (tuberculosis-younger age, fungal), pyogenic abscesses (metastatic infection, post-traumatic), rapidly growing malignant neoplasms (e.g. glioblastoma), hypoglycemia, multiple sclerosis Slow growing neoplasms

## Small Muscle Wasting of the Hand (Fig. 15.12)

**Q.** Write a short note on wasting of small muscles of hand.

### *Causes of Small Muscle Wasting of the Hand (Table 15.59)*

**Table 15.59:** Causes of small muscle wasting of the hand.

**Lesions of vertebra:** Craniovertebral anomalies, vertebral metastasis

**Lesions of spinal cord:** Syringomyelia, cord compression by tumor

**Lesion of anterior horn cell:** Motor neuron disease (MND), poliomyelitis

**Lesions of spinal root:** Cervical cord tumor, pancoast tumor, cervical disk prolapse

**Lesion of brachial plexus:** Cervical rib

**Lesions of peripheral nerve:** Hansen's disease, carpal tunnel syndrome, lead poisoning

**Diseases of muscle:** Distal muscular dystrophy, polymyositis

**Disuse atrophy:** Therapeutic immobilization (e.g. fracture), rheumatoid arthritis, post-paralytic (hemiplegia)

**Fig. 15.12:** Wasting of small muscles of hand.

## MOTOR NEURON DISEASES

**Q. Write a short essay/note on motor neuron disease.**

Motor neuron disease (MND) is a devastating, progressive, **heterogeneous group** of **neurodegenerative** condition caused by loss of upper and lower motor neurons in the spinal cord, cranial nerve nuclei and motor cortex. There is no involvement of sensory or other nonmotor tracts. It causes progressive weakness and eventually death (usually as a result of respiratory failure or aspiration). Various types of motor neuron disease are listed in Table 15.60.

### Clinical Features

**Q. Write short answer on three neurological signs of upper and lower motor neuron disease.**

There are four main clinical patterns. There is no involvement of sensory system. Hence, sensory symptoms (e.g. numbness, tingling and pain) are not present.

#### 1. Amyotrophic Lateral Sclerosis

**Q. Write a short essay/note on amyotrophic lateral sclerosis.**

- Named by Jean Martin Charcot in 19th century. Also known as **Lou Gehrig's disease** after the famous baseball player diagnosed of ALS in 1930.
  - Degeneration of the motor neuron (UMN and LMN) in motor cortex, brainstem and spinal cord.
    - **Amyotrophy:** Atrophy of muscle fibers consequent to denervation due to anterior horn cell degeneration
    - **Lateral sclerosis:** Sclerosis of the anterior and lateral corticospinal tracts which are replaced by progressive gliosis.
- Epidemiology:** Incidence is 1 to 2.7/lakh, prevalence is 2.7 to 7.4/lakh
- Sex predisposition: M > F (2:1 to 7:1), (F > M in bulbar onset ALS).
  - Age: Risk increases with age up to 74 years. Peak onset-sixth to seventh decade (one to two decades earlier in India).
  - Prognosis: 20% of patients survive for 5 years and 10% survive for 10 years.

### **Etiopathogenesis**

- Undetermined etiology. Complex genetic and environmental interaction for neuronal degeneration.
- MND is usually (90–95%) sporadic.
- **Molecular pathway:** Pathological hallmarks observed in axons of MND is the ubiquitinated cytoplasmic inclusions containing the RNA processing proteins TDP43 and FUS. This indicates that protein aggregation may be involved in its pathogenesis similar to other neurodegenerative disorders. Other mechanism involved in pathogenesis may be oxidative neuronal damage, glutamate mediated excitotoxicity, mitochondrial dysfunction and impaired axonal transport.

### **Clinical presentation**

- **Typical/spinal form** of ALS constitutes 2/3rd of cases. They present with simultaneous involvement of upper and lower motor neurons. Usually in one limb, spreading gradually. Often present with focal motor weakness of distal or proximal upper or lower limbs. The focal motor weakness spreads to contiguous muscles in the same region

before involvement of another region. Then involves other limbs and trunk muscles.

- **Pseudoneurotic pattern:** Resembles neuropathy, i.e. involvement of muscles in the apparent distribution of a peripheral nerve. Fasciculations are present on wasted muscles.
- **Monomelic:** Involvement of one limb (as wasted leg syndrome, monomelic amyotrophy, Chopras MND)
- **Pseudopolyneuritic:** Weakness in the both distal lower limbs.
- **Mill's hemiplegic variant:** Weakness restricted to one half of the body.
- **Madras MND:** Associated sensorineural deafness, bifacial and bulbar weakness, bilateral optic atrophy in age <15 years.

## 2. Bulbar/Pseudobulbar Palsy (20%)

- Initially involves the lower cranial nerve nuclei and their supranuclear connections.
- Presents with weakness of respiratory group of muscles (e.g. dysarthria, dysphagia, nasal regurgitation of fluids and choking).
- About 10% present with bilateral upper limb weakness and wasting, flail arm of flail person in barrel syndrome.
- Head drop
- Wasting and fasciculations of tongue seen almost in all patients (Fig. 15.13).
- Cramps in the thighs, abdomen, back or even tongue.
- Nonmotor symptoms: Sleep disturbance, subtle cognitive dysfunction and mood changes.
- Rarely involved: Bladder, bowels, autonomic, extraocular movements and sensory.

## 3. Progressive muscular atrophy

- It presents as a pure lower motor neuron disease with symptoms of weakness, muscle wasting and fasciculation.
- Usually starts in one limb and gradually spreading to involve other adjacent spinal segments.

## 4. Primary lateral sclerosis (rare 1–2%)

The least common form of MND. It involves upper motor neurons and presents with a slowly progressive tetraparesis and pseudobulbar palsy.

**Table 15.60:** Various types of motor neuron disease.

<i>Subset of motor neurons involved</i>	<i>Clinical syndromes</i>
Upper motor neuron (UMN)+ lower motor neuron (LMN)	<ul style="list-style-type: none"><li>• Amyotrophic lateral sclerosis (ALS)</li></ul>
Upper motor neuron (UMN)	<ul style="list-style-type: none"><li>• Pseudobulbar palsy</li><li>• Primary lateral sclerosis</li><li>• Familial spastic paraplegia</li></ul>
Lower motor neuron (LMN)	<ul style="list-style-type: none"><li>• Bulbar palsy</li><li>• Spinomuscular atrophy</li></ul>

**Fig. 15.13:** Tongue wasting with atrophy

### ***Diagnosis of Amyotrophic Lateral Sclerosis***

- No biological marker identified so far.
- Diagnosis is largely by series of clinical and neurological examinations.
- MRI: Coronal T2WI shows bilateral symmetrical hyperintensity along corticospinal tract (thin white arrows) forming a **‘wine glass appearance’** or **‘garland sign’**.
- Myelogram of cervical spine (an X-ray analysis): Detects lesions in selected area of the spinal cord.

- Muscle and/or nerve biopsy.
- Electromyography (EMG) and nerve conduction velocity (NCV) to measure muscle response to nervous stimulation.
  - **Split hand phenomenon:** In cases of severe changes in the thenar eminence and the relative sparing of hypothenar eminence, observed on the EMG study.

## ***Differential Diagnosis of Amyotrophic Lateral Sclerosis***

As amyotrophic lateral sclerosis is untreatable, all secondary causes should be excluded (Table 15.61).

**Table 15.61:** Differential diagnosis of amyotrophic lateral sclerosis.

<p><b>Other motor neuron diseases:</b> Primary lateral sclerosis (UMN only), progressive muscular atrophy (LMN only), progressive bulbar palsy</p> <p><b>Structural lesions:</b> Cervical spondylosis, parasagittal/foramen magnum tumor, spinal cord AV malformation</p> <p><b>Neuropathies:</b> Chronic inflammatory demyelinating polyneuropathy (CIDP)</p> <p><b>Myopathies:</b> Polymyositis, inclusion body myositis</p> <p><b>Neuromuscular junction disorder:</b> Myasthenia gravis</p>	<p><b>Neurodegenerative diseases:</b> Parkinson's, progressive supranuclear palsy, multiple sclerosis</p> <p><b>Malignancy:</b> Primary/metastasis to CNS, motor neuron syndromes with multiple myeloma, lymphoma, lung, breast</p> <p><b>Toxic exposure:</b> Alcohol, heavy metals</p> <p><b>Endocrine:</b> Hyperthyroidism, hyperparathyroidism</p> <p><b>Infectious:</b> HIV, CMV</p>
---	--

### **Treatment**

No treatment to arrest degeneration.

#### ***Drug Therapy***

- **Riluzole:** Dose 100 mg/day. It is a sodium channel blocker that reduces glutamate-induced excitotoxicity. Adverse drug reactions include asthenia, nausea, alterations in liver function tests, headache, abdominal pain, and tachycardia.
- **Trial drugs:** IGF-1, ceftriaxone, edaravone, tamoxifen.
- **Spasticity**
  - Baclofen 5–10 mg twice daily to three times daily.
  - Tizanidine in the dose of 2–4 mg by mouth twice daily up to a total dose of 24 mg daily.
  - Memantine starting at 5 mg daily, increasing by 5 mg a week to a maximum of 20 mg twice a day.
  - Tetrazepam 50 mg at bedtime, increasing by 25 mg a day to a maximum dose of 150 mg taken two to three times a day.

#### ***Rehabilitation***

- Foot drop splint
- Finger extension splint

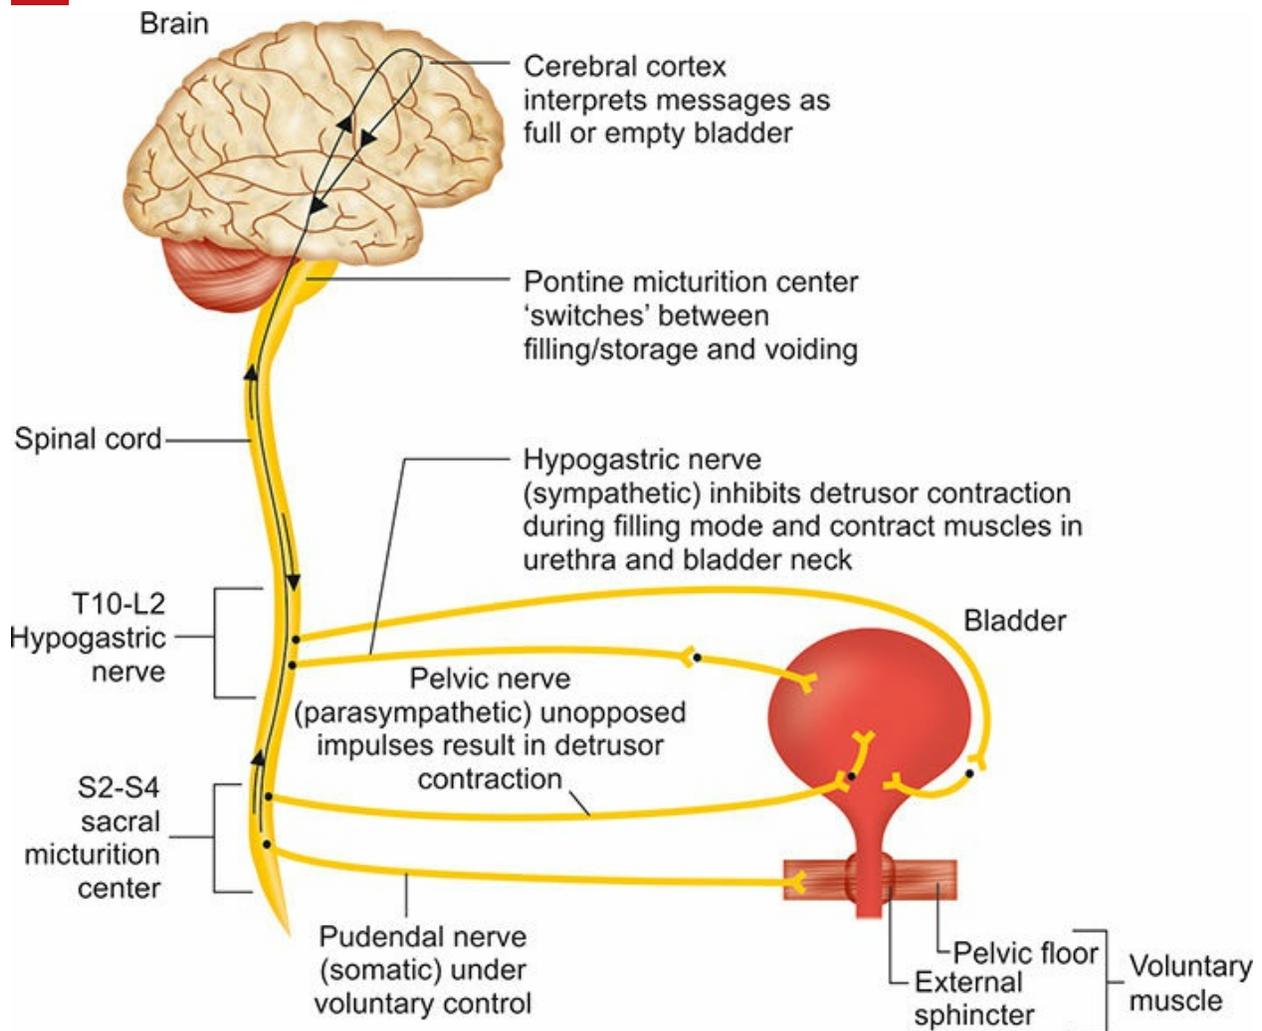

- Respiratory support: Tracheostomy, positive pressure ventilation, cough assisted device.
- Bulbar involvement: Gastrostomy (for feeding), speech therapy.
- Physiotherapy, speech and occupational therapy

## Prognosis

Patient usually does not survive for more than three years, though rarely patients may survive for a decade or longer.

## Nerve Supply of Urinary Bladder (Fig. 15.14)

**Q. Write a short note on nerve supply of urinary bladder.**

**Fig. 15.14:** Nerve supply of urinary bladder

## Neurogenic Bladder

**Q. Write a short note on neurogenic bladder.**

Dysfunction of urinary bladder due to neurological disorders is known as neurogenic bladder.

Various causes of neurogenic bladder are listed in Table 15.62.

**Table 15.62: Various causes of neurogenic bladder.**

Type	<i>Uninhibited bladder/detrusor hyperreflexia</i>	<i>Automatic bladder/Detrusor sphincteric dyssynergia</i>	<i>Autonomous bladder/Detrusor areflexia</i>	<i>Sensory atonic bladder</i>	<i>Motor bladder</i>
Site of lesion	Suprapontine neurologic disorder, mostly frontal lobe	UMN disorder of the suprasacral spinal cord	LMN lesion at the sacral cord	LMN lesion- periph	
Causes	Frontal tumors, parasagittal meningioma, ACA aneurysm, NPH	Spine cord trauma, compressive myelopathy, myelitis	Cauda equina syndrome, conus medullaris lesion, spinal shock	Diabetes mellitus, amyloidosis, tabes dorsalis	Lumbar meningeal tethering syndrome, canal stenosis
Bladder sensation	Preserved	Interrupted	Absent	Absent	Intact
Size of bladder	Normal	Small	Large	Large	Large
Ability to initiate voiding	Present	Absent	Absent	Present	Lost
Type of incontinence	Urge social disinhibition	Urge	Overflow	Overflow	Overflow
Residual urine	Nil	Small	Large amount	Large	Large
Anal sphincter tone	Normal	Normal	Lost	Normal	Lost
Perianal sensation	Normal	Normal	Absent	Absent	Preserved
Bulbocavernous/anal reflex	Normal	Normal	Absent	Absent	Preserved
Treatment	Anticholinergic medication	Self-intermittent catheterization	Continuous catheterization		

## Transverse Myelitis

**Q. Write a short note on transverse myelitis.**

Transverse myelitis (TM) is an acute, usually monophasic, demyelinating inflammatory disorder affecting the spinal cord. It is characterized by acute or subacute motor, sensory and autonomic (bladder, bowel and sexual) spinal cord dysfunction.

- Myelitis refers to inflammation of the spinal cord and transverse signifies the involvement across one spinal cord level.
- Usually 1 or 2 spinal segments are affected with part or all of the cord area at that level involved.
- Varying degree of motor, sensory and autonomic disturbances are produced.

### ***Causes of Transverse Myelitis (Table 15.63)***

**Q.** Write a short note on clinical features of transverse myelitis.

It is usually thought to be postinfectious in origin and up to half of idiopathic cases will have a preceding respiratory or gastrointestinal illness. It is one of cause of a noncompressive spinal cord syndrome in which immune-mediated process may be responsible for neural injury of the spinal cord.

### ***Clinical Features***

- Age: It can occur at any age.
- **Symptoms develop rapidly** over several hours to several weeks which may worsen maximally within 24 hours.

### ***Symptoms***

- Lower limb weakness.
- Sensory: Sensation is diminished or absent below the level of involved spinal cord. Few patients experience tingling or numbness in the legs (subacute paraparesis). **Pain and temperature sensation are diminished.**
- **Bladder and bowel** dysfunction: It results in disturbed **sphincter control.**
- Lhermitte's sign: It is the radiation of paresthesias down the spine or limbs with neck flexion. It may be positive. It suggests intrinsic cervical spinal cord lesion.

### ***Diagnosis***

- First **exclude any mass-occupying lesion** compressing the spinal cord. Early surgical decompression results in complete recovery. MRI and CSF analysis may be useful in the diagnosis.
- **MRI:** MRI is sensitive and shows spinal cord swelling and edema with gadolinium enhancing lesions (single or multiple) at the affected level(s).

MRI is also useful for excluding other treatable causes of spinal cord dysfunction (e.g. spinal cord compression).

- **CSF examination:** Shows cellular pleocytosis (usually monocytes/lymphocytes) often with polymorphs at the onset. Protein is slightly increased and IgG index is elevated. IgG index is a measure of intrathecal synthesis of immunoglobulin (Ig) and is calculated using the following formula:  $(\text{CSF IgG}/\text{serum IgG})/(\text{CSF albumin}/\text{serum albumin})$ . Normal value is  $\leq 0.85$  oligoclonal bands are usually absent.
- **Tests for exclusion of other treatable causes:** These include chest X-ray, tuberculin test, ESR, serologic tests (e.g. for mycoplasma, Lyme disease and HIV), vitamin B<sub>12</sub> and folate levels, antinuclear antibodies and CSF and blood for VDRL (Venereal Diseases Research Laboratory) tests.

#### Treatment

- Treat the underlying cause or associated disorder. Otherwise it is mainly supportive.
- **High dose corticosteroids, intravenous immunoglobulin and plasmapheresis** are used in the treatment of **idiopathic cases**.
- **For severe, refractory cases:** Course of **azathioprine, methotrexate, mycophenolate, or oral cyclophosphamide**

**Outcome** is variable and evolves over days. There may be no recovery. If present it may be **partial or complete** (often partial) and follows over weeks or months (1–3 months).

**Table 15.63:** Causes of transverse myelitis.

<i>Disease</i>	<i>Examples</i>
Bacterial infections	Mycoplasma pneumoniae, Lyme borreliosis, syphilis (tabes dorsalis), tuberculosis
Viral infections	Herpes simplex, herpes zoster, cytomegalovirus, Epstein-Barr virus, enteroviruses (poliomyelitis, Coxsackie virus, echovirus), human T-cell, leukemia virus, human immunodeficiency virus, influenza, rabies
Postvaccination	Rabies, cowpox
Autoimmune diseases	SLE, Sjögren's syndrome, sarcoidosis, multiple sclerosis, neuromyelitis optica
Paraneoplastic syndromes	
Vascular	Thrombosis of spinal arteries, vasculitis secondary to heroin abuse, spinal arteriovenous

malformation (AVM)

# DISEASES OF THE PERIPHERAL NERVOUS SYSTEM

## Introduction

Diseases of the peripheral nervous system are common. They may affect the motor, sensory or autonomic components, either in isolation or combination. Cranial nerves 3–12 share the same tissue characteristics as peripheral nerves and are prone to the same range of diseases.

- **Site of lesion:** It may be (1) dorsal or ventral nerve root (radiculopathy), (2) brachial/lumbosacral nerve plexus (plexopathy) or (3) cranial nerves (except I, II) other sensory, motor, autonomic or mixed nerves (neuropathy). Neuropathy is a pathological process affecting a peripheral nerve or nerves. May be axonal, demyelinating or neuronopathy.

## Classification

Peripheral nerve disorders can be broadly classified into three categories.

1. **Mononeuropathy simplex:** Signifies involvement of a single peripheral nerve (e.g. median nerve in carpal tunnel syndrome).
2. **Mononeuropathy multiplex (now called multiple mononeuropathies):** Simultaneous or sequential several individual nerves involvement usually at random and noncontiguous (e.g. vasculitis, HIV, leprosy).
3. **Polyneuropathy:** Function of numerous peripheral nerves is affected at the same time. This leads to a predominantly diffuse, distal and symmetric deficit usually commencing peripherally. It may be acute, chronic, static, progressive, relapsing or towards recovery. They are motor, sensory, sensorimotor and autonomic. They are classified into demyelinating and axonal types, depending on principal predominant pathological process. Typically, there is widespread loss of tendon reflexes with distal weakness and distal sensory loss.

Damage to peripheral nerve may affect the nerve cell body (axon) or the myelin sheath (Schwann cell), leading to axonal or demyelinating neuropathies.

## Clinical Features

- **Motor nerve involvement:** It produces features of a lower motor neuron lesion.

- **Sensory nerve involvement:** Its features depend on the type of sensory nerve involved; small-fiber neuropathies are usually painful, present with paresthesias. Large fiber neuropathies cause sensory ataxia.
- **Autonomic involvement:** may cause postural hypotension, disturbance of sweating, cardiac rhythm, and gastrointestinal, bladder and sexual functions. Commonly autonomic involvement complicates other neuropathies.

**Diagnosis:** By clinical pattern, nerve conduction/EMG, nerve biopsy, usually sural or radial, and detection of systemic or genetic disease.

## Mononeuropathies

Focal involvement of a single nerve and implies a local process and may be due to direct trauma, compression or entrapment, leprosy, vascular lesions, neoplastic compression or infiltration, etc.

### *Peripheral Nerve Compression and Entrapment*

- Nerves are susceptible to mechanical compression at a certain locations (e.g. ulnar nerve at the elbow, common peroneal nerve at the head of the fibula, radial nerve at spiral groove of humerus, lateral cutaneous nerve of thigh at inguinal ligament, posterior tibial at tarsal tunnel). Focal compression or entrapment is the common cause of a mononeuropathy.
- Entrapment occurs in relatively tight anatomical passages (e.g. the carpal tunnel). At the site of compression, focal demyelination and mild degeneration of distal axonal develops.
- Predisposing causes for entrapment neuropathies include diabetes, excess alcohol or toxins, or genetic syndromes. These are recognized mainly by clinical features and diagnosis is confirmed by nerve conduction studies.
- Usually recover once the primary cause is removed, either by avoiding the precipitation of activity or by surgical decompression.

## Carpal Tunnel Syndrome (CTS)

**Q. Write a short essay/note on carpal tunnel syndrome and its causes.**

- **Common mononeuropathy** due to **entrapment of median nerve** at the wrist.
- CTS is usually not associated with any underlying disease. However, may be seen in: hypothyroidism, 3rd trimester of pregnancy, rheumatoid

disease, amyloidosis in dialysis patients and acromegaly.

- **Clinical features: Nocturnal pain, paresthesia/tingling on palmar aspect of hand and/or forearm and fingers.** It is usually poorly localized and not confined to the anatomical sensory territory of the nerve. At later stages, weakness and wasting of thenar muscles develop.
- **Tinel's sign** (elicited by tapping the flexor aspect of the wrist: this causes tingling and pain) and **Phalen's test** positive. (In Phalen's, the symptoms are reproduced on passive maximal flexion of wrist).
- **Treatment: Wrist splint at night** or a **local steroid injection** in mild cases. In pregnancy CTS is self-limiting and subsides during postpartum. Definitive treatment is **surgical decompression** of the carpal tunnel.

### Mononeuropathy Multiplex

- Simultaneous/sequential damage to multiple noncontiguous nerves (peripheral or cranial nerves).
- **Causes:** Ischemia caused by vasculitis (e.g. Churg–Strauss), microangiopathy in diabetes mellitus. Less common causes include HIV and hepatitis C infection, granulomatous, amyloidosis, leukemic, or neoplastic infiltration, neurofibromatosis, Hansen's disease (leprosy), toxins, paraneoplastic and sarcoidosis.
- **Clinical features:** Symptoms will depend on the specific nerves involved. Several nerves may be affected sequentially or simultaneously, e.g. ulnar, median, radial and lateral popliteal nerves. When multifocal neuropathy is symmetrical, it is difficult distinguishing it from polyneuropathy.
- **Treatment:** Glucocorticoids, Cytotoxic agents.

### Polyneuropathies (Peripheral Neuropathy)

**Q. Write a short essay/note on peripheral neuropathy and its causes/etiology.**

- Polyneuropathy is characterized by a 'length dependent' pattern, occurring first in the longest peripheral nerves and affecting the distal lower limbs before the upper limbs. Sensory symptoms and signs occur in an ascending 'glove and stocking' pattern. Types of peripheral neuropathy are presented in Figure 15.15.

**Causes:** Many diseases can produce polyneuropathy (Box 15.27). However, the etiology is unknown in about 50% of cases.

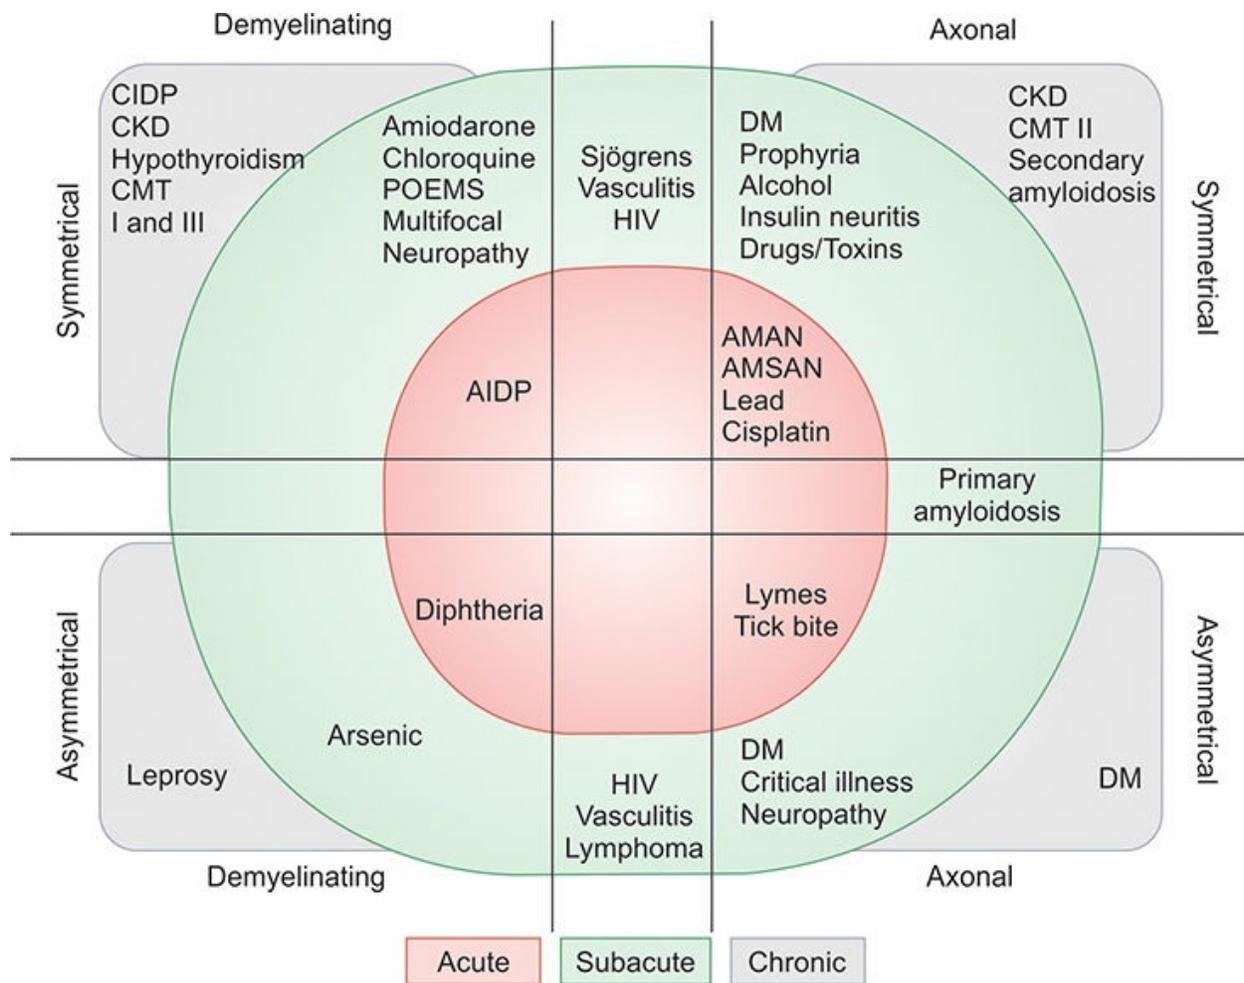

Fig. 15.15: Type of polyneuropathy.

Common causes of axonal and demyelinating chronic polyneuropathies are mentioned in Table 15.64.

**Box 15.27:** Causes of polyneuropathy.

- Vitamin deficiencies:** Thiamine, pyridoxine, vitamin B<sub>12</sub>, vitamin E
- Therapeutic drugs:** Amiodarone, antibiotics (dapson, isoniazid, metronidazole, ethambutol), antiretroviral, chemotherapy (cisplatin, vincristine, thalidomide), phenytoin
- Toxins:** Alcohol, nitrous oxide (recreational use)
- Infections:** HIV, leprosy
- Inflammatory:** Guillain-Barré syndrome, vasculitis (e.g. polyarteritis nodosa, granulomatosis with polyangiitis, SLE), paraneoplastic (antibody-mediated)
- Systemic diseases:** Diabetes, renal failure
- Malignancy:** Infiltration
- Genetic conditions:** Charcot-Marie-Tooth disease (CMT), familial amyloid polyneuropathy, hereditary neuralgic amyotrophy
- Others:** Paraproteinemias, amyloidosis

**Table 15.64: Common causes of axonal and demyelinating chronic polyneuropathies.**

<i>Axonal</i>		<i>Demyelinating</i>
<ul style="list-style-type: none"> <li>• Diabetes mellitus</li> <li>• Alcohol</li> <li>• Uremia</li> <li>• Cirrhosis</li> <li>• Amyloid</li> <li>• Myxedema, acromegaly</li> <li>• Paraneoplastic</li> <li>• Deficiency states: Thiamine, pyridoxine, vitamin B<sub>12</sub>, vitamin E</li> <li>• Hereditary</li> <li>• Infection</li> <li>• Idiopathic</li> </ul>	<ul style="list-style-type: none"> <li>• Drugs and toxins: Amiodarone, antibiotics (dapson, isoniazid, metronidazole, ethambutol), antiretrovirals, chemotherapy (cisplatin, vincristine, thalidomide), phenytoin</li> </ul>	<ul style="list-style-type: none"> <li>• Chronic inflammatory demyelinating polyradiculoneuropathy</li> <li>• Multifocal motor neuropathy</li> <li>• Paraprotein-associated demyelinating neuropathy</li> <li>• Charcot-Marie-Tooth disease type I and type X</li> </ul>

**Q. What are causes of peripheral nerve thickening?**

Causes of peripheral nerve thickening (Table 15.65).

**Table 15.65: Causes of peripheral nerve thickening.**

<ul style="list-style-type: none"> <li>• Leprosy</li> <li>• Chronic inflammatory demyelinating polyneuropathy (CIDP)</li> <li>• Amyloidosis</li> </ul>	<ul style="list-style-type: none"> <li>• Charcot-Marie-Tooth disease</li> <li>• Neurofibromatosis</li> <li>• Diabetes</li> <li>• Acromegaly</li> </ul>	<ul style="list-style-type: none"> <li>• Refsum disease</li> <li>• Idiopathic</li> <li>• Dejerine-Sottas disease</li> <li>• Relapsing GBS</li> </ul>
--	--	--

**Types and Causes of Neuropathy (Box 15.28)**

**Box 15.28:** Types and causes of neuropathy.

- **Small fibersensory neuropathy (painful neuropathy and dissociated sensory loss):** Hereditary sensory neuropathies (early), lepromatous leprosy, diabetes, amyloidosis, Tangiers disease, Fabry’s disease, HIV and antiretroviral therapy neuropathy
- **Large-fiber sensory neuropathy(ataxic neuropathy):** Sjogren’s syndrome, vitamin B<sub>12</sub> neuropathy, cisplatin neuropathy, pyridoxine toxicity, Friedreich’s ataxia, tabes dorsalis.
- **Small and large fiber neuropathy (global sensory loss):** Carcinomatous sensory neuropathy, hereditary sensory neuropathies (late), diabetic sensory neuropathy (late)
- **Motor predominant neuropathies:** Immune mediated-GB syndrome relapsing, heritable motor-sensory neuropathies, acute intermittent porphyria, diphtheritic neuropathy, lead neuropathy, diabetic lumbosacral plexus neuropathy (diabetic amyotrophy)

- **Autonomic neuropathies**
  - Acute: GBS, botulism, porphyria
  - Chronic: Amyloid, diabetes, Sjogren's

## Approach to a Patient with Neuropathy (Box 15.29)

### Investigation of Peripheral Neuropathy (Table 15.66)

**Table 15.66:** Investigation of peripheral neuropathy.

<i>Routine tests</i>	<i>Special tests</i>
<p><b>Blood</b></p> <ul style="list-style-type: none"> <li>• Complete blood count and peripheral smear</li> <li>• Erythrocyte sedimentation rate</li> <li>• C-reactive protein</li> </ul> <p><b>Biochemical tests</b></p> <ul style="list-style-type: none"> <li>• Fasting blood glucose, LDH</li> <li>• Serum protein electrophoresis</li> <li>• Vitamin B<sub>12</sub>, folate</li> <li>• Renal function tests, liver function tests</li> </ul> <p><b>Serology</b></p> <ul style="list-style-type: none"> <li>• ANA, ANCA, HIV testing</li> </ul> <p><b>Others</b></p> <ul style="list-style-type: none"> <li>• Chest X-ray, USG abdomen</li> </ul>	<ul style="list-style-type: none"> <li>• Nerve conduction studies</li> <li>• Vitamins E and A</li> <li>• Nerve biopsy</li> <li>• CSF examination</li> <li>• Serum ACE (Angiotensin converting enzyme)</li> <li>• Serum amyloid</li> <li>• Genetic testing</li> </ul>

#### Treatment

- Depends on the underlying cause.
- Symptomatic treatment (more details refer diabetic neuropathy on pages 108-10).
- **Paresthesia:** Carbamazepine (300–1200 mg/day), amitriptyline (25–50 mg/day) or aspirin (350–1200 mg/day) pregabalin, gabapentin, duloxetine.
- **Weakness:** Physiotherapy

### Box 15.29: Approach to a patient with neuropathy.

**Examine:** Skin, hair, nails and look for 6Ds

- Distribution of the deficits
- Duration
- Deficits (which fibers are involved?)
- Disease pathology (axonal or demyelinating or mixed)
- Developmental or inherited neuropathy
- Drug/toxin exposure

## Guillain-Barré Syndrome and other Immune-mediated Neuropathies

**Q. Write a short essay/note on Guillain-Barré syndrome (GB syndrome) and diagnostic criteria for GBS.**

Guillain-Barré syndrome (GBS) is a **heterogeneous group of immune-mediated conditions**.

GBS is the most common acute, severe fulminant polyradiculopathy/polyneuropathy.

- Usually demyelinating or rarely axonal.
- Often postinfectious, postvaccinal basis
- Monophasic does not recur.

### ***Subtypes of GBS (Table 15.67)***

**Q. What are the variants of GB syndrome?**

### ***Etiology***

#### *Antecedent causes*

- Majority of patients (70%) have preceding acute, influenza-like illness or GI infection. Infections preceding Guillain-Barré syndrome may be due to *Campylobacter jejuni*, cytomegalovirus, Epstein-Barr virus, herpes virus, CMV and *Mycoplasma pneumoniae*, or prior recent vaccination (e.g. for swine flu, influenza rabies (old types)).
- Frequently develop in patients with lymphoma, HIV seropositive, and SLE.

### ***Immunopathogenesis***

- Guillain-Barré syndrome is **an acute-onset immune-mediated demyelinating neuropathy**. Autoimmune basis for AIDP (GBS) and other subtypes. Both cellular and humoral immune mechanism causes damage. Immune response to self-antigen, infection (mentioned above under ‘Antecedent causes’), or vaccine induce antibody responses. Molecular mimicry, i.e. sharing of homologous epitopes between microorganism liposaccharides and nerve gangliosides (e.g. GM1), misdirect the antibodies against host peripheral nerves.

- Antiganglioside antibodies mostly to GM1 common in GBS (20-50%) and anti-GQ1b IgG antibodies seen in MFS (>90%).

### ***Clinical Features***

- Hallmark is an **acute/rapid onset of paralysis** (predominantly motor paralysis with/without sensory) **evolving over days or weeks** with **loss of deep tendon reflexes/jerk (areflexia)**.
- **Motor paralysis** predominant. Weakness beginning in the distal limbs (from lower to upper limbs) that rapidly ascends to affect proximal muscle function (**'ascending paralysis'**). It is more marked in legs than arms and proximally than distally. Pain in the low back, neck, and shoulder, in 50% and is often occur early. The weakness progresses proximally over few days to a maximum of 4 weeks.
- **Sensory involvement is minimal** and may precede muscle weakness. It presents as distal paresthesia or loss of pain sensation.
- Facial and respiratory muscle develops in **20 to 30% of cases requiring ventilatory support**.
- **No fever or constitutional symptoms** at the onset of weakness.
- Bladder dysfunction in late and severe cases.
- Clinical worsening in 4 weeks reaching a plateau and no further progression.
- Autonomic disturbances common like fluctuation of BP, postural hypotension, cardiac dysrhythmias.
- Pain-common symptom acute/deep aching pain in weak muscles. It is self-limited.
- Physical examination shows diffuse weakness with loss of reflexes.
- Miller-Fisher syndrome: It presents with ophthalmoplegia, ataxia and areflexia. Often preceded by diarrhea due to *Campylobacter jejuni* infection. Bickerstaff's brainstem encephalitis (BBE) is characterized by alteration in consciousness, paradoxical hyperreflexia, ataxia, and ophthalmoparesis.

Asbury & Cornblath criteria for Guillain-Barré syndrome is presented in Table 15.68.

**Table 15.67:** Variants of GB syndrome.

<i>Common variants</i>	<i>Less common variants</i>
<ul style="list-style-type: none"> <li>• Acute motor and sensory axonal neuropathy (AMSAN)</li> <li>• Acute motor axonal neuropathy (AMAN)</li> <li>• Miller-Fisher syndrome (MFS)</li> <li>• Pure motor variants</li> <li>• Pure sensory variants</li> <li>• Pure dysautonomia variant</li> <li>• Pharyngeal-cervical-brachial variant</li> <li>• Paraparetic variant (Ropper variant).</li> </ul>	<ul style="list-style-type: none"> <li>• Acral paresthesias with diminished reflexes in either arms or legs.</li> <li>• Facial diplegia or abducens palsies with distal paresthesias</li> <li>• Isolated postinfectious ophthalmoplegia</li> <li>• Bilateral foot-drop with upper limb paresthesias</li> <li>• Acute ataxia without ophthalmoplegia</li> <li>• Bickerstaff's brainstem encephalitis (BBE)</li> </ul>

## ***Investigations/Diagnosis***

- **CSF findings:** Develop after 1 week of illness:
  - Raised protein (100–1000 mg/dL), normal sugar, little or no pleocytosis. Cell count generally <10 cells/mm<sup>3</sup>; rarely may be up to 50 cells/mm<sup>3</sup>, but never above that. This is called as **albumin-cytological dissociation**.
  - CSF pleocytosis (up to 50 cells) is common in patients who have GBS and concurrent HIV infection.
- **Electrodiagnostic study:** Nerve conduction studies:
  - In mild/early stage: Normal
  - In demyelination: Prolonged distal latencies, slow conduction, velocity, conduction block, prolonged F wave latencies. Absent H-reflex.
  - In primary axonal: Reduced amplitude of compound action potential without slow conduction.
- **Antibodies:**
  - Antibodies against GQ1b, a ganglioside component of nerve are found in about 25%, usually the motor axonal form.
  - Miller–Fisher syndrome: Antibodies against GQ1b (ganglioside) have 90% sensitivity.

## ***Differential Diagnosis***

Exclusion of other causes of an acute neuromuscular paralysis: For example, poliomyelitis, botulism, diphtheria, localized spinal cord syndromes or myasthenia gravis, vasculitis, toxins (organophosphates, lead), diphtheria, porphyria, spinal cord or cauda equina syndrome.

**Q. Write a short essay/note on principles of management of Guillain-**

## Barré syndrome.

### Treatment

- Early treatment, each day counts, >2 weeks of 1st motor symptoms immunotherapy not effective.
- Initiative with high dose IV immunoglobulin/plasmapheresis/combination.
- **Intravenous immunoglobulin** IVIg administration has fewer side effects (0.4 g/kg daily infusion) for 5 days. GBS autoantibodies are neutralized by antibodies in IVI g. Patients should be screened for IgA deficiency because severe allergic reactions due to IgG antibodies may develop in patient with congenital IgA deficiency.
- **Plasma exchange:** 50 mL/kg, on 5 separate occasions over 1–2 weeks.
- Glucocorticoid no role.
- Full recovery in 55–69% by 1 year.
- **Worsening case:** Monitoring in intensive care unit blood pressure, cardiac and nutrition. Maintenance of airway and breathing. Ventilatory support may be needed.
- **Supportive measures:** Deep vein thrombosis (DVT) prophylaxis, tracheostomy, chest physiotherapy, skincare, bed sore, joint physiotherapy daily reassurance

### Table 15.68: Asbury & Cornblath Criteria for Guillain-Barré syndrome (GBS).

#### Required features

- Progressive weakness in both arms and legs
- Areflexia (or hyporeflexia).

#### Features supportive of diagnosis

- Progression of symptoms over days to 4 weeks
- Relative symmetry
- Mild sensory signs or symptoms
- Cranial nerve involvement, especially bilateral facial weakness
- Recovery beginning 2 to 4 weeks after progression ceases
- Autonomic dysfunction
- Absence of fever at onset
- Typical CSF (albuminocytologic dissociation)
- EMG/nerve conduction studies (characteristic signs of a demyelinating process in the peripheral nerves)

#### Features casting doubt on the diagnosis

- Asymmetrical weakness
- Persistent bladder and bowel dysfunction
- Bladder or bowel dysfunction at onset
- >50 mononuclear leukocytes/mm<sup>3</sup> or presence of polymorphonuclear leukocytes in CSF
- Distinct sensory level

#### Features that rule out the diagnosis

- Hexacarbon abuse

- Abnormal porphyrin metabolism
- Recent diphtheria infection
- Lead intoxication
- Other similar conditions: poliomyelitis, botulism, hysterical paralysis, toxic neuropathy.

## Plasma Exchange (Plasmapheresis)

**Q. Write a short note on plasma exchange (PE) therapy.**

Plasma exchange (also called plasmapheresis): Plasmapheresis involves the removal of small amounts of plasma (less than 15% of the patient's total blood volume). It can reduce the amount of abnormal protein in the blood. Indications for plasma exchange (PE) therapy is listed in Box 15.30.

**Box 15.30:** Indications for plasma exchange (PE) therapy.

- Glomerulonephritis-anti-GBM disease
- Guillain-Barré syndrome
- Myasthenia gravis
- Autoimmune encephalitis
- Prerenal transplant
- Systemic vasculitis not responding adequately to immunosuppressive therapy
- Thrombotic thrombocytopenic purpura

## NEUROMUSCULAR JUNCTION DISORDERS

### Myasthenia Gravis

**Q. Discuss the etiology, clinical features, investigations, diagnosis, and management/treatment of myasthenia gravis.**

- Myasthenia gravis (MG) is an autoimmune neuromuscular junction disorder.
- Weakness and fatigue of skeletal (preferentially ocular, facial and bulbar) muscles.

### *Pathophysiology (Fig. 15.16)*

### *Pathogenesis of Myasthenia Gravis*

Myasthenia gravis is an autoimmune disease.

- **Antibodies:**

- **AntiAChR antibodies:** It is detected in about 80 to 85% of patients.
- **Anti-MuSK antibodies:** A second group of autoantibodies against muscle specific receptor tyrosine kinase (anti-MuSK antibodies) have been found in anti-AChR antibody negative (about 15–20%) patients.
- **Changes in thymus:** Thymus is abnormal in ~75% of patients with MG. In ~65% the thymus is ‘hyperplastic,’ with active germinal centers. In 10% of patients have thymic tumors (neoplastic). Muscle like cells (myoid cell) within thymus, bearing AChRs on their surface may serve as autoantigen and trigger immune response.

### ***Coexisting Autoimmune Diseases (Box 15.31)***

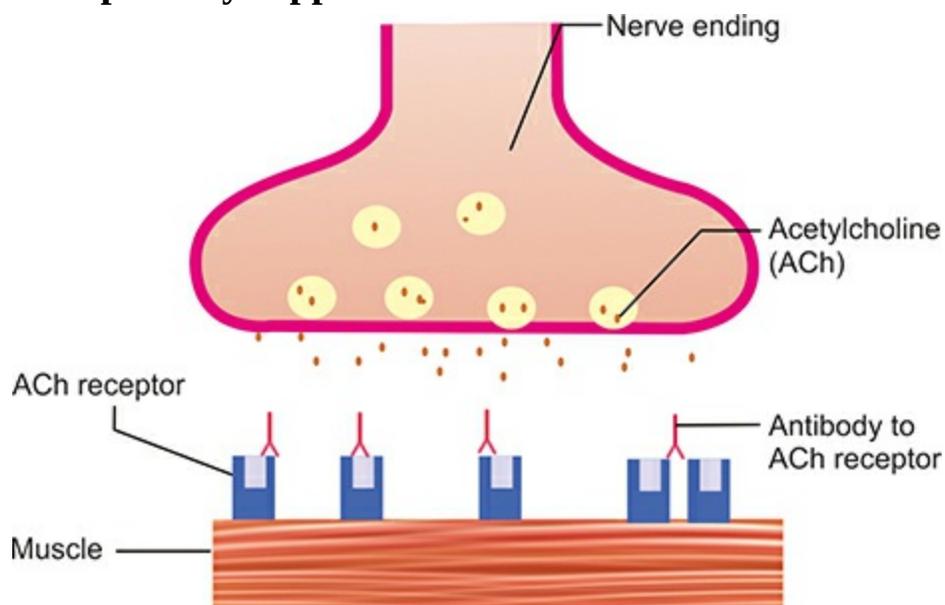

#### ***Clinical Features***

- **Age and gender:** MG is common in women than in men (2:1), with a peak incidence around 30 years of age (15 to 50 years).
- **Cardinal feature: Fluctuating weakness (that worsens with exertion and decrease with rest/sleep) and fatigability of muscles.** Increase with exercise.
- **Muscle affected: Diplopia and ptosis** due to involvement of extraocular muscles. Show more focal muscle involvement (neck, shoulder, facial, jaw, respiratory, and bulbar muscles).
- **Respiratory weakness:** Respiratory muscles involvement may become so severe as to require respiratory assistance. Patient is said to be in due to diaphragmatic and intercostal muscle weakness. Aspiration may occur if the cough is ineffectual.
- **Ocular MG** when weakness is exclusive to the eyelids and extraocular muscles, and **generalized MG** when weakness extends beyond these ocular muscles.
- No sensory signs or signs of involvement of the CNS.
- **Aggravating factors:** Exertion, hot climate, infection, emotion, pregnancy, menstruation, drugs (amino glycoside phenytoin). A temporary increase in weakness may follow **vaccination, menstruation and exposure to extremes of temperature.**

**Course:** Variable, exacerbation and remission in early years. Remission is incomplete and temporary. Most cases have a protracted, lifelong course. Exacerbations are usually unpredictable and unprovoked.

## ***Myasthenic Crisis***

- A **rapid and severe deterioration of myasthenia** is called ‘**myasthenic crisis**’ can bring patient to the brink of respiratory failure and **quadriparesis** in hours.
- A respiratory infection or a sedative medication with NM (neuromuscular) block may be the reason.
- It can develop at any time after the diagnosis of myasthenia.
- Anticipate if patient is restless, anxious with diaphoresis and develops tremor.
- **Require respiratory support.**

**Fig. 15.16:** Pathogenesis of myasthenia gravis. Antireceptor antibodies may inhibit/disturb the normal function of receptors. Autoantibodies to the acetylcholine (ACh) receptor on skeletal muscle cells produce disease by blocking neuromuscular transmission and causing progressive muscle weakness.

### **Box 15.31:** Coexisting autoimmune diseases in myasthenia gravis.

- Hashimoto’s thyroiditis/thyrotoxicosis (in 5–10%)
- Rheumatoid arthritis
- Pernicious anemia
- Scleroderma
- Lupus erythematosus

## ***Diagnosis***

- Diagnosis is based on the basis of **clinical history, physical findings** and

2+ve tests (demonstration of autoantibodies, and electrophysiological studies).

- **Serological tests:** Antibodies against AChR or MuSK.
- **Pharmacological tests:**
  - **Anticholinesterase test:** Drugs inhibiting AChE allow ACh to interact repeatedly with limited number of AChRs producing strength improvement in myasthenic muscles.
  - **Edrophonium test (Tensilon test):** Edrophonium is a rapidly acting acetylcholinesterase inhibitor. Onset of action is rapid (30 seconds) and lasts for short duration (5 minutes). It reverses of muscular weakness dramatically in myasthenia. Test dose (2 mg intravenous) is given to check for reactions. If there is definite improvement drop further test. If negative further 8 mg IV is given. When the test is positive, it produces substantial improvement in weakness, ptosis, diplopia, nasal voice, etc. within 30 seconds and lasts for up to 5 minutes. Positive test is highly suggestive of MG and the sensitivity of the test is 80%. Adverse effect include nausea, diarrhea, salivation, bradycardia, syncope, abdominal cramps, fasciculation (treated with atropine-0.6 mg IV) bronchospasm and syncope.
  - **Neostigmine/Prostigmine test:** 15 mg oral neostigmine, long acting and better evaluation.
- **Ice on eyes/ice pack test (Fig. 15.17):** Apply an ice pack on eye for 3 to 5 minutes. The response is positive when there is increase in at least 2 mm of the palpebral fissure from before to after the test.
- **Electrodiagnostic**
  - **Repeated nerve stimulation (RNS) test:** Electric shock at 2-3 second given to appropriate nerve and corresponding muscle action potential measured. In normal individuals the amplitude of the evoked muscle action potentials does not change at these rates of stimulation. However, in myasthenic patients there is a rapid reduction of >10–15% in the amplitude of the evoked responses during repetitive stimulation.
  - **Single fiber electromyogram:** Most (95%) sensitive.
- **Other tests:**
  - CT, MRI, and X-ray: to exclude thymoma.
  - CBC, ESR, RA factor, thyroid function test.

- Pulmonary function test, fasting blood sugar, Mantoux test, antinuclear antibody (ANA), etc. to exclude other diseases.
- Screening for associated autoimmune disorders.

**Lambert–Eaton myasthenic syndrome (LEMS)** differs from myasthenia gravis in that in LEMS antibodies are against presynaptic calcium channels, deep tendon reflexes are absent and autonomic dysfunction is present and the weakness improves with activity in LEMS. It is most commonly associated with small cell carcinoma of lung and the treatment is with aminopyridines.

## **Q. Write a short note on drugs used in myasthenia gravis.**

### **Treatment**

**Goals:** To increase the activity of acetylcholine on the remaining receptors at the NMJ. Stop the antibody mediated damage at the NMJ.

- 1. Oral anticholinesterases:** Help weakness but do not change the natural history of myasthenia.
  - **Pyridostigmine:** Prolongs acetylcholine action by inhibiting cholinesterase. Onset of action is within 15–30 minutes and lasts for 3–4 hours. Dose 30–60 mg/3 to 4 times daily. Cholinergic crisis characterized by pallor, perspiration, pupillary constriction, paralysis, fasciculation and excessive salivation can be seen with drug over dosage. Muscarinic effects (e.g. colic and diarrhea) are treated with oral atropine/propantheline (antimuscarinic).
- 2. Thymectomy**
  - **Indications:** It is an expert surgical procedure that should be carried out in (1) all patients with generalized MG between the ages of puberty and at least 55 years. (2) May be required for thymoma to prevent spread and treat MG.
  - **Advantages:** Long-term benefit, improves prognosis, negligible medication.
- 3. Immunosuppression**
  - Effective in all. Choice is guided by benefit, risk and urgency. These are used in patients who do not respond to pyridostigmine or who develop relapse on treatment.
  - For immediate: Intravenous immunoglobulin (IVIg) or plasmapheresis.
  - For intermediate: Glucocorticoids, cyclosporine, tacrolimus for 1–3 months.
  - For long-term: Azathioprine, mycophenolate mofetil (less commonly used) for months/years.
  - For refractory: High dose of cyclophosphamide

**Fig. 15.17:** Ice pack test.

**Differences between myasthenic crisis and cholinergic crisis (Table 15.69).**

**Table 15.69:** Differences between myasthenic crisis and cholinergic crisis.

<i>Myasthenic crisis</i>	<i>Cholinergic crisis</i>
<ul style="list-style-type: none"> <li>• Due to disease worsening</li> <li>• Respiratory distress</li> <li>• Increased pulse and blood pressure</li> <li>• Poor cough</li> <li>• Mydriasis</li> <li>• Dysphagia</li> <li>• Weakness</li> <li>• Improve with edrophonium</li> <li>• Treatment: Ventilatory support plus</li> </ul>	<ul style="list-style-type: none"> <li>• Due to drug overdose</li> <li>• Abdominal cramps</li> <li>• Diarrhea</li> <li>• Nausea and vomiting</li> <li>• Excessive secretions</li> <li>• Miosis</li> <li>• Fasciculations</li> <li>• Weakness</li> <li>• Worse with edrophonium</li> </ul>

**Treatment of myasthenic crisis**

- Exacerbation of weakness due to diaphragm and intercostal involvement.
- Treat in intensive care unit (ICU) set up.
- Cause: Infection (most common), cholinergic crisis due to excess anticholinesterase dose.
- Respiratory assistance (preferably noninvasive, using BIPAP).
- Pulmonary physiotherapy.
- Plasmapheresis or IVIg.
- Stop anticholinesterase if using

## DISEASES OF MUSCLE

- Muscle disease is rare and may be hereditary or acquired.
- Hereditary muscle diseases include the muscular dystrophies, muscle channelopathies, metabolic myopathies (including mitochondrial diseases) and congenital myopathies.
- Skeletal muscle disease or myopathies are disorders with structural changes or functional impairment of muscle.

### Muscular Dystrophies

Muscular dystrophies (hereditary myopathies) refer to a group of inherited myopathies/disorders characterized by progressive muscle weakness and wasting (due to destruction of muscle) and may be associated with cardiac and/or respiratory involvement.

**Q. Write a short note on muscular dystrophies or hereditary myopathies.**

Muscular dystrophy is subdivided by their mode of inheritance, age at onset, distribution of involved muscles, rate of progression, and prognosis (Table 15.70).

**Table 15.70:** Various subtypes and its features of muscular dystrophies.

<i>Type and mode of inheritance</i>	<i>Defective gene/protein</i>	<i>Onset age</i>	<i>linical features</i>
Duchenne's-XR	Dystrophin	Before 5 years	Progressive weakness of girdle muscles unable to walk after age 12, progressive kyphoscoliosis, respiratory failure in second and third decade

Becker's-XR	Dystrophin	Early childhood to adult	Progressive weakness of girdle muscles, able to walk after age 15, respiratory failure may develop by 4th decade
Limb-girdle-AD/AR	Several	Early childhood to early adult	Slow progressive weakness of shoulder and hip girdle muscles
Emery Dreifuss-XR/AD	Emerin/Lamins	Childhood to adult	Elbow contractures, humeral and peroneal weakness
Myotonia (DM1 DM2) AD	DMI: Expansion CTG repeat DM2: Expansion CCTG repeat	Childhood to adult, may be infancy if mother is affected (DM1 only)	Slowly progressive weakness of face, shoulder girdle, and foot dorsiflexion preferential proximal weakness in D<2
Facioscapulohumeral-AD (Fig. 15.18)		Childhood to adult	Slowly progressive weakness of face, shoulder girdle, and foot dorsiflexion
Oculopharyngeal-AD	Expansion poly-A RNA binding protein	5th to 6th decade	Slowly progressive weakness of extraocular, pharyngeal and limb muscles

## ***Duchenne Muscular Dystrophy***

### **Q. Write short essay on Duchenne muscular dystrophy.**

- Most common form of muscular dystrophy.
- Caused by a mutation of the gene responsible for producing dystrophin.
- Shows X-linked recessive inheritance and affects predominantly males.
- Duchenne dystrophy is present at birth, but the disorder usually becomes apparent between ages 3 and 5, by age 12, most patients are wheelchair dependent.
- Muscle selectively involved in order of appearance of weakness is iliopsoas, quadriceps, Gluteus-Pretibial muscles, muscles of pectoral girdle, muscles of leg and forearm (at the end).
- **Clinical features:** Use of **Gower's maneuver** while getting up for the floor, toe walking due to foot drop with associated lordotic posture and pseudo hypertrophy of the calves. Cardiomyopathy (DCM) and mental impairment are associated features. But CHF is uncommon. Mental retardation is seen.
- **Investigations**
  - Creatine phosphokinase (CPK) levels are invariably elevated to between 20 and 100 times normal.

- Electromyography (EMG): Features typical of myopathy.
- Muscle biopsy: Definitive diagnosis can be established on the basis of dystrophin deficiency I in biopsied muscle tissue.
- Gold standard: It is genetic testing.

**Fig. 15.18:** Facioscapulohumeral dystrophy (FSHD).

### ***Becker Muscular Dystrophy***

- X-linked disorder, results from defects of the same gene responsible for Duchenne dystrophy.
- Pattern of muscle wasting closely resembles that seen in Duchenne.
- It is a less severe form of disease and much less frequent than Duchenne.
- **Clinical features:** Becker patients ambulate beyond age 15, while patients with Duchenne dystrophy are typically in a wheelchair by the age of 12; allowing for a clinical distinction between Becker and Duchenne dystrophy. Cardiac involvement occurs in Becker dystrophy and may result in heart failure. Mental impairment is uncommon.
- **Investigations:** Serum CK measurement, EMG and muscle biopsy closely resemble those in Duchenne dystrophy.

## ***Limb-Girdle Muscular Dystrophy (LGMD)***

- Most are progressive and affect primarily the pelvic and shoulder girdle muscles. Inheritances can AR or AD and it is due to defect of sarcoglycan.
- **Clinical features:** Respiratory insufficiency from diaphragm weakness may occur. In some patients, cardiac involvement results in congestive heart failure or arrhythmias, occasional patients present with a cardiomyopathy. Intellectual function remains normal.
- **Investigations:** An elevated serum CK level, myopathic EMG findings, and muscle biopsy features indicative of myopathy.

## ***Myotonic Dystrophy***

- It is an autosomal dominant disorder and is the most common adult muscular dystrophy.
- **Clinical features:** Frontal baldness, cataracts (Christmas tree cataract), mental impairment, insulin resistance and gonadal atrophy. Hatchet like face, swan neck deformity is seen. Involvement of distal > proximal, facial muscles and handgrip myotonia are pathognomonic features. Cardiac disturbances occur in most patients with myotonic dystrophy. Disturbances in conduction system are common. Complete heart block and sudden death may occur. Mitral valve prolapse also occurs commonly in myotonic dystrophy patients. Myotonia may improve with phenytoin, mexiletine, and quinidine.

### **Box 15.32:** Causes of endocrine myopathies.

- **Thyroid disorders:** Hypothyroidism, hyperthyroidism
- **Parathyroid disorders:** Hyperparathyroidism, hypoparathyroid- overt myopathy
- **Adrenal disorders:** Glucocorticoid myopathy (endogenous/exogenous) most common, Cushingoid, adrenal insufficiency, primary hyperaldosteronism (Conn's disease)
- **Vitamin deficiency:** Vitamin E, vitamin D

### **Box 15.33:** Causes of high creatinine phosphokinase.

- Brain injury or stroke
- Convulsions
- Delirium tremens
- Dermatomyositis or polymyositis
- Myocarditis
- Muscular dystrophies

- Myopathy
- Rhabdomyolysis
- Pulmonary and myocardial infarction
- Electric shock

## ***Endocrine Myopathies (Box 15.32)***

**Q. Write a short note on causes of endocrine myopathies.**

Causes of high creatinine phosphokinase (Box 15.33).

**Q. List the causes of high creatinine phosphokinase.**

## **DISORDERS OF CEREBELLAR FUNCTION**

- Cerebellum is an infratentorial structure in the posterior cranial fossa, attached to the brainstem by the superior, middle and inferior peduncles. The cerebellum is made up of two hemispheres separated by a midline vermis. There are three lobes anterior, posterior, and flocculonodular lobe.
- Midline lesions can produce severe gait and truncal ataxia.
- Cerebellar hemisphere lesions can produce classic ipsilateral limb ataxia (intention tremor, past pointing and mild hypotonia).

### **Ataxia**

Ataxia may be the result of cerebellar lesion or due to a combination of cerebellar and extracerebellar lesions.

## ***Classification of Ataxia (Table 15.71)***

**Table 15.71: Classification of ataxia.**

### **Acquired or sporadic ataxias**

- **Vascular:** Stroke (infarction, hemorrhage), AV malformations
- **Infectious/postinfectious diseases:** Acute cerebellitis, cerebellar abscess, postinfectious encephalomyelitis, HIV, chickenpox
- **Toxin-induced ataxias:** Alcohol, drugs (antiepileptic agents, lithium, antineoplastics, cyclosporine, metronidazole), heavy metals (mercury), 5-fluorouracil, cytosine arabinoside
- **Structural and neoplastic causes:** Gliomas, ependymoma, cerebellar tumor, meningioma, metastatic disease
- **Immune-mediated:** Multiple sclerosis, cerebellar ataxia with anti-glutamic acid decarboxylase (GAD) antibodies, paraneoplastic syndrome (small-cell lung cancer, breast or ovarian cancer and lymphoma), gluten ataxia

- **Deficiency:** Hypothyroidism, vitamin B<sub>1</sub>, vitamin B<sub>12</sub> and vitamin E

#### Genetic causes

- **Autosomal recessive:** Friedreich ataxia
- **Autosomal dominant:** Spinocerebellar ataxia

## Clinical Features of Cerebellar Lesions

**Q. Write a short note on cerebellar signs.**

### *Cerebellar Ataxia*

**Q. Write a short note on cerebellar ataxia.**

Lesions of the midline vermis of the cerebellum cause truncal ataxia, while lesions of the cerebellar hemispheres cause limb ataxia of the ipsilateral side.

#### 1. Gait ataxia

- Patients will tend to stand with feet well apart and are often frightened to stand.
- Patients tend to reel to the side unilateral lesion or from side to side if central or bilateral (drunken gait) (even if supported).
- Walking along a line of the floor (tandem gait) demonstrates minor degrees of gait ataxia.
- Instability may increase if eyes are closed but patients do not fall. This is not a true positive Romberg's test (true positive Romberg's test is present when there is impaired joint proprioception/posterior. Column involvement is known as sensory ataxia).

#### 2. Truncal ataxia

- Patients cannot sit or stand unsupported and tend to fall backwards.
- It is caused by a midline cerebellar lesion, or may be a feature of post-chickenpox cerebellar syndrome.
- Truncal tremor may be evident-constant jerking of trunk and head (Titubation).
- Lesions of the cerebellar hemisphere cause ipsilateral limb signs.
- The outstretched arm tends to be held hyper pronated at rest and at a slightly higher level than unaffected side (**Riddoch's sign**) and rebounds upwards if gently pressed downwards and then suddenly related by the examiner.

- Finger-nose and heel-knee-shin tests will demonstrate even mild limb ataxia, with terminal intention tremor and dysmetria (past pointing).
- Limb rebound can be demonstrated by gently pushing down on outstretched arms and then suddenly releasing, causing the arm on the affected side suddenly to fly upwards.
- Pendular knee jerks and hypotonia present.

### 3. **Other signs** produced by cerebellar lesions/diseases

- **Cerebellar dysarthria:** Spluttering staccato speech. Scanning dysarthria is a jerky and explosive speech with separated syllables may be demonstrated by asking the patient to repeat ‘baby hippopotamus’.
- **Dyssynergia:** It is difficulty in carrying out complex movements. This results in breaking of an act into its components.
- **Macrographia:** Writing may be larger than normal (contrast with micrographia of Parkinson’s disease).
- **Rapid alternating movements:** Inaccuracies in rapidly repeated movements (dysdiadochokinesia). This is demonstrated by getting the patient to tap back of their own hand repeatedly with the other hand, or to tap their foot on the floor.
- **Tremor:** Unilateral or bilateral intention tremor, or a truncal tremor.
- **Nystagmus:** Coarse nystagmus, worse, on looking to the side of lesion with fast component towards the affected side.
- **Pendular knee jerk:** The reflexes are less brisk and slower in rise and fall. This produces pendular jerk at the knee. It produces three or more swings at the knee when the knee reflex is elicited with patient in sitting posture and the legs hanging from bedside.
- **Nausea and vomiting:** Sudden vomiting (without warning) after a positional change, without preceding nausea, is suggestive of a posterior fossa lesion.

### **Box 15.34:** Mnemonic for cerebellar signs- DANISH.

- **D**ysdiadochokinesia and **D**ysmetria
- **A**taxia
- **N**ystagmus
- **I**ntention tremor
- **S**lurred speech
- **H**ypotonia

**Q. Write a short note on Romberg's sign/test (Romberg's test is a test for Sensory Ataxia).**

- **Romberg's test/sign:** Patient stands upright with the feet together (touching each other) and eyes closed. When there is proprioceptive or vestibular deficit, balance is impaired only when eyes are closed, and the patient may fall if not caught. Minimal lesions can be demonstrated by asking the patient to stand on his toes with eyes closed.

Principle of Romberg's test: It is based on the principle that an individual requires at least two of the three following senses to maintain balance while standing:

- Proprioception (the ability to know one's body in space)
- Vestibular function (the ability to know one's head position in space); and
- Vision (which can be used to monitor [and adjust for] changes in body position).

Mnemonic for cerebellar signs (Box 15.34).

## Hereditary Cerebellar Ataxia-Friedreich's Ataxia

- Most common form of inherited ataxia. Most common form degenerative ataxia caused by unstable trinucleotide GAA expansion in chromosome located on 9q. The protein involved is frataxin.
- It affects spinal cord-dorsal column, spinocerebellar tract and pyramidal tract. There is also loss of dorsal root ganglion cells with depletion of large myelinated fibers in peripheral nerves.
- Age of onset usually between 8 and 16 years.

### *Clinical Features*

- Progressive ataxia of gait (due to spinocerebellar tract involvement).
- Lower limb areflexia and later generalized areflexia.
- Leg weakness and extensor plantar responses (due to pyramidal tract involvement).
- Reduced vibration and joint position sense in lower limbs. It is due to involvement of dorsal column.
- Sensory axonal neuropathy detected on nerve conduction test.
- Other features: Dysarthria, scoliosis (Fig. 15.19), nystagmus, optic atrophy, deafness, diabetes, pes cavus and cardiomyopathy.

Causes of extensor plantar response with absent ankle jerk are listed in Box 15.35.

### *Investigations*

- **Nerve conduction study(NCS):** normal conduction velocity but small or

absent sensory nerve action potential (SNAP)

- CT and MRI normal cerebellar anatomy, cervical atrophy.
- DNA polymerase reaction to detect GAA expansion.

**Treatment: No definite treatment, physiotherapy and occupational therapy, spasticity is treated with baclofen, orthopedic advice and surgery**

## ***Spinocerebellar Ataxia (Late Onset Hereditary Ataxia)***

**Q Write short note on the clinical features of spinocerebellar ataxias.**

- Spinocerebellar ataxia (autosomal dominant cerebellar ataxia/ADCA) is an autosomal dominant disease that present with slowly progressive cerebellar symptoms. Sometimes with associated optic atrophy, ophthalmoplegia, pyramidal and extrapyramidal structure.
- MRI mostly shows olivopontocerebellar atrophy.

**Fig. 15.19:** Patient with scoliosis due to Friedreich's ataxia.

**Box 15.35:** Causes of extensor plantar response with absent ankle jerk.

- Friedreich's ataxia
- Motor neuron disease (ALS)
- Taboparesis in neurosyphilis
- HIV myeloneuropathy
- Subacute combined degeneration of cord (Vitamin B<sub>12</sub> deficiency)

- Hypocupremic myelopathy
- Conus-cauda lesion

## MOVEMENT DISORDERS

### Types of Movements

**Q. Write a short note on CNS disorders characterized by involuntary movements.**

- **Akathisia:** A subjective feeling of inner restlessness that is relieved by movements (e.g. crossing and uncrossing legs, rocking back and forth and pacing).
- **Asterixis:** Sudden periods of cessation of muscle contraction best seen when the patient's arms are extended in front. It is a negative myoclonus.
- **Athetosis:** Slow, sinuous, writhing movements, usually of the distal parts of the limbs.
- **Ballismus:** Wild flinging, movements that represent large amplitude proximal choreiform movements. Ballismus is often unilateral (hemiballismus).
- **Chorea:** Semipurposeful flowing movements that flit from one part of the body to another in a continuous and random pattern. Chorea can be defined as involuntary movements that are abrupt, unpredictable and nonrhythmic, resulting from a continuous random flow of muscle contractions.
- **Dyskinesia:** A general term for any excessive movement. The term dyskinesia is often used as an abbreviation for 'tardive dyskinesia' (repetitive oral movements often seen in patients taking certain psychiatric medications).
- **Dystonia:** Twisting movements that are often sustained for variable periods of time with a directional preponderance resulting in posturing.

Algorithmic approach to movement disorders is given in Flowchart 15.4.

**Q. Write a short note on myoclonus and its causes.**

- **Myoclonus:** Myoclonic movements are sudden, brief, shock-like involuntary movements, which are usually positive (caused by muscle contraction), but can sometimes be negative (due to brief loss or inhibition of muscular tonus, as in asterixis—for example, when caused by hepatic

encephalopathy [‘liver flap’] or in uremic encephalopathy) (Table 15.72).

- **Tics:** Tics are sudden and jerky movements, but in this case the keyword for recognition is the ‘stereotyped’ character of the recurrent movements. Repetitive, stereotypic movements or sounds that are suppressible and that relieve a feeling of inner tension.
- **Tremor:** Regular, oscillatory movements that may be present at rest or with action. Tremor is characterized by involuntary, rhythmic and sinusoidal alternating movements of one or more body parts.

**Q. Write a short note on hemiballismus.**

- **Hemiballismus:** Violent flinging movements of the limbs. It is usually unilateral, and hence called hemiballismus.

Cause of some important movement disorders are listed in Table 15.72.

## PARKINSON’S DISEASE

**Q. Describe the etiology, clinical features/manifestations, diagnosis and management of Parkinson’s disease.**

**Q. What is parkinsonism? How would you classify parkinsonism? Discuss the management of idiopathic parkinsonism.**

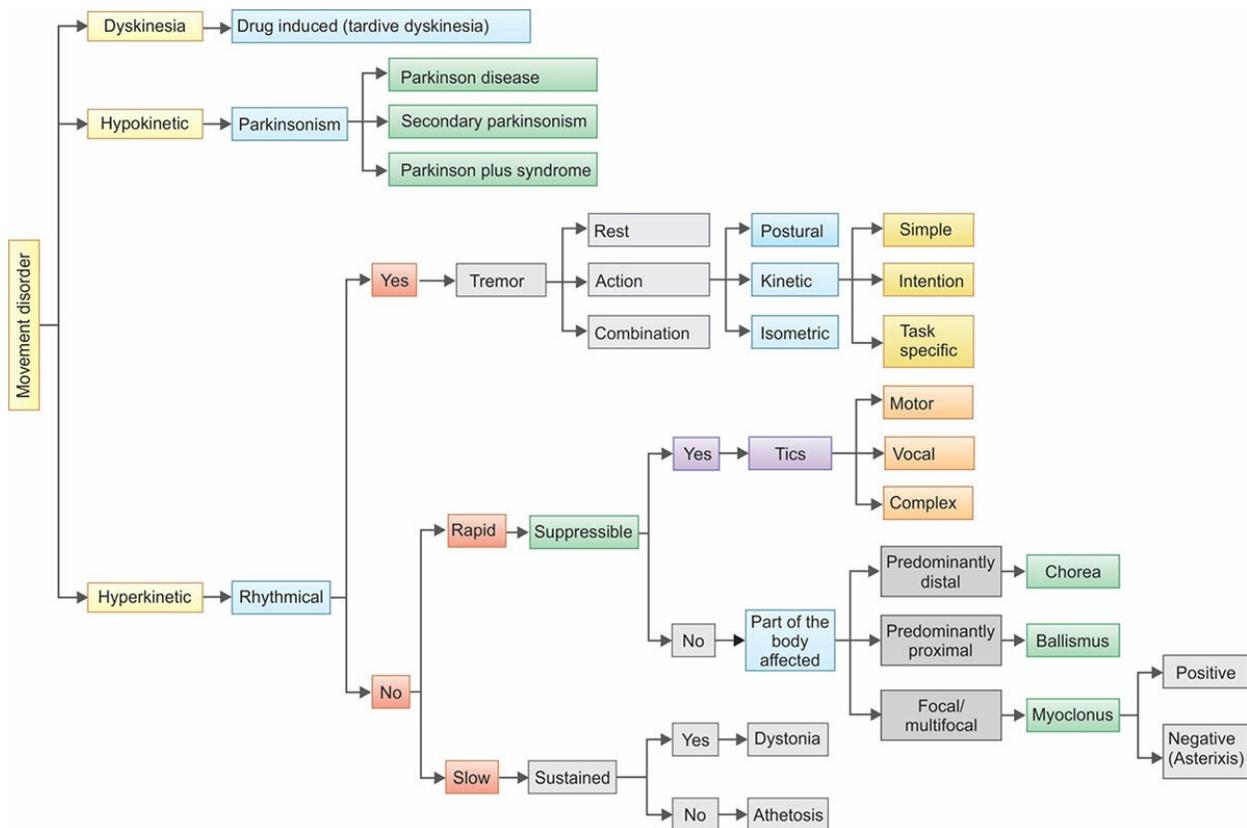

- **Parkinsonism** is a syndrome consisting of a variable combination of **tremor, rigidity, bradykinesia**, and a characteristic **disturbance of gait and posture**.
- **Classification of Parkinsonian disorders** (Flowchart 15.5): There are many causes for Parkinsonism but the most common cause is Parkinson’s disease (PD).

**Table 15.72:** Cause of some important movement disorders.

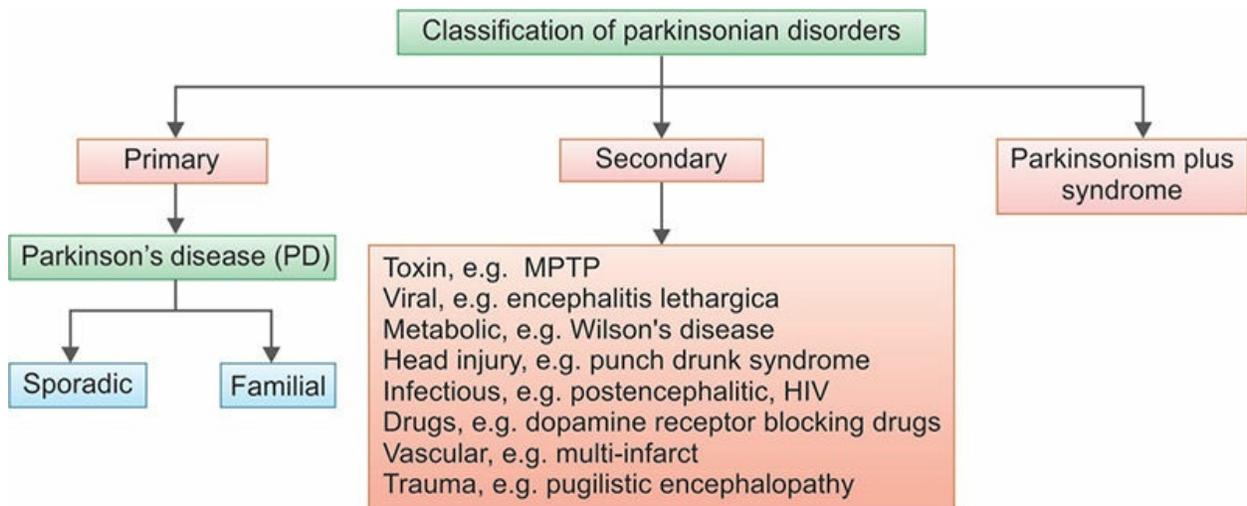

<i>Name of disorder</i>	<i>Causes</i>	<i>Treatment</i>
Asterixis	<ul style="list-style-type: none"><li>• Hepatic encephalopathy</li><li>• Uremic encephalopathy</li><li>• Carbon dioxide narcosis</li></ul>	Haloperidol, tetrabenazine

**Flowchart 15.4:** Algorithmic approach to movement disorders.

**Flowchart 15.5:** Classification of parkinsonian disorders.

(MPTP: manganese, 1-methyl 4-phenyl tetrahydropyridine)

## Idiopathic Parkinson's Disease (Paralysis Agitans)

- It is a chronic, **progressive disorder** in which **idiopathic parkinsonism** occurs without evidence of more widespread neurologic involvement.
- Parkinson's disease is distinct from other parkinsonian syndromes both clinically and pathologically.

- **Age and gender:** Its incidence increases sharply with age. Parkinson's disease (PD) generally commences in middle or late life and average age of onset is about 60 years. Prevalence is higher in men than women (M:F 1.5:1). It leads to progressive disability with time.

## ***Etiology***

Cause of idiopathic Parkinson's disease (PD) is not known. Probably multiple interacting environmental risk factors and genetic susceptibility plays a role.

- **Environmental factors:**
  - Small increased risk with rural living and drinking well water.
  - Pesticide exposure.
  - Oxidative stress: Chemical compound methyl-phenyl-tetrahydropyridine (MPTP) is a potent mitochondrial toxin. It causes severe Parkinsonism in young drug users of MPTP by producing oxidative stress leading to death of neuronal cell.
  - Nonsmokers have a higher risk of PD than smokers.
- **Genetic factors:** Genetic factors may play a role and several single genes causing parkinsonism have been identified.
  - **Sporadic:** Idiopathic PD is not usually familial, but there is a significant genetic component in early onset PD (onset before 40).
  - Mutations in many genes has been found in familial cases. Several genetic loci for Mendelian inherited monogenic forms of PD have been identified, designated as PARK 1–11. They are rare but cause early onset and familial PD.

## ***Pathological Features***

- **Hallmark of PD: Degeneration and depletion of the pigmented dopaminergic neurons** in the substantia nigra pars compacta (SNc), reduced striatal dopamine, and the presence of  $\alpha$ -synuclein and intracytoplasmic proteinaceous eosinophilic inclusions in nigral cells known as Lewy bodies.
- Probably environmental or genetic factors alter the  $\alpha$ -synuclein protein, rendering it toxic. This leads to formation of Lewy body within the nigral cells. Lewy bodies are also seen in the basal ganglia, brainstem and cortex. Lewy bodies contain tangles of  $\alpha$ -synuclein and ubiquitin. They become

gradually more widespread and increase as the disease progresses.

- The loss of dopaminergic neurotransmission in the nerve cells (>80%) in the substantia nigra and other nuclei in the midbrain responsible for the symptoms of Parkinson's disease.

## ***Clinical Manifestations***

λ. **Motor symptoms:** Always asymmetrical in onset and become bilateral within a year.

- **Tremor** is an early and presenting symptom in 70% of patients.
  - Frequency is 4–6 Hz tremor and is typically **most prominent at rest** and **worsens with emotional stress**.
  - Typically tremor starts with the fingers and hands at rest.
  - Often described as pill rolling of finger and wrist, because the patient appears to be rolling something between thumb and forefinger. It often begins with rhythmic flexion-extension of the fingers, hand, or foot, or with rhythmic pronation-supination of the forearm. Initially, it may be confined to one limb or to the two limbs on one side before becoming more generalized. It also affects jaw and chin, but not the head.
  - Disappear on voluntary movement and sleep.
- **Rigidity**
  - It is a sign rather than a symptom. Increased **resistance to passive movement** is characteristic clinical feature that accounts for the flexed posture of many patients. Rigidity causes stiffness and a flexed posture.
  - Stiffness on passive limb movement is described as **'lead pipe'** rigidity because the increase in muscle tone is present throughout the range of movement. Unlike spasticity, it is not dependent on speed of movement.
  - When tremor is superimposed on the rigidity, a ratchet like jerkiness is felt, described as **'cogwheel' rigidity**.
- **Akinesia or bradykinesia**
  - Poverty/slowing of movement are the hallmark **of PD**. **Slowness**/difficulty of initiating **voluntary movement** and an associated **reduction in automatic movements**, such as swinging

of the arms when walking.

- There is **fixity of facial expression** (facial immobility—**mask like face**) (Fig. 15.20), with widened palpebral fissures and infrequent blinking.
- Repetitive tapping (at about 2 Hz) over the glabella (Glabellar tap) produces a sustained blink response (**Myerson's sign**), in contrast to the response of normal subject. Frequency of spontaneous blinking decreases producing a serpentine stare.

**Fig. 15.20:** Mask like facies in Parkinson's disease.

- The **combination of tremor, rigidity, and bradykinesia** results in small, tremulous, and often **illegible/difficult handwriting (micrographia)**. It results in difficulty in activities such as tying shoelaces or buttoning, and difficulty rolling over in bed.
- **Postural changes:** A stooped posture is characteristic feature.
- **Gait changes:** Slow shuffling, freezing and reduced arm swing, small stride length, slow turns, festinating gait (tendency to advance rapid short steps) and catching center of gravity. Feet may be glued to floor. Postural instability and freezing may result in fall forward. Reduced eye blink.
- **Speech and swallowing:** Speech becomes softer (soft voice-

hypophonia), quiet, indistinct, flat/monotonous and stuttering. Increased salivation/drooling, and dysphagia (swallowing difficulty is a late feature) which may lead to aspiration pneumonia as a terminal event.

- **Cognitive and psychiatric changes:** Cognitive impairment/dementia, depression, sleep disturbances may be present.

### 3. Nonmotor features (Table 15.73)

Some non-motor symptoms (NMS) may precede the onset of more typical motor symptoms.

**Table 15.73: Nonmotor symptoms of Parkinson’s disease.**

<b>Autonomic dysfunction</b> <ul style="list-style-type: none"> <li>• Orthostatic hypotension</li> <li>• Urinary incontinence</li> <li>• Constipation</li> <li>• Sexual problems</li> </ul>	<b>Neuropsychiatric</b> <ul style="list-style-type: none"> <li>• Anxiety</li> <li>• Depression</li> <li>• Apathy</li> <li>• Psychosis</li> <li>• Dementia</li> </ul>	<b>Sensory problems</b> <ul style="list-style-type: none"> <li>• Reduces sense of smell (hyposmia)</li> <li>• Pain</li> </ul>
<b>Sleep disorders</b> <ul style="list-style-type: none"> <li>• Restless legs</li> <li>• Insomnia</li> <li>• Daytime somnolence</li> </ul>	<b>Rheumatological</b> <ul style="list-style-type: none"> <li>• Frozen shoulder</li> <li>• Periarthritis</li> <li>• Swan neck deformity</li> </ul>	<b>Other</b> <ul style="list-style-type: none"> <li>• Seborrhea</li> </ul>

### *Investigation/Diagnosis*

- Diagnosis is made on **clinical grounds**.
- **Structural imaging** (CT or MRI) is **usually normal**.
- **Functional dopaminergic imaging:** By single photon emission computed tomography (SPECT) or positron emission tomography (PET) is **abnormal** and shows reduced uptake of striatal dopaminergic markers, particularly in the posterior putamen. However, it is not specific for PD.
- **Dopamine transporter (DaT) imaging:** It is performed by the use of a radiolabelled ligand binding to dopaminergic terminals to know the extent of nigrostriatal cell loss. It may be rarely required to distinguish PD from other causes of tremor, or drug-induced parkinsonism.

Stages of Parkinson’s disease (Table 15.74).

**Table 15.74: Hoehn and Yahr stage of Parkinson's disease.**

<i>Stage</i>	<i>Disease state</i>
--------------	----------------------

I	Unilateral involvement only, minimal or no functional impairment
II	Bilateral or midline involvement, without impairment of balance
III	First sign of impaired righting reflex, mild to moderate disability
IV	Fully developed, severely disabling disease; patient still able to walk and stand unassisted
V	Confinement to bed or wheelchair unless aided

**Q. What are the stages of Parkinson's disease?**

**Differential Diagnosis**

1. **Secondary parkinsonism** (Table 15.75).

**Table 15.75: Causes of secondary parkinsonism.**

<p><b>Toxin:</b> Manganese, 1-methyl 4-phenyl tetrahydropyridine (MPTP), carbon monoxide, manganese, mercury, carbon disulfide, cyanide, methanol</p> <p><b>Viral:</b> Encephalitis lethargica, Creutzfeldt-Jakob disease</p> <p><b>Metabolic:</b> Wilson's disease</p> <p><b>Head injury:</b> Punch drunk syndrome</p> <p><b>Infectious:</b> Postencephalitic, HIV, SSPE, Prion diseases</p>	<p><b>Drugs:</b> Dopamine receptor blocking drugs, reserpine, tetrabenazine, alpha methyl dopa, lithium, flunarizine, cinnarizine</p> <p><b>Vascular:</b> Multi-infarct, Binswangers disease</p> <p><b>Trauma:</b> Pugilistic encephalopathy</p> <p><b>Others:</b> Parathyroid abnormalities, hypothyroidism, brain tumors, paraneoplastic, normal pressure hydrocephalus (NPH), psychogenic</p>
---	--

2. **Parkinson-plus syndromes** (Table 15.76).

**Fig. 15-21: Reptilian stare in progressive supranuclear palsy (PSP).**

**Q. What are the ‘Parkinson plus’ syndromes?**

**Table 15.76: Parkinson plus syndromes and its features.**

<i>Syndrome</i>	<i>Features</i>
<b>Progressive supranuclear palsy (PSP, Steele-Richardson-Olszewski syndrome)</b>	Slow ocular saccades, eyelid apraxia, and restricted eye movements with particular impairment of downward gaze and reptilian stare (Fig. 15.21). Frequently experience hyperextension of the neck with early gait disturbance and falls. MRI may reveal a characteristic atrophy of the midbrain with relative preservation of the pons (the ‘hummingbird sign’ on mid-sagittal images)
<b>Multiple-system atrophy (MSA)</b>	Parkinsonism in conjunction with cerebellar signs and/or early and prominent autonomic dysfunction, usually orthostatic hypotension. Cerebellar and brainstem atrophy (the pontine ‘hot cross buns’ sign in MSA-c)
<ul style="list-style-type: none"> <li>• Parkinsonian (MSA-P) or striatonigral degeneration</li> <li>• Cerebellar (MSA-C) or olivopontocerebellar atrophy</li> <li>• Autonomic (MSA-A) form or Shy-Drager syndrome</li> </ul>	
<b>Corticobasal ganglionic degeneration (Rebeitz-</b>	Asymmetric dystonic contractions and

Kolodny-Richardson syndrome)	clumsiness of one hand coupled with cortical sensory disturbances manifest as apraxia, agnosia, focal myoclonus, or alien limb phenomenon
<b>Dementia with lewy bodies</b>	Early onset dementia, visual hallucinations
<b>Parkinsonism-dementia complex of Guam</b>	Motor neuron disease plus Parkinson's
<b>Guadeloupean parkinsonism</b>	Levodopa-unresponsive parkinsonism, postural instability with early falls, and pseudobulbar palsy

## Q. Write a short essay/note on drugs used in Parkinson's disease.

### Treatment

**A. Symptomatic pharmacologic treatment:** Drug treatment in PD is symptomatic rather than curative. None of the currently available drugs are neuroprotective.

- **Anticholinergic drugs**
  - Nonselective muscarinic antagonists are helpful, especially in **relieving tremor**. For example, **trihexyphenidyl, benztropine, and orphenadrine**.
  - Treatment is started with small dose (2 mg), which is gradually built up until benefit occurs or side effects limit further increments.
  - **Adverse effects:** Urinary retention, dry mouth, blurred vision, worsening of glaucoma, constipation, confusion and hallucinosis in elderly. Hence, rarely used as first-line drugs unless patient has severe tremors. They should be avoided in patient above 65 years of age.
- **Levodopa**
  - Levodopa, the metabolic precursor of dopamine. It is the single **most effective drug** available for the treatment. It **provides symptomatic benefit** in most patients with parkinsonism and is often particularly helpful in **relieving bradykinesia**. Resolve hypokinesia and rigidity first and tremor later. Levodopa is metabolized by MAO (monoamine oxidase) and COMT (catechol-O-methyl-transferase). Its plasma half-life is around two hours. Early use lowers mortality rate. Combined with a dopa decarboxylase inhibitor—benserazide (cobeneldopa) or carbidopa (cocareldopa) to reduce the adverse effects (e.g. nausea and hypotension).
  - **Adverse drug reactions:**
    - ◆ Postural hypotension, fluctuations in response.
    - ◆ Mydriasis, brownish discoloration of the urine, abnormal smell, transient elevations of transaminases and BUN.
    - ◆ GIT effects: Nausea and vomiting.
    - ◆ Cardiovascular: Tachycardia, ventricular extrasystoles, atrial fibrillation.
    - ◆ Dyskinesias, behavioral disturbances.
  - **'On/off' effect:** Important late complications of levodopa therapy. It is like a light switch; without warning, all of a sudden, person goes from full control to complete reversion back to bradykinesia, tremor, etc. It lasts from 30 minutes to several hours and then get control again. The on-off phenomenon can be controlled in part by reducing dosing, intervals, administering levodopa 1 hour before meals and restricting dietary protein intake or treatment with dopamine agonists.
- **MAO-B Inhibitors**

- Monoamine oxidase type B **facilitates breakdown of excess dopamine** in the synapse. They produce **asymptomatic motor benefit** when used as a monotherapy and **enhance the efficacy of carbidopa levodopa formulations** when used as adjuncts voided, e.g. selegiline, rasagiline.
- The addition of selegiline, a monoamine oxidase B inhibitor, reduces the metabolic breakdown of dopamine and may slow down the degeneration in the substantia nigra.
- **Dopamine receptor agonists**
  - Dopamine receptor agonists are classified as ergot derived (**bromocriptine, pergolide and cabergoline**) or non-ergot derived (**pramipexole, ropinirole, rotigotine and apomorphine**).
  - **Side effects:** Produce impulse control disorders (e.g. pathological gambling, binge eating and hypersexuality) and daytime somnolence. Dopamine agonists are contraindicated in patients with psychotic disorders and are best avoided in those with recent myocardial infarction, severe peripheral vascular disease, or active peptic ulceration.
  - Ergot-derived agonists are no longer recommended because of rare but serious fibrotic side effects including cardiac valvular fibrosis.
  - Nonergot dopamine agonists are preferable to ergot-derived dopamine agonists. They are used as an alternative or an addition to levodopa therapy.

**Q. Write a short note on COMT (Catechol-O-methyltransferase) inhibitors.**

- **COMT (Catechol-O-methyltransferase) inhibitors**
  - Catechol-O-methyl-transferase produces peripheral breakdown of levodopa (e.g. **entacapone and tolcapone**). Entacapone prolongs the duration of levodopa by decreasing its peripheral metabolism. The more potent tolcapone is less preferred because of rare but serious hepatotoxicity.
- **Dopamine facilitator**
  - **Amantadine:** It is an antiviral agent that potentiates dopaminergic function by influencing the synthesis, release, reuptake of dopamine. It has a mild antiparkinsonian effect and short-lived effect on bradykinesia. Hence, it is rarely used and are reserved for patients who are unable to tolerate other drugs. Amantadine-either alone or combined with an anticholinergic agent, helpful for mild parkinsonism. It acts by potentiating the release of endogenous dopamine.
  - **Adverse effects:** Livedo reticularis, peripheral edema, confusion and other anticholinergic effects.
- **Peripheral dopamine decarboxylase inhibitors (PDI)**
  - It does not penetrate the BBB (blood brain barrier); reduce the peripheral metabolism of levodopa. Increase plasma levels of levodopa, prolongs the plasma half-life of levodopa, increase available amounts of dopa for entry into the brain and reduce the daily requirement of levodopa by 75%. For example, **carbidopa, benseraside**.
- **Neuroprotective agents that alter pathogenesis**
  - MAO inhibitors: Selegiline and rasagiline
  - Antiexcitotoxicity drugs: Riluzole
  - Bioenergetic antioxidant agent, coenzyme Q10
  - Antiapoptotic kinase inhibitors (e.g. CEP-1347)
  - Adenosine A2A receptor antagonists (e.g. istradefylline).

**B. Surgical Treatment**

- **Indications:** Most common indications for surgery in PD are intractable tremor and drug-

induced motor fluctuations or dyskinesias.

- Different surgeries are:
  - **Stereotactic surgery** (ventrolateral thalamotomy) tried in unilateral cases.
  - **Pallidotomy** improves tremor and dyskinesia
  - **Deep brain stimulation (DBS)**: Stereotactic insertion of electrodes into the brain is most often performed bilaterally and simultaneously. **Best site is subthalamic nucleus.** DBS in these areas alleviates Parkinsonian motor signs particularly during the off periods and reduces troublesome dyskinesias, dystonia and motor fluctuations that result from drug administration. DBS is usually reserved for patients with medically refractory tremor or motor fluctuations.
  - Neurotransplantation of embryonic mesencephalic dopaminergic cells directly into the putamen.
  - Intracranial delivery of fetal cell transplantation or specific growth factors is and gene therapy in the experimental stage and stem cells.

## ***Characteristic Features of Extrapyrarnidal Lesion (Table 15.77)***

**Q. Write short note on characteristic features of extrapyramidal lesion.**

**Table 15.77:** Characteristic features of extrapyramidal lesion.

<b><i>Sign</i></b>	<b><i>Site of lesion</i></b>
Resting tremor	Substantia nigra, red nucleus
Muscular rigidity	Substantia nigra, putamen
Hypokinesia	Substantia nigra, globus pallidum
Chorea	Caudate nucleus
Hemiballismus	Subthalamic nucleus
Dystonia, athetosis	Putamen

## **CHOREA**

**Q. Write a short note on chorea and mention the disease which causes chorea.**

### **General Features**

- Irregular, semipurposeful, abrupt, rapid, brief, jerky, unsustained movements that flow randomly from one part of the body to another. These movements disappear during sleep.
- When choreic movements are more severe, assuming a flinging, sometimes violent, character, they are called ballism.

## Causes of Chorea (Table 15.78)

**Table 15.78:** Causes of chorea.

**Rheumatic** (Sydenham's chorea)

**Huntington's chorea**

**Encephalitis**, e.g. Japanese encephalitis, measles, mumps

**Vascular**, e.g. HIV-related (toxoplasmosis, progressive multifocal leukoencephalopathy, HIV encephalitis)

**Immunologic**, e.g. systemic lupus erythematosus, antiphospholipid antibody syndrome, paraneoplastic syndromes, acute disseminated encephalomyelopathy, celiac disease

**Drugs**, e.g. L-dopa, oral contraceptive, phenytoin

Degenerative disorders of the brain

Benign hereditary

Pregnancy (Chorea gravidarum)

Endocrine-metabolic dysfunction, e.g. adrenal insufficiency, hyper/hypocalcemia, hyper/hypoglycemia, hypernatremia, liver failure

Miscellaneous, e.g. anoxic encephalopathy, cerebral palsy, kernicterus, multiple sclerosis, post-traumatic

### Signs in Chorea

- Involuntary protrusion and retraction of the tongue (**jack in the box**).
- Inability to hold the hands above head with palms facing each other as it results in pronation of arms so that palms face outwards (**pronator sign**).
- Milking action of patient's fingers if asked to grasp the physician's fingers (**milk-maid sign**).

### Sydenham's Chorea (Saint Vitus Dance)

- **Most common cause of chorea in children.**
- It is self-limiting condition, non-suppurative **complication of group A  $\beta$ -hemolytic streptococcal pharyngitis**. It follows acute rheumatic fever by 4–6 months. Severity varies and disorder may continue for a few months.
- It is due to molecular mimicry between streptococcal and central nervous system antigens. Infection by group A  **$\beta$ -hemolytic streptococci** in genetically predisposed individual leads to formation of cross-reactive antibodies. These antibodies disrupt the basal ganglia function. Inflammation is seen in caudate nucleus.
- **Clinical features:** It is a **neuropsychiatric disorder**. Clinical features include both **neurological abnormalities** (chorea, weakness and

hypotonia) and **psychiatric disorders** (such as emotional liability, hyperactivity, distractibility, obsessions and compulsions). These abnormalities lead to inability to perform normal activities of daily living (ADL) including eating, talking, dressing, writing, walking, learning and socializing, and thus impact negatively on the child's quality of life.

- **Common sign is motor impersistence.** It can be demonstrated by an inability to sustain eye closure or tongue protrusion.
- Evaluation for valvular heart disease is a must. Antistreptolysin-O (ASLO) titers and ESR are often normal.

#### **Treatment**

##### ***Symptomatic***

- **Sodium valproate** 200–600 mg TID is the first line drug.
- If valproate is not effective, risperidone, a potent dopamine D2 receptor blocker, may be given to control chorea. The dose is 1–2 mg BID.
- Haloperidol 0.5–1.5 mg BD or TID is used occasionally.
- Other drugs include pimozide, carbamazepine, clonidine and phenobarbital.
- Penicillin prophylaxis is necessary to reduce risk of cardiac involvement due to future streptococcal infections.

## **Huntington's Disease/Chorea (HD)**

**Q. Write a short essay on the transmission and clinical features of Huntington's disease.**

Huntington's disease is a progressive, fatal, highly penetrant autosomal dominant disorder characterized by motor, behavioral, and cognitive dysfunction. Onset is typically between the ages of 25 and 45 years.

### ***Etiology***

- Huntington's disease is caused by an **increase in the number of polyglutamine (CAG) repeats (>40)** in the coding sequence of the huntingtin gene located on the short arm of chromosome 4.
- The disease manifests earlier if the number of repeats are larger.
- The gene encodes the highly conserved cytoplasmic protein huntingtin, which is widely distributed in neurons throughout the CNS, but its function is not known.

### ***Manifestations***

- **Early stages:** Chorea tends to be focal or segmental, but progresses over time to involve multiple body regions. Dysarthria, gait disturbance, and oculomotor abnormalities are common features.
- **Advancing disease:** There may be a reduction in chorea and emergence of dystonia, rigidity, bradykinesia, myoclonus, and spasticity.
- HD patients eventually develop behavioral and cognitive disturbances, and the majority progress to dementia. Depression with suicidal tendencies, aggressive behavior, and psychosis can be prominent features.

#### Treatment

Multidisciplinary approach, with medical, neuropsychiatric, social, and genetic counseling for patients and their families.

- Medical:
  - HD chorea is self-limited and is usually not disabling.
  - Psychosis can be treated with atypical neuroleptics. Depression and anxiety is treated with appropriate antidepressant and anti-anxiety drugs.
  - No adequate treatment for the cognitive or motor decline.
  - Promitochondrial agents such as ubiquinone and creatine are being tested as possible disease-modifying therapies.

## TREMOR

**Q. Write a short note on definition of tremor and mention its types with examples.**

Tremor is an unintentional, **rhythmic** muscle movement involving **to-and-fro** movements (oscillations) of one or more parts of the body produced by alternating or synchronous contractions of antagonist muscles. It is the most common of all involuntary movements and can affect the hands, arms, head, face, voice, trunk, and legs.

### Causes of Tremor (Table 15.79)

**Table 15.79:** Causes of tremor.

<b>Physiological:</b> Anxiety	<b>Drug induced:</b> Amphetamine, steroids
<b>Drugs:</b> Beta agonists, alcohol	<b>Alcohol withdrawal,</b> liver failure
<b>Intention tremor:</b> Cerebellar lesion	<b>Mercury poisoning</b>
<b>Thyrotoxicosis</b>	Wilson's disease (wing beating tremor)

### Types/Nature of Tremor

- **Resting tremor** occurs when the muscle is relaxed. For example, tremor occurring when the hands are lying on the lap or hanging next to the trunk while standing or walking. It may be shaking of the limb, even when the individual is at rest. It is usually observed only in the hand or fingers and is seen in Parkinson's disease.
- **Action tremor** is detected during any type of movement of an affected body part. There are several subtypes of action tremor.
- **Postural tremor** occurs when an individual maintains a position against gravity. For example, holding the arms outstretched.
- **Kinetic tremor** occurs during movement of a part of the body. For example, moving the wrists up and down.
- **Intention tremor** is present during a purposeful movement toward a target. For example, touching a finger to one's nose during a medical examination.
- **Task-specific tremor** occurs when performing highly skilled, goal-oriented tasks. For example, as handwriting or speaking.
- **Isometric tremor** occurs during a voluntary muscle contraction that is not accompanied by any movement.

## Classification

Tremor is most commonly classified by its appearance and cause or origin.

- **Essential tremor (benign essential tremor):** It is the most common of the forms of abnormal tremor.
  - It may be mild and nonprogressive or slowly progressive. **Most commonly observed in the hands** but may involve the head, voice, tongue, legs, and trunk. Tremor of the hands is typically present as an action tremor.
  - **Triggers:** Heightened emotion, stress, fever, physical exhaustion, or low blood sugar may trigger tremors and/or increase their severity. It decreases on alcohol consumption.
- **Parkinsonian tremor** is characteristically as a resting tremor (refer page 1010).
- **Dystonic tremor** occurs in individuals affected by dystonia. It may affect any muscle. Dystonic tremors occur irregularly and often relieved by complete rest.

- **Cerebellar tremor** is a slow tremor of the extremities that occurs at the end of a purposeful movement (intention tremor). For example, trying to press a button or touching a finger to the tip of one's nose.
  - Caused by lesions in or damage to the cerebellum, e.g. stroke, tumor, or multiple sclerosis. Cerebellar damage can also result in a 'wing-beating' type of tremor which is a combination of rest, action, and postural tremors. Cerebellar tremor may be associated with dysarthria (speech problems), nystagmus (rapid involuntary movements of the eyes), gait problems, and postural tremor of the trunk and neck.
- **Psychogenic tremor** (functional tremor) can appear as any form of tremor movement. The characteristics may vary but generally include sudden onset and remission, increased incidence with stress. Many individuals have a conversion disorder or psychiatric disease.
- **Orthostatic tremor** detected as rhythmic muscle contractions in the legs and trunk immediately after standing.
- **Physiologic tremor** occurs in every normal individual. It may be exaggerated by strong emotion (such as anxiety or fear), physical exhaustion, etc. It is generally not caused by a neurological disease.
  - Rubral tremor/Holme's tremor—seen in midbrain lesions.

## ORGANIC BRAIN SYNDROME

**Q. Write a short note on organic brain syndrome (OBS).**

It is an abnormal mental state characterized by changes in orientation, memory, judgment and affect. It is due to diffuse impairment of brain tissue.

- The two most important types of OBS are delirium (refer page 1086) and dementia is discussed on page 1145.

## COMA

**Q. How would you investigate and manage a 50-year-old patient presenting with coma?**

### Definitions

#### *Consciousness*

- It means the state of patient's awareness of self and environment and his responsiveness to external stimulation and inner need.
- Consciousness is maintained by two separate anatomical and physiological systems:
  - Ascending reticular activating system (ARAS) projecting from brainstem to thalamus determines arousal (the level of consciousness).
  - Cerebral cortex determines the content of consciousness.

### ***Confusion***

- Traditionally referred as '**clouding of sensorium**'.
- It denotes inability to think with customary speed, clarity and coherence, accompanied by some degree of inattentiveness and disorientation.
- Confusion results most often from process that influences the brain globally, such as toxic or metabolic disturbance or a dementia.

### ***Drowsiness***

- The inability to sustain a wakeful state without application of stimuli externally is called drowsiness.
- Slow arousal is elicited by speaking to the patient or applying a tactile stimulus.

### ***Stupor***

- A state in which the person can be aroused only by repeated vigorous stimuli is called as stupor.
- There is either absence or slow and inadequate response to spoken commands.
- It is common to find restless or stereotyped motor activity. In these patients there is a reduction in the natural shifting of positions.
- When left unstimulated, these patients quickly return to a sleep-like state.

### ***Coma***

Coma is a condition characterized by a deep sleep like stage from which the patient cannot be aroused even with vigorous, continuous stimulation. The patient does not make any localized responses. However, the patient may grimace or show withdrawal responses to painful stimuli.

### **Classification of Coma (Table 15.80)**

**Q. Write a short essay/note on causes of coma.**

**Table 15.80: Classification of coma.**

**Coma without focal signs or meningism**

- **Exogenous intoxicants:** Alcohol, barbiturate, opiates
- **Endogenous metabolic disturbances:** Anoxia, hypoglycemia, diabetic ketoacidosis (DKA), hyperosmolar non-ketotic state (HONK), uremia, hepatic failure, hyponatremia or hypernatremia, Addisonian crisis, carbon monoxide poisoning, myxedema
- **Severe systemic infections:** Septicemia, typhoid fever, cerebral malaria, pneumonia, peritonitis, Waterhouse Friedrichsen syndrome
- **Circulatory collapse** (shock) from any cause
- **Postseizure states**
- Hypertensive encephalopathy
- Hyperthermia and hypothermia
- Concussion
- Acute hydrocephalus

**Coma with meningism**

- Subarachnoid hemorrhage (SAH)
- Acute bacterial meningitis
- Viral meningoencephalitis
- Neoplastic meningitis
- Parasitic meningitis
- Pituitary apoplexy

**Coma with focal signs**

- Hemispherical hemorrhage or massive cerebral infarction
- Brainstem infarction
- Brain abscess, subdural empyema, herpes encephalitis
- Epidural and subdural hemorrhage, brain contusion
- Brain tumor
- Miscellaneous: TTP, fat embolism, ADEM, cortical vein thrombosis, focal infarction caused by bacterial endocarditis

## Approach to a Patient with Coma

**Q. How do you proceed to investigate and manage a case of coma?**

### *History*

- Enquire about history of diabetes, hypertension, head injury, convulsions, alcohol or drug use, circumstances in which patient was found, medications in hospitalized patient like anesthetics, sedatives,

antiepileptic, opiates, antidepressants, antipsychotics.

## ***Onset of Coma***

- Sudden onset of coma would suggest a vascular cause possibly SAH or brainstem involvement.
- Rapid progression from hemispheric signs to coma: Intracerebral hemorrhage.
- Protracted course: Tumor, abscess, chronic SDH.
- Altered sensorium (delirium) preceding coma, with no focal neurological deficits indicates metabolic encephalopathy.

### **General Examination**

- **Signs of trauma:** (a) Raccoon eyes, (b) Battle's sign and (c) CSF rhinorrhea or otorrhea
- **Blood pressure:**
  - Hypertension suggests: (a) hypertensive encephalopathy or (b) intracerebral hemorrhage
  - Hypotension suggests: (a) myocardial infarction, (b) septicemia, (c) Addison disease, (d) alcohol or barbiturate intoxication, (e) internal hemorrhage.
- **Pulse:** Bradycardia with periodic breathing and hypertension (Cushing reflex) suggests raised ICP.
- **Temperature:**
  - **Hypothermia** suggests: (a) alcohol or barbiturate intoxication, (b) myxedema, (c) advanced tubercular meningitis, (d) peripheral circulatory failure
  - **Hyperthermia** suggests: (a) systemic infection, (b) meningoencephalitis, (c) heatstroke, (d) anticholinergic drugs abuse
- **Signs of meningeal irritation:** (a) Meningitis, (b) SAH
- **Fundus:** Raised ICP (papilledema), subhyaloid hemorrhages (SAH), and hypertensive encephalopathy.
- **Smell of breath:** For ketones, alcohol and hepatic fetor.
- **Skin inspection:**
  - Rash suggests meningococemia, staphylococcal endocarditis, typhus, rocky mountain spotted fever (RMSF)
  - Excessive sweating suggest hypoglycemia or shock
  - Diffuse petechiae suggest TTP, DIC, fat embolus

## ***Neurological Assessment***

- Neurological assessment is done to determine the depth of coma (GCS), brainstem function, and lateralization of pathology.
- Observation first without examiner intervention.
- Observe the posture of the limb, position of the eyes and head, spontaneous movement, pattern of respiration.
- Yawning and spontaneous shifting of body position indicates minimal

degree of unresponsiveness.

- Multifocal myoclonus almost always indicates metabolic disorder.
- Assess responsiveness by noting patient’s reaction to calling his name, or to noxious stimuli such as supraorbital or sternal pressure.

## Evaluation of Severity of Coma (Tables 15.81 and 15.82)

**Table 15.81: Edinburgh classification of coma.**

Grade 0 : Fully conscious
Grade 1: Drowsy, but responds to verbal command
Grade 2: Unconscious, but responds to minimal pain stimulus
Grade 3: Unconscious, but responsive to strong pain stimulus
Grade 4: Unconscious, with no response to pain.

**Table 15.82: Glasgow coma score (GCS).**

	Score
<b>Eye opening (E)</b>	
• Spontaneous	4
• To speech	3
• To pain	2
• None	1
<b>Best motor response (M)</b>	
• Obeys (normal)	6
• Localizes (localized to pain)	5
• Withdraws to pain	4
• Abnormal flexion	3
• Abnormal extension	2
• None	1
<b>Verbal response (V)</b>	
• Oriented normal conversation	5
• Confused (disoriented) conversation	4
• Inappropriate words	3
• Incomprehensible sounds (no words, only sounds)	2
• None	1
Coma Score = E + M + V	

Always present GCS as breakdown, not a sum score (unless 3 or 15). Score < 8 indicates severe injury.

- Minimum sum: Deeply comatose = 3
- Maximum sum: Fully conscious = 15

**Q. Write short essay/note on Edinburgh classification of coma.**

**Q. Write short essay/note on Glasgow coma scale.**

### ***Newer Scales for Prognosis of Coma***

**FOUR** (Full Outline of Unresponsiveness) SCALE

New Coma Scale is devised in 2005, Four components (Eye, motor, brainstem, respiration)

Each component has maximum of score of four.

**AVPU:** Alertness, response to Verbal stimuli, response to Painful stimuli, or Unresponsive

**ACDU:** Alertness, Confusion, Drowsiness, and Unresponsiveness

**Grady Scale:** Scale of I to V along a scale of confusion, stupor, deep stupor, abnormal posturing, and coma.

### ***Stages of Coma***

- Grade I: Individuals who respond with recognition when their name is called and **do not lapse into sleep** when left undisturbed.
- Grade II: The person lapses into sleep when undisturbed and is aroused only when **a pin is tapped gently over the chest wall.**
- Grade III: Patient who winces in response to deep pain stimulus. Deep pain stimulus **may result in abnormal postural reflexes either unilateral or bilateral.**
- Grade IV: Deep pain stimulus may result in **decorticate or decerebrate** posturing.
- Grade V: The patient who maintains a state of **flaccid unresponsiveness inspite of deep pain stimulation.**

### ***Posture in Comatose Patient***

- **Decerebrate rigidity:** It consists of opisthotonus, clenching of jaws, stiff extension of limbs with internal rotation of arms and plantar flexion of feet. Extensor posturing arises in variety of settings: Midbrain compression, cerebellar lesions, metabolic, drug intoxication, etc.
- **Decorticate rigidity:** Arms in flexion and adduction and legs extended signify lesion rostral to midbrain.
- Extensor posture of arms with weak flexor responses of legs is seen with lesions at level of vestibular nuclei.

## **Brainstem Reflexes (Brainstem Function) (Box 15.36)**

### **Box 15.36: Brainstem reflexes.**

- Pupillary size and reactivity
- Ocular movements
- Corneal responses

- Ocular-vestibular reflexes
- Pattern of breathing (respiratory pattern)

**Q. Write short note on brainstem reflexes.**

As a rule, when these brainstem activities are preserved, particularly the pupil reactions and eye movements, coma must be ascribed to bilateral hemispherical disease. However, a mass in the hemispheres may cause coma and also produce herniation.

## Pupillary Reactions (Table 15.83 and Fig. 15.22)

**Table 15.83:** Interpretation of pupillary reactions.

<i>Pupillary reactions</i>	<i>Interpretation</i>
• <b>Symmetrically reactive round pupils</b>	• Exclude midbrain damage
• <b>Enlarged and unreactive pupil (&gt;5 mm)</b>	• Intrinsic midbrain lesion (ipsilateral) or by ipsilateral mass
• <b>Oval and slightly eccentric pupils</b>	• Early midbrain or third nerve compression
• <b>Bilateral dilated and unreactive pupils</b>	• Severe midbrain damage by transtentorial herniation or anticholinergic drugs toxicity (atropine, TCA)
• <b>Dilatation of one pupil</b> that then becomes fixed to light	• Compression of the III cranial nerve and is a neurosurgical emergency
• <b>Reactive bilaterally small but not pinpoint (1–2.5 mm)</b>	• Metabolic encephalopathy or thalamic hemorrhages
• <b>Bilateral pinpoint (very small less than 1 mm) but reactive pupil</b>	• Opioid or barbiturate overdose or bilateral pontine hemorrhage
• <b>Bilateral midpoint reactive pupils</b> (i.e. normal pupils)	• Metabolic comas, coma due to sedative drugs except opiates
• <b>Bilateral light fixed, dilated pupils</b>	• Cardinal sign of brain death in deep coma of any cause, but particularly in barbiturate intoxication and hypothermia

## Eye Movements and Position (Fig. 15.23)

- In light coma of metabolic origin, eyes wander conjugately from side to side in random fashion. These movements disappear as coma deepens.
- **Adducted eye at rest:** 6th nerve palsy. If it is bilateral it is due to raised ICT.
- **Abducted eye at rest:** 3rd nerve palsy.
- **Conjugate deviation of eyes towards hemispheric** lesion and away from unilateral pontine

lesion.

- **Downward and inward deviation of eyes:** Lesions of thalamus and upper midbrain.
- **Eyes turn toward convulsing side in focal seizures.**
- **Ocular bobbing:** It is characterized by brisk downward and slow upward movements of the eyes associated with loss of horizontal eye movements. It is diagnostic of lesions in midbrain and pons.
- **Ocular dipping:** It is characterized by slow downward followed by faster upward movement in patients with normal horizontal gaze. It indicates diffuse cortical anoxic damage and drug intoxication.
- **Dysconjugate eyes (divergent ocular axes):** Brainstem lesion, e.g. skew deviation (one eye up, one eye down)
- **Oculocephalic reflex:** Also called doll's-eye movement.
  - Elicited by briskly turning or tilting the head.
  - In coma of metabolic origin or due to lesions of bihemispherical structures, the response consists of conjugate movements of eyes in the opposite direction.
  - Positive response indicates: Intact oculomotor, abducent, midbrain and pons.
  - Absent reflex indicates: Damage within brainstem. It can be also due to profound overdose of sedatives or anticonvulsants.

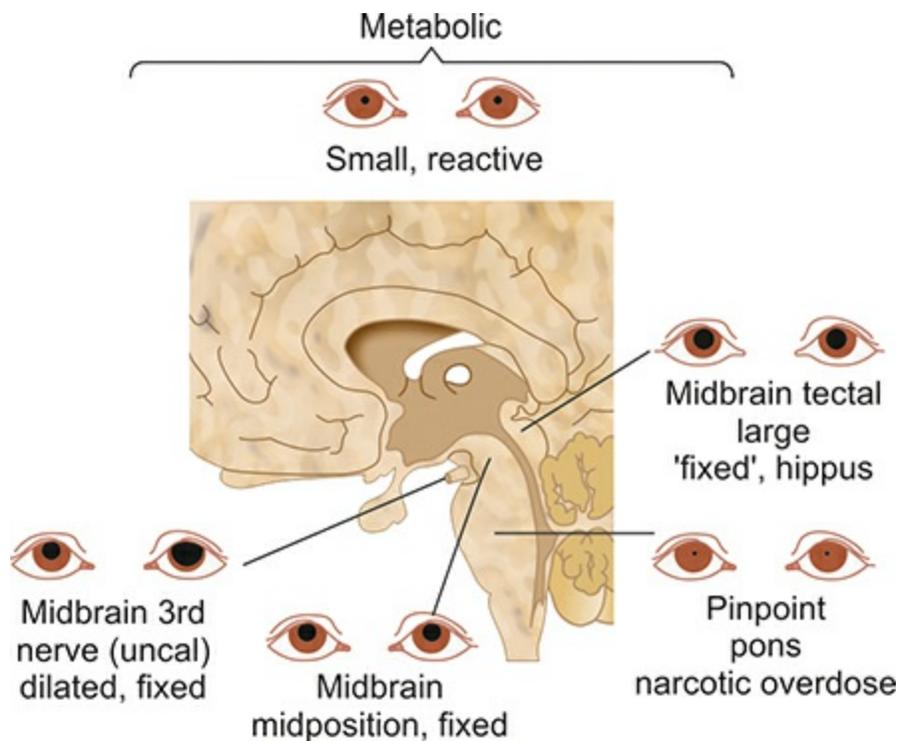

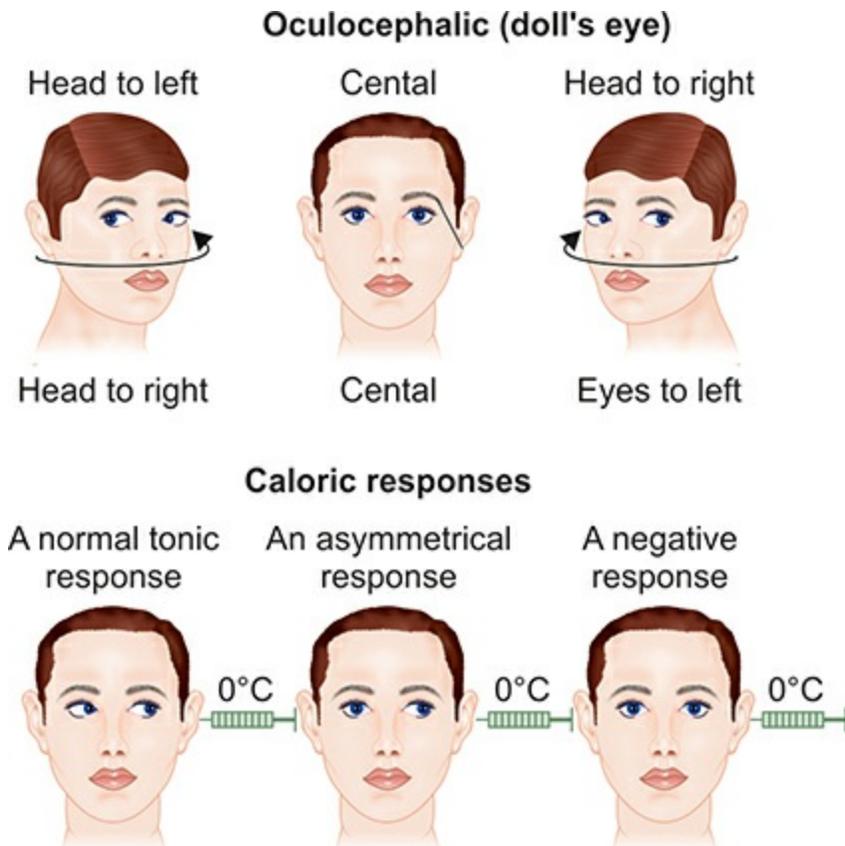

Fig. 15.22: Pupillary reactions in coma.

**Fig. 15.23:** Eye movements and position.

### ***Oculovestibular or Caloric Test***

- **Method:** Irrigate the external auditory canal with cold water.
- **Normal response:** Causes slow conjugate deviation of eyes towards irrigated ear followed in few seconds by compensatory nystagmus (i.e. fast component away from irrigated ear).
- **Interpretation:**
  - Loss of conjugate ocular movements in brainstem damage.
  - Loss of fast corrective nystagmus in metabolic or bilateral hemispherical damage. The eyes are tonically deflected to side irrigated with cold water and this position may be held for 2–3 minutes.

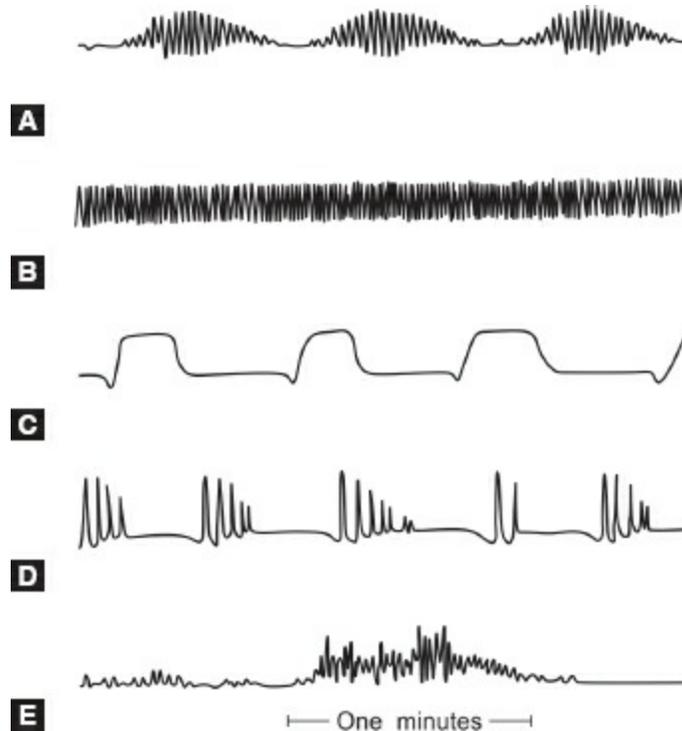

### ***Respiratory Patterns (Figs. 15.24A to E)***

- **Slow, shallow, regular breathing:** Metabolic or drug depression.
- **Cheyne-Stokes respiration** (alternating hyperpnea and periods of apnea): Massive supratentorial lesions, bilateral cerebral lesions and mild metabolic disturbance.
- **Central neurogenic hyperventilation:** Lesions of lower midbrain and upper pons either primary or secondary to transtentorial herniation.

- **Apneustic breathing:** Lower pontine lesions.
- **Biot's or ataxic breathing:** Lesions of dorsomedial part of medulla.
- **Agonal gasps:** Bilateral lower brainstem damage and terminal respiratory pattern.
- **Acidotic (Kussmaul) respiration** (deep, sighing hyperventilation): In diabetic ketoacidosis and uremia

## Laboratory Studies and Imaging

- Complete blood count
- Random blood sugar
- Renal function tests and liver function tests
- Serum electrolytes
- Urine examination for specific gravity, glucose, acetone and protein content.
- Arterial blood gases analysis: For acidosis or high CO levels
- Chest X-ray
- ECG
- CT or MRI scan: Quick and effective in demonstrating all types of brain hemorrhage and mass lesions.
- Lumbar puncture: It should be performed in coma only after careful risk assessment. It should not be performed when there is a suspicion of an intracranial mass lesion. CSF examination may help in the diagnosis of meningoencephalitis or other infection, or in subarachnoid hemorrhage.
- Electroencephalography (EEG): It may be useful in the diagnosis of metabolic coma, encephalitis and nonconvulsive status epilepticus.
- **Drugs screen:** Blood alcohol and salicylates, urine toxicology (e.g. screening for benzodiazepines, narcotics, amphetamines, etc.).
- Others, e.g. cerebral malaria and porphyria.

**Figs. 15.24A to E:** Respiratory patterns: (A) Cheyne-Stokes respiration; (B) Central neurogenic hyperventilation; (C) Apneustic breathing; (D) Cluster breathing; (E) Ataxic/Biot's breathing.

## Differential Diagnosis

- **Coma vigil (vegetative state—VS):** Patient is comatose, but the eyelids are open giving the appearance of being awake. Patients can open their eyes or have random limb and head movements but there is complete absence of response to commands or to communicate. It is usually due to extensive cortical damage. Brainstem function is intact. Hence, breathing is normal without the need for mechanical ventilation. Patients may remain in this vegetative state for years. Even after 12 months if there is no recovery, it is called permanent vegetative state (PVS).
- **Minimally conscious state (MCS):** A condition in which patient have some limited/inconsistent (fluctuating) signs of awareness (unlike patients with vegetative state). These include nonreflexive response to sensory stimulation, awareness of the self or the environment, or language comprehension or expression.
- **Akinetic mutism:** It refers to a state in which the patient is partially or fully awake, but remains entirely silent and immobile. The patient does nothing voluntarily and has sleep/wake cycles and can maintain vital functions. It may be seen in bilateral frontal lobe lesions, hydrocephalus and a mass in the region of third ventricle.
- **Locked-in-state (locked-in syndrome or pseudocoma):** The patient is fully aware and alert but unable to communicate except through eye movements. There is complete paralysis except vertical eye movements and intact lid movements (blinking in ventral). This syndrome is due to extensive transverse lesions in the pontine and midbrain (infarction).
- **Conversion reaction:** Patients have normal pupils, corneal reflexes and plantar reflexes. These patients may keep their eyes firmly closed and resist the opening of the eye by examiners. Their eyes roll up when the lids are raised. It may be due to feigned or hysterical state.
- Psychogenic coma.

- Brainstem death is discussed below.

### Treatment

- **General management:** Comatose patients require careful nursing, maintenance of the airway, and breathing frequent monitoring of vital functions.
- **Specific treatment:** Diagnosis of the underlying cause/lesion should be done as early as possible and appropriate specific treatment is to be given. For example:
  - **Diabetic with hypoglycemic coma:** Administer hypertonic glucose without waiting for reports. However, bedside estimation of blood glucose and administer dextrose only if the blood glucose is below 100 mg/dL.
  - **Alcoholic with coma:** Administer glucose and vitamin B<sub>1</sub> 100 mg intravenously, without waiting for reports.
- **Longer-term management**
  - **Skin care:** Change the posture every 2 to 3 hours and keep the skin clean and dry to avoid pressure/bed sores and pressure palsies.
  - **Eye care:** To prevent corneal damage (lid taping, irrigation).
  - **Oral hygiene:** Mouthwashes and suction.
  - **Fluids:** Through nasogastric tube or IV. Have a secure IV line.
  - **Feeding:** Nutrients through a fine-bore nasogastric tube.
  - **Sphincters:** Catheterization of urinary bladder and rectal evacuation.
  - **Posture of the patient:** Prevent the aspiration of gastric contents by positioning the patient in prone or lateral position.

## BRAIN DEATH

### Q. Write a short note on brain death.

Brain death occurs from irreversible brain injury which is sufficient to permanently eliminate all cortical and brainstem function (i.e. loss of all functions of the brain, including the brainstem).

- Because the vital centers in the brainstem maintain cardiovascular and respiratory functions, brain death is incompatible with survival despite mechanical ventilation and cardiovascular and nutritional supportive measures.
- It develops when intracranial pressure (ICP) exceeds cerebral perfusion pressure (CPP) and results in cessation of cerebral blood flow (CBF) and oxygen delivery.
- Significance of brain death:
  - It permits the withdrawal of costly life-saving equipment and drugs.
  - Family can be offered the opportunity for organ donation.

## Diagnosis of Brain Death

Brain death is a **clinical diagnosis**. No other tests are necessary and complete clinical examination including independent brain death determinations by two licensed physicians is conclusive.

### *Clinical Evaluation (Prerequisites)*

- Establish known irreversible cause of coma.
- The first and foremost critical step in establishing the diagnosis of brain death is to **establish an irreversible, untreatable cause of the brain injury** (e.g. global ischemia due to cardiac arrest, intracranial bleed and severe head injury).
- **Exclude** potentially **reversible conditions** like hypothermia, drug intoxication, poisoning, metabolic disorders (e.g. hypoglycemia, acidosis, electrolyte imbalance). Hypothermia should also be excluded—rectal temperature must exceed 35 °C.
- Achieve body temperature >36°C.
- Achieve normal systolic BP (>100 mm Hg).

### *Clinical Evaluation (Neuro-assessment)*

- **Establish coma**
- **Establish absence of brainstem reflexes**
  - Pupillary reflex (absent)
  - Eye movements
    - ◆ Occulo-cephalic: Absent (dolls eye movements)
    - ◆ Occulo-vestibular: Absent (cold caloric test)
  - Facial sensation and motor response: No corneal reflex, no jaw reflex, no grimacing to deep pressure on nail bed, supraorbital ridge or temporomandibular joint
  - Pharyngeal (gag) reflex absent
  - Tracheal (cough) reflex absent.

### *Establish Apnea by Apnea Test*

**Prerequisites for apnea test:** Body temperature >36°C, systolic blood pressure ≥100 mm Hg, normal electrolytes profile, normal PaCO<sub>2</sub> (35–45 mm Hg).

- **Procedure of apnea test**

- Connect a pulse oximeter and disconnect the ventilator.
- Deliver 100% O<sub>2</sub> by catheter through endotracheal tube at 6 L/minute.
- Observe for respiratory movement at least for 8–10 minutes.
- Discontinue testing: If BP drops to <90 mm Hg and PaO<sub>2</sub> decreases to 85% by pulse oxymetry for 30 seconds.
- **If respiratory drive/movement** is observed after 8 minutes. Take next blood sample for blood gas studies. This indicates apnea test result is negative.
- **Absence of respiration drive: If respiratory movements are absent** and arterial PaCO<sub>2</sub> is 60 mm Hg or 20 mm Hg increase over a baseline normal PaCO<sub>2</sub> indicates apnea **test** result is **positive** and **supports the clinical diagnosis of brain death.**

### ***Ancillary Tests/Confirmatory Testing***

- Electroencephalography (EEG): Electrocerebral silence absence of electrical activity during at least 30 minutes.
- Cerebral angiography: Absence of intracranial blood flow.
- PET: Glucose metabolism studies/dynamic nuclear brain scan: ‘Hollow-skull’ sign of brain death.

### ***Documentation***

Time of death is the time the arterial PaCO<sub>2</sub> reached the target value OR when ancillary test officially interpreted.

## DISEASES OF CRANIAL NERVES

### **I. Cranial Nerve: Olfactory Nerve**

Common causes of anosmia (Table 15.84).

**Table 15.84: Common causes of anosmia.**

<ul style="list-style-type: none"> <li>• Acute/chronic inflammatory nasal disease</li> <li>• Heavy smoking</li> <li>• Intracranial tumor compressing the olfactory bulb</li> </ul>	<ul style="list-style-type: none"> <li>• Head injury</li> <li>• Atrophy of olfactory bulb</li> <li>• Chronic meningeal inflammation</li> <li>• Parkinson’s disease</li> </ul>
--	---

### **II. Cranial Nerve: Optic Nerve**

#### ***Clinical Examinations***

- Optic nerve is tested by various modalities of vision: Visual acuity, visual

fields, color vision, fundoscopy.

### ***Visual acuity***

- Snellen's chart is used to measure visual acuity for distant vision.
- Visual acuity for near vision is tested by Jaeger's chart.

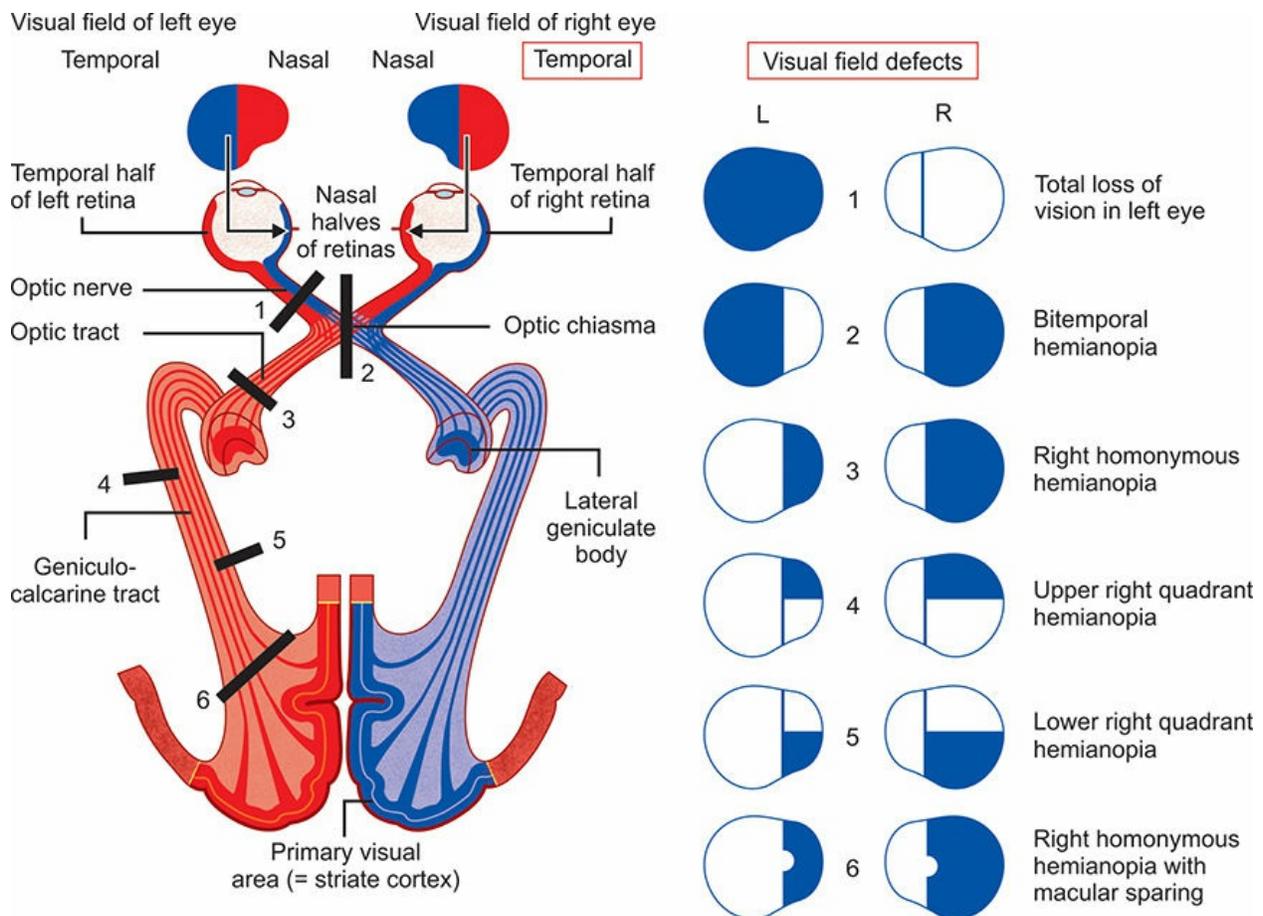

### ***Pathway of optic nerve (Fig. 15.25)***

**Q.** Write short essay/note on anatomy of optic nerve/visual pathway.

**Q.** Write short essay/note on field defects produced and localization of lesions at various levels.

### ***Visual fields***

- Visual can be impaired by damage to the visual system anywhere from the eyes to the occipital lobes.
- One can localize the site of the lesion with considerable accuracy by mapping the visual field deficit by finger confrontation and then correlating it with the topographic anatomy of the visual pathway.
- At the optic chiasma, fibers from nasal ganglion cells decussate into the contralateral optic tract. Symmetric compression of the optic chiasm by a pituitary adenoma, meningioma, craniopharyngioma, glioma, or aneurysm results in a bitemporal hemianopia.
- A unilateral postchiasmal lesion leaves the visual acuity in each eye unaffected, although the patient may read the letters on only the left or right half of the eye chart.
- Damage to the optic radiations in the temporal lobe (Meyer's loop) produces a superior quadrantic homonymous hemianopia, whereas injury to the optic radiations in the parietal lobe results in an inferior quadrantic homonymous hemianopia.
- Lesions of the primary visual cortex give rise to dense, congruous hemianopic field defects by post-cerebral artery infarct. They have macular sparing, because collaterals from the middle cerebral artery supply the macular representation at the tip of the occipital lobe.
- Destruction of both occipital lobes produces cortical blindness. This condition can be distinguished from bilateral prechiasmal visual loss by noting that the pupil responses and optic fundi remain normal.

**Fig. 15.25:** Various visual field defects depending on the location of lesion.

### Visual loss

Lesions in any areas between the retina and the visual cortex can produce visual loss. Patterns of visual field loss are shown in Figure 15.25.

- **Visual symptoms involving one eye:** Due to lesions anterior to the optic chiasm.
- **Transient visual loss:** It is the sudden onset of visual loss lasting less than 15 minutes. It is usually due to vascular disease and may be difficult to identify whether the visual loss was monocular (carotid circulation) or binocular (vertebrobasilar circulation).

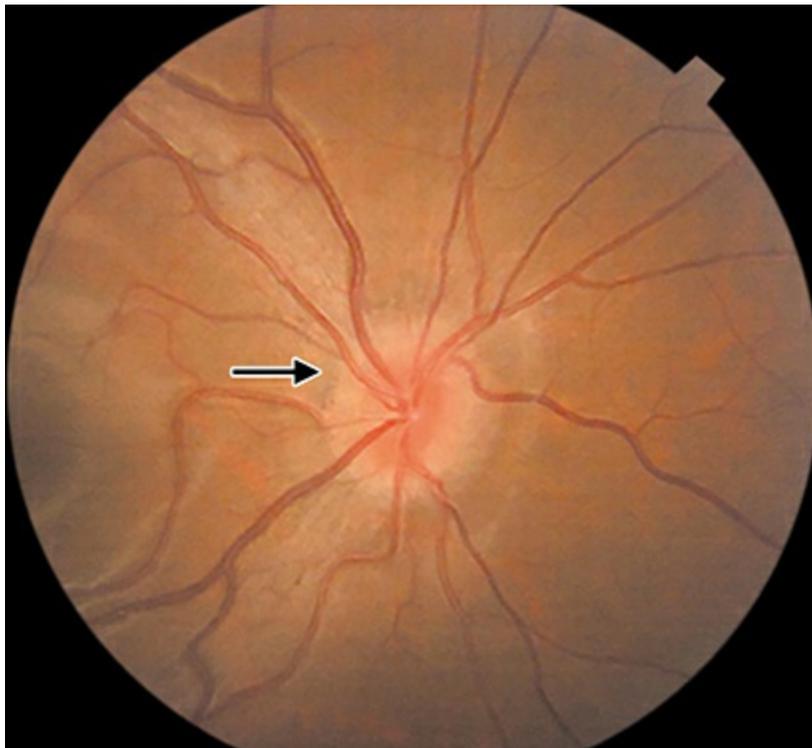

### Color vision

- The retina has three classes of cones, with visual pigments of differing peak spectral sensitivity: red (560 nm), green (530 nm), and blue (430 nm).
- The red and green cone pigments are encoded on the X chromosome; the

blue cone pigment on chromosome 7.

- Most common anomaly of color vision are the various types of red-green deficiency inherited as sex-linked recessive condition. Only males are affected (X-linked) and present in 8% males.
- Ishihara color plates can be used to detect red-green color blindness.
- Acquired defects of color vision occur in macular and optic nerve diseases, and due to certain drugs (e.g. ethambutol, chloroquine).

*Papilledema (Fig. 15.26)*

**Fig. 15.26:** Fundoscopy showing papilledema.

Papilledema is the edema (swelling) of the optic disc  $>3$  diopters. This term has been used only for passive swelling of the optic disc secondary to raised intracranial pressure.

*Causes of papilledema (Table 15.85)*

**Table 15.85:** Causes of papilledema.

**Optic nerve damage**

- Demyelination (optic neuritis/papillitis)
- Anterior ischemic optic neuropathy

**Raised intracranial pressure**

- Cerebral mass lesion (tumor, abscess, granulomas)

<ul style="list-style-type: none"> <li>• Toxins (e.g. methanol)</li> <li>• Infiltration of optic disc by glioma, lymphoma and sarcoidosis</li> </ul>	<ul style="list-style-type: none"> <li>• Obstructive hydrocephalus, diffuse brain edema</li> <li>• Idiopathic intracranial hypertension</li> <li>• Cerebral venous sinus thrombosis</li> </ul>
<p><b>Ocular blockage of venous drainage</b></p> <ul style="list-style-type: none"> <li>• Central retinal venous block</li> <li>• Cavernous sinus thrombosis</li> </ul>	<p><b>Systemic disorders affecting retinal vessels</b></p> <ul style="list-style-type: none"> <li>• Hypertension</li> <li>• Vasculitis: Giant cell arteritis and other autoimmune vasculitides</li> <li>• Hypercapnia, hypercalcemia</li> <li>• COPD (hypercapnea)</li> </ul>

It develops due to obstruction of venous outflow along with stasis of axoplasmic flow within the optic nerve. It also develops due to any cause that produces edema in the head of the optic nerve (e.g. local causes).

**Q. Write a short note on the causes of papilledema.**

*Argyll-Robertson pupil*

**Q. Write a short note on Argyll-Robertson pupil.**

It is the pupillary change where accommodation reflex is present but light reflex is impaired.

*Findings (Box 15.37) and causes (Box 15.38)*

**Box 15.37:** Ophthalmological findings in Argyll-Robertson pupil.

- Pupils: Small, irregular and unequal in size
- Iris: Atrophy and de-pigmentation
- Light reflex: Absent for direct (always) and consensual (usually stimulus)
- Accommodation reflex: Intact
- Ciliospinal reflex: Absent

**Box 15.38:** Causes of Argyll-Robertson pupil.

- Neurosyphilis (tabes dorsalis) generally bilateral
- Diabetes
- Multiple sclerosis
- Sarcoidosis
- Tumors of pineal region

Site of lesion: Tectum of the midbrain or peripherally in the branch of III cranial nerve.

## ***Pinpoint pupil***

**Q.** Write a short note on the causes of pinpoint pupil.

*Causes of pinpoint pupil (Box 15.39)*

**Box 15.39:** Causes of pinpoint pupil.

- Pontine hemorrhage
- Organophosphorus poisoning
- Opium poisoning
- Pilocarpine instillation
- Thalamic hemorrhage (occasionally)

## ***Adie's pupil***

**Q.** Write a short note on Adie's pupil.

- Normally, pupil reaction to light is absent or markedly reduced when tested in the routine examination. However, Adie's pupil reacts slowly with prolonged maximal stimulation.
- Once the Adie's pupil reacts to accommodation, the pupil remains tonically constricted and dilates very slowly.
- **Cause:** Destruction of ciliary ganglion.

*Causes of blindness (Box 15.40)*

**Box 15.40:** Causes of blindness.

- Cataract leading cause (47.9%)
- Glaucoma (12.3%)
- Age-related macular degeneration (AMD) (8.7%)
- Corneal opacities
- Diabetic retinopathy
- Childhood blindness
- Trachoma

**Q.** Write a short note on causes of blindness.

**Horner's Syndrome (Fig. 15.27)**

**Fig. 15.27:** Left Horner's syndrome.

**Q. Write short essay/note on Horner's syndrome.**

- Horner's syndrome is a syndrome complex caused by the involvement of the oculosympathetic tract.
- **Sympathetic nervous supply to the eye** consist of three neuron pathway:
  1. Fibers through the IIIrd nerve innervate levator muscle of eyelid (Muller's muscles).
  2. Fibers through nasociliary nerve supply the blood vessels of eye.
  3. Fibers through long ciliary nerve innervate pupil.
- Damage to any part of the pathway results in Horner's syndrome.

**Components of Horner's Syndrome (Box 15.41)**

**Causes of Horner's Syndrome**

- **Cerebral and brainstem lesions:** Hemispherectomy, massive cerebral infarction, brainstem demyelination
- **Cervical cord lesions:** Syringomyelia and cord tumors (e.g. ependymoma, glioma)
- **Thoracic root level:** Apical lung tumor (pancoast 'tumor) or TB, cervical rib, trauma to brachial plexus
- **Sympathetic chain and carotid artery in neck:** Following thyroid/laryngeal/carotid surgery, carotid artery dissection, neoplastic infiltration, cervical sympathectomy
- **Miscellaneous:** Congenital Horner's syndrome, cluster headache (transient), idiopathic.

**Box 15.41:** Components of Horner's syndrome.

- Miosis due to reduced pupillodilator activity
- Partial ptosis of eyelid
- Enophthalmos
- Anhidrosis of ipsilateral half of face
- Absence of ciliospinal reflex

## III, IV, VI Cranial Nerves: Oculomotor, Trochlear and Abducens Nerves

### *Ptosis (Fig. 15.28)*

**Fig. 15.28:** Unilateral ptosis.

- Normal palpebral fissure 9 mm to 12 mm.
- The **narrowing of the palpebral fissures due to inability to open an upper eyelid** is called ptosis.
- Ptosis may be congenital or acquired, unilateral or bilateral, partial or complete
  - **Congenital ptosis:** It is due to bilateral congenital hypoplasia of the third nerve nuclei, and results in bilateral ptosis.
  - **Acquired ptosis:** Acquired ptosis may be unilateral or bilateral.

### *Causes of ptosis*

**Q.** Write a short note on the causes of ptosis.

- **Causes for unilateral ptosis (Box 15.42)**

**Box 15.42:** Causes of unilateral ptosis.

- Third cranial nerve lesion
- Lesion of cervical sympathetic pathway (Horner's syndrome)
- Lesions of the upper eyelid

- **Causes for bilateral ptosis:** Bilateral ptosis occurs when there is a lesion of the third nerve nucleus, supplying the levator palpebrae superioris in the midbrain (as a single nucleus in the midbrain supplies the levator

palpebrae superioris of both eyes). Its causes are listed in Box 15.43.

- **Partial ptosis:** Occurs with lesion of the cervical sympathetic pathway (Horner's syndrome) due to weakness of the tarsal muscles, innervated by cervical sympathetic nerves. The upper eyelids can however be raised voluntarily.
- **Complete ptosis:** This occurs with third nerve lesions due to paralysis of the levator palpebrae superioris, innervated by the third nerve. The patient is not able to voluntarily open the affected eye.

#### **Box 15.43:** Causes of bilateral ptosis.

- Myopathies
- Myasthenia gravis
- Bilateral Horner's syndrome
- Snake bite
- Botulism

### **Ptosis and Pupillary Size**

- Ptosis with a small pupil: Horner's syndrome
- Ptosis with a large pupil: IIIrd nerve palsy (compressive lesions).
- Ptosis with normal pupillary size: Infarction of IIIrd nerve, myasthenia gravis, myopathies or GB syndrome.

## **Ophthalmoplegia**

### **Q. Write short note on internuclear ophthalmoplegia.**

- Ophthalmoplegia is the paralysis or weakness of the eye muscles.

### ***Internuclear Ophthalmoplegia (Fig. 15.29)***

- Caused by a lesion of the medial longitudinal fascicle (MLF), which carries signals from the abducens nucleus to the contralateral medial rectus oculomotor subnucleus.
- The abducens nerve and MLF coordinate conjugate horizontal eye movements with co-contraction of ipsilateral lateral rectus and contralateral medial rectus muscles.
- Classic signs of unilateral internuclear ophthalmoplegia include impaired adduction of the ipsilesional eye and abducting nystagmus of the contralateral eye.

- Despite ipsilateral adduction weakness with direct motility testing, adduction is often intact with convergence because convergence signals to the medial rectus nucleus are distinct from the MLF.
- Multiple sclerosis and microvascular brainstem ischemia are the most common causes.

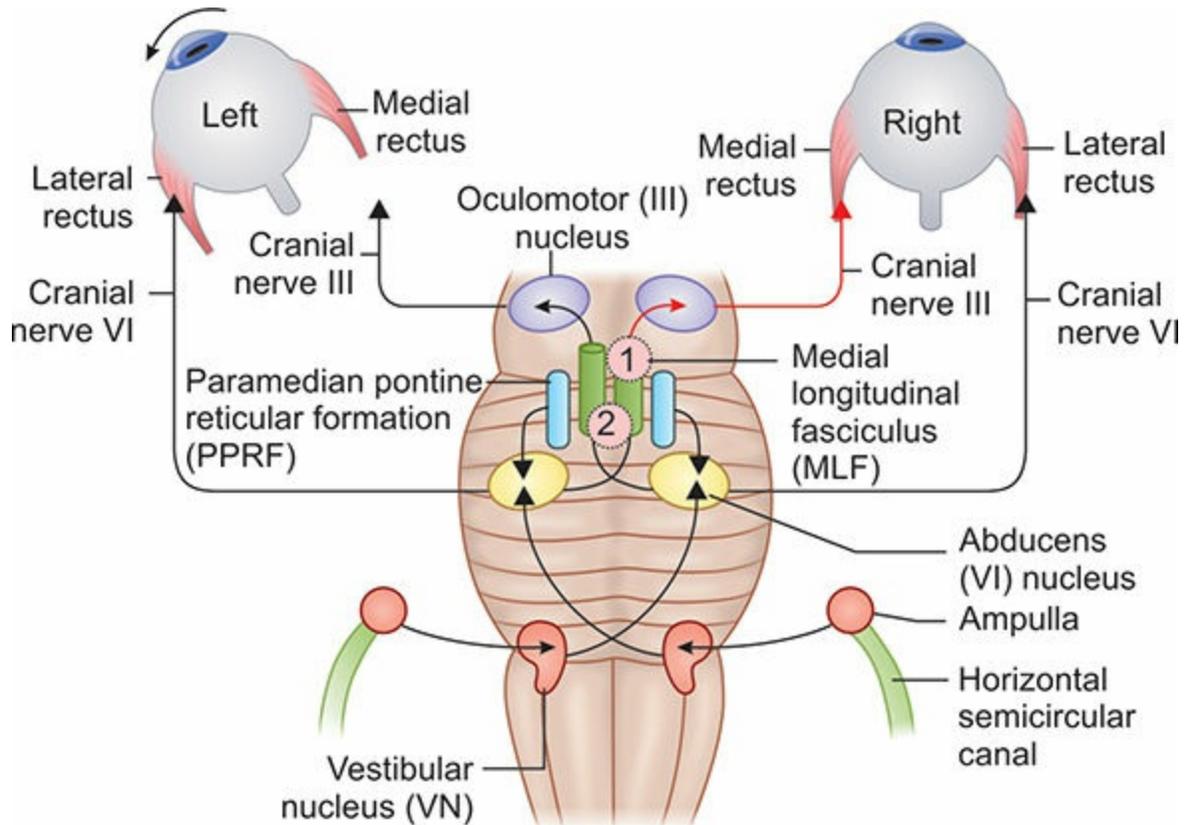

Fig. 15.29: Lesions of medial longitudinal fascicle (MLF).

## Diplopia

### Q. Write a short note on diplopia.

Diplopia means double vision. Most common subjective complaint elicited by lesions in the oculomotor system. Occurs more frequently with lesions of the extraocular muscles or oculomotor nerves than with supranuclear lesions which result in gaze palsies.

#### • Monocular diplopia

- The first point to clarify is whether diplopia persists in either eye after covering the fellow eye. If it does, the diagnosis is monocular diplopia.
- The cause is usually intrinsic to the eye. For example, corneal

aberrations, uncorrected refractive error, cataract, or foveal traction may give rise to monocular diplopia.

- **Binocular diplopia**

- Diplopia alleviated by covering one eye is binocular diplopia and is caused by disruption of ocular alignment, occurs only if both eyes are open.
- Binocular diplopia occurs from a wide range of processes: For example, infectious, neoplastic, metabolic, degenerative, inflammatory, and vascular.
- Here two images, one real and one false are formed. The real image is closer to the eye and distinct; the false image is farther away from eye and indistinct.

## *Nystagmus*

### **Q. Write a short note on the causes of nystagmus.**

Nystagmus is involuntary, conjugate, repetitive and rhythmic movement of eyeballs. It is a sign of disease of the retina, cerebellum and/or vestibular systems and their connections.

#### *Types of nystagmus*

##### *Pendular nystagmus*

A rapid to and from oscillation to either side of the midline, of equal amplitude. It is usually vertical and present in all directions of gaze. The causes are generally ocular such as macular abnormalities, high infantile myopia, etc.

##### *Jerk nystagmus*

- It is a fast/slow oscillation off the target, followed by a fast corrective saccade. It is usual in neurological disease and is seen in vestibular, VIII nerve, brainstem, and cerebellar lesions. Types of jerk nystagmus are:
  - **Horizontal or rotary jerk** nystagmus is a to- and- fro movement in the horizontal plane. It may be either of peripheral (vestibular) or central origin (VIII nerve, brainstem, cerebellum and connections).
    - ◆ In peripheral lesions, nystagmus is acute and transient (minutes or hours) and accompanied by severe vertigo.

- ◆ In central lesions nystagmus is long lasting (weeks, months or more). Vertigo tends to wane after days or weeks, the nystagmus outlasting it.
- **Vertical nystagmus** involves the oscillations in an up-and-down direction. It is never labyrinthine in origin, and the quick phase is usually upwards (upbeat nystagmus). It is caused central lesions [due to intrinsic disturbance of the brainstem such as cerebrovascular accidents (CVA) and drugs].
- **Rotatory nystagmus:** Oscillations are of rotary character. It occurs in both labyrinthine and brainstem disease.
- An ataxic nystagmus involves the dissociation of rhythm in the two eyes, seen in internuclear ophthalmoplegia, due to lesions of the median longitudinal bundle.
- **Miscellaneous forms of nystagmus**
  - Optokinetic nystagmus is a normal phenomenon best observed when sitting opposite someone in a railway carriage.
  - See-saw nystagmus is spontaneous nystagmus, one eye moving up while the other moves down. Lesion in the suprasellar region anterior to the third ventricle.
  - Convergence-retraction nystagmus: Attempted upgaze provokes a jerk nystagmus with the fast phase inwards, in a convergent manner. Lesion of the upper midbrain near pineal gland.
  - Downbeat nystagmus is a vertical nystagmus, with fast phase directed downwards. Lesion at the foramen magnum, commonly Chiari malformations.

## Vth Cranial Nerve: Trigeminal Nerve

### ***Trigeminal Neuralgia (Tic Douloureux)***

- Trigeminal neuralgia is also known as **prosopalgia or Fothergill's disease**. Tic Douloureux means painful jerking.
- It is a neuropathic disorder. It is defined as sudden, episodes of usually unilateral, severe, brief, stabbing, intense, lancinating, recurring pain in the distribution of one or more branches of the Vth cranial nerve (trigeminal nerve).
- Middle age and later. Usually starts in the 6th and 7th decades and major

risk factor is hypertension.

## ***Etiology***

**Q. Write a short essay/note on the causes of trigeminal neuralgia.**

Usually produced due to compression of the trigeminal nerve at or near the pons by an ecstatic vascular loop. Pain similar to trigeminal neuralgia can be seen in other conditions (Table 15.86).

**Table 15.86: Causes of trigeminal neuralgia.**

<ul style="list-style-type: none"><li>• Usually idiopathic</li><li>• Demyelination of the nerve</li><li>• Multiple sclerosis</li><li>• Petrous ridge compression</li></ul>	<ul style="list-style-type: none"><li>• Post-traumatic neuralgia</li><li>• Intracranial tumors</li><li>• Intracranial vascular abnormalities</li><li>• Viral etiology</li></ul>
--	---

## ***Clinical features***

### *Pain*

- **Characteristics of pain:** Sudden, unilateral, intermittent (paroxysmal), sharp, shooting/knifelike/lancinating/electric shock like. Pain rarely crosses the midline. In extreme cases, the patient will have a motionless face known as the ‘frozen or mask like face’. In 10–12% of cases it is bilateral and usually due to intrinsic brainstem pathology (e.g. multiple sclerosis) or expanding cranial tumor (acoustic schwannomas, meningiomas, epidermoids).
- **Duration of pain:** Pain is of short duration (lasting seconds), but may recur with variable frequency (may be many times a day). Attacks do not occur during sleep.
- Pain occurs along the cutaneous distribution of the fifth nerve (Full or branches). Pain usually commences in the mandibular division but may spread to involve the maxillary and occasionally the ophthalmic divisions.
- Pain is precipitated by minor trauma to the trigger zones (e.g. slight touch, chewing, shaving, rinsing mouth, exposure to cold wind). Common trigger zones can be external/cutaneous (around the ala of nose, corners of lips and cheek) or internal/intraoral (teeth, gingivae, tongue). Trigger area on the face are so sensitive that touching or even air currents can trigger an episode.

- Neither objective signs of sensory loss nor signs of V nerve dysfunction can be demonstrated on examination.

**Differential diagnosis:** Re-activation of the varicella zoster virus (refer pages 152-4) is seen in older people and has predilection for ophthalmic division of the trigeminal nerve.

**Q. Write a short essay/note on treatment of trigeminal neuralgia.**

**Treatment**

- **First line of treatment: Carbamazepine** (anticonvulsant) to be started with a dose of 100–200 mg/day, increase in 2–3 weeks to 200–400 mg TID.
- **Second line of treatment:** Baclofen, lamotrigine, oxcarbazepine, phenytoin, gabapentin, pregabalin, sodium valproate.
- **Long-acting anesthetic agents:** Localized pain is managed by injecting any of the following into the particular branch of the nerve.
  - Alcohol injection
  - Peripheral glycerol injection
- **Surgery:** Indicated if drug fails or not tolerated.
  - Peripheral neurectomy (nerve avulsion)
  - Open procedures (intracranial procedures)
  - Microvascular decompression
  - Percutaneous rhizotomies
  - Gamma knife radiosurgery: Using stereotactic imaging of the trigeminal nerve root entry zone, radiation to delivered to trigeminal nerve.

## VIIth Cranial Nerve: Facial Nerve (Fig. 15.30)

### *Causes of Facial Nerve Palsy (Table 15.87)*

**Q. Write a short essay/note on:**

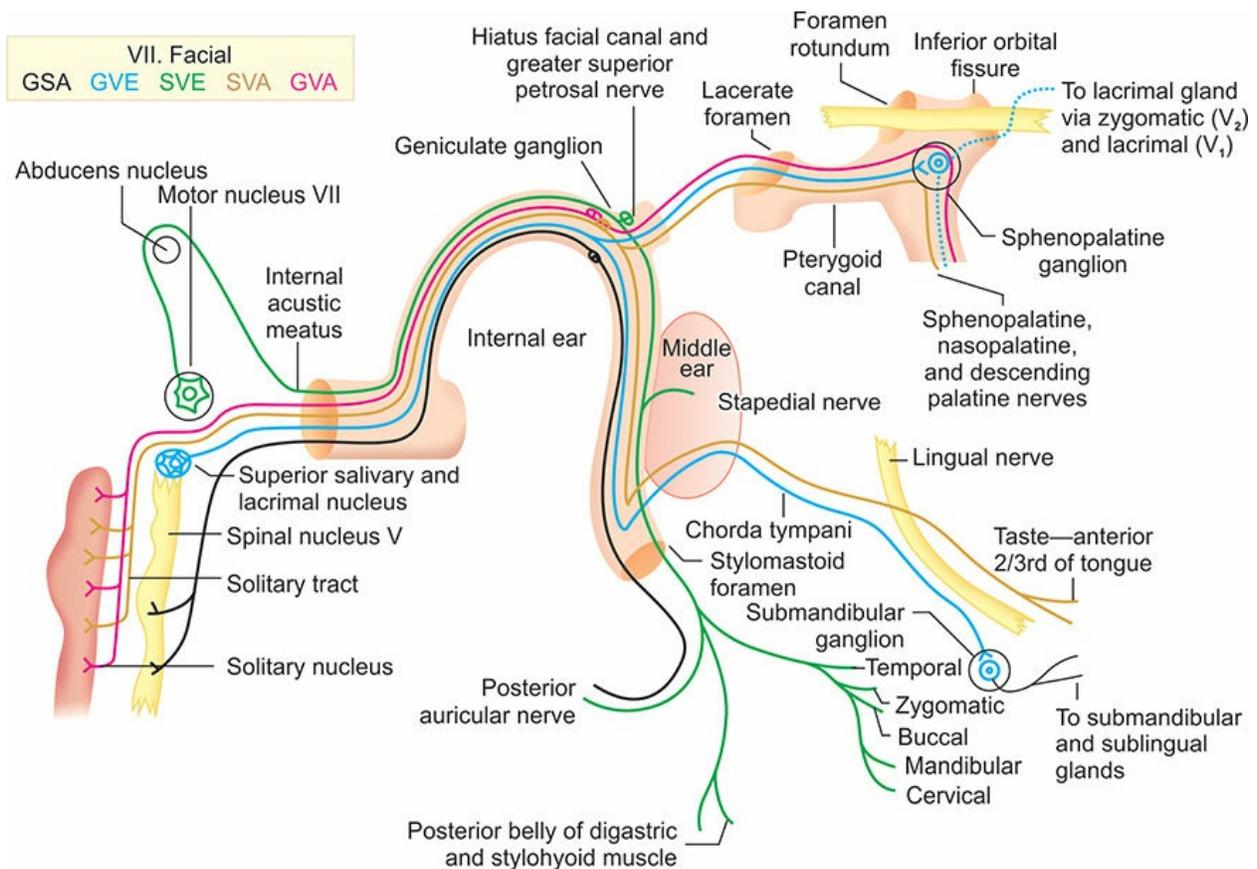

- **Causes of LMN type of VIIth cranial nerve palsy.**
- **Causes of VIIth cranial nerve palsy.**

**Table 15.87: Causes of facial nerve palsy.**

<i>Unilateral</i>	<i>Bilateral</i>
<b>Upper motor neuron (UMN)</b> <ul style="list-style-type: none"> <li>• Vascular (stroke)</li> <li>• Tumor</li> <li>• Multiple sclerosis</li> </ul>	<b>Upper motor neuron (UMN)</b> <ul style="list-style-type: none"> <li>• Vascular (multi-infarct dementia)</li> <li>• Motor neuron disease</li> </ul>
<b>Lower motor neuron (LMN)</b>	<b>Lower motor neuron (LMN)</b>

- Bell's palsy
- Ramsay Hunt syndrome
- Parotid tumor
- Head injury
- Skull base tumor
- Basal meningitis
- Diabetes mellitus
- Hypertension
- Chronic suppurative otitis media

- Guillain-Barré syndrome
- Sarcoidosis (uveoparotid tumor)
- Leprosy
- Lyme's disease
- Leukemia
- Lymphoma
- Moebius
- Melkersson Rosenthal
- Toxin: Thalidomide
- Bilateral Bell's palsy

**Fig. 15.30:** Facial nerve anatomy.

## ***Bell's Palsy***

**Q. Discuss the etiology, clinical features, differential diagnosis and management of Bell's palsy.**

**Q. Write a short essay/note on Bell's palsy.**

Most common form of unilateral isolated lower motor neuron (LMN) type of

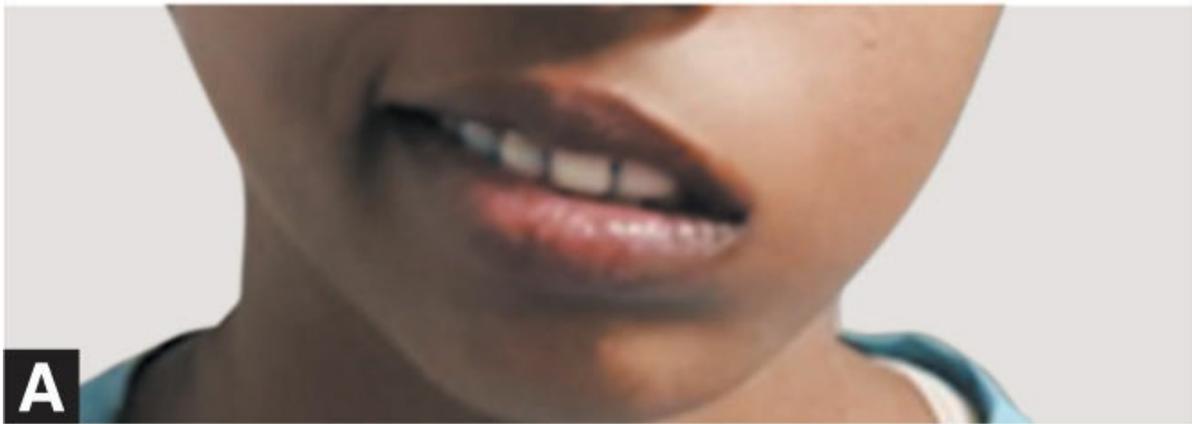

facial paralysis is Bell's palsy.

### *Pathophysiology*

- Main cause of Bell's palsy is thought to be latent herpes viruses (herpes simplex virus type 1 and herpes zoster virus), which are reactivated from cranial nerve ganglia. It causes **swelling of nerve within** the tight petrous bone **facial canal**.
- Herpes zoster virus shows more aggressive biological behavior than herpes simplex virus type 1.
- Polymerase chain reaction (PCR) techniques have isolated herpes virus DNA from the facial nerve during acute palsy.
- Inflammation of the nerve initially results in a reversible neurapraxia,

### *Clinical manifestations*

- **Race:** Slightly higher in persons of Japanese descent. Familial incidence 4.1%.
- **Age and gender:** Highest in persons aged 15–45 years. It is rare below the age of 15 and above the age of 60. No gender difference exists.
- **Onset is fairly abrupt**, with **pain around the ear** preceding the unilateral facial weakness (maximal weakness by 48 hours). Patients often describe the face as 'numb' and sometimes give the history of exposure to cold.
- **Associated symptoms:** Hyperacusis, decreased production of tears and saliva, and altered taste, otalgia or aural fullness and facial or retroauricular pain.
- Less common in pregnancy but prognosis is significantly worse in pregnant women.
- **Examination:** Shows features of isolated lower motor neuron facial paralysis. On the affected side **following features are observed**. These include:
  - **Paralysis of all the muscles of facial expression (Fig. 15.31A).**

**Figs. 15.31A and B:** Bell's palsy (A) with Bell's phenomenon (B).

- Drooping of corner of mouth, effacement of creases and skin fold.
- Involvement of frontalis makes frowning difficult. Eye closure is weak because of involvement of orbicularis oculi
- Drooling of saliva from angle of mouth.
- Action of the levator anguli oris on the normal side, makes the angle of

mouth to deviate to the opposite side of the lesion, when the patient shows his teeth.

- When the closure of the eyelid is attempted, the eye on the paralyzed side rolls upwards (Bell’s phenomenon)(Fig. 15.31B).
- Due to exposure of the cornea, patient may develop exposure keratitis and corneal ulceration.

*Investigation*

- No specific confirmatory diagnostic test.
- CSF may show mild lymphocytosis.
- MRI may reveal swelling and uniform enhancement of the geniculate ganglion and facial nerve and in some cases, entrapment of the swollen nerve in the temporal bone.

**Differences between upper motor and lower motor neuron facial palsy (Table 15.88).**

**Table 15.88:** Differences between upper motor and lower motor neuron facial palsy.

<i>UMN (upper motor neuron) facial palsy</i>	<i>LMN (lower-upper motor neuron) facial palsy</i>
• Lower part of the face is involved	• Both lower and upper part of the face is involved
• No Bell's phenomenon	• Bell's phenomenon is seen
• Taste is not effected	• Taste is effected
• No hyperacusis	• Hyperacusis may be present if nerve to stapedius is involved
• Usually associated with hemiplegia	• Usually not associated unless any pontine lesion is present causing crossed hemiplegia
• Site of the lesion is above facial nucleus usually in the internal capsule	• Usually in the nucleus or distal to the nucleus
• No wasting or atrophy	• Wasting or atrophy may be present

**Differences between bilateral upper motor and bilateral lower motor neuron facial palsy (Table 15.89).**

**Sequelae of Bell’s palsy**

**Table 15.89:** Differences between bilateral upper motor and bilateral

## lower motor neuron facial palsy.

<b><i>Bilateral UMN palsy</i></b>	<b><i>Bilateral LMN Palsy</i></b>
Emotional fibers—spared	Bell’s phenomenon present
Emotional incontinence present	Emotional fibers—affected
Associated with bilateral long tract signs	Long tract signs—absent
Jaw jerk—exaggerated	Jaw jerk—normal
Corneal reflex—present	Corneal reflex—absent
Taste sensation—spared	Taste sensation—absent
Gag reflex—exaggerated	

- **Incomplete recovery:** Facial asymmetry persists; eye cannot be closed resulting in epiphora. A weak oral sphincter causes drooling and difficulty in taking food.
- **Exposure keratitis:** Eye cannot be closed, tear film from the cornea evaporates causing dryness, exposure keratitis and corneal ulcer.
- **Synkinesis (mass movement):** When the patient wishes to close eye corner of mouth also twitches or vice versa.
- **Tics and spasm:** Result of faulty regeneration of fibers. Involuntary movements are seen on the affected side of face.
- **Contractures:** Results from fibrosis of atrophied or fixed contraction of a group of muscles.
- **Crocodile tears (gustatory lacrimation):** Unilateral lacrimation with mastication. Due to faulty regeneration of parasympathetic fibers which now supply lacrimal gland instead of the salivary glands.
- **Frey’ syndrome (gustatory sweating):** Sweating and flushing of skin over the parotid during mastication. It results from parotid surgery.
- Anomalous regeneration of the seventh nerve fibers. Originally connected with the orbicularis oculi come to innervate the orbicularis oris, closure of the lids may cause a retraction of the mouth. Jaw opening causing closure of the eyelids on the side of the facial palsy is termed **Marcus–Gunn jaw-winking phenomenon**.

### **Treatment**

- Severe facial weakness may produce inability to blink and lead to **exposure keratitis**. Use of **lubricating eye drops** may be needed, and **paper tape** to close the eye during sleep.
- Massage of weekend muscles.

### **Medical treatment of Bell’s palsy.**

- Steroids (Prednisolone) 1 mg/kg/day for 5–7 days and then tapered over the next one week.
- Antiviral agents: for 5–7 days.
  - Famciclovir 500 mg BD.
  - Valacyclovir 500 mg BD.
  - Aciclovir 800 mg five times a day.

**Surgical decompression**—only if no resolution of symptoms after 2 weeks.

# INTRACRANIAL PRESSURE

**Q. Discuss the clinical manifestations and management of increased intracranial pressure.**

## Raised Intracranial Pressure

- Normal intracranial pressure in adults is less than 10–15 mm Hg. There are normal regular waves due to pulse and respiration.
- With increased pressure ‘pressure waves’ appear. With continued rise of ICP, the perfusion pressure (PP) falls. When PP falls cerebral blood flow (CBF) is reduced. Electrical cortical activity fails if CBF is 20 mL/100 gm/min.
- When intracranial pressure reaches mean arterial pressure circulation to the brain stops.
- Raised intracranial pressure (RIP) may be caused by mass lesions, cerebral edema, obstruction to CSF circulation causing hydrocephalus, impaired CSF absorption and cerebral venous obstruction.

## *Common Causes of Raised ICP (Table 15.90)*

## *Clinical Features*

**Q. Write short note on clinical manifestations of increased intracranial pressure/tension.**

- Signs and symptoms of underlying cause.
- **Features of raised ICP (Box 15.44).**

**Box 15.44:** Features of raised intracranial pressure (ICP).

- Diffuse anterior headache worse on lying/straining
  - Vomiting
  - Diplopia (6th nerve involvement)
  - Papilledema
  - Bradycardia, raised blood pressure
  - Impaired conscious level: Drowsiness and mental deterioration
  - Seizures
- The speed of increase in the pressure influences presentation.

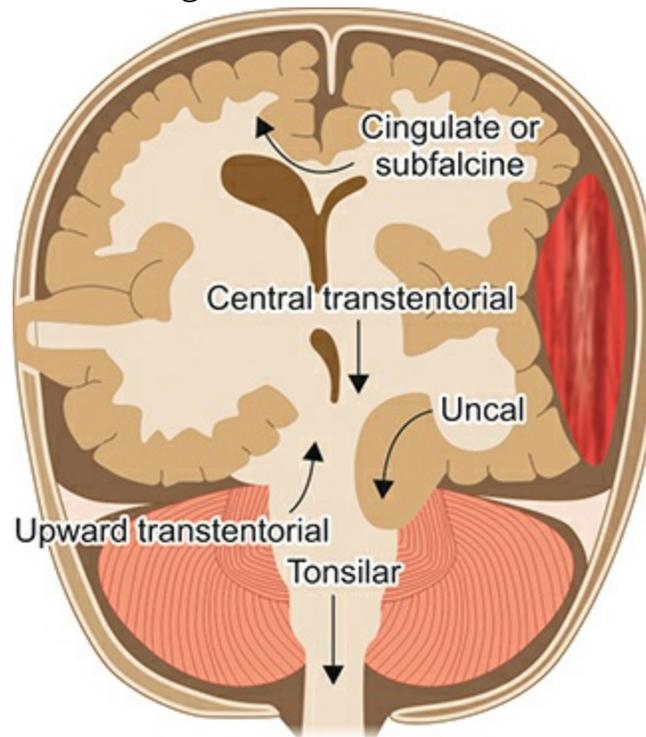

**Table 15.90: Common causes of raised intracranial pressure.**

<i>Primary or intracranial causes</i>	
<p><b>Mass lesions</b></p> <ul style="list-style-type: none"> <li>• <b>Intracranial hemorrhage</b> (traumatic or spontaneous): Extradural or subdural hematoma, intracerebral hemorrhage</li> <li>• <b>Brain tumor:</b> Posterior fossa tumor or high-grade gliomas</li> <li>• <b>Infective:</b> Cerebral abscess, tuberculomas, cysticercosis, hydatid cyst</li> <li>• <b>Colloid cyst</b> (in ventricles)</li> </ul>	<p><b>Disturbance of CSF circulation</b></p> <ul style="list-style-type: none"> <li>• <b>Obstructive</b> (noncommunicating) <b>hydrocephalus:</b> Obstruction within ventricular system</li> <li>• <b>Communicating hydrocephalus:</b> Obstruction outside ventricular system</li> </ul> <p><b>Obstruction to venous sinuses</b></p> <ul style="list-style-type: none"> <li>• Cerebral venous thrombosis</li> <li>• Trauma (fractures overlying sinuses)</li> </ul>
<p><b>Diffuse brain edema or swelling</b></p> <ul style="list-style-type: none"> <li>• Meningoencephalitis</li> <li>• Trauma (diffuse head injury, near-drowning)</li> <li>• Subarachnoid hemorrhage</li> <li>• Metabolic (e.g. water intoxication)</li> <li>• Idiopathic intracranial hypertension</li> <li>• Postneurosurgery</li> </ul>	
<i>Secondary or extracranial causes</i>	
<ul style="list-style-type: none"> <li>• Hypoxia or hypercarbia (hypoventilation)</li> <li>• Hyperpyrexia</li> <li>• Drug and toxins (e.g. valproate sodium, lead intoxication)</li> </ul>	<ul style="list-style-type: none"> <li>• Hepatic failure</li> <li>• Seizure</li> <li>• Reye's syndrome</li> <li>• High-altitude cerebral edema</li> </ul>

- **Acute:** If ICP has risen acutely (as in aggressive tumors), there is no time for compensatory mechanisms to develop and causes leading early symptoms, including sudden death. The pulse rate is slower, BP may be elevated (Cushing's reflex) and respiratory depression (Cushing's triad).
- **Slow:** Compensatory mechanisms develop (e.g. alteration in the volume of fluid in CSF spaces and venous sinuses) which minimize symptoms. Raised ICP of more than a few days will result in papilledema.
- VI cranial nerve palsy: Due either to stretching of the long slender nerve or to compression against the petrous temporal bone ridge. It may be unilateral or bilateral.
- Other cranial nerve III, V and VII may also be involved.

## Herniation Syndromes

Raised ICT may cause displacement and herniation of the brain. Types of herniation are presented in Figure 15.32.

**Fig. 15.32:** Types of herniation.

### ***Supratentorial Herniation***

- **Uncal:** Most frequent herniation in which downward displacement of the medial temporal lobe (uncus) through the tentorium occurs.
- Results in ipsilateral pupil dilatation, decreased level of consciousness, changes in respiratory patterns, respiratory arrest, and contralateral hemiplegia.
- **Subfalcine** herniation results in opposite lower limb weakness (ACA involvement).

### ***Central/Transtentorial Herniation***

Results in loss of consciousness, small reactive pupils advancing to fixed/dilated pupils, respiratory changes leading to respiratory arrest and decorticate posturing advancing to flaccidity.

### ***Infratentorial Herniation***

Downward herniation of the cerebellar tonsils through the foramen magnum

may compress the medulla oblongata (tonsillar coning) causing respiratory and cardiac arrest.

## ***Uncal Syndrome***

- Herniation of the temporal lobe (medial) transtentorially results in uncal syndrome.
- It produces drowsiness in early stages and is accompanied by unilateral pupillary dilatation.
- Sometimes due to lateral mass effect, opposite cerebral peduncle is crushed against the tentorium. This causes Babinski sign and weakness of arm and leg ipsilateral to the lesion (**Kernohan Woltman sign**).

## **Investigations**

- Depending on the underlying lesion/etiology.
- CT head: It may show midline shift and compression of basal cisterns.
- ICP monitoring: It is done in selected cases. For example, patients with Glasgow coma scale  $\leq 8$  and CT scan show hematoma, contusion, edema, herniation or compressed basal cisterns.

**Q. Write short essay/note on initial management of raised intracranial tension.**

**Q. Write short essay on management of increased intracranial pressure.**

### **Treatment/Management of Increased Intracranial Pressure**

#### **Aims (Box 15.45)**

**Box 15.45:** Aims of management of increased intracranial pressure.

- Relieve the cause (e.g. surgical decompression of mass).
- Steroids to reduce vasogenic edema or shunt.
- Procedure to relieve hydrocephalus.
- Supportive treatment: Maintenance of fluid balance, blood pressure control, head elevation, and use of diuretics such as mannitol. Intensive care support may be required.

#### **Airway management**

– GCS  $< 8$  require intubation to protect airway.

- **Head positioning:** Head should be kept in midline, with around 15–30 degree elevation.
- **Temperature control:** Temperature can be lowered with acetaminophen and cooling blankets. Shivering prevented by neuromuscular block.
- **Hemodynamic management:** Maintain mean arterial pressure above 90 mm Hg. Administer normal saline to achieve a central venous pressure of 5 to 10 mm Hg. Serum sodium to be

maintained between 140 and 150 mmol/L.

- **Seizure management:** Prophylactic antiepileptics (phenytoin)
- **Analgesia, sedation and neuromuscular block**
  - Analgesia: Opioid like fentanyl and morphine
  - Sedation: Benzodiazepines like lorazepam and midazolam
  - Neuromuscular block: Pancuronium and vecuronium

### **Specific Therapy**

- **Mannitol:** Osmotic diuretic
  - Mechanism: Rheologic and osmotic
  - Adverse effect: (1) intravascular volume depletion and (2) acute renal failure
- **Glycerol** acts in a similar fashion but is used less often.
  - Glycerol has caloric value and is beneficial for nutritional support.
  - Renal function do not determine the diuretic action. Hence, it can be given to patients with renal insufficiency.
  - Side effect: is intravascular hemolysis, which can be prevented by giving a low concentration (<20%) at a slow infusion rate (>1 hour).
  - Glycerol is most effective via enteroduodenal administration.
- **Frusemide:** 20 mg 8 hourly.
- **Hypertonic saline:** A more recent treatment for increased ICP is IV administration of 3–23.4% hypertonic saline. IV boluses can reduce ICP and augment CPP for several hours. Creates an osmotic gradient and draws water from the intracellular and extracellular spaces into the intravascular compartment. Potential side effects are listed in Box 15.46.

**Box 15.46:** Side effects of treatment by hypertonic saline in raised ICP.

- Hyperosmolar central pontine myelolias
- Congestive heart failure
- Subdural hematomas
- Coagulopathy (rarely)

– The trauma guidelines recommend: Continuous infusion of 3% saline between 0.1 and 1.0 mL/kg/hour. Administration on a sliding scale, with the minimal dose needed to maintain ICP less than 20 mm Hg. Care to be taken while using hypertonic saline to decrease ICP, the osmolarity has to be maintained below 360 mOsm/L.

- **Steroids: Dexamethasone** 4 mg 6 hourly. Helps only in reducing vasogenic edema around tumor, abscess or subdural hematoma. Routine administration of steroids should be avoided in patients with traumatic brain injury and raised ICP.
- **Barbiturate coma in refractory cases:** Pentobarbital 5 mg/kg lowers ICP by lowering the rate of the body's metabolic process, oxygen consumption and carbon dioxide production. Burst suppression correlates with maximal metabolic suppression.
- **Hyperventilation:** Mechanism by which hyperventilation decreases raised intracranial tension is by decreasing cerebral blood volume by vasoconstriction. **Hyperventilation** resulting in drop in PaCO<sub>2</sub> to around 25–35 decreases cerebral blood flow.
- **Management of underlying cause** wherever possible or applicable.

### **Surgical Management**

- Management of underlying cause of raised ICP.

- **Mass lesion:** Surgical decompression of mass lesion, removal of space-occupying lesion. Surgical decompression is a life-saving procedure in which limited frontal or temporal lobectomies are done.
- **Hydrocephalus:** Ventriculoatrial or ventriculoperitoneal shunting.

## TUMORS OF THE NERVOUS SYSTEM

Among CNS tumors glial tumors are the most common, accounting for 50 to 60% of primary brain tumors. Meningiomas account for about 25% and schwannomas for about 10%. Few primary tumors are listed in Table 15.91.

**Table 15.91:** Few common tumors of CNS.

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• Astrocytomas               <ul style="list-style-type: none"> <li>– Low-grade astrocytoma</li> <li>– High-grade astrocytoma</li> </ul> </li> <li>• Oligodendrogliomas</li> <li>• Ependymomas</li> </ul> | <ul style="list-style-type: none"> <li>• Medulloblastoma</li> <li>• CNS lymphoma (more common in HIV patients)</li> <li>• Meningiomas</li> <li>• Schwannomas</li> </ul> |
|--|---|

### Cerebellopontine (CP) Angle Tumors

**Q. Write a short note on cerebellopontine angle (CP angle) tumors.**

Cerebellopontine (CP) angle is an area of lateral cistern containing CSF, arachnoid tissue, cranial nerves and its associated vessels.

- CP angle tumors constitute the most common posterior fossa tumors and majority of them are benign.
- Various CP angle tumors are listed in Table 15.92.

**Table 15.92:** Cerebellopontine angle tumors.

- |   |  |
|---|--|
| <ul style="list-style-type: none"> <li>• Vestibular schwannoma/acoustic neuroma</li> <li>• Meningioma</li> <li>• Cerebellar glioma</li> </ul> | Less likely: Arachnoid cyst, nonacoustic cranial nerve schwannomas, vascular malformations, dermoids, teratomas, and lipomas |
|---|--|

### Clinical Features

- Most common: Progressive unilateral sensory neural hearing loss (SNHL) (retrocochlear) present in 95% of cases and often accompanied by tinnitus which is present in 65% of cases.
- Rare presentations include facial numbness or pain, earache or facial

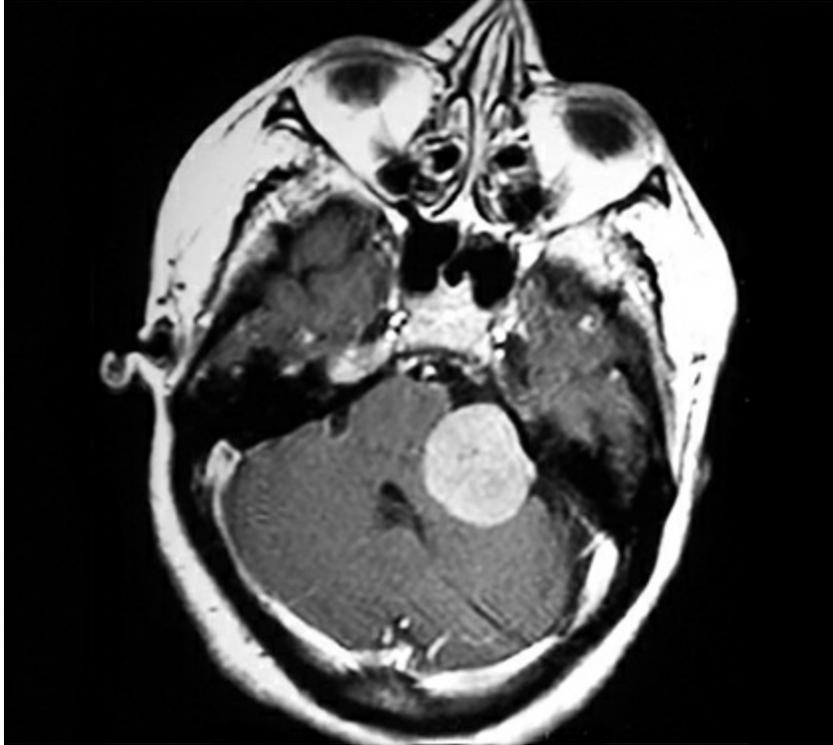

weakness, cerebellar ataxia or symptoms of hydrocephalus (headache, visual disturbance, mental status change, nausea, and vomiting).

## ***Signs***

- Ear: Normal otoscopy
- Cranial nerves:
  - 5th cranial nerve: Earliest sign is impaired corneal reflex. Motor functions are affected rarely.
  - 7th cranial nerve: Sensory first; loss of sensation in the posterior superior aspect of external auditory canal (EAC) called Hitselberger sign. Lower motor neuron facial palsy develops later.
  - 9th and 10th cranial nerve: Palsy-palatal, pharyngeal and laryngeal paralysis.
- Eyes: Nystagmus.
- Cerebellar signs present (ipsilateral).

## ***Investigations***

- **Audiological tests:** It shows features of retrocochlear hearing loss (high frequency SNHL), recruitment negative, poor speech discrimination score and presence of roll-over phenomenon.
- **Acoustic reflex:** Nearly in 75% patients the stapedial reflex is lost.
- **Caloric test:** It is diminished or absent. Normal test finding does not eliminate the diagnosis.
- **Plain X-ray:** The best view is periorbital view; difference of 1 mm in the vertical height of internal acoustic meatus is significant.
- **CT-scan (Fig. 15.33):** It cannot detect intermeatal tumors.

**Fig. 15.33:** CT showing CP angle tumor.

- **MRI:** With gadolinium enhancement is gold standard.

#### **Treatment**

- Surgical excision
- Radiotherapy: Stereotactic radiosurgery (gamma knife) may stop the growth of vestibular schwannoma mainly in small intracanalicular and extracanalicular lesions
- Radiosurgery is recommended in bilateral vestibular schwannomas (e.g. Morbus Recklinghausen) but only when the tumors are small.
- Annual imaging is recommended for all patients being managed conservatively for the rest of their life or until vestibular schwannoma growth is seen to a certain limit.

## **Acoustic Neuroma (Schwannoma)**

### **Q. Write short note on acoustic neuroma.**

- It is a benign tumor which arises from Schwann cells of the 8th cranial (vestibular) nerve. Majority are sporadic and unilateral.
- Common between the fourth and sixth decade of life, with a slight female preponderance.
- Site: Commonly arises near the nerve's entry point into the medulla or in the internal auditory meatus and extends into the cerebellopontine angle.

Constitutes 80–90% of tumors at the cerebellopontine angle.

**Clinical features:** Unilateral progressive hearing impairment/loss, sometimes with tinnitus. Large tumors may manifest signs and symptoms of cerebellar and brainstem involvement.

**Investigations:** MRI is the investigation of choice.

**Management:** Total surgical excision is the treatment of choice. Stereotactic radiosurgery (radiotherapy) may be used for some tumors.

## MISCELLANEOUS

### Neuroimaging

**Q. Write a short note on radiological investigation used in neurology.**

- About 90% of neurological cases can be diagnosed by history alone, with a lesser contribution from examination and investigation.
- Investigations include assessment of structure (imaging) and function (neurophysiology).
- Neurological imaging is used for **assessment of structure**. Various techniques include X-rays (plain X-rays, computed tomography (CT), CT angiography, myelography and angiography), magnetic resonance [MR imaging (MRI), MR angiography (MRA)] and ultrasound (Doppler imaging of blood vessels). However, it is now possible to use imaging techniques to assess CNS function also.
- **Single photon emission clinical tomography (SPECT)** scanning can be used to mark cerebral blood flow by using a lipid-soluble radioactive tracers. It is useful in dementia or epilepsy. SPECT is also useful in the **diagnosis of movement disorders** (e.g. by examining dopamine activity to assess the function of the basal ganglia in patients with suspected parkinsonism).

### *Magnetic Resonance Imaging*

Magnetic resonance imaging (MRI) is an imaging technique used mainly in medical field to produce high-quality images of the inside structures of the human.

The principle of MRI is based on the presence of hydrogen atom in all

human tissues. A hydrogen nucleus/atom is a proton whose electrical charge creates a local electrical field. Protons in body tissue are aligned to the magnetic axes. When protons are surrounded by a sudden strong magnetic impulses/field (as in an MRI machine), the protons are aligned along the field. Application of a radiofrequency wave at right angles to their alignment and are imaged. Then the field is suddenly reduced and the protons resonate and spin, then revert to their normal alignment. When the magnitude and rate of energy release occurs with return to baseline alignment, images are made at different phases of relaxation. They are known as T<sub>1</sub>, T<sub>2</sub>, T<sub>2</sub> STIR, FLAIR, diffusion weighted imaging (DWI) and other sequences. Recording is done by a coil. These intensities are used to produce images. T<sub>2</sub>-weighted sequence accentuate substances that contain fat and T<sub>2</sub>-weighted sequence accentuates substances that contain water.

**Interpretation:** In the brain, T<sub>2</sub>-weighted images reveal the nerve connections of white matter and appear white (hyperintense), the congregations of neurons of gray matter appear gray, and cerebrospinal fluid appears dark. These are reversed in T<sub>2</sub>-weighted imaging.

*Neurological indications for MRI (Box 15.47)*

**Box 15.47:** Neurological indications for MRI.

MRI is the investigation of choice for the evaluation all neurological disorders:

- Structural imaging: Produces high-quality soft tissue images. Useful in the investigation of disease of posterior fossa and temporal lobes, inflammatory conditions (e.g. multiple sclerosis), and in investigating epilepsy
- Magnetic resonance angiography (MRA) to study blood vessels in the neck or brain
- Functional MRI: Mainly research tools
- MR spectroscopy: Mainly research tools

**Q. Write a short note on neurological indications for MRI.**

**Advantages and Disadvantages of MRI**

Advantages and disadvantages of MRI are presented in Table 15.93.

**Table 15.93:** Advantages and disadvantages of MRI.

<i>Advantages of MRI</i>	<i>Disadvantages</i>
<ul style="list-style-type: none"> <li>• High-quality soft tissue images</li> <li>• No ionizing radiation involved</li> </ul>	<ul style="list-style-type: none"> <li>• Expensive and time consuming</li> <li>• Less widely available</li> </ul>

- Non-invasive
- Distinguishes between white and gray matter both in the brain and cord
- Spinal cord and nerve roots are directly imaged
- Pituitary imaging
- Resolution superior to CT
- Useful for demonstration of tumors (posterior fossa and temporal lobes), infarction, hemorrhage, MS plaques, posterior fossa, foramen magnum and cord. Detailed and accurate evaluation of breast cancers
- MR angiography (MRA) images blood vessels without contrast
- Cardiovascular MRI: Gold standard for quantifying ventricular volumes, ejection fraction and myocardial mass
- MRA images blood flow, not vessel anatomy
- Spatial resolution not as good as CT
- Requires experienced reader
- Not good for evaluation of bone cortex
- Claustrophobic
- Less effective than CT in detecting air (lungs) or gas (as in infection or bowel perforation)
- Contrast (gadolinium) reactions
- Contraindications for MRI include: Implanted cardiac pacemakers, vagus nerve stimulators, implanted cardioverter-defibrillators (ICD), cochlear implants and deep brain stimulators

### ***Contrast MRI***

- Gadolinium is used as intravenous contrast to assess the vascularity in tumors and inflammatory lesions.
- Side effects: Headache, nausea, pain and sensation of cold at the injection site, dizziness, and rarely nephrogenic systemic fibrosis (fibrosis of dermis, joints and internal organs including lungs and heart). Contrast (gadolinium) imaging can worsen renal failure, so its best avoided in Acute kidney injury (AKI)/chronic kidney disease (CKD).

### ***Special forms of MRI***

- Diffusion MRI: To measure the movement or diffusion of extracellular water molecules.
- MR angiography helps us to evaluate intracranial vessels noninvasively to find for aneurysms, stenosis or malformations.
- Magnetic resonance spectroscopy
- Functional MRI to assess blood flow during specific tasks (e.g. speaking, remembering, calculation).

**Complications:** MRI is a safe procedure. However, if a metal is present nearby serious injuries may develop when metal gets attracted to strong magnets of MRI and may act like a missile.

### ***X-ray/CT Plain X-rays, CT, CTA***

- Applications: Radiculography, myelography, intra-arterial angiography
  - X-rays: For fractures or foreign bodies
  - CT: First line for stroke
  - Intra-arterial angiography: Gold standard for vascular lesions.

**Advantages:** Easily available, relatively economical, and relatively quick.

### ***Ultrasound-Doppler Studies***

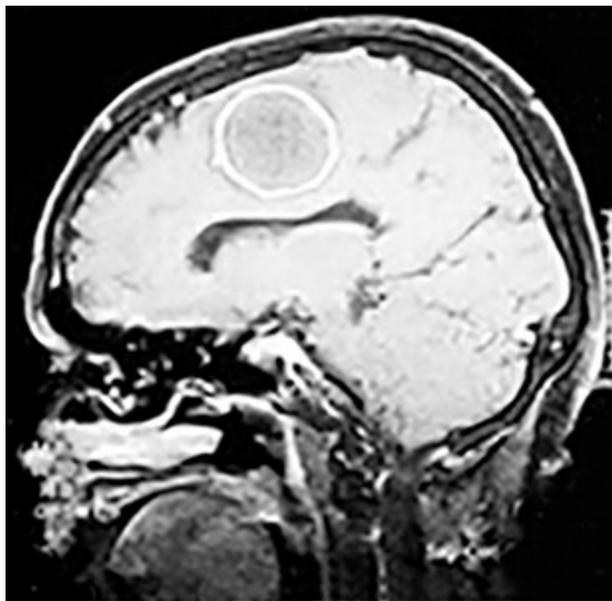

- Cheap, quick and noninvasive.
- B mode and color ultrasound are useful in identifying carotid stenosis.

### ***Radioisotope***

For establishing the diagnosis, we need to do radioisotope scan, single photon emission tomography (SPECT) and positron emission tomography.

### **Q. Discuss the differential diagnosis for ‘Ring enhancing lesions’.**

It is abnormal radiological findings observed in MRI or CT scans obtained using radio-contrast. On the image, it appears as an area of decreased density surrounded by a bright rim from concentration of the enhancing contrast dye (Fig. 15.34).

**Fig. 15.34:** Ring enhancing lesion on MRI.

### **Causes in the Brain**

- Infections: Early brain abscess, tuberculoma, CNS toxoplasmosis, cysticercosis, fungal infections

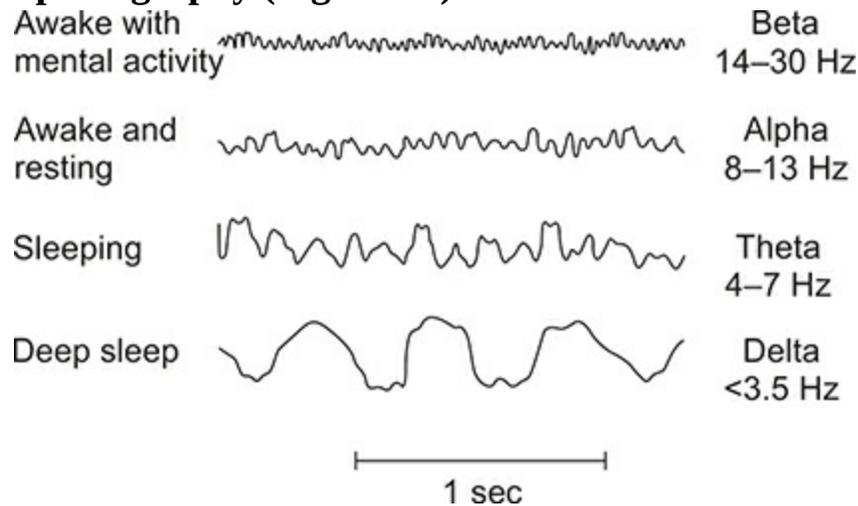

(nocardiosis, cryptococosis), neurosyphilis.

- Inflammatory: Demyelinating disorders (multiple sclerosis, ADEM), sarcoidosis, Behcet's disease, Whipples disease.
- Vascular: Cerebral venous thrombosis and several other vasculitic disorders.
- Neoplastic: Primary (e.g. glioblastoma, low-grade gliomas, CNS lymphoma) and metastasis.

## NEUROPHYSIOLOGICAL TESTING

**Q. Write a short note on electroencephalography.**

- **Electroencephalography (Fig. 15.35)**

**Fig. 15.35:** Normal adult brain waves seen in electroencephalography.

- The electroencephalogram (EEG) recorded from scalp by placing electrodes on the scalp. It is used to detect electrical activity arising in the cerebral cortex. Rhythmic activity is recorded as waves (alpha, beta, gamma, theta, mu, and delta).
- **Usefulness**
  - ◆ In progressive and continuous disorders such as reduced consciousness, classification and prognosis in epilepsy and diffuse brain diseases [encephalitis, prion (Creutzfeldt–Jakob) diseases and metabolic states (e.g. hypoglycemia, hepatic coma)].
  - ◆ **Role in epilepsy:** To confirm the clinical diagnosis and differentiation of primary generalized attacks from focal epilepsies.
- **Video EEG:** Useful in definitive diagnosis of epilepsy.
- **Ambulatory EEG** is analogous to Holter monitor for cardiac arrhythmias.

## Lathyrism

### Q. Write short note on lathyrism.

Lathyrism is a paralyzing disease caused by eating seeds of *Lathyrus sativus* (khesari dal).

**Epidemiology:** It is prevalent mostly people in India (e.g. Madhya Pradesh, Uttar Pradesh, Bihar and Odisha), Bangladesh, Pakistan, Nepal and Algeria.

**Etiology:** *Lathyrus sativus* (khesari dal) is a good source of protein. It is relatively cheap pulse and is consumed mostly by the poor agricultural laborer. But it contains L-ODAP ( $\beta$ -N-oxalyl-L- $\alpha$ -diamino propionic acid) also called  **$\beta$ -N-oxalyl-amino-L-alanine, or BOAA**, which is an excitatory neurotoxin and glutamate agonist. If the diets containing more than 30% of this dhal is consumed over a period of 2–6 months will produce lathyrism.

**Clinical features:** Affects mainly young males between 15 and 45 years of age. In humans it mainly affects nervous system and is called neurolathyrism which produces **pure motor spastic paraplegia**. Sensations and sphincters are preserved.

### Stages

- **Latent stage:** Patient appears healthy but when subjected to physical stress exhibits ungainly gait. If the disease is recognized at this stage, age, withdrawal of pulse from the diet will result in complete remission of disease.
- **No-stick stage:** During this stage, the patient walks with difficulty having short jerky steps but does not need the aid of a stick.
- **One-stick stage:** The patient walks with a crossed gait with a tendency to walk on toes and develops musculoskeletal stiffness. Use of a stick is necessary to maintain balance.
- **Two-stick stage:** Symptoms are more severe at this stage. Due to excessive bending of the knees and crossed legs, the patient requires support by two crutches for support. The gait is slow and clumsy and complains of easy tiredness after walking a short distance.
- **Crawler stage:** Finally spastic paralysis develops which becomes irreversible. It becomes impossible to maintain erect posture as the knee joints cannot support the weight of the body. The thigh and leg muscles become atrophied and patient crawls by throwing his weight on his hands.

## ***Prevention***

- **Vitamin C prophylaxis** 500–1000 mg for a week
- **Banning the crop** if possible
- **Removal of toxin:**
  - **Steeping method:** Soaking the pulse in hot water for 2 hours and the soaked water is drained off completely. The pulse is washed again with clean water and then drained off and dried in the sun. There will be loss of vitamins and minerals by this method.
  - **Parboiling:** Suitable for large scale operation and is similar to parboiled rice. It destroys trypsin inhibitors.

# Toxicology

# CHAPTER 16

## Clinical Assessment of Ingested Poison

**Q.** Enumerate the clinical features in general that would help you in diagnosing the poison ingested.

Various parameters in clinical assessment to determine the type of poisons are listed in Table 16.1.

**Table 16.1:** Characteristic features and the type of poisons.

<i>Characteristics</i>	<i>Type of poison</i>
<b>ODOR</b>	
Bitter almonds	Cyanide
Acetone	Isopropyl alcohol, methanol, paraldehyde, salicylates
Alcohol	Ethanol
Wintergreen	Methyl salicylate
Garlic	Arsenic, thallium, organophosphates
<b>OCULAR SIGNS</b>	
Miosis (small pupil size)	Narcotics (except meperidine), organophosphates, muscarinic mushrooms, clonidine, phenothiazines, chloral hydrate, barbiturates (late), PCP (phencyclidine)
Mydriasis (large pupil size)	Atropine, alcohol, cocaine, amphetamines, antihistamines, tricyclic antidepressants, cyanide, carbon monoxide
Nystagmus	Phenytoin, barbiturates, ethanol, carbon monoxide
Lacrimation	Organophosphates, irritant gas or vapors
Retinal hyperemia	Methanol
Poor vision	Methanol, botulism, carbon monoxide
<b>CUTANEOUS SIGNS</b>	
Needle tracks	Heroin, phencyclidine (PCP), amphetamines
Bullae	Carbon monoxide, barbiturates
Dry, hot skin	Anticholinergic agents, botulism

Diaphoresis	Organophosphates, nitrates, muscarinic mushrooms, aspirin, cocaine
Alopecia	Thallium, arsenic, lead, mercury
Erythema	Boric acid, mercury, cyanide, anticholinergics
Cyanosis	CNS depressant
<b>ORAL SIGNS</b>	
Salivation	Organophosphates, salicylates, corrosives, strychnine
Dry mouth	Amphetamines, anticholinergics, antihistamine
Burns	Corrosives, oxalate-containing plants
Gum lines	Lead, mercury, arsenic
Dysphagia	Corrosives, botulism
<b>INTESTINAL SIGNS</b>	
Cramps	Arsenic, lead, thallium, organophosphates
Epigastric tenderness	Salicylates, nonsteroidal anti-inflammatory drugs (NSAIDs)
Diarrhea	Antimicrobials, arsenic, iron, boric acid
<b>Characteristics</b>	<b>Type of poison</b>
Constipation	Lead, narcotics, botulism
Hematemesis	Aminophylline, corrosives, iron, salicylates
<b>CARDIAC SIGNS</b>	
Tachycardia	Atropine, aspirin, amphetamines, cocaine, cyclic antidepressants, theophylline
Bradycardia	Digitalis, narcotics, mushrooms, clonidine, organophosphates, $\beta$ -blockers, calcium-channel blockers
Hypertension	Amphetamines, LSD (lysergic acid diethylamide), cocaine, PCP
Hypotension	Phenothiazines, barbiturates, tricyclic antidepressants, iron, $\beta$ -blockers, calcium-channel blockers
Cardiac conduction delays (Wide QRS)	Cocaine, tricyclic antidepressants, lignocaine, propoxyphene, antiarrhythmics (e.g. quinidine, flecainide)
<b>RESPIRATORY SIGNS</b>	
Depressed respiration	Alcohol, narcotics, barbiturates
Increased respiration	Amphetamines, aspirin (salicylates), ethylene glycol, carbon monoxide, cyanide
Pulmonary edema	Hydrocarbons, heroin, organophosphates, aspirin
<b>CNS SIGNS</b>	
Ataxia	Alcohol, antidepressants, barbiturates, anticholinergics, phenytoin, narcotics
Coma	Sedatives, narcotics, barbiturates, PCP, organophosphates, salicylates, cyanide, carbon monoxide, cyclic antidepressants, lead
Hyperpyrexia	Anticholinergics, quinine, salicylates, LSD, phenothiazines, amphetamines, cocaine

Hypothermia	CNS depressant (opioids, chlorpromazine)
Muscle fasciculation	Organophosphates, theophylline
Muscle rigidity	Cyclic antidepressants, PCP, phenothiazines, haloperidol
Extrapyramidal signs	Phenothiazines, haloperidol, metoclopramide
Paresthesia	Cocaine, camphor, PCP, MSG (monosodium glutamate)
Peripheral neuropathy	Lead, arsenic, mercury, organophosphates
Altered behavior	LSD, PCP, amphetamines, cocaine, alcohol, anticholinergics, camphor
Seizures	Tricyclic antidepressants (TCA), INH, selective serotonin reuptake inhibitors (SSRIs)
<b>METABOLIC</b>	
Metabolic acidosis	Cyanide, ethylene glycol, metformin, methanol, salicylates

## Toxidromes (Table 16.2)

**Q. List the common toxidromes that are commonly encountered in clinical practice.**

Based on history and clinical findings, it may be possible to define a syndrome associated with certain poisons. This is called toxidrome.

**Q. Write short essay on general principles of management of an ingested a poison.**

### Management/Treatment

#### Goals of Treatment

These include: (A) Support of vital signs, (B) Reduce absorption of the toxin, (C) Enhance of poison elimination and (D) Neutralize toxin.

#### A. Supportive care

Patients who are seriously poisoned must receive early appropriate management. Outcome depends on appropriate nursing and supportive care, and on appropriate treatment of complications. The aims are:

- To **maintain physiologic homeostasis** till poison is eliminated from the body and the patient resumes normal physiological functions.
- To **prevent and treat secondary complications**: Supportive therapy for central nervous system (e.g. cerebral edema), cardiopulmonary system (e.g. pulmonary edema, pneumonia) and renal system with proper care for coma, seizures, hypotension, bedsores, arrhythmias, sepsis, thromboembolic disease, coagulopathy, hypoxia and acute renal failure.

#### B. Reduce Absorption of the Toxin

*Inhalational exposure*: Evacuation from toxic environment and provision of supplemental oxygen.

*Dermal exposure*: Removal of contaminated clothing and shower or irrigation of affected site (dust before shower for dry chemical).

*For eye exposure*: Removal of chemicals by copious irrigation of the affected eye by up to 1 liter of

saline or symptomatic improvement occurs.

*Oral exposure:* Inducing emesis, performing gastric lavage, activated charcoal, whole bowel irrigation, cathartics.

#### *Gastric decontamination*

- **Emesis induction:** Forced emesis, if patient is awake (using saline, ipecac).
- **Gastric lavage** should be considered for life-threatening poisons that cannot be treated effectively with other therapies.
  - **Time of lavage:** Gastric lavage decreases absorption by 42% if done 20 minutes and by 16% if performed at 60 minutes.
  - **Method:** Performed by first aspirating the stomach and then repetitively instilling and aspirating fluid. Choice of fluid is tap water— 5–10 mL/kg. Left lateral position better and delays spontaneous absorption.

No evidence that larger tube better. Simplest, quickest and least expensive way is by using funnel.

#### **Box 16.1:** Complications of gastric lavage.

- Aspiration pneumonia
- Perforation of the esophagus
- Laryngospasm/hypoxia/tension pneumothorax
- Tachycardia and cardiac dysrhythmias (atrial and ectopic beats)
- Fluid and electrolyte imbalance—hyponatremia; water intoxication.

Preferably done on awake patients. Presence of an ET tube does not prevent aspiration, and is preferred, if GCS (Glasgow Coma Scale) is low.

**Contraindication:** Comatose patients, corrosive poisoning, kerosene (hydrocarbons) poison and in patients with convulsions.

- Complications of gastric lavage (Box 16.1):
- **Activated charcoal administration:** 50–100 g activated charcoal should be administered at a rate of not less than 12.5 g/h through nasogastric tube.
- **Cathartics:** Sorbitol magnesium citrate, magnesium sulphate, sodium sulphate as cathartic. for patients who have ingested materials that are absorbed slowly.
- **Dilution-milk/other drinks:** Advised only after the ingestion of corrosives (acids, alkali).
- **Whole bowel irrigation:** 1500–2000 mL/h through a nasogastric tube. It is performed by administering a bowel-cleansing solution containing electrolytes and polyethylene glycol by gastric tube. It may be used for potentially toxic ingestions of sustained release or enteric-coated drugs or to remove illicit drug.
- **Endoscopic or surgical removal** of ingested substance may be useful in rare situations (e.g. ingestion of a potentially toxic foreign body that fails to transit the gastrointestinal tract).

#### *C. Enhance of Poison Elimination*

- **Indications:** Increased elimination is possible only if
  - Drug is distributed predominantly in the ECF (extracellular fluid) and drugs that have a low protein binding.
- **Methods:** Keep a good urine output 150–200 mL/hr.
  - **Alkalinization of urine using sodium bicarbonate to produce urine with a pH  $\geq$  7.5:** For salicylate, methotrexate and phenobarbital poisoning.
  - **Extracorporeal removal:**

- ◆ **Hemodialysis:** For barbiturates, salicylates, acetaminophen, valproate, alcohols, glycols.
- ◆ **Hemoperfusion:** For theophylline, digitalis, paraquat lipid-soluble drugs.

D. Neutralize Toxin

**Q. Write short note on antidote.**

By toxin-specific antidotes (Table 16.3).

**Table 16.2: Various toxidrome and related findings.**

<b>Toxidrome</b>	<b>Vital signs</b>	<b>Mental status</b>	<b>Pupils</b>	<b>Other findings</b>	<b>Examples</b>
Anticholinergic (Fig. 16.1)	Hyperthermia, tachycardia, hypertensive, tachypnea	Hyperthermia agitated, hallucinating	Mydriasis	Dry flushed skin, urinary retention	Antihistamines, TCAs, atropine, scopolamine, antispasmodics
Cholinergic (Fig. 16.2)	Bradycardia (muscarinic), tachycardia and hypertension (nicotinic)	Confused, coma	Miosis	<b>SLUDGE</b> (Salivation, lacrimation, urination, diarrhea, GI upset, emesis)	Organophosphate pesticides, nerve agents, physostigmine
Hallucinogen	Hyperthermia, tachycardia, hypertension	Hallucination, synesthesia, agitation	Mydriasis	Nystagmus	PCP (phencyclidine), LSD (lysergic acid diethylamide), mescaline
Opioid	Hypothermia, Bradycardia, Hypotension, bradypnea	CNS depression, coma	Miosis	Hyporeflexia, pulmonary edema	Opioids (heroin, morphine, methadone, dilaudid, etc.)
Sedative-hypnotic	Hypothermia, bradycardia, hypotension, bradypnea	CNS depression, confusion, coma	Miosis	Hyporeflexia	Benzodiazepines, barbiturates, alcohols
Serotonin syndrome (Fig. 16.3)	Hyperthermia, tachycardia, hypertension, tachypnea	Confused, agitated coma	Mydriasis	Tremor, myoclonus, diaphoresis, hyperreflexia, trismus, rigidity	MAOIs, SSRIs, meperidine, dextromethorphan
Sympathomimetic (Fig. 16.4)	Hyperthermia, tachycardia, tachypnea	Agitated hyperalert, paranoia	Mydriasis	Diaphoresis, tremors, hyperreflexia, seizures	Cocaine, amphetamines, pseudoephedrine

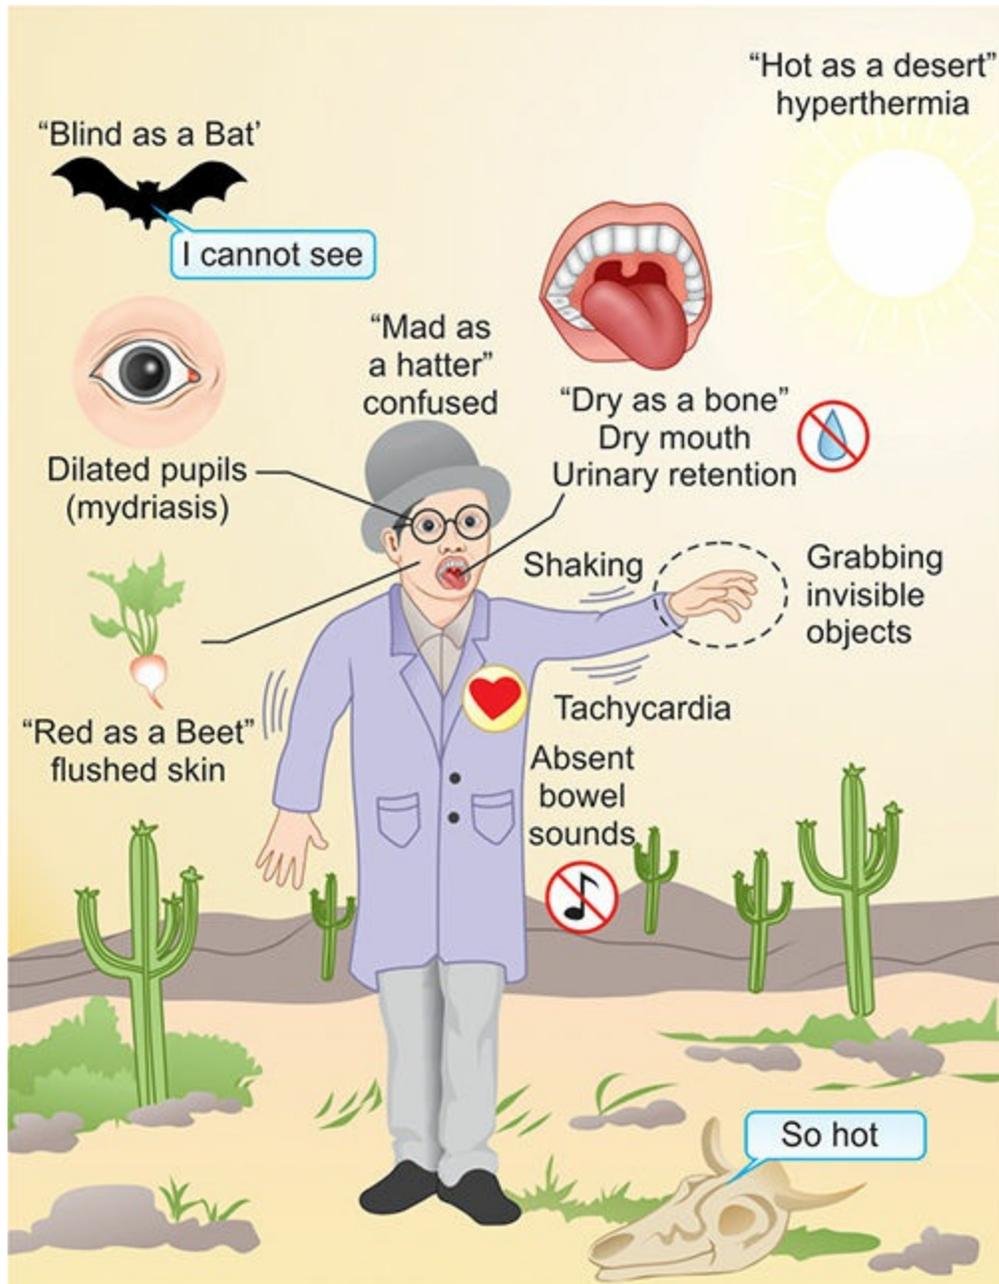

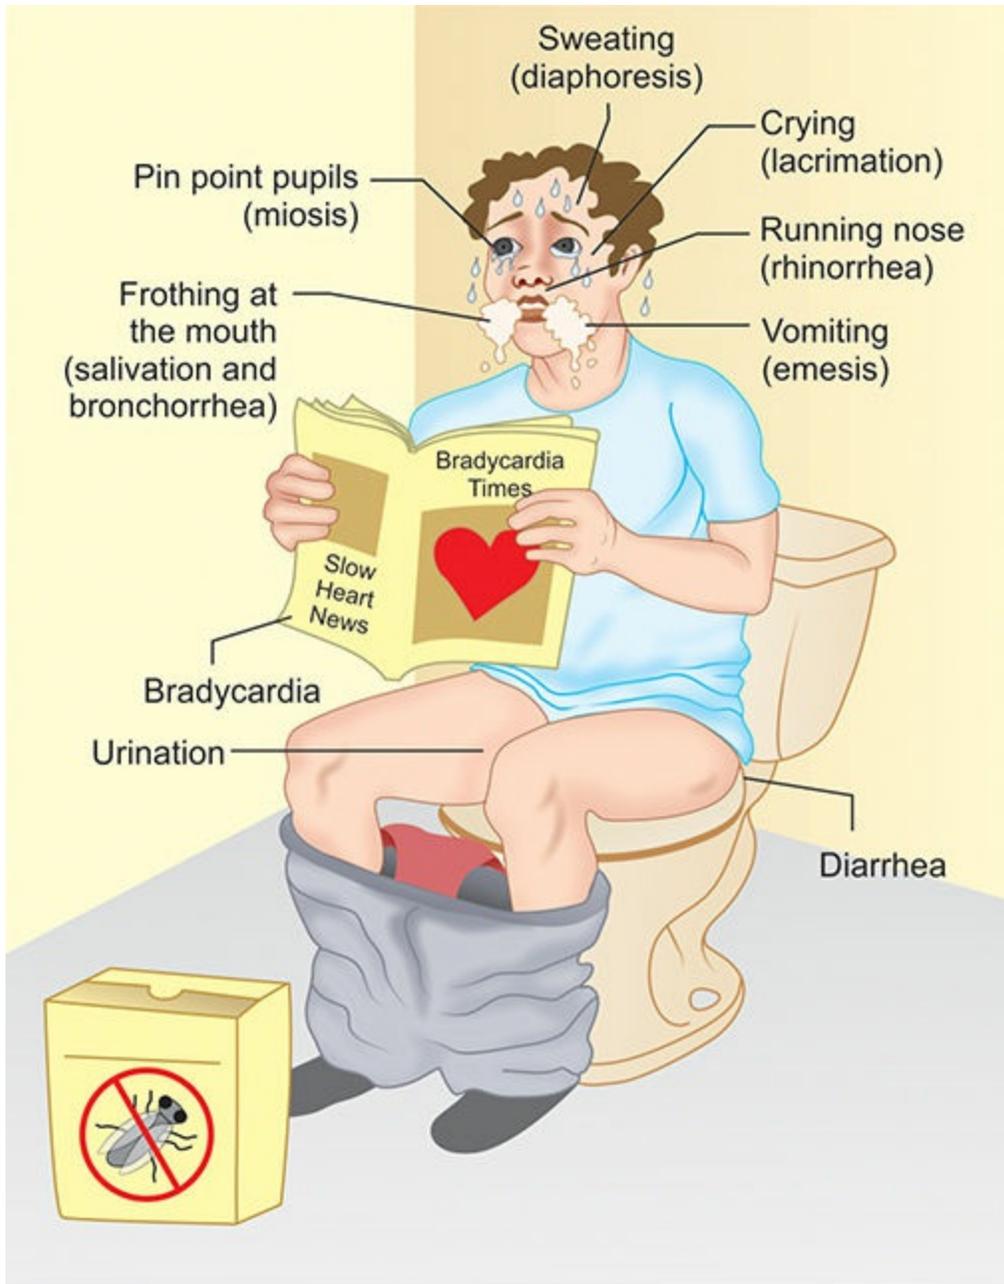

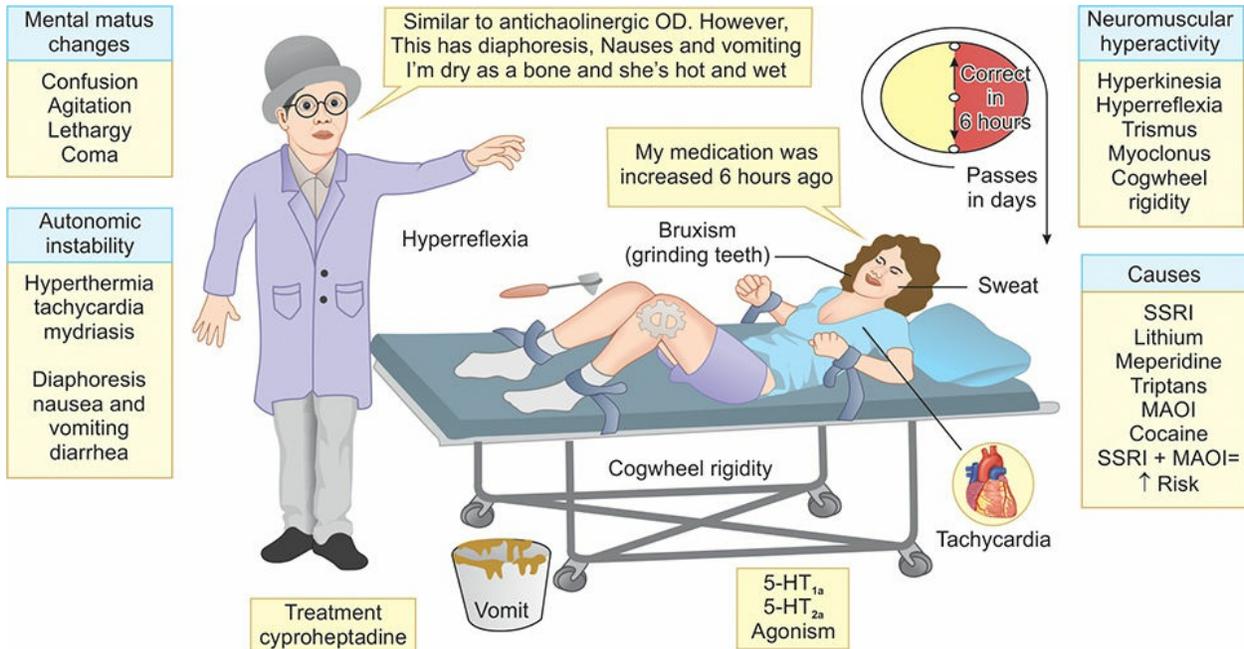

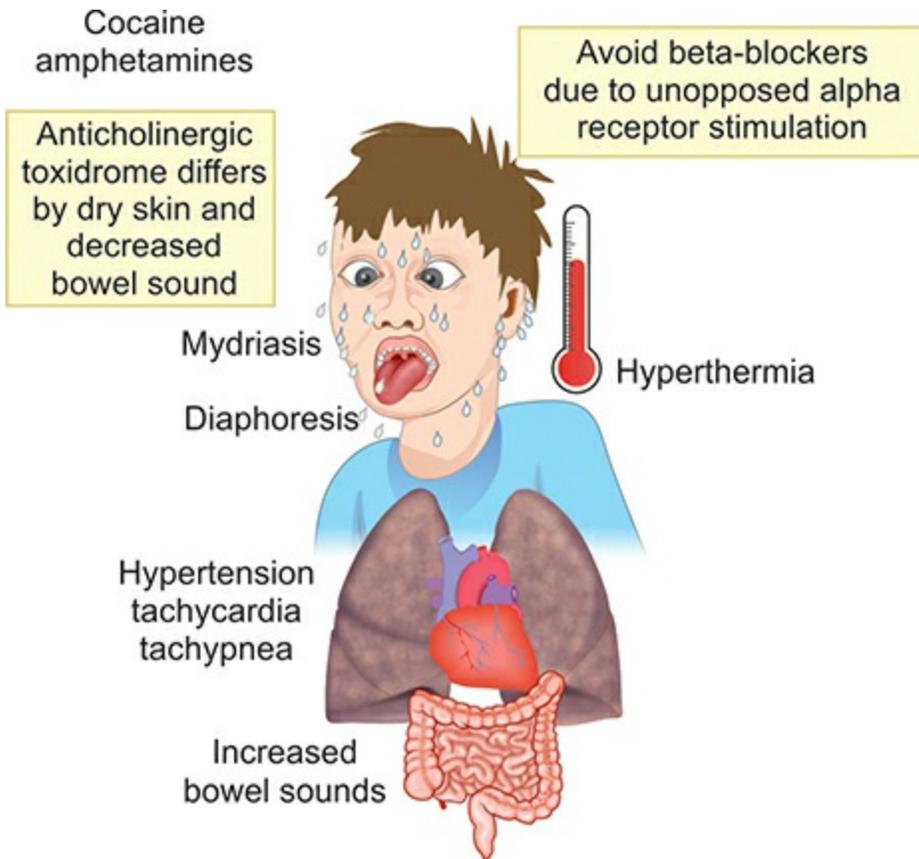

Fig. 16.1: Anticholinergic toxidrome.

**Fig. 16.2:** Cholinergic toxidrome.

**Fig. 16.3:** Serotonin syndrome.

**Fig. 16.4:** Sympathomimetic toxidrome.

**Table 16.3: Toxin-specific antidotes.**

<i>Toxin/poison</i>	<i>Specific antidote</i>	<i>Toxin/poison</i>	<i>Specific antidote</i>
Acetaminophen	N-acetyl cysteine	Methanol	Ethanol, fomepizole
Anti-cholinergics	Physostigmine	Methemoglobinemia	Methylene blue
Benzodiazepines	Flumazenil	Glycol	Ethanol, fomepizole
Beta- blockers	Glucagon	Opioid	Naloxone
	Calcium	Oral hypoglycemics	Glucose
	Insulin + dextrose/lipid emulsion therapy	Organophosphate	Atropine/2-PAM (pralidoxime)
Calcium-channel blockers	Glucagon		
	Insulin+dextrose (hyperinsulinemia euglycemia therapy)	Snake bites	Snake antivenom
	Calcium/lipid emulsion therapy	Sulfonylurea	Octreotide + dextrose
Carbamate	Atropine	Tricyclic antidepressants	Sodium bicarbonate
Carbon monoxide	Hyperbaric oxygen	Warfarin	Vitamin K
		Copper	Penicillamine, dimercaprol, Ca EDTA
Cyanide	Amyl nitrite pearls Sodium nitrite (3% solution) Sodium thiosulfate (25%)	Iron	Desferroxamin
		Lead	CaEDTA, dimercaprol, British anti-Lewisite (BAL)
		Mercury	DMPS (2,3-Dimercapto-1-propane sulfonic acid), DMSA (dimercaptosuccinic acid), BAL
Digoxin	Digoxin antibodies	Arsenic	BAL and derivatives
Heparin	Protamine sulfate	Antimony	BAL and derivatives
INH	Pyridoxine		

## INSECTICIDE POISONING

**Q. Write short essay/note on clinical manifestations, diagnosis, complications and management of organophosphorus and carbamate poisoning.**

### Organophosphate and Carbamate Poisoning

Organophosphorus (OP) compounds are widely used as pesticides in developing countries and are a common cause of poisoning.

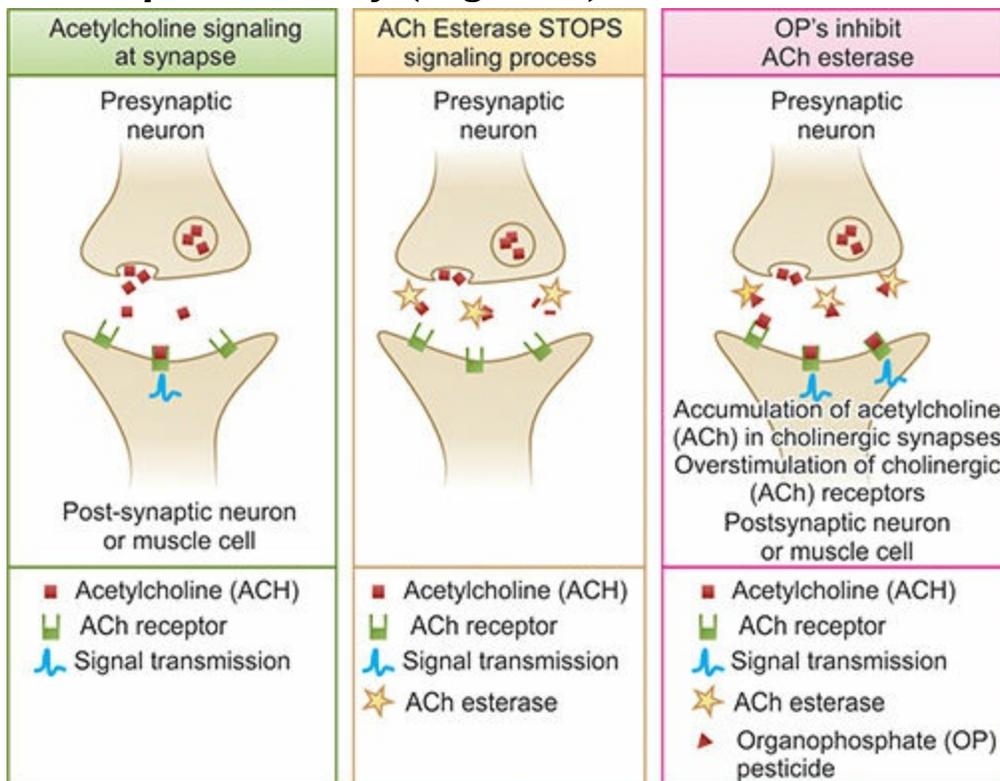

## ***Classification of Organophosphate and Carbamate (Box 16.2)***

**Box 16.2:** Classification of organophosphate and carbamate.

- **Organophosphorus**
  - **Diethyl organophosphorus:** Quinalphos, chlorpyrifos, diazinon, triazophos, phorate dimethoate, parathion-ethyl
  - **Dimethyl organophosphorus:** Monocrotophos, dichlorvos, acephate, malathion, fenthion, mathamidophos and phosphamidon
- **Carbamate:** Methomyl
- **Organochlorine:** Endosulfan, endrin
- **Pyrethroids:** Cypermethrin, alphacypermethrin, deltamethrin, cyhalothrin.
- **Neonicotinoid:** Imidacloprid, acetamiprid.

**Mode of intoxication:** It may occur through ingestion, inhalation or dermal absorption.

## ***Mechanism of OP Toxicity (Fig. 16.5)***

**Fig. 16.5:** Mechanism of organophosphorus poisoning.

- OP compounds irreversibly bind to serine-OH group at the active site of acetylcholinesterase (AChE) and phosphorylate. This inactivates the enzyme AChE.
- It leads to the accumulation of acetylcholine (ACh) in cholinergic synapses.
- Spontaneous hydrolysis of the OP-enzyme complex allows reactivation of the enzyme. However, loss of a chemical group from the OP-enzyme complex prevents further enzyme reactivation, a process known as **'aging'**. Aging is characterized by loss of alkyl group + strengthening of covalent bond.
- Phosphorylated AChE is very stable. Inhibition of enzyme activity → accumulation of ACh in the synapse and NMJ. It causes overstimulation of cholinergic receptors. After aging has taken place; new enzyme needs to be synthesized before function can be restored.

### ***Clinical Course after Acute Poisoning (Table 16.4)***

**Q. Write short essay/note on clinical signs of organophosphorus poisoning.**

### ***Triphasic Illness***

#### 1. *Acute cholinergic syndrome*

- **Onset:** Cholinergic symptoms within first 24 hours.
- **Features:** Garlic-like odor in the breath/vomit/clothes, bradycardia (80%), miosis, fasciculations, twitching, convulsions, flaccid paralysis of limbs and extraocular muscles, central depression of respiratory system.

#### 2. *Intermediate syndrome*

- **Onset:** 24–96 hours after poisoning, after the cholinergic phase settles
- **Mechanism:** Excess Ach at NMJ causes down-regulation of nicotinic receptors and muscles affected.
- **Features:** Characterized by proximal neck muscle leading to respiratory distress and failure without muscarinic signs, without intervention, cyanosis, coma and death occurs rapidly.
- **Duration:** Lasts for few days to about 3 weeks.

#### 3. *OP-induced delayed polyneuropathy (OPIDN)*

- **Onset:** 1–3 weeks after acute exposure
- **Mechanism:** Due to degeneration of long myelinated nerve fibers. Pure motor or sensor-motor.
- **Features:** Characterized by cramps in the legs, numbness and paresthesia in the distal upper and lower limbs, shuffling gait, foot and wrist drop. Other features are: wasting, DTR reduced/absent, pyramidal tract signs absent.
- **Recovery is incomplete.**

**Table 16.4:** Clinical course after acute organophosphorus poisoning.

<i>Time of manifestation</i>	<i>Mechanism</i>	<i>Manifestation</i>
<i>Due to cholinergic excess</i>		
Acute (minutes to 24 hours) Acute cholinergic syndrome	Nicotinic receptor action	<i>Musculoskeletal:</i> Weakness, fasciculations, cramps, paralysis
		<i>Cardiovascular:</i> Tachycardia, hypertension
	Muscarinic receptor action	<i>Gastrointestinal:</i> Increased salivation, nausea, vomiting, abdominal pains, diarrhea, fecal incontinence <i>Genitourinary:</i> Urinary incontinence <i>Cardiovascular:</i> Bradycardia, hypotension <i>Respiratory:</i> Rhinorrhea, stridor, bronchospasm, bronchorrhea, cough <i>Ocular:</i> Lacrimation, miosis <i>Skin:</i> Flushing, diaphoresis, cyanosis
	Central receptors	Anxiety, restless, convulsions, insomnia, tremors, respiratory depression
<i>Other than cholinergic excess</i>		
Delayed (24 hours to 2 week)-Intermediate syndrome	Nicotinic receptor action	Intermediate syndrome
	Muscarinic receptor action	Bradycardia, miosis, salivation
	Central receptors	Coma, extrapyramidal manifestation
<i>Late (beyond 2 week):</i> Delayed polyneuropathy	Peripheral neuropathy target esterase	Peripheral neuropathy

### **Diagnosis of Organophosphate Poisoning**

- **Clinical diagnosis:** Dreisbach’s severity of organophosphorus poisoning is presented in Table 16.5.

- **Laboratory:**
  - Red cell cholinesterase
  - Plasma [Pseudo, Butyryl (Bu)] cholinesterase.
  - **ECG:** The most common ECG abnormality was prolonged QTc and sinus tachycardia
  - **ABG:** Hypoxemia.

**Table 16.5:** Dreisbach’s classification showing severity of poisoning.

<i>Grade</i>	<i>Symptoms</i>
Mild	Nausea
Moderate	Lacrimation, salivation, miosis, fasciculation
Severe	Incontinence, apneic spells, ARDS, areflexia seizures, coma

**Q. Write short essay/note on drugs used with dosage and treatment of organophosphorus poisoning.**

**Management of Organophosphate**

**Acute Cholinergic Syndrome**

*Steps*

- Assess and record 15-point Glasgow Coma Scale (GCS) (Refer Table 15.82)
- Measure pulse rate and blood pressure and auscultate the lungs.
- *Make patients to lie down in the left lateral position:* With head lower than the feet.
- Start oxygen.
- Intubate, if the patient has a respiratory distress. Start atropine quickly to reduce bronchorrhea responsible for respiratory distress.
- Set-up an infusion of 0.9% normal saline. Aim at systolic blood pressure 80 mm Hg and urine output >30 mL/h.
- Remove the contaminated clothes and thoroughly wash the skin with soap and water.
- Perform gastric decontamination with gastric lavage once the patient is stabilized and within two hours of ingestion. Skin exposure would require irrigation of the skin with copious amounts of water and liberal use of soap. Eye exposure should be irrigated with copious amount of normal saline.
- Give activated charcoal (50 g in 200 mL) (Not much benefit due to rapid absorption of poison into blood).

*Drugs Used*

**1. Atropine**

- Early use of sufficient doses of atropine is **life-saving in patients with severe toxicity**. It reverses ACh-induced bronchospasm, bronchorrhea, bradycardia and hypotension.
- **When the diagnosis is uncertain:**

- **Atropine test:** To be performed, if not sure that the patient has consumed OP.
  - ◆ **Inject 0.6–1 mg IV atropine:** If pulse rate goes up by 25 per minute or skin flushing develops patient has mild or no toxicity or OP poisoning is unlikely.

### Dose and mode of administration of atropine

- **Bolus**
  - Inject 1.8–3 mg (3–5 mL) of atropine bolus.
  - *Check three things after five minutes:* pulse, blood pressure and chest crepitations.
  - Aim for heart rate >80 beats per minute, SBP >80 mm Hg, and a clear chest.
  - If the above-mentioned objectives are not achieved, double the atropine dose every five minutes.
  - Review patient every 5 minutes. Once these parameters start improving, repeat last same or smaller dose of atropine. If there is persistent and satisfactory improvement in these parameters after 5 min, atropine infusion can be planned.
- **Atropine infusion**
  - Calculate total dose of atropine required for rapid atropinization.
  - Start hourly atropine infusion at 10–20% of total dose of atropine required for atropinization.
  - Most patients do not need >3–5 mg per hour of atropine infusion.
  - Use three-point checklist (**secretions, heart rate, pupils**) to reduce infusion rate by 20% every 4 hourly once the patient is stable. Target end points for atropine infusion are presented in Box 16.3.
  - Bronchorrhea is the most important sign for titrating dose of atropine once patient is stable.

### Atropine toxicity = absent bowel sounds + fever + confusion

- Stop atropine infusion for 60 min, if patient has developed atropine toxicity. Re-start infusion at lower rate, once the temperature comes down and the patient gets calm. If atropine is contraindicated, glycopyrrolate can be used for bronchorrhea. **Glycopyrronium bromide** can be an alternative for peripheral symptoms.

### Box 16.3: Target end points for atropine infusion.

- Clear chest on auscultation
- Heart rate >80 beats per min (WHO recommends >100 bpm)
- Systolic BP >80 mm Hg
- Pupils no longer pinpoint
- Dry axillae

### Q. Write short essay/note on pralidoxime (2-PAM).

**2. Pralidoxime (2-PAM):** Pralidoxime reactivates acetylcholinesterase enzymes by removing the phosphoryl group deposited by the organophosphate.

- Only to treat organophosphorus poisoned patients.
- *Bolus dose:* 30 mg/kg (i.e. 1–2 g for adults) in 100 mL normal saline over 15–30 minutes.
- *Maintenance dose:* Continuous infusion of 8–12 mg/kg per hour.
- PAM must be given by infusion. Go slow, both for bolus and maintenance. A fast infusion can cause vomiting, hypertension, cardiac arrhythmia or a cardiac arrest.
- Give PAM until atropine is no longer required.

### 3. Benzodiazepines

- *Agitation and seizures*: Diazepam 10 mg slow IV push, repeated as necessary. Up to 30–40 mg diazepam per 24 hours can be given.

#### Ventilator

- Ventilatory support should be started before the patient develops respiratory failure.

#### Other therapies:

- **Magnesium sulfate** blocks ligand-gated calcium channels, resulting in reduced acetylcholine release from presynaptic terminals, thus improving function at neuromuscular junctions, and reduced CNS over-stimulation mediated via NMDA receptor activation.
- **Sodium bicarbonate** in place of oximes.
- **Alpha2-adrenergic receptor agonist** clonidine also reduces acetylcholine synthesis and release from presynaptic terminals.
- **Hemodialysis and hemofiltration** role not yet clear.
- **Butyryl cholinesterase** scavenges OP in plasma, reducing the amount available to inhibit acetylcholinesterase in synapses.

**Drugs for future:** *Huperzine A and ZT-1*: HupA has been proven to be a powerful, highly specific, and reversible inhibitor of acetylcholinesterase.

## Chronic Organophosphate Poisoning

### Clinical features

- Delay polyneuropathy (OPIDN)
- Neuropsychiatric disorder
- **Triorthocresyl phosphate (To CP) poisoning** associated polyneuropathy also called as **Ginger Jake Paralysis**. Owing to the consumption of ginger which was used in manufacture of bootleg alcohol and was adulterated with TOCP. It usually manifests after about 10 to 20 days causes distal predominant neuropathy.
- **Diagnosis:** Clinical diagnosis, by suspicious and exclusion.

**Treatment:** Not established. Only supportive measures.

### Carbamates

#### **Q. Discuss management of carbamate poisoning.**

- Examples: Sevin, baygon, lannate, carbaryl, aldicarb
- Medicinal forms include physostigmine, pyridostigmine and neostigmine.
- Cholinesterase inhibitors that are **structurally related to organophosphates**. Transiently and reversibly inhibit cholinesterase (< 6 hrs). Regeneration of enzyme occurs within minutes to hours, therefore aging does not occur.
- **Symptoms** of intoxication are similar to organophosphates, but are of shorter duration.
- Carbamates do not effectively penetrate into CNS, so **less central toxicity** and no seizures.
- Atropine therapy usually not needed for longer than 6-12 hours.

- **Avoid pralidoxime (2-PAM):** Since irreversible binding does not occur, it is not needed, and potentially can worsen some carbamate poisonings.

## ORGANOCHLORINE POISONING

**Q. Write short essay on organochlorine poisoning.**

### Classification of Organochlorine (Box 16.4)

#### Acute Organochlorine Poisoning

- *Prodromal symptoms:* Tremor, ataxia, myoclonus, dizziness, confusion, paresthesia of mouth, nausea, vomiting.
- *Typical presentation:* **Status epilepticus** followed by respiratory failure, cardiac arrhythmias, rhabdomyolysis and acute renal failure.

**Box 16.4:** Classification of organochlorine.

Dichlorodiphenyl methane: DDT, methoxychlor

Hexachlorocyclohexane: Lindane

Cyclodienes

- Aldrin, chlordane, dieldrin
- Endrin, endosulfan, heptachlor

Chlordecone (kepone): Mirex

- *Treatment:*
  - **Control seizure:** The same way as ‘status epilepticus’: Benzodiazepines, phenobarbital, phenytoin.
  - Prevent complications

#### Subacute Organochlorine Poisoning

- **Hyperexcitability stage:** Tachycardia, tremor, hyperreflexia.

- **Treatment**
  - **Symptomatic treatment:** Anxiolytic
  - **Enhance elimination:** Cholestyramine

#### Chronic Organochlorine Poisoning

- Organochlorine insecticides interfere with endocrine and reproductive systems.
- Individuals who work with the insecticides show low sperm count and motility, infertility and abortion.
- The insecticides can be carcinogenic to animals.

## SNAKEBITE

**Q. Name the commonly encountered poisonous snakes. Discuss the clinical manifestations, diagnosis and management of snakebites.**

**Box 16.5:** Classification of poisonous snakes.

1. **Elapidae (neurotoxic):** Examples
  - Common *cobra/nag* or *kalsap* or *najanaja*.
  - King Cobra: *Raj nag* or *najahanna* or *njabangarus*.
  - Krait: Subgrouped into: (a) common krait or *bangarus caeruleus*; (b) banded krait or *bangarus fasciatus*; (c) coral snake; (d) tiger snake; (e) mambas; and (f) death adder.
2. **Viperidae (vasculotoxic):** They are grouped into:
  - **Pitiless Vipers:** These include: a) russel viper; and b) saw-scaled viper.
  - **Pit Vipers:** These include: (a) pit viper—*crotalidae*; and (b) common green pit viper.
3. **Hydrophidae (myotoxic):** About 20 types of sea snakes are found in India. All are poisonous.

### Classification of Poisonous Snakes (Box 16.5)

India is estimated to have the highest snakebite mortality in the world. World Health Organization (WHO) estimates place the number of bites to be 83,000 per annum with 11,000 deaths.

### Snake Venom

Snake may be venomous or nonvenomous. When a venomous snake bites, it may excrete venom. **Snake venom** is a **toxin (hematotoxin, neurotoxin, or cytotoxin)**. **Composition of snake venom is mentioned in Table 16.6.**

**Table 16.6:** Various components of snake venom and their actions.

<b>Component</b>	<b>Action</b>
Serine proteases	Hemolysis
Other proteases	Hemolysis
Phospholipase A2	Myotoxic, cardiotoxic, neurotoxic, increases vascular permeability
Hyaluronidase	Local tissue destruction
Neurotoxin	
• Alpha-bungarotoxin, cobrotoxin	Postsynaptic inhibition
• Beta-bungarotoxin, crotoxin	Presynaptic inhibition

### Snakebite

Teeth bite marks difference between poisonous and nonpoisonous snakes (Fig. 16.6).

- **Poisonous:** Two fang marks with or without marks of outer teeth.
- **Nonpoisonous:** Two fang marks with number of small teeth marks.

Differences between poisonous and nonpoisonous snakes are shown in Figures 16.6A and B and Table 16.7.

### *Clinical Feature of Snakebite*

**Q. Write short essay/note on:**

- **Clinical features of poisonous snakebite.**
- **Cobra bite envenomation—features and treatment.**

**Q. Write short essay/note on complications of poisonous (cobra).**

Signs, symptoms and complications of snakebite are listed in Table 16.8.

**Asymptomatic (dry bite):** Significant proportion of snakebites do not result in envenomation. Patients without clinical features of local or systemic envenomation should be closely observed for 24–48 hours.

#### **Box 16.6:** Prognosis assessment in snakebite.

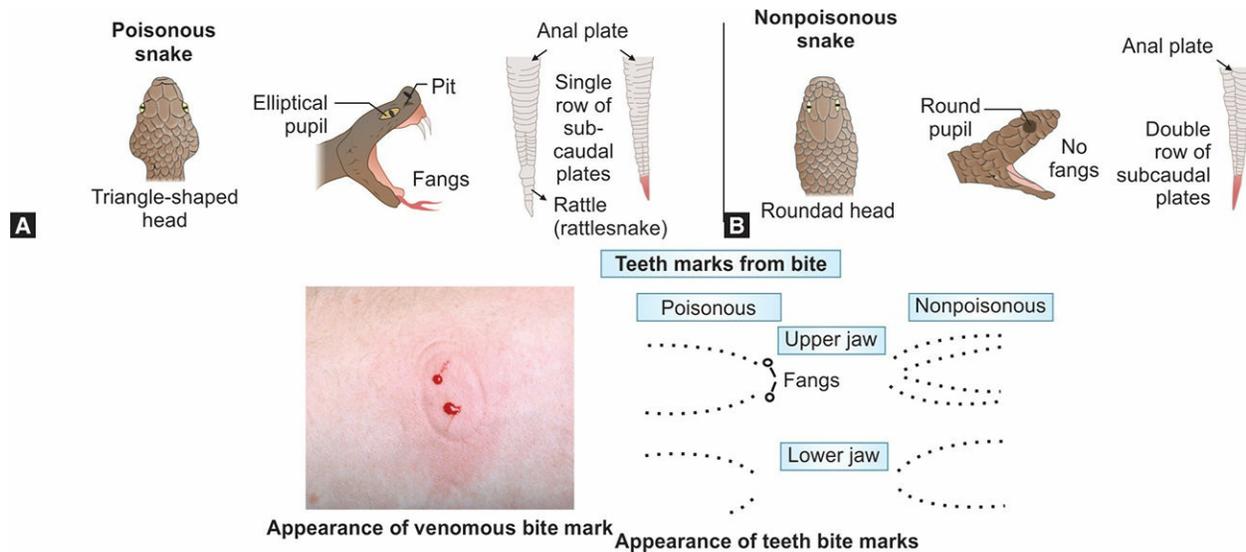

- Time of bite
- Activity at the time of bite
- First aid action taken since the bite
- Clinical examination
- **Twenty minutes whole blood clotting test (WBCT).**

#### **Prognosis Assessment in snakebite (Box 16.6).**

**Table 16.7:** Differences between poisonous and nonpoisonous snake.

<i>Points</i>	<i>Poisonous snakes</i>	<i>Nonpoisonous</i>
1. Belly scales	<i>Large:</i> They cover the entire breadth of belly	<i>Small:</i> They never cover
2. Head scales	a. Usually small in vipers b. May be large in pit vipers c. Cobras and Coral snakes where third labial touches the eye and nasal shields d. Kraits, where there is no pit and the third labial does not touch the nose and eye	Are usually large with exceptions as outlined under poisonous snakes
3. Fangs	Are hollow-like hypodermic	Short and solid

	needle	
4. Tail	Compressed	Not markedly compressed
5. Habits	Usually nocturnal	Not so
6. Teeth bite marks	Two fang marks with or without marks of other teeth	Two fang marks with number of small teeth marks

**Figs. 16.6A and B:** Differences between poisonous (A) and nonpoisonous snake (B).

**Table 16.8:** Local and systemic features/complications of snakebites.

Local features	Systemic features
<p><b>A. Elapid bite</b></p> <p><b>Fang marks, burning pain, swelling and discoloration, serosanguineous discharge.</b>            Local symptoms are milder than in viperine bite</p>	<p><b>Preparalytic stage:</b> Vomiting, headache, giddiness, weakness and lethargy  <b>Paralytic stage: Ptosis,</b> ophthalmoplegia, drowsiness, convulsion, bulbar paralysis, respiratory failure, death, paradoxical respiration: Intercostal muscle paralysis, stomach pain (Krait), submucosal hemorrhage in stomach. Neck muscle weakness (<b>Broken neck sign</b>)  <b>Krait bites:</b> Present in early morning with paralysis and can be <b>mistaken for STROKE.</b></p>
<p><b>B. Viperid bite</b></p> <ul style="list-style-type: none"> <li>• <b>Rapid swelling at bite site</b></li> <li>• <b>Discoloration</b></li> <li>• <b>Blister formation</b></li> <li>• <b>Bleeding from bite site</b></li> <li>• <b>Pain</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>Generalized bleeding:</b> Epistaxis, hemoptysis, hematemesis, bleeding gums, hematuria, melena, hemorrhagic areas over skin and mucosa</li> <li>• <b>Lateralizing neurological symptoms</b> such as asymmetrical pupils, intracranial bleed</li> <li>• <b>Hypotension:</b> Resulting from</li> </ul>

	<p>hypovolemia/direct vasodilation</p> <ul style="list-style-type: none"> <li>• <b>Low back pain</b>, indicative of early renal failure</li> <li>• <b>Muscle pain:</b> Rhabdomyolysis</li> <li>• <b>Muscle pain:</b> Rhabdomyolysis</li> <li>• <b>Parotid swelling:</b> Conjunctival edema, subconjunctival hemorrhage</li> <li>• <b>Renal failure:</b> Russel viper, hump nosed pit viper.</li> <li>• <b>Long-term complication:</b> Hypopituitarism and cardiotoxicity</li> <li>• Saw-scaled viper generally does not cause renal failure</li> </ul>
<b>C. Hydrophid bite</b>	
<ul style="list-style-type: none"> <li>• <b>Local swelling</b></li> <li>• <b>Pain</b></li> </ul>	<ul style="list-style-type: none"> <li>• Stiffness, myoglobinuria, renal failure</li> </ul>

## Laboratory Investigations

- *Nonspecific:* Hemogram, serum creatinine, serum amylase, creatine phosphokinase (CPK).
- PT, FDP and fibrinogen level in viper bite as it interferes with clotting mechanism.
- *ABG, and electrolyte:* For systemic manifestation.
- *Urine examination:* For proteinuria, myoglobinuria.
- *ECG:* Nonspecific changes such as bradycardia and AV-block.

## Q. Write short essay/note on management of viper bite.

### Management

The first aid (Box 16.7) being currently recommended is based around the mnemonic: 'Do it R.I.G.H.T.'

**Box 16.7:** First aid currently recommended for snakebite **"Do it R.I.G.H.T."**

**R** = Reassure the patient. Seventy percent of all snakebites are from nonvenomous species. Only 50% of bites by venomous species actually envenomate the patient.

**I** = Immobilize in the same way as a fractured limb. Use of bandages or cloth is to hold the splints and should to block the blood supply or apply pressure. Do not compress by tight ligatures, because they can be dangerous!

**GH** = Get to Hospital Immediately. Traditional remedies have NO PROVEN benefit in treating snakebite.

**T** = Tell the physician about any systemic symptoms that develop on the way to hospital (e.g. ptosis).

## A. Specific treatment

### Antisnake venom (ASV)

Indications for ASV are presented in Table 16.9.

#### Q. Write short essay/note on indications for anti-snake venom therapy.

- Classification of severity of snake bite is presented in Table 16.10.
- **Dosage of ASV:** Ideally administer within 4 hours but effective, if given within 24 hours:
  - In **mild cases, 5 vial (50 mL); in moderate cases, 5 to 10 vial and in severe cases, 10 to 20 vial.**

Additional infusion containing 5 to 10 vials are infused until progression of swelling ceased and systemic symptoms are disappeared.

- **Mode of administration** ASV is given slowly as IV injection or infusion @ rate of 2 mL/minute. ASV dilute 5–10 mL/kg body weight of normal saline or 5% dextrose and infused over 1 hour. ASV should **never give locally at site of snakebite.**

**Adverse reaction of ASV (Box 16.8):** It may develop in 20% patients.

**Table 16.9:** Indications for antisnake venom (ASV).

<ul style="list-style-type: none"> <li>• <b>Neurotoxicity</b></li> <li>• <b>Bleeding/coagulopathy</b> <ul style="list-style-type: none"> <li>– Spontaneous systemic bleeding</li> <li>– WBCT (20 minutes whole blood clotting test) &gt; 20 min</li> <li>– Thrombocytopenia (platelet &lt; 1 lac)</li> </ul> </li> <li>• <b>Myoglobinuria/hemoglobinuria</b></li> </ul>	<ul style="list-style-type: none"> <li>• <b>Cardiac toxicity</b></li> <li>• <b>Local swelling involving more than half of the bitten limb</b></li> <li>• <b>Rapid extension of swelling</b></li> <li>• <b>Development of an enlarged tender lymph node draining the bitten limb</b></li> <li>• <b>Acute renal failure</b></li> </ul>
---	--

**Table 16.10:** Classification of severity of snake bite.

	<i>Envenomation</i>			
	<i>Absent</i>	<i>Mild</i>	<i>Moderate</i>	<i>Severe</i>
Fang marks	+/-	+	+	+
Local reaction	–	Moderate	Severe	Severe
• Pain	Absent	Minimum	Moderate	Severe
• Local edema	Absent	(0–15 cm)	(15–30 cm)	>30 cm
• Erythema	Absent	+	+	+
• Ecchymosis	Absent	+/-	+	+
Systemic features	No	No	Weakness, sweating, syncope, nausea, vomiting, thrombocytopenia	Hypotension, paresthesia, ptosis, broken neck sign, coma, pulmonary edema, respiratory failure

**Table 16.11:** Any one of the following suggests early anaphylactic reaction.

• Urticaria	• Chills	• Diarrhea	• Hypotension
• Itching	• Nausea	• Abdominal cramps	• Bronchospasm
• Fever	• Vomiting	• Tachycardia	• Angioedema

### B. Supportive therapy

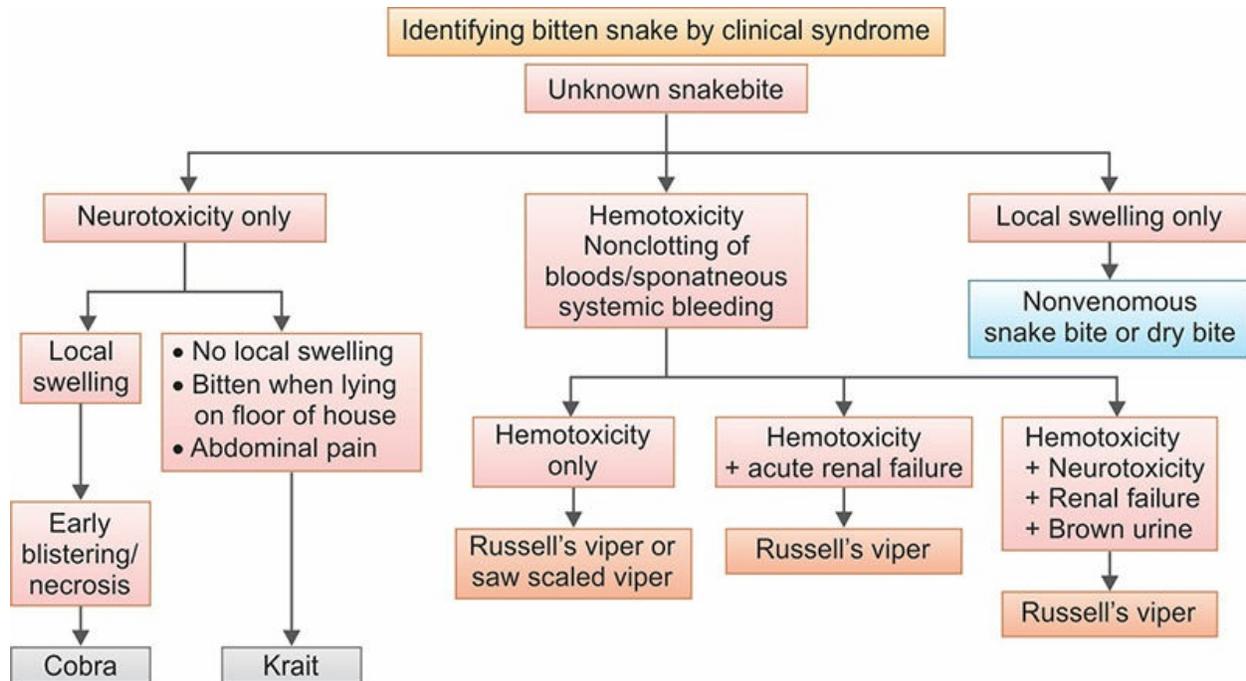

- **For coagulopathy:** If it does not reverse after ASV therapy. Fresh- frozen plasma, cryprecipitate (fibrinogen, factor VIII), fresh whole blood, platelet concentrate can be administered.
- **For bulbar paralysis and respiratory failure.**
  - ASV alone not sufficient.
  - Tracheostomy, endotracheal intubation and mechanical ventilation.
  - Inj. of *neostigmine*: About 50 to 100 µg/kg/4 hours as a continuous infusion.
  - *Glycopyrrolate*: About 0.25 mg can be given before neostigmine in place of atropine as glycopyrrolate does not cross blood brain barrier.
- Renal failure: Hemodialysis/peritoneal dialysis.
- Capillary leak syndrome: Methyl prednisolone (10 mg/kgQ8H) × 3 days.
- Compartment syndrome: Fasciotomy.
- Surgical debridement of wound
- Care of bitten part: Antibiotic prophylaxis and tetanus toxoid.

### Box 16.8: Adverse reactions of antisnake venom (ASV).

1. **Early anaphylactic reaction (Table 16.11):** It may develop within 10 minutes to 3 hours. Patient should be monitored closely.
  - **Treatment of anaphylactic reaction:**
    - ◆ Discontinue ASV.
    - ◆ *Adrenaline*: 1:1000 IM (0.5 mg/kg in adult and 0.01 mg/kg in children). It can be repeated every 5 min, if necessary.
    - ◆ *H1 antihistaminic*: IV 1 mg of chlorpheniramine maleate (CPM).
    - ◆ IV hydrocortisone.
2. **Late serum sickness:** Develops in 1–12 days. Characterized by fever, nausea, vomiting, diarrhea, arthritis, nephritis, myoglobinuria, etc. Treatment consists of:
  - **Oral antihistaminic:** 5 days course of oral anti histaminic. For adults—CPM 2 mg/6 hour and for children—0.25 mg/kg/day in divided dose.
  - **Prednisolone:** For patient who fail to response within 24 hour. Dose: 5 mg/6 hour in adult and 0.7 mg/kg/day in divided dose in children.

Algorithm approach to the identification of type of snakebite is presented in Flowchart 16.1.

**Flowchart 16.1:** Algorithm approach for the identification of type of snake bitten by clinical syndrome in snakebite

## SCORPION BITE

**Q. Write short essay on clinical features, diagnosis and treatment of scorpion sting bite.**

• **Scorpion venom:**

- It is clear, colorless toxalbumin and can be classified as either neurotoxic or hemolytic.
- Toxicity is more than snake. However, during bite only small quantity is injected.
- Venom is strong autonomic stimulator and releases large amount of catecholamine from adrenals.
- Mortality (except in children) is negligible, and can cause acute pancreatitis.

### Signs and Symptoms

1. **In case of hemolytic venom:**

- Reaction is predominantly local and **simulates the viper snake bite**. However, the scorpion sting bite shows only one hole in the center of reddened area at the site of bite.
- The extremity will have severe pain and edema.

## 2. In case of neurotoxic venom:

- Symptoms are **similar to cobra bite**.
- Usually no mark reaction in local area.
- **Symptoms:** Nausea, vomiting, severe restlessness, paralysis, fever, cardiac arrhythmia, convulsions, cyanosis, coma, and respiratory depression. Death may occur within hours from pulmonary edema and cardiac failure.

Diagnosis is confirmed by ELISA testing.

### Treatment

- Immobilize the limb and apply a tourniquet above the sting.
- Pack sting in ice, and incise and use suction, and wash with weak solution of ammonia, borax or potassium permanganate.
- A local anesthetic (2% novocaine or 5% cocaine) is injected at site of pain.
- A specific antivenom is available for most species.
- Calcium gluconate IV to control local swelling.
- Adrenergic symptoms (hypertension and/or pulmonary edema): Prazosin (selective peripheral alpha-1 adrenergic antagonist).
- Barbiturate to reduce convulsions.
- Morphine is contraindicated. Give intravenous fentanyl 1 mcg/kg for pain.
- Atropine is valuable to prevent pulmonary edema.
- Treatment of massive pulmonary edema: By oxygen, intravenous aminophylline or intravenous nitroprusside.

## Hymenoptera (Bee, Wasp, Hornet) Stings

- In sensitized individuals, a single sting may result in rapid and potentially fatal anaphylaxis with hypotension (shock), bronchospasm, angioedema. Intramuscular 0.1% adrenaline can be life-saving.
- Mass attacks by bees can be life-threatening even in non-sensitized individuals, through the direct action of venom causing hemolysis, rhabdomyolysis, pulmonary edema, acute renal failure and adrenergic effects.
- No antivenom is available.
- Treatment is symptomatic.

## SEDATIVE DRUG POISONING

### Benzodiazepines Poisoning (BZD)

**Q. Write short essay/note on benzodiazepine overdose and management.**

**Mode of Action**

- BZDs exert their effect via modulation of the gamma-aminobutyric acid A (GABA-A) receptor.
- Gamma-aminobutyric acid (GABA) is the main inhibitory neurotransmitter of the central nervous system.

**Types (Table 16.12)**

**Table 16.12: Various categories of benzodiazepines.**

<b>Hypnotic</b>	<b>Antianxiety</b>	<b>Anticonvulsant</b>
<ul style="list-style-type: none"><li>• Diazepam</li><li>• Flurazepam</li><li>• Nitrazepam</li><li>• Alprazolam</li><li>• Temazepam</li><li>• Triazolam</li></ul>	<ul style="list-style-type: none"><li>• Diazepam</li><li>• Chlordiazepoxide</li><li>• Oxazepam</li><li>• Lorazepam</li><li>• Alprazolam</li></ul>	<ul style="list-style-type: none"><li>• Diazepam</li><li>• Lorazepam</li><li>• Clonazepam</li><li>• Clobazam</li></ul>

**Clinical Features of Over Dosage**

Oral benzodiazepines (BZD) taken in overdose without a coingestant rarely cause significant toxicity. The classic presentation of a patient with an isolated BZD overdose consists of CNS depression with normal vital signs.

- **Toxic symptoms:** Sedative action on the CNS.
- **Large doses:** Neuromuscular blockade.
- **Intravenous injection:** Peripheral vasodilation, fall in BP, shock. Propylene glycol (1, 2 propanediol) is the diluent used in parenteral formulations of diazepam and lorazepam which itself causes cardio and neurotoxicity.

Of note, most intentional ingestions of BZDs involve a coingestant, the most common being *ethanol*.

**Acute poisoning**

- **Mild:** Drowsiness, ataxia, weakness
- **Moderate to severe:** Vertigo, slurred speech, nystagmus, partial ptosis,

lethargy, hypotension, respiratory depression, coma (stage 1 and 2).

- **COMA (Stage 1):** Responsive to painful stimuli but not to verbal or tactile stimuli, without any disturbance in respiration or BP.
- **COMA (Stage 2):** Unconscious, not responsive to painful stimuli, no disturbance in respiration or BP.

### ***General Diagnostic Testing***

- Fingertick glucose, to rule out **hypoglycemia** as the cause of any alteration in mental status.
- **Acetaminophen and salicylate levels**, to rule out these common coingestions.
- Electrocardiogram (ECG), as it affect the QRS or QTc intervals.
- Pregnancy test in women of childbearing age.

#### **Life Supportive Procedures and Symptomatic/Specific Treatment**

- Airway, breathing and circulation.
- Endotracheal intubation.
- Assisted ventilation.
- Supplemental oxygen intravenous fluids, inotropes, if needed.

#### **Decontamination**

Gastrointestinal decontamination with activated charcoal (AC) (usually of no benefit in cases of isolated BZD ingestion and increases the risk of aspiration).

#### **Antidote Treatment: Flumazenil**

- **Mode of action:** competitive antagonism. Complete reversal of benzodiazepine effect with a total slow IV dose of 1 mg.
- Administered in a series of smaller doses beginning with 0.2 mg and progressively increasing by 0.1–0.2 mg every minute until a cumulative total dose of 3.5 mg is reached.
- Resedation occurs within ½ hr–2 hours.
- **Side effects:** nausea, vomiting, arrhythmias, convulsions.
- **Contraindication:** Status epilepticus.

## **Barbiturate Poisoning**

**Q. Write short essay on clinical features and treatment of barbiturate poisoning.**

- Nonselective CNS depressants.
- **Mode of action:** Direct CNS depressants-bind to GABA receptors → prolongs the opening of chloride channel. Inhibits excitable cells of the CNS.

## Classification (Table 16.13)

**Table 16.13:** Classification of barbiturates.

<i>Long acting (6–12 hours)</i>	<i>Intermediate acting (3–6 hours)</i>	<i>Short acting (&lt;3 hours)</i>	<i>Ultrashort acting (&lt;15–20 min)</i>
Mephobarbital Phenobarbitone	Amobarbital Aprobarbitone Butobarbital	Hexobarbitone Pentobarbitone Secobarbital	Thiopentone Methohexitone

## Signs and Symptoms (Table 16.14)

**Table 16.14:** Adverse and toxic effects of barbiturate poisoning.

<i>Adverse effects</i>	<i>Toxic effects</i>
<ul style="list-style-type: none"><li>• Residual depression</li><li>• Paradoxical excitement</li><li>• Hypersensitivity reactions—localized swelling of eyelid, cheek or lip, erythematous or exfoliative dermatitis</li><li>• Synergistic action with ethanol and antihistamines</li></ul>	<ul style="list-style-type: none"><li>• Slurred speech, ataxia, lethargy, confusion, headache, and nystagmus</li><li>• CNS depression, coma, shock</li><li>• Pupils—first constricted, later dilate because of hypoxia</li><li>• Hypothermia</li><li>• Cutaneous <b>bullae</b> (blisters) (Fig. 16.7)</li><li>• Death due to respiratory arrest or cardiovascular collapse</li></ul>

**Fig. 16.7:** Barbiturate blister.

### Management of Barbiturate Poisoning

- No Specific **antidote**.

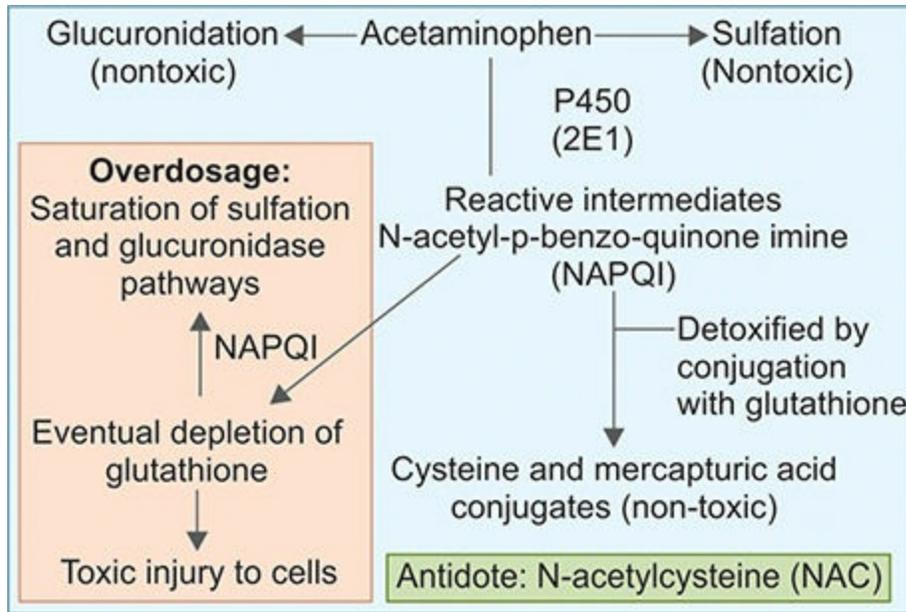

- Barbiturate poisoning is more **dangerous** than benzodiazepine poisoning.
- Management is **supportive**.
  - Cardiorespiratory support.
  - Clean the air ways by thorough suctioning and insertion of oral airways.
  - If the patient is comatose, prompt intubation is strongly advocated because of worsening of respiratory failure.
  - Correction of dehydration by CVP-guided fluid therapy depending on the serum electrolytes.
  - Treat hypotension by intravenous infusion of plasma expanders and vasopressors. In refractory cases, steroids are given.
  - *Measures to prevent absorption:*
    - ◆ Gastric lavage.
    - ◆ Activated charcoal is administered orally or by nasogastric tube.
  - *Measures for removal barbiturates:*
    - ◆ Frequent doses of activated charcoal.
    - ◆ Forced diuresis with alkalization of urine.
    - ◆ Hemodialysis and hemoperfusion.

## ANALGESIC POISONING

### Paracetamol (Acetaminophen) Poisoning

**Q. Write short essay on paracetamol poisoning and its treatment.**

- Toxicity unlikely to result from a single dose of less than 150 mg/kg in child or 7.5 to 10 g for adult.
- Toxicity is likely with single ingestions greater than 250 mg/kg or those greater than 12 g over a 24-hour period.
- Virtually all patients who ingest doses in excess of 350 mg/kg develop severe liver toxicity unless appropriately treated.

**Fig. 16.8:** Acetaminophen metabolism.(NAPQI, N-acetyl-p-benzoquinone imine).

### ***Mechanism of Paracetamol Toxicity (Fig. 16.8)***

**Toxicity is due to formation of an intermediate reactive metabolite, which binds covalently to cellular proteins, leading to cell death. This causes hepatic and occasionally renal failure. In therapeutic doses, the toxic intermediate metabolite is detoxified in reactions requiring glutathione. **With overdose, glutathione reserves become depleted.****

#### **Clinical Manifestations of Toxicity**

- **Stage I (0.5 to 24 hours)**
  - No symptoms; nausea, vomiting and malaise.
- **Stage II (24 to 72 hours)**
  - Subclinical elevations of hepatic aminotransferases (AST, ALT).
  - Right upper quadrant pain, with liver enlargement and tenderness. Elevations of prothrombin time (PT), total bilirubin, and oliguria and renal function abnormalities may become evident. Acute kidney injury is due primarily to acute tubular necrosis.
- **Stage III (72 to 96 hours)**
  - Fulminant hepatic failure; Jaundice, confusion (hepatic encephalopathy), a marked elevation in hepatic enzymes, hyperammonemia, and a bleeding diathesis hypoglycemia, lactic acidosis, renal failure (25%) and death.
- **Stage IV (4 days to 2 weeks)**
  - Recovery phase that usually begins by day 4 and is complete by 7 days after overdose.

#### **Treatment Options**

- **Activated charcoal:**
  - Within four hours of ingestion.

- May reduce absorption by 50–90%.
- Single oral dose of one gram per kilogram.
- *Disadvantage*: Inhibits absorption of oral methionine.
- **Gastric lavage**: Only for massive ingestions (e.g. >600 mg/kg).
- **Gastric lavage**: Only for massive ingestions (e.g. >600 mg/kg).
- **Antidote: N-acetylcysteine (NAC) (Box 16.9)**
  - *Properties*:
    - ◆ *MOA*: A glutathione precursor.
    - ◆ Limits the formation and accumulation of NAPQI.
    - ◆ Powerful anti-inflammatory and antioxidant effects.
  - *Dosage and administration*:
    - ◆ IV infusion or oral tablets.
    - ◆ 150 mg/kg over 15 minutes; 50 mg/kg over next 4 hours; 100 mg/kg over next 16 hours up to 36 hours.
    - ◆ Most effective, if started within 8–10 hours after ingestion. Beyond 8 hours, NAC efficacy progressively decreases.
  - Oral N-acetylcysteine treatment regimen consists of a 72-hour oral course given as a 140 mg/kg loading dose followed by 17 doses of 70 mg/kg every four hours (total dose 1330 mg/kg). This regimen has the theoretical advantage of delivering the antidote to the portal circulation in patients with oral ingestions. Side effects include nausea, flushing, urticaria, bronchospasm, angioedema, fever, chills, hypotension, hemolysis and rarely, cardiovascular collapse.
- Alternate medication: **oral methionine**.
- **Liver transplantation (Box 16.10)**

It is life-saving for fulminant hepatic necrosis.

**Box 16.9:** Indications for N-acetylcysteine in paracetamol poisoning.

- All patients with a serum acetaminophen concentration above the possible hepatic toxicity line on the Rumack-Matthew nomogram
- Patients with an estimated ingestion of greater than 140 mg/kg
- Patients with an unknown time of ingestion.
- Patients with a presentation more than 24 hours after ingestion with elevated transaminases.

**Box 16.10:** Indications for liver transplantation for paracetamol poisoning (King's College Criteria).

- Acidosis (pH <7.3), or
- PT (Prothrombin time) >100 sec
- Creatinine >3.4 mg/dL
- Grade 3 encephalopathy (or worse)

## Aspirin Toxicity

**Q. Write short note on salicylates poisoning and its management.**

## ***Mechanism of Toxicity***

- Acetyl salicylic acid (ASA) is hydrolyzed to salicylic acid. Responsible for therapeutic and toxic effects.
- *Direct stimulation of respiratory center:* Medulla
- *Uncouples oxidative phosphorylation:*
  - Increase in O<sub>2</sub> consumption and CO<sub>2</sub> production
  - Increase respiration leading to respiratory alkalosis.
- *Renal excretion of bicarbonate, Na and K:* Metabolic acidosis
- *Inhibition of mitochondrial respiration:* Increase pyruvate and lactic acid → metabolic acidosis.
- Disruption of Krebs's cycle metabolism and glycolysis → Hyperglycemia, ketonemia.

## ***Signs and Symptoms (Table 16.15 and Box 16.11)***

Salicylate poisoning can occur in two settings—an **acute toxicity** and a **chronic toxicity** (Table 16.16).

### **Management of Aspirin Overdose**

- **Initial supportive therapy.**

#### ***Specific Management***

##### *A. Decreasing absorption*

- **Activated Charcoal:** Given in those who have taken more than 250 mg/kg body weight less than 1 hour ago.
- **Gastric lavage:** It is advised in patients who have taken more than 500 mg/kg body less than 1 hour ago.

##### *B. Increasing drug elimination*

- **Urinary alkalinization:**
  - Alkalinizing urine from pH 5 to 8 increases renal elimination of ASA from 1.3 mL/min to 100 mL/min.
  - Serum half-life decreases from 48 hours to 6 hours.
  - This is done by giving an infusion of sodium bicarbonate.
- **Hemodialysis (Box 16.12):**
  - Used in severe life-threatening overdose.
  - Aims to correct the acid-base disturbances while removing the salicylate.

**Box 16.11:** ASPIRIN mnemonic.

- Altered mental status (lethargy—coma)
- Sweating/diaphoresis
- Pulmonary edema

- Increased vital signs (hypertension, increased respiratory rate, tachycardia)
- Ringing in the ears
- Irritable
- Nausea and vomiting

**Table 16.15:** Differences between acute and chronic aspirin toxicity.

<i>Feature</i>	<i>Acute</i>	<i>Chronic salicylism</i>
Age	Young adult	Older adults/infants
Cause	Overdose	Treatment misuse
Coingestion	Frequent	Rare
Mental status	Normal	Altered
Clinical presentation	Early	Late
Mortality	Low with treatment	High
Serum levels (mg/dL)	40 to $\geq 120$	30 to $\geq 80$

**Table 16.16:** Features of salicylate poisoning.

<i>Central nervous system</i>	<i>Signs and symptoms</i>	<i>Laboratory findings</i>
Hyperactivity	Nausea, vomiting	Respiratory alkalosis
Irritability	Tinnitus, hearing loss	Anion gap metabolic acidosis
Delirium	Pulmonary edema	Coagulation abnormalities
Agitation	Hyperventilation (tachypnea and/or hyperpnea)	Urinary ketones
Vertigo	Hyperthermia	Hyperkalemia
Slurred speech	Tachycardia	Hyperlactatemia (mild)
Hallucination	Volume depletion	
Lethargy	Arrhythmias	
Stupor	Diaphoresis	
Seizures		
Coma		
Cerebral edema		

**Box 16.12:** Absolute indications for hemodialysis in aspirin toxicity.

- Renal failure
- Congestive heart failure
- Acute lung injury
- Persistent CNS disturbances
- Progressive deterioration in vital signs
- Severe acid-base or electrolyte imbalance, despite appropriate treatment
- Hepatic compromise with coagulopathy
- Salicylate concentration (acute)  $>100$  mg/dL (in the absence of the above).

---

## CYANIDE POISONING

**Q.** Write short essay on management of cyanide poisoning.

### Cyanide

- Present in bitter almonds (250 mg CN/100 g plant tissue), cassava (104 mg CN/100 g plant tissue), wild cherries (140–370 mg CN/100 g plant material) and other foods.
- Used extensively in industry for fumigation, electroplating, and mining activities.

**Routes of Exposure** of cyanide is mentioned in Box 16.13.

**Box 16.13:** Routes of exposure of cyanide.

- **Gas:** Inhalation (e.g. hydrogen cyanide and cyanogen chloride).
- **Liquid:** Inhalation (aerosol), ingestion, skin contact (e.g. hydrocyanic acid).
- **Solid:** Inhalation, ingestion, skin contact (e.g. cyanide salts).

### *Clinical Manifestations of Cyanide Poisoning*

- **Onset of cyanide poisoning**
  - **Inhalation** (rapid onset, seconds to minutes), **ingestion** and **skin contact** (delayed onset, 15–30 minutes).
- Death may occur within 6–8 minutes after inhalation of a high concentration. 2–5 mg/kg of it is lethal
- **Mechanism:** Inhibits mitochondrial cytochrome oxidase and an ‘asphyxiating’ agent.
- Common final pathway for cyanide intoxication is **cellular hypoxia**.
  - **Metabolic acidosis:** Nonspecific symptoms.
  - **CNS: Dizziness, nausea, vomiting, drowsiness, tetanus, trismus, hallucinations.**
  - **CVS: Dysrhythmia, hypotension.** Tachycardia and hypertension may occur transiently in early stages.
  - **Respiratory: Dyspnea, initial hyperventilation followed by hypoventilation** and **pulmonary edema.** Cyanosis not apparent, since blood is adequately oxygenated.

## Laboratory Diagnosis

- **Blood cyanide levels** can be estimated, but empiric treatment is almost always required before laboratory results are available.
- **High anion gap metabolic acidosis.**
- **Arterial and venous pO<sub>2</sub> may be elevated.**

### Treatment

- **Activated charcoal:** For alert, asymptomatic patients following ingestion.
- **Supplemental oxygen:** 100% for suspected exposure.
- Supportive care.
- **Sodium nitrite:**
  - **Mechanism:** Forms **methemoglobin**, competes with cytochrome oxidase for free cyanide; combines with cyanide to form cyanmethemoglobin.
  - **Dose:** (1) Adults: 300 mg IV over 5 minutes; slower if hypotension develops and (2) children: 0.12–0.33 mg/kg IV infused as above.
- **Amyl nitrite:** An inhaled drug, similar to sodium nitrite but with little systemic distribution. Second line agent used when sodium nitrite is not available.
- **Sodium thiosulfate:**
  - **Mechanism:** Sulfur donor promotes rhodanese activity, detoxifies cyanide as it is released from cyanmethemoglobin. Directly detoxifies cyanide by conversion to thiocyanate; too slow to be useful as a first-line intervention.
  - **Dose:** (i) Adults: 12.5 g IV over 10–20 minutes following administration of sodium nitrite, and (ii) Children: 412.5 mg per kg IV over 10–20 minutes.
- **Hydroxocobalamin**
  - **Mechanism:** Direct binding agent, **chelates cyanide.**
  - **Dose:** 4 to 5 g IV
- **Dicobalt edetate** is an intravenous chelator of cyanide which can be used.

## Anticholinergic Toxidrome

**Q. Write short essay/note on causes of anticholinergic syndrome.**

### Causes of Anticholinergic Toxidrome (Table 16.17)

**Table 16.17:** Various causes of anticholinergic syndrome.

#### Natural alkaloids

- Atropine (from the plant *Atropa belladonna*/Deadly nightshade)
- Hyoscine (Scopolamine) (from *Hyoscyamus niger*/henbane)
- Datura stramonium (plant—Jimson)

#### Synthetic compounds

- *Mydriatics: Tropicamide (eye drops)*
- *Antisecretory antispasmodics: Glycopyrrolate, oxybutynin*
- *Antiparkinsonian drugs: Benhexol, bztropine*

weed/Angel's trumpet)	
<b>Semisynthetic derivatives</b>	<b>Miscellaneous</b>
<ul style="list-style-type: none"> <li>• Homatropine (eye drops)</li> <li>• Tiotropium bromide</li> </ul>	<ul style="list-style-type: none"> <li>• Tricyclic antidepressants, e.g. Amitriptyline</li> <li>• Phenothiazines, e.g. Prochlorperazine</li> <li>• Antihistamines, e.g. Cyclizine</li> <li>• Neuroleptics, e.g. Olanzapine</li> </ul>

## NEUROTOXIC PLANT POISONS

### Datura Poisoning

**Q. Write short essay/note on clinical feature and management of datura poisoning.**

- Datura stramonium (jimson seed) **causes anticholinergic syndrome**. The active **toxic agents include atropine and scopolamine**. Atropine and related compounds **block acetylcholine at the receptor sites of postganglionic synapses of the cholinergic nerves**.
- **All the parts of datura plant (Figs. 16.9A and B) are poisonous**, but the seeds and fruit are the most toxic.
- **Mode of poisoning:** Most popular mode of poisoning is by mixing the seeds in sweets and given to others with the intention of thefts.

**Figs. 16.9A and B:** Datura: (A) Seed; (B) Flower.

## **Clinical Features**

- Toxic symptoms often appear within 30 minutes of ingestion and last for 24–48 hours.
- Clinical features include tachycardia and the other features are described as **'blind as a bat, mad as a hatter, red as a beet, hot as a hare, dry as a bone, the bowel and bladder lose their tone, and the heart runs alone.'**
  - *Hot as a hare:* Cutaneous vasodilatation leading to anhidrotic hyperthermia.
  - *Blind as a bat:* Ciliary muscle paralysis, mydriasis, dilated pupils.
  - *Dry as a bone:* Anhidrosis, dryness of mouth, urinary retention, decreased bowel motility.
  - *Red as a beet:* Cutaneous vasodilatation causing flushing.
  - *Mad as a hatter:* CNS arousal, agitation, delirium, hallucinations.
  - In can be fatal-producing stupor, coma and convulsions. Death is due to respiratory paralysis or cardiovascular collapse.

### **Management**

- Gastric lavage and supportive therapy.
- Activated charcoal adsorbs the alkaloids.
- Control of hyperthermia.
- Benzodiazepines to treat agitation.
- Role of physostigmine, a cholinesterase inhibitor is not clear.

## **CARDIOTOXIC PLANT POISONS (FIGS. 16.10A to C)**

Cardiotoxic plant poisons inhibit  $\text{Na}^+/\text{K}^+$ -ATPase pump leading to overall increase in intracellular  $\text{Na}^+$  ions and secondary increase in intracellular  $\text{Ca}^{2+}$  levels.

- *Symptoms:* On ingestion, they produce burning sensation, abdominal pain, nausea, vomiting, diarrhea, dizziness and numbness in oral and perioral region.
- Most important cardiotoxic effects are sinus bradycardia, varying degrees

of heart block, ventricular ectopics, ventricular tachycardia which can be fatal.

#### Management of Cardiotoxicity

- Atropine 0.6 mg, orciprenaline 10 mg to maintain heart rate around 80/minute. Severe bradycardia may need pacemaker insertion.
- Sodium bicarbonate 50 ml IV 6th hourly, if ABG shows acidosis.

**Figs. 16.10A to C:** (A) Oleander plant; (B) Cleistanthus collinus; (C) Calotropis.

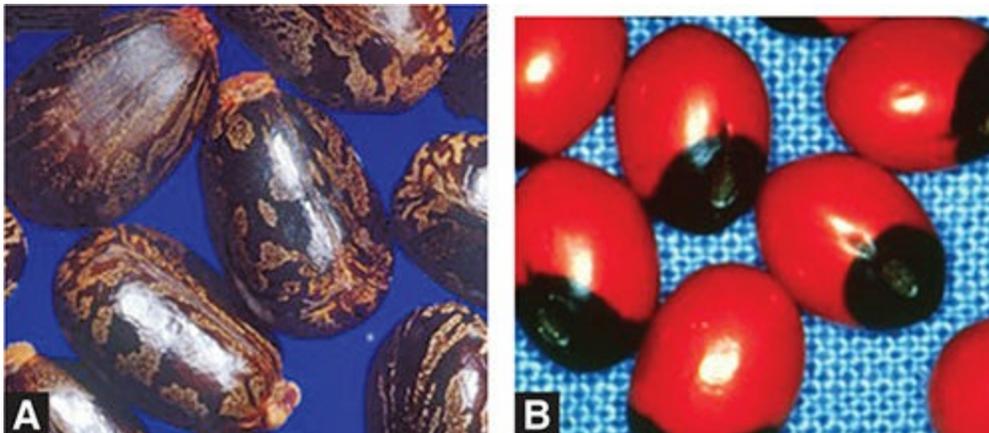

## GASTROINTESTINAL TOXIC PLANT POISONS

Ricinus communis (Fig. 16.11A) contains ricin and abrus precatorius (Fig. 16.11B) contains abrin.

### *Clinical Features*

- Gastrointestinal upset, vomiting, diarrhea, abdominal pain, GI bleeding.
- Hematuria, acrocyanosis, shock, dehydration and hemolysis.
- Abnormal liver function tests (LFT) and renal function tests (RFT).

**Treatment: Supportive.**

**Figs. 16.11A and B:** (A) Ricinus communis contains ricin; (B) Abrus precatorius contains abrin.

## OPIOID POISONING

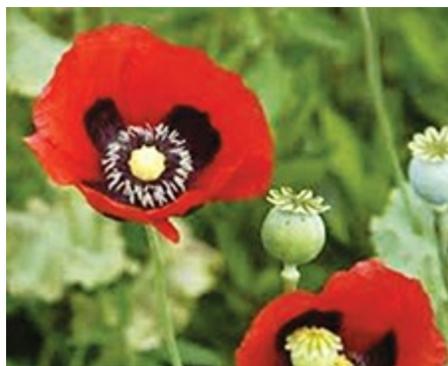

**Q. Write short essay/note on opiate over dosage, clinical features of opioid tolerance and its management.**

Opium is extracted from poppy seeds (*Papaver somniferum*) (Fig. 16.12).

**Opioid agonists:** Morphine, heroin, hydromorphone, fentanyl, codeine.

### Opioid Tolerance

- Tolerance is a **diminished responsiveness to the drug's action** that is seen with many compounds.
- Tolerance can be demonstrated by a decreased effect from a constant dose of drug or by an increase in the minimum drug dose required to produce a given level of effect.
- **Physiological tolerance** involves changes in the binding of a drug to receptors or changes in receptor transductional processes related to the drug of action. This type of tolerance **occurs in opioids**.
- Molecular basis of tolerance involves glutaminergic mechanisms (glutamate-excitatory amino acid neurotransmitter).
- **Physiological dependence** occurs **when the drug is necessary for normal physiological functioning**—this is demonstrated by the withdrawal reactions.
- **Withdrawal reactions** are usually the **opposite of the physiological effects** produced by the drug.

**Fig. 16.12:** Poppy seeds.

**Opioid toxicity** is related to opioid receptors in non-nociceptive pathways

and counter-opioid responses. It is determined by genetics, organ function, and co-medications.

Acute action and withdrawal signs of opioids are listed in Table 16.18.

**Treatment of opioid toxicity**

- Ensure adequate ventilation
- Management of complications such as ARDS

**Antidote—Naloxone, Naltrexone**

- **MOA:** Pure opioid antagonist competes and displaces narcotics at opioid receptor sites.
- **Naloxone:** IV (preferred), IM, intratracheal, subcutaneous: 0.4–2 mg every 2–3 minutes as needed.

**Table 16.18:** Acute action and withdrawal signs of opioids.

<i>Acute action</i>	<i>Withdrawal signs</i>
<ul style="list-style-type: none"> <li>• Analgesia</li> <li>• Respiratory depression</li> <li>• Euphoria</li> <li>• Relaxation and sleep</li> <li>• Tranquilization</li> <li>• Decreased blood pressure</li> <li>• Constipation</li> <li>• Pupillary constriction</li> <li>• Hypothermia</li> <li>• Drying of secretions</li> <li>• Reduced sex drive</li> <li>• Flushed and warm skin</li> </ul>	<ul style="list-style-type: none"> <li>• Pain and irritability</li> <li>• Hyperventilation</li> <li>• Dysphoria and depression</li> <li>• Restlessness and insomnia</li> <li>• Fearfulness and hostility</li> <li>• Increased blood pressure</li> <li>• Diarrhea</li> <li>• Pupillary dilation</li> <li>• Hyperthermia</li> <li>• Lacrimation, runny nose</li> <li>• Spontaneous ejaculation</li> <li>• Chilliness and ‘gooseflesh’</li> </ul>

## Carbon Monoxide

**Q. Write short note on carbon monoxide poisoning—signs and symptoms.**

Carbon monoxide (CO) is a colorless, odorless gas generated by faulty appliances burning organic fuels. It is also present in vehicle exhaust fumes. It produces toxicity by binding with hemoglobin and cytochrome oxidase, which decreases the delivery of oxygen to tissue and inhibits cellular respiration.

### *Clinical Features*

Acute severe carbon monoxide poisoning produces non-specific symptoms

such as headache, nausea, irritability, weakness and tachypnea. Later, ataxia, nystagmus, drowsiness and hyperreflexia may develop leading to coma, respiratory depression, cardiovascular collapse and death. Myocardial ischemia/infarction, cerebral edema, and rhabdomyolysis (with myoglobinuria and renal failure) may occur. Long-term exposure can lead to Parkinsonism.

### ***Treatment of Carbon Monoxide Poisoning***

Administration of normobaric 100 percent oxygen is the therapy of choice for most cases, while hyperbaric oxygen therapy is reserved for severe poisonings.

### **Methanol Poisoning**

**Q. Write a short note on toxicity, clinical features and management of methanol poisoning.**

- Methanol is a mild CNS depressant.
- *Metabolism:* Methanol itself is not toxic. However, its metabolites namely formaldehyde and formic acid are responsible for its toxicity.

### ***Clinical Features***

- Early clinical features are due to methanol, whereas late features are due to the methanol metabolite formic acid.
  - **Features due to methanol:** Methanol produces nausea, vomiting, abdominal pain, headache, vertigo, confusion, obtundation, convulsions and coma.
  - **Features due to formic acid:** Metabolic acidosis and **retinal injury**. The retinal manifestations include clouding and diminished vision, dancing and flashing spots, dilated or fixed pupils, and hyperemia of the optic disc, retinal edema and blindness.
- **Other manifestations:** Rapid breathing due to metabolic acidosis, myocardial depression, bradycardia, shock and anuria.
- **Complication:** Putaminal necrosis producing rigidity, tremor, masked faces and monotonous speech.

### ***Diagnosis***

- Confirmation by **measurement of serum methanol level**, which is

usually more than 20 mg/dL.

- Methanol-induced formic acidosis can be confirmed by a large anion gap, low serum bicarbonate and elevated serum formate levels.
- Osmolol gap is elevated due to methanol.

#### Management

- **In early stages:**
  - **Gastrointestinal decontamination.**
  - **Correction of systemic acidosis** with sodium bicarbonate.
- **Ethanol therapy:** Indicated in patients with visual symptoms or methanol level exceeding 20–30 mg/dL. Ethanol blocks conversion of methanol to formic acid by inhibiting alcohol dehydrogenase.
- **Hemodialysis:** Indicated (i) when methanol level exceeding 50 mg/dL, (ii) those with visual signs, and (iii) those with metabolic acidosis unresponsive to bicarbonate.
- **Antidote of methanol poisoning:** 4-methylpyrazole or fomepizole is a direct, potent inhibitor of alcohol dehydrogenase. It may be more effective than ethanol, which is a competitive antagonist.
- **Co-factor therapy:** Folinic acid (leucovorin) is given in addition to ethanol or 4-methylpyrazole. It acts by enhancing the rate of degradation of formic acid to carbon dioxide.

## Ethylene Glycol Poisoning

- Produces similar symptoms as methanol poisoning, however, renal failure is more common.
- Treatment is on same lines as methanol poisoning. Supplementation of thiamine and pyridoxine as cofactor therapy.

## ALUMINIUM PHOSPHIDE POISONING

**Q. Discuss the clinical features and management of aluminum phosphide poisoning.**

Aluminum phosphide (ALP) poisoning is known worldwide, especially in developing countries such as India. Lethal dose of ALP is 1–1.5 g.

ALP, when ingested, liberates a lot of phosphine gas → phosphine leads to non-competitive inhibition of the cytochrome oxidase of mitochondria, blocking the electron transfer chain and oxidative phosphorylation, producing an energy crisis in the cells.

The severe toxicity of ALP particularly affects the cardiac and vascular tissues, which manifests as profound and refractory hypotension, congestive heart failure, methemoglobinemia, myocarditis, pericarditis and

subendocardial infarction, cardiac arrhythmias, lactic acidosis and respiratory failure.

### **Management**

It is supportive, the main objective is to provide effective oxygenation, ventilation and circulation till phosphine is excreted. Gastric decontamination using activated charcoal, potassium permanganate and medicated liquid paraffin have been tried. No definite antidote available.

## **RODENTICIDE POISONING**

- Rodenticides are composed of superwarfarins, thallium, barium carbonate, aluminum phosphide (ALP) and zinc phosphide.
- Rodenticides containing aluminum or zinc phosphide are hepatotoxic and can cause acute fulminant hepatic failure (ALF). Patients admitted with aluminum or zinc phosphide poisoning often develop hepatic necrosis, renal failure, metabolic acidosis and refractory hypotension.
- Superwarfarin rodenticides cause coagulopathy and bleeding > Followed by a next line with treatment background.
- Treatment is supportive. Fresh frozen plasma, cryoprecipitate supplementation. N acetyl cysteine for ALF. Liver transplantation for fulminant ALF.

# **Nutrition and Environmental Medicine**

# CHAPTER 17

## HALLMARKS OF CANCER

**Q.** Write short essay/note on:

- Proto-oncogene, oncogene and tumor suppressor gene.
- Genetic basis of transformation of a normal cell into a malignant cell.

### Regulation of Cancer Cell Growth

Normal cell may undergo malignant transformation by corrupting any one of the normal steps involved in cell proliferation. Abnormal regulation of cell growth in cancer can occur as the result of several mechanisms. All cancers show eight fundamental changes in cell physiology. These are considered the hallmarks of cancer and include:

**Table 17.1:** Examples of oncogenes and associated tumors.

<i>Classification of oncogenes</i>	<i>Example/s of associated tumor/s</i>
<b>Growth Factors</b>	
PDGF (platelet-derived growth factor)	Non-small cell cancer of lung
TGF- $\alpha$ (tumor growth factor-alpha)	Hepatocellular cancer
<b>Growth Factor Receptors</b>	
EGFR (epidermal growth factor receptor)	Lung and gastrointestinal tumors
Her 2/neu receptor	Breast cancer
<b>Signal Transducing Proteins</b>	
KRAS	Adenocarcinoma of colon, lung, and pancreas
NRAS	Hematopoietic tumors, melanomas
ABL	Chronic myeloid leukemia, acute lymphoblastic leukemia
<b>Nuclear-Regulatory Proteins/Transcription Factors</b>	
C-MYC	Burkitt lymphoma

<i>N-MYC</i>	Neuroblastoma
<b>Cell Cycle Regulators</b>	
Cyclin D	Breast, esophageal, and liver cancers

1. **Self-sufficiency in growth signals (activation of cell growth): Proto-oncogenes** are normal cellular genes, which encode a number of nuclear proteins that **regulate normal cell proliferation, differentiation, and survival**. Genes that promote **autonomous cell growth** in cancer cells are called **oncogenes** and are altered/mutated versions of proto-oncogenes.

**Oncogenes and Oncoproteins:** Oncogenes can promote cell growth in the absence of normal growth-promoting/mitogenic signals. Oncoproteins are products of oncogenes and resemble the normal products of proto-oncogenes. Oncoproteins production is not under normal regulatory control → cells proliferate without the usual requirement for external signals and are freed from checkpoints → **growth becomes autonomous**.

**Classification of oncogenes (Table 17.1):** Oncogenes are classified depending on the function of gene product (oncoprotein).

2. **Insensitivity to growth-inhibitory signals (inhibition of tumor suppressor genes):**

- Normally, the products of tumor suppressor genes have a negative regulatory control of cell growth.
- Second mechanism of carcinogenesis results from failure of growth inhibition, due to **deficiency of normal tumor suppressor genes and their products**.
- **Tumor suppressor genes** apply brakes to cell proliferation and prevent uncontrolled/abnormal cell proliferation and induce repair or self-death (apoptosis). Important tumor suppressor genes are *RB*, *p53*, *BRCA1* and *BRCA2* genes.
- Structural abnormalities associated with oncogenes are presented in Table 17.2. and few examples of tumor suppressor genes and tumors in which they are affected are listed in Table 17.3.

3. **Growth-promoting metabolic alterations:** Cancer cells show a distinctive form of cellular metabolic alteration (even in the presence of adequate oxygen) characterized by high levels of glucose uptake and increased conversion of glucose to lactose (fermentation) via the glycolytic pathway. This is known as the **Warburg effect** or aerobic glycolysis.

4. **Evasion of cell death/apoptosis:** Apoptosis is a programmed cell death and is one of the normal protective mechanism by which a cell with DNA damage (mutation) undergo cell death. Mutations in the genes that regulate apoptosis may lead to neoplasm. Example, Some members of the Bcl-2 family (Bcl-2, Bcl-XL) are anti-apoptotic, while others (Bax, Bak) are pro-apoptotic. In few malignant cells, decreased apoptoses are associated with increased levels of Bcl-2/Bcl-XL or decreased levels of Bax/Bak.
  5. **Limitless replicative potential:** All malignant tumors contain cells that are immortal and have limitless replicative potential.
    - **Cancer stem cells:** At least few cells in all cancers have stem cell-like properties and are called cancer stem cells.
    - **Reactivation of telomerase:** During the course of repeated cell cycles, there is progressive shortening of telomeres, which is prevented by an enzyme called telomerase. Cancer cells can replicate an infinite number of times and this is associated with maintenance of telomere length.
  5. **Development of sustained angiogenesis:** Solid tumors cannot grow without vascularization and are achieved mainly by **neoangiogenesis**.
  7. **Ability to invade and metastasize** (invasion and metastasis): Invasion into surrounding tissues is associated with loss of cell-cell cohesion, which is mediated by cell adhesion molecules (CAMs). Metastasis of tumor cells occurs through intravasation into the vascular and lymphatic vessels.
3. **Ability to evade the host immune response.**

**Table 17.2: Structural abnormalities associated with oncogenes.**

<i>Oncogene</i>	<i>Aberration</i>	<i>Neoplasm</i>
abl	t(9;22)	CML, AML, ALL
myc	t(8;14)	Burkitt lymphoma, B-ALL, T-ALL
bcl-1, bcl-2	t(11;14)	B-cell lymphoma
tcl-1, tcl-2	t(11,14)	T-cell lymphoma

BRCA2 (13q)	Regulator/DNA repair		
WT1 (11p)	Transcription	Wilms' tumor	Lung cancer

## CANCER TREATMENT

Cancer treatments are divided into four main types: surgery, chemotherapy (includes hormone therapy and molecular targeted therapy), radiation therapy (includes photodynamic therapy), and biologic therapy (includes immunotherapy and gene therapy). Most often used in combination. For example, surgery and radiation therapy.

### **Q. Write short note on adjuvant and neoadjuvant chemotherapy.**

The primary goal of cancer treatment is to cure the cancer. In situations where cure cannot be achieved, the goal shifts towards palliation, the amelioration of symptoms, and preservation of quality of life. Treatment of cancers may be undertaken in spite of severe and perhaps life-threatening toxicities.

- **Palliation:** Palliation is the relief of tumor symptoms, preservation of quality of life and prolongation of life of patient with cancer. When cure is not possible, palliation is possible in many cancers. **Aim of palliative chemotherapy is to improve the quality of life with minimal toxicity.** It may cause a small increase in survival.
- **Adjuvant treatment:** It is administered after surgery. Main aim is to increase the disease-free and overall survival.

- **Neoadjuvant treatment:** It is the treatment given to patients without macroscopic evidence of metastases and who are at risk of recurrence from micrometastases, following treatment given for the primary lesion. It is given as chemotherapy, radiotherapy or hormonal treatment before primary surgery. This is aimed to shrink the tumor, to improve the local excision, treat any micrometastases and improve the survival.
- **Chemoprevention:** It is the use of pharmacological agents to prevent cancer developing in individuals who are identified as having a risk of particular cancer.

## Surgical Treatment

Surgical intervention is of pivotal importance for diagnosis (biopsy). Also surgery can be used for curative or palliative purposes.

## Systemic Chemotherapy

**Q. Write short note on classification of chemotherapeutic agents.**

### *Mechanism of Action (Fig. 17.1)*

### *Combination Therapy*

It consists of combination of chemotherapeutic agents. Combinations usually include drugs from different classes. They aim at targeting several pathways and gaining maximum therapeutic effect. Purpose of combination therapy are: (i) to prevent drug resistance, (ii) to gain maximum therapeutic effect and (iii) to limit the side effects of different drugs.

### *Adverse/Side Effects*

The five most common side effects include *vomiting, hair loss, tiredness, myelosuppression, and mucositis.*

### *Cyclophosphamide*

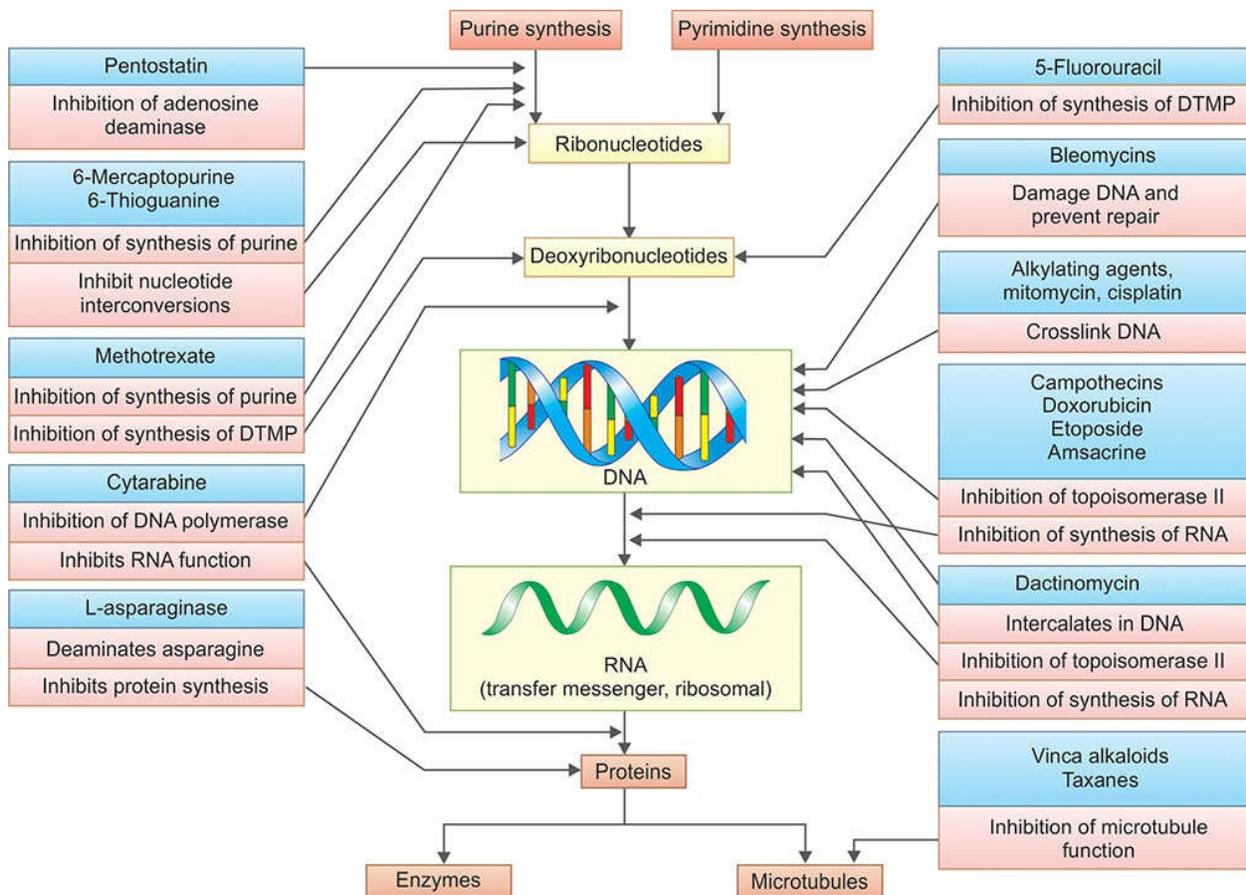

**Q. Write short note on cyclophosphamide.**

Cyclophosphamide is a direct DNA-interactive alkylating agent that inhibits the DNA synthesis. Uses and toxicity of cyclophosphamide are presented in Table 17.4.

---

**Table 17.4: Uses and toxicity of cyclophosphamide.**

Uses	Toxicity
<ul style="list-style-type: none"> <li>Autoimmune disorders: Systemic lupus erythematosus (SLE), rheumatoid arthritis, Wegener's granulomatosis, polyarteritis nodosa (PAN) and other systemic vasculitis refractory ITP.</li> <li>Lymphomas</li> <li>Leukemias, carcinoma breast, Ewing's sarcoma, gestational trophoblastic tumors</li> <li>Stem cell transplant conditioning</li> <li>Nephrotic syndrome, (corticosteroid refractory or intolerant)</li> </ul>	<ul style="list-style-type: none"> <li>Bone marrow depression resulting in cytopenias</li> <li>Chemical cystitis and bladder carcinoma. Severe cystitis can be prevented/treated by 2-mercaptoethanesulfonate (MESNA)</li> <li>Hepatotoxicity</li> <li>Sporadic interstitial pneumonitis leading to pulmonary fibrosis</li> <li>Cardiac dysfunction (high dose)</li> <li>Alopecia, oligospermia, sterility, amenorrhea</li> </ul>

**Fig. 17.1:** Mechanism of action of various chemotherapeutic drugs.

## Methotrexate

**Q. Write short note indications/uses and toxicity of methotrexate.**

- Methotrexate is an indirectly DNA-interacting, folic acid antagonist,

which function as an antimetabolite. Methotrexate inhibits dihydrofolate reductase enzyme. These cells without reduced folates die a ‘thymine-less’ death.

- Uses and toxicity of methotrexate (Table 17.5).

**Table 17.5: Uses and toxicity of methotrexate.**

<i>Uses</i>	<i>Toxicity</i>
<ul style="list-style-type: none"> <li>• Choriocarcinoma</li> <li>• Rheumatoid arthritis and other connective tissue disorders</li> <li>• Leukemias: Meningeal leukemia prophylaxis or treatment</li> <li>• Psoriasis, acute graft versus host disease prophylaxis, lupus nephritis</li> </ul>	<ul style="list-style-type: none"> <li>• Bone marrow suppression</li> <li>• Hepatotoxicity, increase in transaminases, hepatic fibrosis (chronic low-dose)</li> <li>• Megaloblastic anemia</li> <li>• Mucosal irritation: Ulcerative enteritis, ulcerative dermatitis</li> <li>• Renal failure itself at high doses</li> <li>• Pulmonary fibrosis</li> <li>• Chemical arachnoiditis and CNS dysfunction (with administration to the intrathecal space)</li> </ul>

The toxicity of methotrexate is antagonized by administering folinic acid (citrovorum factor).

## **Cisplatin**

### **Q. Write short note on cisplatin.**

- Cisplatin is a platinum-based chemotherapy drug (others include carboplatin and oxaliplatin) that produces cross-linking of DNA preventing division of cells.
- Uses and toxicity of cisplatin (Table 17.6).

**Table 17.6: Uses and toxicity of cisplatin.**

<i>Uses</i>	<i>Toxicity</i>
<ul style="list-style-type: none"> <li>• Sarcomas</li> <li>• Carcinomas               <ul style="list-style-type: none"> <li>– Small cell cancer of lung</li> <li>– Ovarian carcinoma</li> <li>– Bladder carcinoma</li> <li>– Breast carcinoma</li> </ul> </li> <li>• Lymphoma</li> <li>• Germ cell tumors</li> </ul>	<ul style="list-style-type: none"> <li>• Nephrotoxicity</li> <li>• Electrolyte disturbances: hypomagnesemia, hypokalemia and hypocalcemia</li> <li>• Nausea and vomiting</li> <li>• Neurotoxicity (stocking-and-glove sensorimotor neuropathy)</li> <li>• Ototoxicity: Hearing loss</li> <li>• Alopecia</li> <li>• Bone marrow suppression</li> </ul>

---

## Hormone Therapy

Hormones act as growth factors. For example estrogen is capable of stimulating the growth of breast and endometrial cancers and androgen the growth of prostate cancer. Removal of these growth factors may result in apoptosis and regression of the cancer. Examples are given in Box 17.1.

## Immunotherapy

Stimulation of the patient's immune system can sometimes change the natural history of a malignancy. Example, interferons are naturally occurring cytokines that mediate the cellular immune response. They are used in the treatment of melanoma and lymphoma, and they are beneficial as adjuvants (after surgery and chemotherapy respectively) to delay recurrence. **Rituximab** is an antibody against the common B-cell antigen CD20, and improves survival in diffuse large cell non-Hodgkin's lymphoma when combined with chemotherapy, and is also as a palliative therapy in advanced follicular non-Hodgkin's lymphoma. Activation of the immune system by using **Bacillus Calmette-Guérin (BCG)** is used for bladder cancer.

**Box 17.1:** Hormone therapy in cancer.

- **Antiestrogen therapy:** Breast tumors with positive estrogen receptor (ER) by tamoxifen Toremifene, Raloxifene.
- **Pure antiestrogen receptor downregulator:** Fulvestrant for carcinoma breast
- **Somatostatin analogues:** Octreotide for pituitary tumors
- **LHRH and anti-androgens:** In prostate cancer, luteinizing hormone releasing hormone (LHRH) analogues such as goserelin and/or anti-androgens such as bicalutamide, flutamide
- **Aromatase inhibitors:** Letrozole, Anastrozole, Exemestan used for carcinoma breast
- **Progestogen:** Endometrial and breast cancer.

---

## Biological Therapies

**Q. Write short essay/note on various types of targeted therapy in cancer patients.**

- Molecular targets are usually located in tumor cells. However, some targeted agents may target other cells that may affect the growth of tumor cells (e.g. antiangiogenic agents may target endothelial cells).
- Targeted therapies have a high specificity toward tumor cells and decreased toxicity to normal tissues.
- Targeted therapies are often used in combination with chemotherapy or

<i>Monoclonal antibodies</i>	<i>Target</i>	<i>Cancer(s)</i>
Alemtuzumab	CD52	CLL
Bevacizumab	VEGF	Colon, lung, breast, kidney, and brain
Cetuximab	EGFR1	Colon, H&N
Panitumumab	EGFR1	Colon
Rituximab	CD20	Lymphomas
Trastuzumab	HER-2	Breast
Olaparib, rucaparib	Poly ADP ribose polymerase (PARP)	Ovary
Onartuzumab, emibetuzumab	HGF–cMET	Non-small cell lung cancer
Ipilimumab	CTLA-4	Unresectable melanoma
Nivolumab, pembrolizumab	PD-1	Refractory non-small cell lung cancer

- **Tyrosine kinase inhibitor (TKI) (Table 17.8).**
- **Inhibitor of Her2:** Lapatinib inhibits Her2 and increases the survival in breast cancer.
- **Inhibitor of signaling by EGFR and VEGFR:** TKIs sunitinib and sorafenib inhibit signaling by EGFR and VEGFR in metastatic renal cancer. Erlotinib and gefitinib are effective in lung cancer.

**Table 17.8:** Various tyrosine kinase inhibitors and the cancers in which it is used.

<i>Tyrosine kinase inhibitors</i>	<i>Cancer in it is used</i>
Imatinib	CML, GIST, others
Dasatinib	CML, ALL
Nilotinib	CML
Gefitinib	Lung
Erlotinib	Lung, pancreas
Lapatinib	Breast
Sorafenib	Kidney, liver
Sunitinib	Kidney

### *Proteasome inhibitors*

- Inhibition of the proteasome leads to apoptosis in cancer cells. **Bortezomib** is the proteasome inhibitor used in myeloma (relapsed/refractory) and in some types of NHL.

The first molecular target for targeted cancer therapy was the cellular receptor for the female sex hormone estrogen (Box 17.2), which many breast cancers require for growth. Currently approved conjugated antibodies are listed in Box 17.3.

### **Box 17.2:** Therapy targeted at the estrogen receptor.

- Selective estrogen receptor modulators (SERMs)
  - Tamoxifen
  - Toremifene
- Estrogen receptor inhibitor and destroyer
  - Fulvestrant
- Estrogen synthesis inhibitors–aromatase inhibitors (AIs)
  - Anastrozole
  - Letrozole
  - Exemestane

### **Box 17.3:** Conjugated antibodies currently approved.

- Radio-conjugated antibodies
  - Tositumomab
  - Ibritumomab
  - Both used against refractory lymphomas
- Toxin-conjugated antibody
  - Gemtuzumab ozogamicin
  - Used against AML

## **Radiation Therapy (Radiotherapy)**

It involves treating the cancer with ionising radiation and it may be curative for certain localized cancers. Ionising radiation can be delivered by radiation emitted from the decay of radioactive isotopes or by high-energy radiation beams (e.g. X-rays).

**Principle:** Radiation delivers energy to tissues exposed to radiation. It causes ionization and excitation of atoms and molecules. The biological effect is brought through the generation of single- and double-stranded DNA breaks. This, in turn, induces apoptosis of cells through the production of short-lived free radicals (e.g. oxygen-derived free radicals) which damage proteins and membranes.

**Methods employed:** Usually employed methods are:

- **External beam (or teletherapy) from a linear accelerator source** is the

most commonly used form of radiotherapy. It involves application from a distance by a linear accelerator.

- **Brachytherapy** is the direct application of a radioactive source in close contact with the tissue or into a tumor. This delivers a very high (intense exposure), localized dose of radiation. It is used for localized cancers of the head and neck and cancer of the cervix, prostate and endometrium.
- **Fractionation** is the delivery of the radiation dose in increments separated by at least 4–6 hours. It tries to exploit any advantage in DNA repair between normal and malignant cells.
- **Hyperfractionation** is when more than one fraction/day is given. This method improves the outcome in head and neck and lung cancer.
- **Intravenous injection of a radioisotope** (Systemic radionuclides): It can be delivered by intravenous or intracavitary routes. It provides radiation targeted to particular tissue uptake via surface antigens or receptors. Examples include 131-iodine for cancer of the thyroid and 89-strontium for the treatment of bone metastases from prostate cancer.
- Presently used other types of cancer therapy are listed in Box 17.4. Biotherapeutic agents are listed in Box 17.5.

**Box 17.4:** Other novel types of cancer therapies now in use.

- Proteasome inhibitors (Bortezomib)
- mTOR inhibitors (Temozolimus, Everolimus)
- DNA demethylating agents (Azacitidine, Decitabine)
- Histone deacetylase inhibitors (Vorinostat)
- Translocation targeters (retinoic acid)
- Antiangiogenic agents (Thalidomide, Lenalidomide)

**Box 17.5:** Biotherapeutic agents.

- Interferons
- Interleukins
- Cancer vaccines
- Immunomodulatory agents
- Colony-stimulating factors
- Monoclonal antibodies
- Gene therapy

## ***Side Effects of Radiotherapy***

- *Early side effects:* They may occur within days to weeks of treatment and it depends on tissue sensitivity, fraction size and treatment volume. These include anorexia, nausea, malaise, mucositis, esophagitis, diarrhea, alopecia, and myelosuppression.
- *Later side effects:* They occur from months to years later. They are not related to the severity of the acute effects and are brought out by different mechanism. Late effects are due to loss of slowly proliferating cells and ischemia and fibrosis produced due to local endarteritis. The tissue involved includes skin, bone, mouth, bowel, bladder, vagina, lung, heart, etc.
- *Secondary malignancies* following radiotherapy may develop 10–20 years after the cure of the primary cancer. These include hematological malignancies and solid tumors at the irradiated tissues.

### Box 17.6: Immunosuppressive drugs.

- Calcineurin inhibitors (specific T cell inhibitors): For example, cyclosporine, tacrolimus
- Antiproliferative drugs (cytotoxic drugs): Azathioprine, cyclophosphamide, methotrexate, chlorambucil, mycophenolate mofetil (MMF)
- Glucocorticoids: Prednisolone and others
- Antibodies: Muromonab CD3, antithymocyte globulin (ATG), Rho (D) immunoglobulin

## Immunosuppressive Drugs

### Q. Write short note on immunosuppressive drugs.

These drugs inhibit cellular and/or humoral immunity response and have major role in organ transplantation and autoimmune diseases. Immunosuppressive drugs are listed in Box 17.6.

## ONCOLOGIC EMERGENCIES

### Q. Write short note on:

- **Emergency conditions related to tumors.**
- **Clinical features and treatment of tumor lysis syndrome.**

Oncologic emergencies are listed in Table 17.9.

**Table 17.9: Oncologic emergencies.**

--	--	--

**Metabolic or hormonal problems:**

- Hypercalcemia
- Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
- Lactic acidosis
- Hypoglycemia
- Adrenal insufficiency

**Treatment related:**

- Tumor lysis syndrome
- Human antibody infusion reactions
- Febrile neutropenia
- Thrombocytopenia
- Pulmonary infiltrates
- Hemorrhagic cystitis
- Hyperviscosity syndrome
- Disseminated intravascular coagulation
- Hypersensitivity reactions to antineoplastic drugs

**Pressure or obstruction:**

- Superior vena cava syndrome
- Epidural spinal cord compression
- Pericardial effusion/cardiac tamponade
- Intestinal obstruction
- Urinary obstruction

## Tumor Lysis Syndrome (TLS) (Fig. 17.3)

Tumor lysis syndrome (TLS) is treatment related complication.

It can develop 1–5 days post-chemotherapy treatment of leukemias and lymphomas.

- Metabolic triad of **hyperuricemia, hyperkalemia, hyperphosphatemia**.
- Can also lead to **renal failure and hypocalcemia** as secondary complications.
- It is due to release of the breakdown products of dying tumor cells. Chemotherapeutic agents cause cell lysis and cell death with release of intracellular components into the bloodstream.
- Breakdown of nucleic acid, catabolism of hypoxanthine and xanthine lead to elevated uric acid.
- Potassium and phosphate are present at high levels in cytoplasm.
- Risk factors are: Large tumor burden, high-growth fraction, increased pre-treatment LDH or uric acid, or pre-existing renal insufficiency.

### *Clinical Features*

Lysis of malignant cells causes several metabolic abnormalities/disturbances.

These include **hyperkalemia** (leads to cardiac arrhythmias), **hyperphosphatemia** (produces acute renal failure), **hyperuricemia** (produces acute renal failure), hyperuricosuria, **hypocalcemia** (results in seizures, muscle cramps, tetany and arrhythmia), and consequent acute uric acid nephropathy and renal failure.

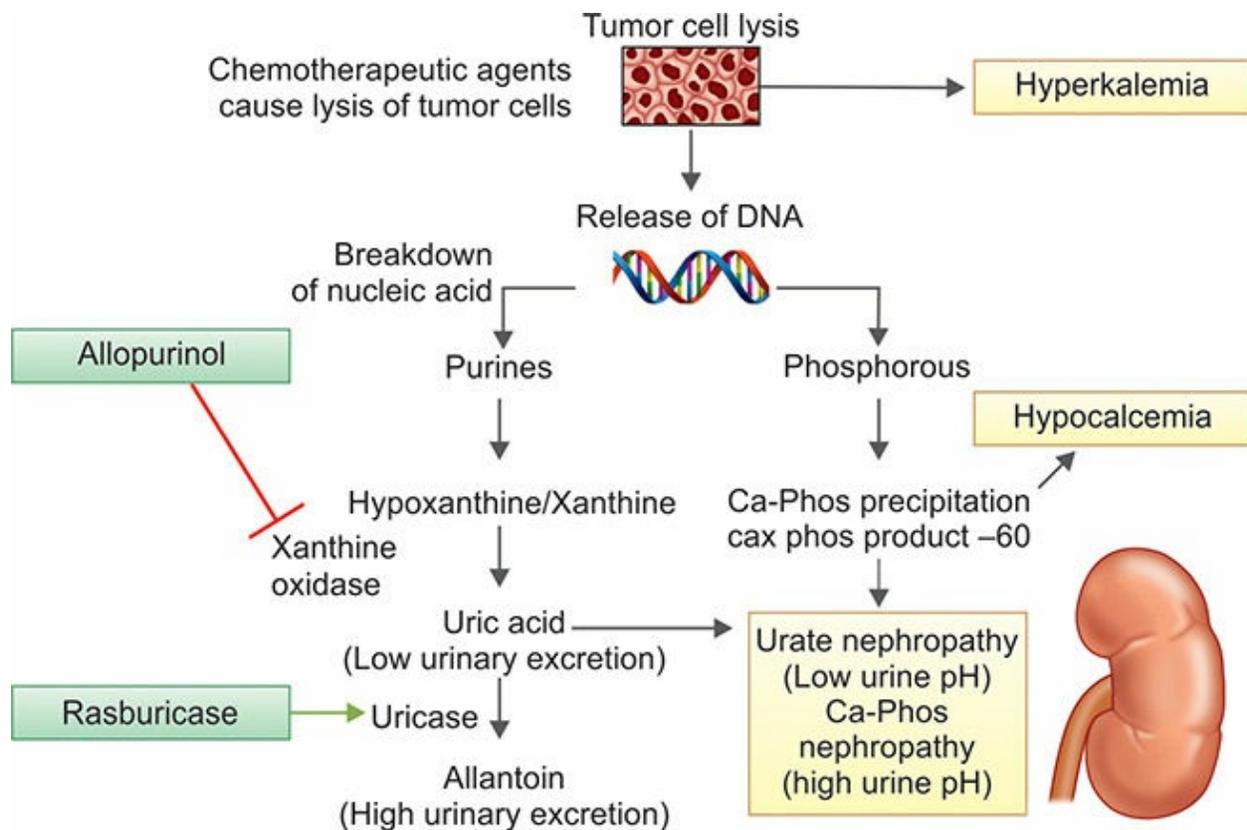

Fig. 17.3: Mechanism of tumor lysis.

## Prophylaxis

Patient at high risk: Leukemia, high grade lymphoma, rapidly proliferating bulky solid tumor (e.g. small cell) must receive vigorous prehydration, allopurinol and careful metabolic monitoring.

### Treatment Intravenous hydration is of prime importance.

- **Rasburicase** (works for prevention and treatment)
  - Contraindicated in G6PD deficiency.
  - Rasburicase (recombinant urate oxidase) converts uric acid into allantoin, which is an inactive and soluble metabolite and is easily excreted by the kidneys.
- Alkalinization of urine to promote uric acid excretion is controversial (it may worsen hypocalcemic tetany). Allopurinol can be used to decrease uric acid.
- Management of life-threatening hyperkalemia with antihyperkalemic measures.
- For hypocalcemia, infuse calcium gluconate under ECG monitoring. Hyperphosphatemia can be treated by giving aluminium hydroxide orally or hemodialysis.
- Early dialysis (hemodialysis is preferred) is required when uric acid >10 mg/dL, phosphorus >10 mg/dL or creatinine >10 mg/dL.

## Febrile Neutropenia/Neutropenic Sepsis/Neutropenic Fever

**Q. Write short essay/note on febrile neutropenia.**

- Neutropenia (decrease of neutrophils below normal range) is a common complication of malignancy. It can occur secondary to chemotherapy, radiotherapy (if large amounts of bone marrow are irradiated) or as a component of pancytopenia due to infiltration of the bone marrow by malignancy.
- Neutropenic fever is defined as a fever/pyrexia of  $38^{\circ}\text{C}$  for more than 1 hour in a patient with a neutrophil count  $<500/\text{mm}^3$ . The risk of sepsis is dependent on the severity and duration of neutropenia and the presence of other risk factors (e.g. intravenous or bladder catheters).

### ***Clinical Features***

- The typical presentation is with high fever. Neutropenic patients are prone to bacterial and fungal infection, most often from endogenous source (e.g. enteric bowel flora). Carefully examine for potential foci of infection. However, examination usually does not define the primary source of the infection. Signs and symptoms of infection may be minimal, particularly in patients receiving corticosteroids.
- Apart from fever, patients may also have nonspecific symptoms (e.g. nausea, diarrhea, drowsiness, breathlessness).
- Hypotension is a bad prognostic feature and may lead to systemic circulatory shutdown and organ failure.

### ***Investigations***

- Full blood count, cultures (urine, sputum, stool depending on the case), chest X-ray, and swabs for culture (throat, central line, wound). Before antibiotic therapy, two sets of blood cultures from a peripheral vein and any indwelling venous catheters should be sent.

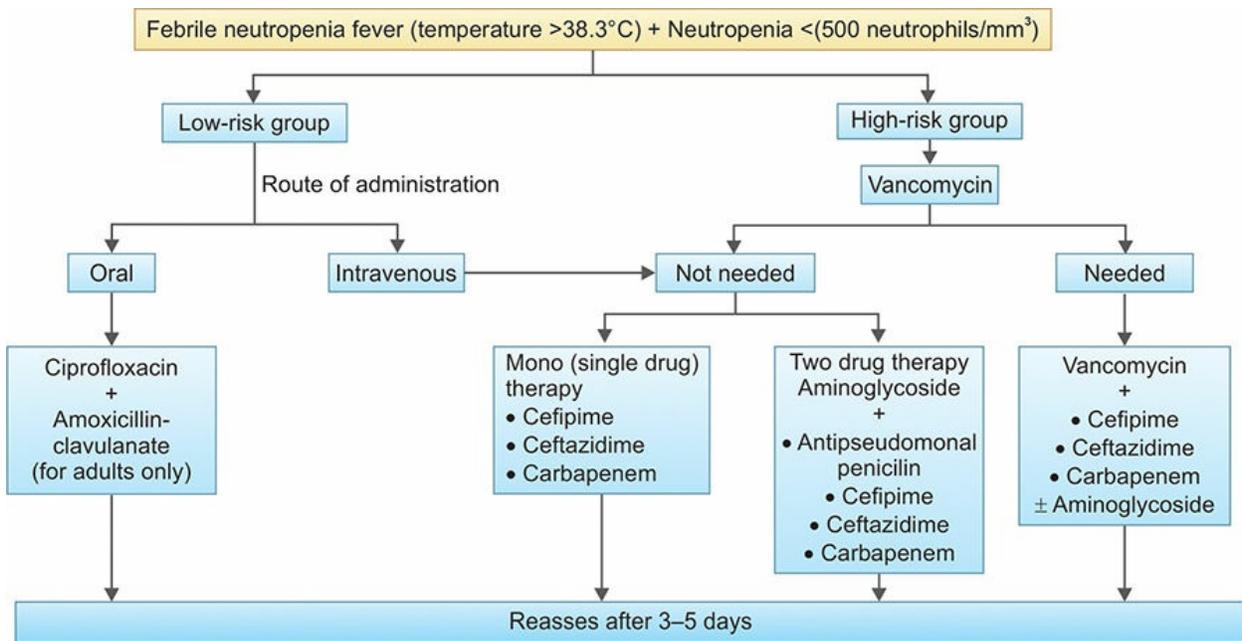

#### **Treatment**

- Antibiotics (Flowchart 17.1).
- Antifungal: If there is no response for antibiotics after 72–96 hours, treatment with amphotericin B or voriconazole should be given to cover fungal infection.
- Growth Factors: G-CSF, GM-CSF are given to improve the blood counts.
- Other supportive therapy: Patients with signs of systemic illness, such as tachycardia, hypotension, oliguria require urgent admission and resuscitation with intravenous fluids to restore circulatory function. Other supportive therapy includes inotrope therapy, ventilation or hemofiltration.

### Prophylactic fluoroquinolones

- It is given to high-risk and intermediate risk groups (consists of patients receiving high-dose chemotherapy and those with hematological malignancy) in which the anticipated duration of neutropenia is more than 7 days.
- Prophylactic fluoroquinolones are not indicated in patients with solid tumors undergoing standard outpatient cyclical chemotherapy in which the anticipated duration of neutropenia is less than 7 days, because it may lead to microbial resistance.

**Flowchart 17.1:** Algorithm for the antibiotic and their mode of administration in febrile neutropenia.

## INVESTIGATIONS IN ONCOLOGY

### Tumor Markers

**Q.** Write short essay/note on tumor markers with examples/serum tumor markers.

- Tumor markers are biochemical substance/product of malignant tumors that can be detected in the cells themselves or in serum/blood and/or body fluids.
- Tumor markers can be a normal endogenous products produced in excess by cancer cells or products of newly switched on genes that remained

quiescent in the normal cells.

- Concentration increases with tumor progression, highest levels when tumors metastasize.
- Include diverse molecules, such as serum proteins, oncofetal antigens, hormones, metabolites, receptors and enzymes
- Tumor markers may be useful in management in certain cancers (**Box 17.7**). In a particular patient, rising and falling levels of the tumor marker are usually associated with increasing or decreasing tumor burden, respectively.

### **Box 17.7:** Usefulness of tumor markers.

- Screening populations at risk
- Diagnosis
- Prognosis
- Detection of recurrence
- Monitoring response to treatment
- Immunodetection of metastatic sites

### ***Disadvantage***

Tumor markers are not in themselves completely specific enough for the diagnosis of malignancy. They may also be raised in few benign lesions. Few markers are specific for a single individual tumor. Most are found with different tumors of the same tissue type. They are present in higher quantities in blood from cancer patients than in blood from both healthy subjects and patients with benign diseases. However, once a malignancy has been diagnosed and shows elevated levels of a tumor marker, the marker can be used to assess response to treatment.

### ***Types of Markers (Table 17.10)***

#### ***$\alpha$ -fetoprotein***

#### **Q. Write short note on $\alpha$ -fetoprotein.**

- **$\alpha$ -fetoprotein** is an oncofetal antigen produced by the liver and gastrointestinal tract epithelium in the fetus. The  $\alpha$ -fetoprotein (AFP) gene is completely repressed in fully matured fetus and disappears immediately after birth.

- It is abundant in fetal blood and its level in normal adults is below 15 ng/mL after birth.

### *Causes of raised $\alpha$ -fetoprotein*

- During prenatal period: Amniotic fluid AFP is elevated with open spina bifida, anencephaly and atresia of esophagus.
- Postnatal life:
  - **Hepatocellular carcinoma:** In about 70% of patients it shows very high levels ranging from 500 ng/mL to 5 mg/mL.
  - **Nonseminomatous testicular tumors:** Embryonal carcinoma, teratomas, choriocarcinoma and yolk sac carcinoma.
  - **Germ cell tumors** of ovaries and extragonadal germ cell tumors.
  - Neoplasms of gastrointestinal tract.
  - **Liver disorders:**
    - ◆ Hepatitis: Minimal elevation in **acute or chronic hepatitis.**
    - ◆ **Hepatocellular carcinoma:** High AFP level ( $\geq 400$  ng/mL) is associated with large tumor size, bilobar involvement, portal vein thrombosis and a lower median survival rate.
  - Normal pregnancy: May be elevated up to 500 ng/mL in maternal serum.

**Table 17.10:** Common tumor markers.

<i>Tumor marker</i>	<i>Associated tumors</i>
<b>1. Enzymes</b>	
• Alkaline phosphatase (ALP)	Hepatoma, secondaries in liver, ovarian, lung, gastrointestinal cancers and Hodgkin's disease.
• Placental alkaline phosphatase (PLAP)	Seminoma
• Prostatic acid phosphatase (PAP)	Prostate carcinoma
• Neuron-specific enolase (NSE)	Small-cell carcinoma of lung, neuroblastoma
• Tartarate-resistant acid phosphatase (TRAP)	Hairy cell leukemia
<b>2. Hormones</b>	
• Human chorionic gonadotropin (hCG)	Trophoblastic tumors, nonseminomatous tumors of testis

• Calcitonin	Medullary carcinoma of thyroid
• Catecholamine	Pheochromocytoma
• Ectopic hormones	Paraneoplastic syndromes (Table 17.11)
<b>3. Oncofetal antigens</b>	
• $\alpha$ -Fetoprotein	Cancer of liver, nonseminomatous germ cell tumors of testis
• Carcinoembryonic antigen (CEA)	Carcinomas of the colon, pancreas, lung, and stomach. May also be elevated in cigarette smoking, peptic ulcer disease, inflammatory bowel disease, pancreatitis, hypothyroidism, cirrhosis and biliary obstruction
<b>4. Carbohydrate markers/mucins and other glycoproteins</b>	
• CA-125	Ovarian cancer
• CA 15-3	Breast carcinoma, pancreatic, lung, ovarian, colorectal and liver cancer in some benign breast and liver diseases
• CA 19-9	Pancreatic and colorectal cancer
<b>5. Specific proteins</b>	
• Immunoglobulins	Multiple myeloma and other gammopathies
• Prostate-specific antigen (PSA)	Prostate carcinoma. Other conditions include prostatitis, benign prostatic hypertrophy, prostatic trauma and after ejaculation
• Ferritin	Nonspecific, Hodgkin lymphoma, leukemia, liver, lung and breast cancer
• Thyroglobulin	Differentiated thyroid cancer
• S-100	Melanoma
• Inhibin A & B	Granulosa cell tumor
• Catalase, profilin 1, CD59	Oral squamous cell carcinoma
<b>6. Receptor markers</b>	
• Estrogen and progesterone receptors	Breast cancer as indicators for hormonal therapy
• C-erbB2 (HER-2 Neu)	Co-receptor in epidermal growth factor action, overexpression associated with cancer
<b>7. Genetic changes</b>	
• Bcr-Abl mutation	Chronic myeloid leukemia
<b>8. New molecular markers</b>	
• p53, APC, RAS mutants in stool and serum	Carcinoma colon
• p53 and RAS mutants in sputum	Lung cancer

and serum

**9. Mitochondrial markers mT DNA**

Carcinoma breast, prostate, lung, thyroid, colon

Significance of elevated AFP and hCG is listed in Box 17.8.

**Box 17.8:** Significance of elevated AFP and hCG.

**Elevated AFP only**

*Non-neoplastic*

- Ataxia telangiectasia
- Hereditary persistence of AFP
- Viral hepatitis
- Substance-induced liver damage

*Malignancy*

- Hepatocellular carcinoma

**Elevated hCG only**

*Non-neoplastic*

- Marijuana use
- Primary hypogonadism

*Neoplastic*

- Pure seminoma
- Gonadotroph adenoma

**Elevated AFP or hCG or both**

*Neoplastic*

- Nonseminomatous germ cell tumor
- Gestational trophoblastic disease
- Poorly differentiated adenocarcinoma

AFP =  $\alpha$  fetoprotein, hCG = human chorionic gonadotropin

## PARANEOPLASTIC SYNDROMES

**Q.** Write short essay/note on paraneoplastic syndromes.

**Definition:** Paraneoplastic syndromes are **symptom complexes in cancer patients which are not directly related to mass effects or invasion or metastasis or by the secretion of hormones indigenous to the tissue of origin.**

**Frequency:** Though they occur in 10–15% of patients, it is important because:

- **May be the first manifestation** of an occult neoplasm.
- **May be mistaken for metastatic disease** leading to inappropriate

treatment.

- May present clinical problems which **may be fatal**.
- Certain tumor products causing paraneoplastic syndromes may be **useful in monitoring recurrence** in patients who had surgical resections or are undergoing chemotherapy or radiation therapy.

Some paraneoplastic syndromes, their mechanism and common cancer causing them are listed in Table 17.11.

**Table 17.11: Paraneoplastic syndromes.**

<i>Clinical syndromes</i>	<i>Cause/mechanism</i>	<i>Associated cancer (example)</i>
<b>1. ENDOCRINOPATHIES</b>		
Cushing syndrome	ACTH or ACTH-like substance	Small-cell carcinoma of lung
Syndrome due to inappropriate antidiuretic hormone secretion	Antidiuretic hormone or atrial natriuretic hormones	Small-cell carcinoma of lung
Hypercalcemia	Parathyroid hormone-related protein (PTHrP), TGF- $\alpha$ , TNF, IL-1	Squamous cell carcinoma of lung
		Renal carcinoma
Carcinoid syndrome	Serotonin, bradykinin	Bronchial carcinoid
Hypoglycemia	Insulin or insulin-like substance	Fibrosarcoma
Polycythemia	Erythropoietin	Renal carcinoma, hepatocellular carcinoma
<b>2. NEUROLOGIC (NEUROMYOPATHIC) SYNDROMES (refer Table 6.101)</b>		
<b>3. CUTANEOUS SYNDROMES</b>		
Acanthosis nigricans (refer Fig. 22.8)	Immunological; secretion of epidermal growth factor	Carcinoma of stomach, lung and uterus
Paraneoplastic pemphigus	Immunological	B-cell lymphoproliferative disorders (80%), CLL, Castleman disease, thymoma
Dermatomyositis	Immunological	Bronchogenic, breast carcinoma
Sign of Leser-Trelat (Rapid increase in number and size of seborrheic keratosis)	Immunological	Adenocarcinoma (stomach, rectum, breast, lungs, colon)
Exfoliative dermatitis	Immunological	Lymphoma
Acquired diffuse palmoplantar keratoderma (Fig. 17.4)	Immunological	Cancers of breast, lung, stomach and leukemia
Bazex syndrome	Immunological	Squamous cell carcinoma of the

(Acrokeratosis paraneoplastica)(Fig. 17.5)		upper aerodigestive tract
Pityriasis rotunda	Immunological	Hepatocellular, gastric and prostate cancer, leukemia, lymphoma
Paget's disease		Invasive breast carcinoma
Erythema gyratum repens	Immunological	Transitional carcinoma of the kidney and adenocarcinoma of lung, breast and esophagus
Sweet's syndrome		Leukemia
Pyoderma ganagrenosum		AML, CML, myeloma
Necrolytic migratory erythema		Glucagonoma
<b>4. CHANGES IN OSSEOUS, ARTICULAR, AND SOFT TISSUE</b>		
Hypertrophic osteoarthropathy and clubbing of the fingers	Not known	Bronchogenic carcinoma
<b>5. VASCULAR AND HEMATOLOGIC SYNDROMES</b>		
Venous thrombosis (Trousseau syndrome)	Tumor products like mucins which activate clotting	Pancreatic carcinoma
		Bronchogenic carcinoma
Disseminated intravascular coagulation	Procoagulant substance: Cytoplasmic granules (e.g. acute promyelocytic leukemia cells), or mucus (adenocarcinomas)	Acute promyelocytic leukemia, prostatic adenocarcinomas
Nonbacterial thrombotic endocarditis	Hypercoagulability	Advanced mucus-secreting adenocarcinomas
<b>6. RENAL SYNDROMES</b>		
Nephrotic syndrome	Tumor antigens, immune complexes	Various cancers
<b>7. AMYLOIDOSIS</b>		
Primary amyloidosis	Immunological (AL-amyloid light chain protein)	Multiple myeloma
Secondary amyloidosis	AA (amyloid associated) protein	Renal cell carcinoma and other solid

(ACTH: adrenocorticotrophic hormone; IL: interleukin; TGF: transforming growth factor; TNF: tumor necrosis factor)

**Fig. 17.4:** Plantar keratoderma.

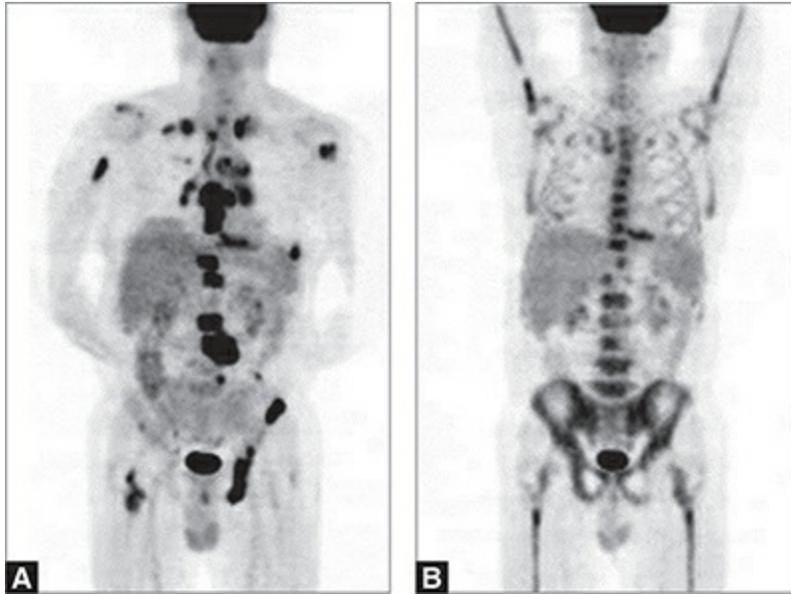

**Fig. 17.5:** Bazex syndrome.

## **POSITRON EMISSION TOMOGRAPHY**

**Q.** Write short note on the role of positron emission tomography in oncology.

- Positron emission tomography (PET) detects metabolic activity of tumor cells following injection of small amounts of radioactive tracers, such as fluorodeoxyglucose (FDG).
- Uses:
  - It is used for screening for (1) preliminary diagnosis, (2) accurately assess the severity and spread of cancer, (3) biopsy guidance, (4) staging, (5) prognostication, (6) therapeutic planning and (7) judging response to therapy.
  - PET has been found to be useful in several malignancies including melanoma, lymphoma, lung cancer, esophageal cancer, head and neck cancer, breast cancer and thyroid cancer.
  - Useful in diagnosing certain cardiovascular and neurological diseases because it highlights areas with increased, diminished or no metabolic activity.
  - Also positive in patients with granulomatous diseases, like tuberculosis and sarcoidosis.
- Method:
  - FDG is injected intravenously and is transported from the plasma to the cells by glucose transporters (GLUT 1 and GLUT 4).
  - It undergoes phosphorylation within the cell by the enzyme hexokinase and is converted to FDG-6-phosphate. FDG-6-phosphate is not further metabolized and gets trapped in the cell.
- Cancer cells have increased anaerobic glycolysis and decreased levels of glucose-6-phosphatase. Because of this, cancer cells limit further metabolism of the tracer in cancer cells.
- PET-CT combines the functional information from a PET scan with the anatomical information from a CT scan. It can pinpoint the exact location of abnormal activity. It is used to evaluate patients with various cancers (e.g. including lung cancer and lymphoma)(Figs. 17.6A and B).

**Fig. 17.6A and B:** PET images of a case of non-Hodgkin's lymphoma. (A) Before chemotherapy; (B) After 2 cycles of ABVD.

## ONCOGENIC VIRUSES

Various viruses implicated in human tumors and associated lesions are listed in Table 17.12.

**Table 17.12:** Various viruses implicated in human tumors and associated lesions.

<i>Type of virus</i>	<i>Lesions</i>
<b>ONCOGENIC RNA VIRUSES</b>	
• Human T-cell lymphotropic virus type-1	Adult T-cell leukemia/lymphoma
<b>ONCOGENIC DNA VIRUSES</b>	
<b>1. Human Papillomavirus</b>	
A. Low-oncogenic risk HPV—benign lesions of squamous epithelium	
◆ HPV types 1, 2, 4, and 7	Benign squamous papilloma (wart)
◆ HPV-6 and HPV-11	Condylomata acuminata (genital warts) of the vulva, penis, and perianal region
	Laryngeal papillomas
B. High-oncogenic risk HPV—malignant tumors	
◆ HPV types 16 and 18	Squamous cell carcinoma of the cervix and anogenital region
	Oropharyngeal cancers (tonsil)

<b>2. Epstein-Barr Virus</b>	Burkitt lymphoma (requires cofactor-malaria) Nasopharyngeal cancer
<b>3. Hepatitis B and C Viruses</b>	Hepatocellular carcinoma
<b>4. Human Herpes Virus-8</b>	Kaposi's sarcoma Pleural effusion lymphoma, multicentric Castleman disease
<b>5. Merkel Cell Polyoma Virus</b>	Merkel cell carcinoma

# Psychiatry

# CHAPTER 18

## Mental State Examination

**Q.** Write short essay on mental status examination and its definition.

Assessment of mental status involves different spheres as listed in Box 18.1:

### *General Appearance and Behavior*

- **Grooming:** Note whether patient is well-groomed or has poor hygiene
- **Attitude of patient:** Cooperative/Hostile/Agitated
- **Signs of anxiety:** Excess perspiration, tensed voice
- **Otto Veraguth sign:** Increased forehead marking seen in depression.
- Note any abnormalities of alertness or motor behavior (e.g. restlessness or retardation)
- Arousal-determine the level of consciousness (especially in case of delirium).

**Box 18.1:** Features to be observed during assessment of mental status.

- General appearance and behavior
- Speech
- Mood and affect
- Thought—form, content, possession, flow
- Perception
- Cognition—arousal, orientation, memory, attention, abstract thinking
- Judgment and intellectual ability
- Insight

### *Speech*

Observe the speed and fluency, including slow (retarded) speech and word-finding difficulty.

## ***Mood and Affect***

- **Mood:** Ask the patient how he feels. For example, sad/happy/anxious/tensed/worried/anhedonic (lack of ability to experience pleasure from previously pleasurable activities).
- **Affect:** Assessed by observing facial expression, posture, movements. For example, depressed/elated. Elevated mood with excess energy and reduced need for sleep (suggests mania). Feeling guilty or hopeless (suggests depression). Note whether patient has thoughts of self-harm? If so, enquire about plans. Note whether patient is excessively worried about many things (suggests anxiety).

## ***Thoughts***

- **Formation:** Is the speech coherent? Or is there loosening of association? (suggests schizophrenia).
- **Content:** Determined by asking “What are your main concerns?” Look for presence of delusions, obsession. Ask the patient whether he or she thinks of himself as powerful, important or gifted (grandiose delusion) which suggests mania.
- **Possession:** Ask the patient if the thoughts are his own or if it is controlled by external source. For example, thought insertion, withdrawal, broadcast.

## ***Cognitive Function***

**Q. Write short essay on how is memory tested clinically?**

## ***Memory***

- **Registration of memories/Immediate memory:** It is judged by asking the patient to repeat simple new information (e.g. name and address, immediately after hearing it).
- **Short-term memory:** It is judged by asking the patient to repeat simple new information (as mentioned above) after an interval of 1–2 minutes, during which time the patient’s attention should be diverted elsewhere.
- **Long-term memory:** It is judged by asking the patient to recall previous events ( $\geq 6$  minutes).
- Memory functions can also be classified as **episodic memory** (for specific events and contexts) and **semantic memory** (for vocabulary and

concepts).

- **Concentration:** It is assessed by serial 7s test in which the patient is asked to subtract 7 from 100 and then 7 from the answer, and so on.
- **Orientation:** This is assessed by asking the patient during psychiatric interview about place (exact location); time (during the examination i.e. day, date, month and year) and person/details of personal identity (e.g. name, date of birth, marital status and address).
- **Intellectual ability:** This can be assessed from the history and can also be assessed during the interview from the patient's speech, vocabulary and grasp of the interviewer's questions.

### ***Patients' own understanding of their symptoms ('insight')***

- Ask the patient about what he or she thinks about their symptoms, and whether they need treatment.
- Lack of insight is characterized by a failure to accept that one is ill and/or in need of treatment and is a feature of acute psychosis.

## **Delusions and Hallucinations**

### **Q. Write short note on delusions.**

**Delusions:** It is a belief held with strong conviction despite superior evidence to the contrary (strongly held false beliefs). It is a disorder of content of thought.

Types of delusion: These are based on their content.

- **Persecutory:** e.g. Conviction that others are out to get me, conviction that individual has cancer.
- **Grandiose:** e.g. belief that one has special powers or status.
- **Nihilistic:** e.g. conviction that 'My head is missing', 'I have no body', 'I am dead'.
- **Erotomanic delusions** (e.g. believing a movie star loves them)
- **Somatic delusions** (e.g. believing head is filled with air/ worms)
- **Delusions of reference** (e.g. believing story in a book is referring to them)
- **Delusions of control/passivity** (e.g. believing one's thoughts and movements are controlled by aliens).
- Other delusions are delusions of misinterpretation, hypochondrial delusions, fantastic/bizarre delusions, delusions of passivity, delusions of

jealousy, delusion.

In contrast, **overvalued ideas** are strongly held but not fixed.

**Q. Write short note on hallucinations, its definition and types.**

**Hallucinations:** These are perceptions without external stimuli (**wakeful sensory experiences of content that is not actually present**). They can occur in any sensory modality, most common being **visual or auditory**. For example, hearing voices when no one else is present, or seeing 'visions'. Other types include tactile (cocaine bug), olfactory, gustatory, command kinesthetic/psychomotor, lilliputian and complex hallucinations.

**Pseudohallucinations:** These are hallucinations that are perceived as originating in the external world, not in the patient's own mind. In Narcolepsy 2 specific hallucinations are seen. **Hypnagogic:** They occur when falling asleep. **Hypnopompic:** They occur on waking.

**Box 18.2:** Serotonin syndrome.

- Life-threatening condition associated with increased serotonergic activity in the central nervous system most often due to SSRI overdose.
- Symptoms are diaphoresis, tachycardia, hyperthermia, hypertension, vomiting, diarrhea, tremor, muscle rigidity, myoclonus, hyperreflexia, and bilateral Babinski sign
- Treatment involves stopping of all serotonergic agents, Supportive care to normalize vital signs, hyperthermia and autonomic instability, sedation with benzodiazepines and administration of serotonin antagonists (Cyproheptadine)

**Box 18.3:** Features of cheese reaction.

- Cheese, beer, wine, meat, fish, yeast (contain large amount of tyramine and other indirectly acting amines) → due to irreversible block of MAO. These escape degradation in intestinal wall and liver → reach to circulation and displace large amount of noradrenalin from loaded nerves → Hypertensive crises (CVA, encephalopathy)
- Treatment: IV phentolamine, prazosin

In contrast, **illusions** are misperceptions of real external stimuli (e.g. mistaking a shrub for a person in poor light).

## PSYCHO PHARMACOLOGY

### Antidepressants

**Q. Write short note on:**

- **Antidepressants/newer antidepressants**
- **Tricyclic antidepressants**
- **Selective serotonin re-uptake inhibitors (SSRIs).**

Various types of antidepressants and their side effect in Table 18.1.

Serotonin syndrome and cheese reaction are described in Boxes 18.2 and 18.3 respectively

**Table 18.1: Various types of antidepressants and their side effects.**

<b>Group and drug</b>	<b>Side effects</b>
<b>TRICYCLIC ANTIDEPRESSANTS (TCAs)</b> <b>NA + 5 HT reuptake inhibitor</b> <ul style="list-style-type: none"><li>• Imipramine, amitriptyline, trimipramine, doxepin, dothiepin, clomipramine, dosulepin</li></ul> <b>Predominantly NA reuptake inhibitor</b> <ul style="list-style-type: none"><li>• Desipramine, nortriptyline, amoxapine, reboxetine</li></ul>	<ul style="list-style-type: none"><li>• Anticholinergic—dry mouth, bad taste, constipation, epigastric fullness, urinary retention (more common in elderly male), blurred vision, palpitation</li><li>• Sedation, mental confusion, weakness</li><li>• Increased appetite and weight, sweating, fine tremors, precipitation of seizures, postural hypotension, cardiac arrhythmias, rashes and jaundice</li></ul>
<b>SELECTIVE SEROTONIN REUPTAKE INHIBITORS (SSRIs)</b> <ul style="list-style-type: none"><li>• Fluoxetine, fluvoxamine, paroxetine, sertraline, citalopram, escitalopram</li></ul>	<ul style="list-style-type: none"><li>• Gastric upset, nausea, interfere with ejaculation, nervousness, restlessness, insomnia, anorexia, headache, diarrhea, epistaxis, ecchymosis, serotonin syndrome</li></ul>
<b>REVERSIBLE INHIBITOR OF MAO-A (RIMAs)</b> <ul style="list-style-type: none"><li>• Moclobemide, clorgyline (isocarboxazid, phenelzine, tranylcypromine)</li></ul>	<ul style="list-style-type: none"><li>• ↑ appetite (phenelzine)</li><li>• ↓ appetite (tranylcypromine)</li><li>• Hepatotoxicity, SLE, drug and food interactions (Cheese reaction)</li></ul>
<b>ATYPICAL ANTIDEPRESSANTS</b> <ul style="list-style-type: none"><li>• Trazodone, mianserine, mirtazapine, venlafaxine, duloxetine, tianeptine, amineptine, bupropion</li></ul>	<ul style="list-style-type: none"><li>• Priapism (trazodone), bone marrow suppression, hepatotoxicity</li></ul>

## Mood-stabilizing Agents

**Q. Write short note on lithium and its side effects.**

If antidepressants are given, they should be combined with a mood-stabilizing drug (mentioned below) to avoid ‘switching’ the patients into

(hypo)mania. The main drugs consist of lithium, sodium valproate, divalproex, carbamazepine. Others include lamotrigine, gabapentin, topiramate, olanzapine, quetiapine and risperidone.

### ***Lithium (Lithium Carbonate)***

**Q. Write short note on lithium and its side effects.**

#### ***Indications:***

- It is the drug of choice (first-line medication) and is also used for the treatment of acute mania, and in combination with a tricyclic as an adjuvant treatment for resistant depression. It is used for both treatment and prophylaxis of mood episodes.
- Bipolar and schizoaffective disorders.
- Adjunctive treatment of major depressive disorder.

#### ***Mechanism of action:***

Lithium partly replaces sodium and is nearly equally distributed in and outside the cell—this affects ionic fluxes across the brain cells. Decrease the release of NA and DA without affecting 5 HT release or inhibits hydrolysis of inositol-1-phosphate.

It has a narrow therapeutic range. Hence, a regular blood monitoring is needed to maintain a plasma level of **0.5–1.0 mmol/L**.

#### ***Side effects:***

- **Dose-related:** Tremor, convulsions, gastrointestinal distress (nausea, vomiting) and headache.
- **Acne and weight gain:** Long-term use may result in weight gain, interfere with patient compliance, exacerbate psoriasis.
- **Cardiac conduction:** Prolonged QRS, heart blocks, T wave inversions, ECG changes usually benign.
- **Hypothyroidism, nephrogenic diabetes insipidus,** increased calcium and parathormone, and renal failure.
- Teratogenicity: Associated with **Ebstein's anomaly**, and should not be given during the first trimester of pregnancy.
- Leukocytosis: Usually occurs and seems to be benign.

### ***Divalproex***

- Treatment of choice for rapid-cycling bipolar disorder, or when lithium cannot be used.
- Time course of treatment response is similar to lithium.
- **Side effects:** Sedation, cognitive impairment, tremor, GI distress and hepatotoxicity.
- **Teratogenicity:** Associated with **spina bifida**.

### ***Carbamazepine***

- Second-line choice for treatment of bipolar disorder when **Lithium** and **Divalproex** are ineffective or contraindicated.
- **Side effects:** **Agranulocytosis** hematologic toxicity, hyponatremia and hepatotoxicity.

### ***Sodium Valproate (An Anticonvulsant) and Olanzapine (An Antipsychotic)***

- They can be used both as prophylaxis in bipolar disorder, and as second-line alternative to lithium.
- **Side effects:** Valproate can cause birth defects and, hence, should not be given to women of child-bearing age. Olanzapine can produce weight gain.

### ***Gabapentin***

#### **Q. Write short note on gabapentin.**

This lipophilic GABA derivative crosses to the blood brain barrier and enhances GABA release but does not act as agonist at GABA receptor. It is used primarily to treat focal seizures and neuropathic pain, can also be used for bipolar disorders.

### ***Antipsychotic Medications (APMs, Fig. 18.1)***

#### **Q. Write short notes on antipsychotic medications.**

Classification of antipsychotic drugs is mentioned in Box 18.4.

Differences between Differences between typical and atypical neuroleptic drugs is mentioned in Table 18.2.

## Indications

- **Psychomotor agitation:** High-potency APMs (Haloperidol) parenteral.
- **Schizophrenia:** Treatment of choice for acute psychotic episodes and for prophylaxis
- **Other psychotic disorders:** Treatment of psychoses and cognitive disorders due to general medical conditions and substances, delusional disorder, brief psychotic disorder, schizophreniform disorder and other rarer psychotic disorders.
- **Mood disorders:** Treatment of agitation and psychosis during mood episodes.
- **Sedation:** Useful when Benzodiazepines are contraindicated (especially in older patients) or as an adjunct during anesthesia.
- **Movement disorders:** Treatment of choice for Huntington disease and Tourette disorder.

## General Adverse Effects

- **Sedation:** Due to the blockade of antihistaminic activity.
- **Hypotension:** Effect is due to alpha-adrenergic blockade and is most common with low potency antipsychotic medications.
- **Anticholinergic symptoms:** Dry mouth, blurred vision, urinary hesitancy, constipation, bradycardia, confusion and delirium.
- **Endocrine effects:** Gynecomastia, galactorrhea and amenorrhea.
- **Dermal and ocular syndromes:** Photosensitivity, abnormal pigmentation, cataracts. Thioridazine can cause retinitis pigmentosa.
- **Cardiac conduction abnormalities:** Ziprasidone prolongs QT interval.
- **Agranulocytosis:** Clozapine
- **Movement syndromes:** Tardive dyskinesia.
- **Extrapyramidal syndromes (EPS):** Newer APMs cause minimal or no EPS. Low-potency APMs (e.g. chlorpromazine, thioridazine) cause less EPS than higher-potency APMs, but has more sedative effects.
  - **Metabolic syndrome-Weight gain, diabetes, and dyslipidemia**
  - **Cholestatic jaundice**
  - **Neuroleptic malignant syndrom**

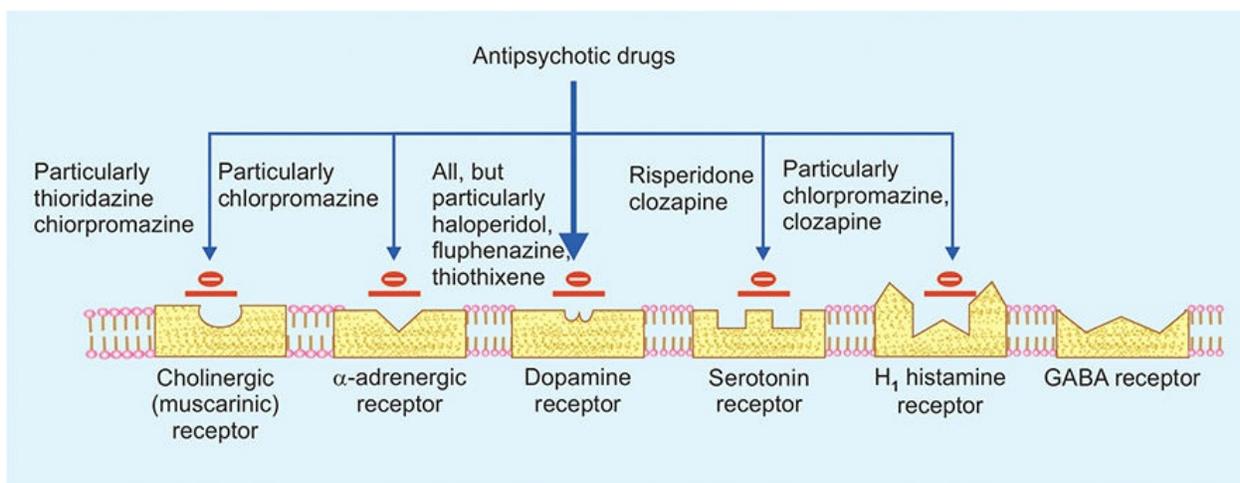

Fig. 18.1: Antipsychotic drugs and their action.

**Table 18.2:** Differences between typical and atypical neuroleptic drugs.

	<i>Typical neuroleptic</i>	<i>Atypical neuroleptic</i>
<b>Mode of action</b>	D2 antagonist	<ul style="list-style-type: none"> <li>• 5-HT<sub>2A</sub> antagonist</li> <li>• D2 antagonist</li> <li>• Rapid D2 dissociate</li> </ul>
<b>Other effect</b>	Antagonism of H <sub>1</sub> , M <sub>1</sub> , alpha-1 receptor, among other	Antagonism of H <sub>1</sub> , M <sub>1</sub> , 5-HT <sub>2c</sub> , alpha 1 receptor, among other
<b>EPS and tardive dyskinesia</b>	Pronounced	Less
<b>Effect on schizophrenia symptoms</b>	Good effect with positive symptoms	Better effect on negative symptoms
<b>Withdrawal symptoms</b>	Few	More
<b>Metabolic side effects</b>	Few	Marked (glycemic, lipid)

**Box 18.4:** Classification of antipsychotic drugs.**Typical antipsychotics/First Generation**

- Phenothiazines (chlorpromazine, perphenazine, fluphenazine, thioridazine)
- Thioxanthenes (flupenthixol, clopenthixol)
- Butyrophenones (haloperidol, droperidol)

**Atypical antipsychotics/Second Generation**

- Aripiprazole, asenapine, brexpiprazole, cariprazine, clozapine, iloperidone, lurasidone, olanzapine, paliperidone, pimavanserin, quetiapine, risperidone, ziprasidone

**Mechanism of action** of most first and second-generation antipsychotics: It appears to be post-synaptic blockade of brain dopamine D<sub>2</sub> receptors. Exceptions

- Aripiprazole and brexpiprazole are D<sub>2</sub> receptor partial agonists
- Cariprazine is a D<sub>3</sub>-preferring D<sub>3</sub>/D<sub>2</sub> receptor partial agonist
- Pimavanserin, is a serotonin 5HT<sub>2A</sub> inverse agonist and antagonist with no dopamine D<sub>2</sub> affinity

**Anxiolytic (Antianxiety) Medications****Table 18.3:** Antianxiety drugs.

<i>Benzodiazepine</i>	<i>Azapirones</i>	<i>Others</i>
<ul style="list-style-type: none"> <li>• Diazepam</li> <li>• Chlordiazepoxide</li> <li>• Oxazepam</li> <li>• Lorazepam</li> <li>• Alprazolam</li> </ul>	<ul style="list-style-type: none"> <li>• Buspirone</li> <li>• Gepirone</li> <li>• Ipsapirone</li> </ul>	<ul style="list-style-type: none"> <li>• Beta blocker: Propranolol</li> <li>• Antihistaminics: Hydroxyzine</li> <li>• SSRIs and other antidepressant drugs</li> </ul>

**Q.** Write short notes on anxiolytic (antianxiety) medications.

Various antianxiety drugs are listed in Table 18.3. Indications are mentioned in Box 18.5.

Features of benzodiazepines and buspirone are mentioned in Boxes 18.6 and Box 18.7 respectively.

**Zolpidem:** Used in initial insomnia-t  $\frac{1}{2}$  2–3 hours. Side effects include headache, nausea, dry mouth, etc.

**Zopiclone:** Also acts on GABA receptors, and has short duration of action.

**Suredone, bretazenil, imidazenil, alpidem, abecarnil:** Anxiolytic as well as anticonvulsant.

## ELECTROCONVULSIVE THERAPY (ECT)

**Q. Write short note on electroconvulsive therapy (ECT).**

Electroconvulsive therapy (ECT) is a psychiatric treatment in which a brief electrical stimulus (of high voltage) is given to the brain via electrodes placed on the temporal fossa. The electrical charge lasts from 1 to 4 seconds, and causes an epileptic-like seizure. Types of electroconvulsive therapy is indicated in Box 18.8.

**Box 18.5:** Indications for anxiolytic (antianxiety) medications.

- Adjustment disorder with anxious mood: Benzodiazepines with supportive psychotherapy
- Panic disorder: Alprazolam, SSRIs, imipramine and clonazepam decrease frequency and intensity.
- Generalized Anxiety Disorder: Venlafaxine, other SSRIs and buspirone decrease overall anxiety.
- Obsessive compulsive disorder: SSRIs and clomipramine decrease obsession thinking.
- Social phobia: SSRIs and buspirone decrease fear associated with social situations.

**Box 18.6:** Features of benzodiazepines.

- Mechanism: Bind to specific CNS receptors that modulate **GABA** transmission.
- Commonly used for the treatment of anxiety, insomnia and for the treatment of elderly patients.
- Used for prevention of **alcohol withdrawal**.
- **Chlordiazepoxide** is used for prevention of **alcohol withdrawal**.
- First choice for **emergency treatment of acute anxiety and severe mania**.
- **Alprazolam** is the first choice for **panic attack**.
- **Benzodiazepines** that don't interact with **P450**: **lorazepam, oxazepam and temazepam**.

### Adverse Effects

- Sedation, disinhibition and abuse.
- Impairment of cognitive and motor performance.

- Tolerance and withdrawal.
- Possible teratogenicity.

### Box 18.7: Features of buspirone.

- Used for the treatment of generalized anxiety disorder and social phobia
- Lag time of about **1 week** before clinical response
- **No additive effect** with **alcohol** or **sedative-hypnotics**
- No withdrawal syndrome
- No sedation or cognitive impairment
- Headache may occur.

### Box 18.8: Types of electroconvulsive therapy (ECT).

- **Direct:** Not practiced in present day
- **Modified:** Use general anesthesia and muscle relaxants
- **Unilateral ECT:** Right unilateral (RUL) has less cognitive effect, may be less clinically effective
- **Bilateral ECT:** Most common, most effective, most cognitive dysfunction.

## Procedure for Modern ECT

- **Electrode placement:** Electrodes are placed on the side of a patient's head just above the temporal fossa. Each electrode is placed 2.5–4 cm (1–1.5 inches) at the midpoint on a line joining the tragus of the ear and the lateral canthus of the eye.
- The patient is given anesthetic injections and a muscle relaxant to stop muscle contractions that can lead to trauma to muscles and bones.
- A small electric current is passed through the brain. Most patients remit with 6 to 12 treatments.

## Indications

### **Q. Write short note on indications for electroconvulsive therapy (ECT).**

- **Severe depression:** Severe episodes/symptoms, when a rapid antidepressant response is needed (e.g. due to failure to eat or drink in depressive stupor; high suicide risk), previous history of good response to ECT, patient preference and suicidal ideas.
- **Failure to response to drug treatments** or patient not able to tolerate side effects of drugs (e.g. puerperal depressive disorder or postpartum psychosis).
- **Severe catatonia**
- **Schizophrenia psychosis when medications are insufficient or symptoms are severe.**
- **Confusional state (to complete seizure activity)**
- **Depressive stupor.**

- Neuroleptic malignant syndrome.

## Contraindications

- **Absolute:** Increased intracranial pressure (ICP), aortic aneurysm.
- **Relative**
  - Cardiovascular diseases: Coronary artery disease, hypertension, aneurysms, arrhythmias.
  - Cerebrovascular disease: Recent strokes, space-occupying lesions, aneurysms.
  - Severe pulmonary diseases: Tuberculosis, pneumonia, asthma.
  - Deep vein thrombosis (DVT).

**Risks and side effects:** ECT is safe with few side effects.

- Impairment of cognition: Period of confusion immediately after ECT and generally lasts for few minutes to several hours.
- Memory loss: May forget weeks/months before treatment, during treatment, or after treatment has stopped. Usually improves within couple of months. Permanent loss of memory is rare.
- Myalgia, dislocation and fractures.
- Medical complications: Nausea, vomiting, headache, aspiration, and jaw pain.

## MOOD DISORDERS

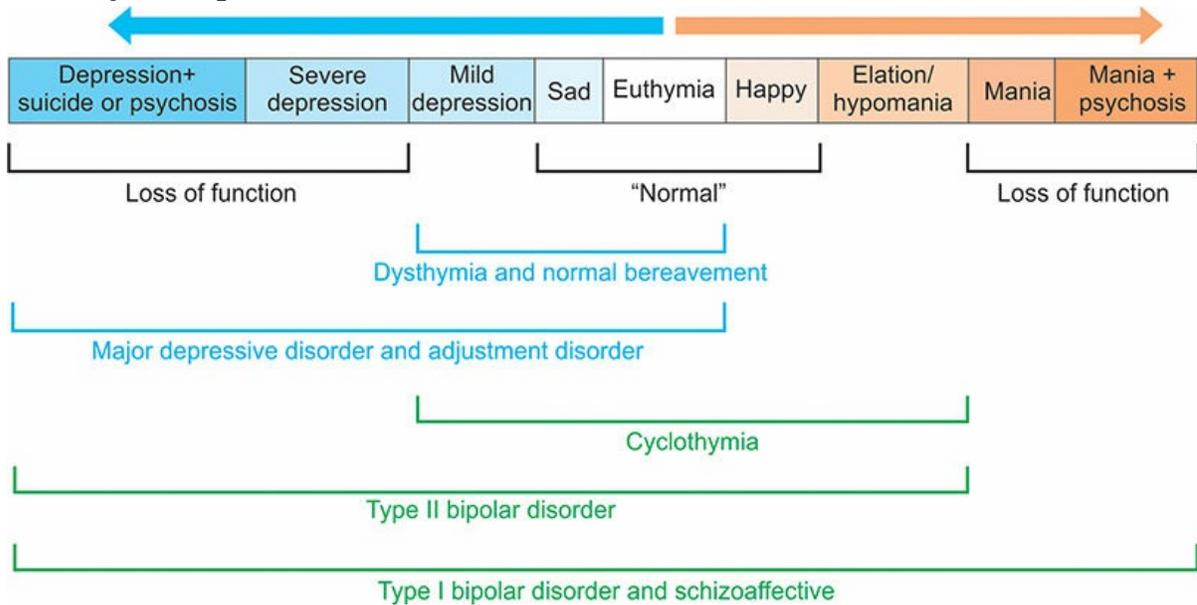

**Q. Write short essay on:**

- **Mood/affective disorders and its classification.**
- **Bipolar affective disorders.**
- Mood or affective disorders are among the most common diagnoses in psychiatry. Mood refers to a pervasive and sustained emotion. (as differentiated from affect, which is the immediately expressed and observed emotion).
- Mood disorders are characterized by a disturbance of behavior, mood and may be either depression or mania.

## Categories/Classification of Mood Disorder (Table 18.4 and

**Fig. 18.2)**

- **Unipolar disorder:** Only one end of the emotion spectrum and characterized by one or more episodes of low mood and associated symptoms (depression form).
- **Dysthymic disorder:** Characterized by chronic low-grade depressed mood without sufficient other symptoms to count as ‘clinically significant’ or ‘major’ depression.

**Fig. 18.2:** Spectrum of mood disorder.

- **Bipolar disorder:** cycling between both ends of the emotion spectrum and characterized by episodes of elevated mood interspersed with episodes of depression (both manic and depression).

**Mood (affective) disorders** can be classified into **primary and secondary**.

- **In primary affective disorder,** the affective episodes (mania or depression) are **not secondary to any other psychiatric or physical illness**.
- **In secondary affective disorder,** the affective episodes **are secondary to another psychiatric or physical illness**.

**Table 18.4:** Classification of mood disorder.

<i>Unipolar</i>	<i>Bipolar</i>	<i>Mood disorders with known etiology</i>
Major depressive disorder	Bipolar I disorder	Substance-induced mood disorder
Dysthymic disorder	Bipolar II disorder	Mood disorder due to general medical

		condition
	Cyclothymic disorder	Depression, mania, bipolar disorders, depression-affect, mood, syndrome

## Unipolar Disorder

### *Major Depressive Disorder*

**Q. Write short essay/note on depression and discuss treatment of depressive illness.**

**Q. Write short essay/note on clinical features and management of severe depression.**

- Depressive disorders are characterized by persistent low mood, loss of interest and enjoyment, and reduced energy that usually impairs day-to-day functioning.
- **Major depressive disorder** is characterized by one or more major episodes of depression (i.e. at least 2 weeks of mood depression or loss of interest + at least four additional symptoms of depression).
- **Age and gender:** Onset is early 20s. Highest rates between 15 and 24 years, women have 2 times the rates as men.
- **Number of episodes:**
  - **Single episode:** Of major depression.
  - **Recurrent:** Two or more episodes of major depression.
  - **Persistent depressive disorder (dysthymia):** Low mood persisting for more than 2 years could be either minor dysthymic disorder or chronic major depression.

Diagnostic criteria for major depressive episode are presented in Box 18.9.

#### **Box 18.9:** Diagnostic criteria for major depressive episode.

**Mood:** Depressed mood most of the day, nearly everyday (dysphoria)

**Sleep:** Insomnia or hypersomnia

**Interest:** Marked decrease in interest and pleasure in most activities (anhedonia)

**Guilt:** Feelings of worthlessness or inappropriate guilt

**Energy:** Fatigue or low energy nearly everyday

**Concentration:** Decreased concentration or increased indecisiveness

**Appetite:** Increased or decreased appetite or weight gain or loss

**Psychomotor:** Psychomotor agitation or retardation

**Suicidality:** Recurrent thoughts of death, suicidal ideation, suicidal plan, suicide attempt

General criteria for a major depressive episode require five or more of the above symptoms to be present for at least 2 weeks; **one symptom must be** depressed mood or loss of interest or pleasure. **The symptoms must also cause distress or impairment.**

### **Q. Write short note on reactive depression.**

**Reactive depression** is a type of clinical depression characterized by an inappropriate state of depression. It is precipitated by events in the individuals life (to be differentiated from normal grief) arising as a consequence of severe traumatic events in life (e.g. the loss of home in a fire). Reactive depression becomes a clinical concern if the depression lasts too long without signs of recovery or if the depression becomes too deep (e.g. leading to suicidal feelings). Most of the time, reactive depressions resolves itself.

#### **Treatment of depression**

Both drug and psychotherapy (e.g. cognitive behavioral therapy, interpersonal therapy) are effective in the treatment of depression either alone or in combination. Medication alone also can relieve symptoms. However, the combined approach generally provides the patient with the quickest and most sustained response.

#### **Drug treatment (pharmacotherapy)**

All antidepressants are potentially effective in patients whose depression is secondary to medical illness, as well as those in whom it is the primary problem. They are effective in moderate and severe depression. Usually, 2–6 weeks at a therapeutic dose level are needed to observe a clinical response. Commonly used antidepressants are listed in Table 18.1.

#### **Psychological treatments**

- Mild-to-moderate depression: Both cognitive behavioral therapy (CBT) and interpersonal therapy (IPT) are as effective.
- Severe depression: Antidepressant drugs are preferred.

Risk of suicide in an individual with a depressive disorder is 10 times more than that in the general population.

#### **Nonpharmacologic treatments**

- Electroconvulsive therapy (ECT): Highly effective for depression and may have a more rapid onset of action than drug treatments. ECT may be indicated if patient is suicidal or worried about side effects from medications.

## **Acute Mania**

### **Q. Write short essay/note on clinical features of mania.**

Mania is an abnormally elevated mood state. Clinical features are presented in Table 18.5.

**Table 18.5: Clinical features of acute mania.**

<b>Changes in Mood</b> Irritability, excitability, exhilaration, hostility, anxious, hyper, wound-up	<b>Changes in Perceptions</b> Inflated self esteem, feeling superior, hallucinations, paranoia, increased appetite	<b>Changes in Speech</b> Rapid, pressured speech, incoherent speech, clang associations	<b>Increased Social Behavior</b> Unnecessary phone calls, increased sexual activity, talkative and sociable
<b>Increased Energy</b> Little fatigue, despite decreased sleep; insomnia, increased productivity, doing several things at once, making lots of plans, taking on too many responsibilities, others seem slow, restlessness, difficulty staying still		<b>Impaired Judgment</b> Lack of insight, inappropriate humor and behaviors, impulsive or thrill-seeking behaviors: increased alcohol consumption; financial extravagance; dangerous driving; sexual promiscuity	<b>Changes in Thought Patterns</b> Distractibility, inability to concentrate, creative thinking, flight of ideas, racing thoughts, disorientation, disjointed thinking, grandiose thinking

Diagnostic criteria for manic episode (Table 18.6).

**Table 18.6:** Diagnostic criteria for manic episode.

<i>Three to four of the following criteria are required during the elevated mood period</i>	
Self-esteem: highly inflated, grandiosity	Attention: easy distractibility
Sleep: decreased need for sleep, rested after only a few hours	Activity: increased goal-directed activity
Speech: pressured	Hedonism: high excess involvement in pleasurable activities (sex, spending, travel)
Thoughts: racing thoughts and flight of ideas	

**Elevated mood:** It has 4 stages depending on severity of manic episodes (Table 18.7).

**Table 18.7:** Stages of elevated mood.

<b>Stage</b>	<b>Features</b>
Euphoria (stage-I) hypomania	Increased sense of psychological well being and happiness not in keeping with ongoing events
Elation (stage-II)	Moderate elevation of mood with increased psychomotor activity
Exaltation (stage-III)	Intense elation of mood with delusions of Grandeur.

Ecstasy (stage-IV)

Severe elevation of mood, intense sense of rapture or blissfulness seen in delirious or stuporous mania

### Treatment of Mania

- Mood stabilising agents (discussed earlier)
- Electroconvulsive therapy (ECT) (discussed earlier)

## Bipolar Disorder

### Q. Write short essay on bipolar affective disorders.

Bipolar disorder is characterized by episodes of elevated mood interspersed with episodes of depression (both manic and depressive).

- Elevated mood when mild or shortlived is known as hypomania, or when severe or chronic, is called mania.
- The lifetime risk of developing bipolar disorder is about 1–2%. The lifetime risk of suicide is about 5–10%.
- **Types:** As per DSM-5, bipolar disorders are divided into: bipolar I disorder, bipolar II disorder, cyclothymic disorder, substance/medication induced bipolar disorder and bipolar disorder due to another medical condition
  - **Bipolar I disorder:** It is characterized by the occurrence of one or more manic or mixed episodes (usually), and usually one or more major *depressive* episodes.
  - **Bipolar II disorder:** It is characterized by the occurrence of one or more major depressive episodes, at least one *hypomanic* episode and without any manic or mixed episode.

## Cyclothymic Disorder

### Q. Write short note on features of cyclothymia.

Characterized by:

- Chronically fluctuating mood states—numerous periods of hypomania and depression
- Duration of at least 2 years in adults and 1 year in adolescents and children
- Individual is not without symptoms for more than 2 months at a time
- There are no major depressive, manic, or mixed episodes during the initial 2 years. After the initial 2 years, there may be superimposed manic, mixed, or depressive episodes.
- Substance/medication induced bipolar disorder
- Bipolar disorder due to another medical condition.

## Management and Prognosis of Bipolar Disorders

**Antidepressants:** Depression should be treated as described in the treatment of depressive disorder (refer Table 18.1).

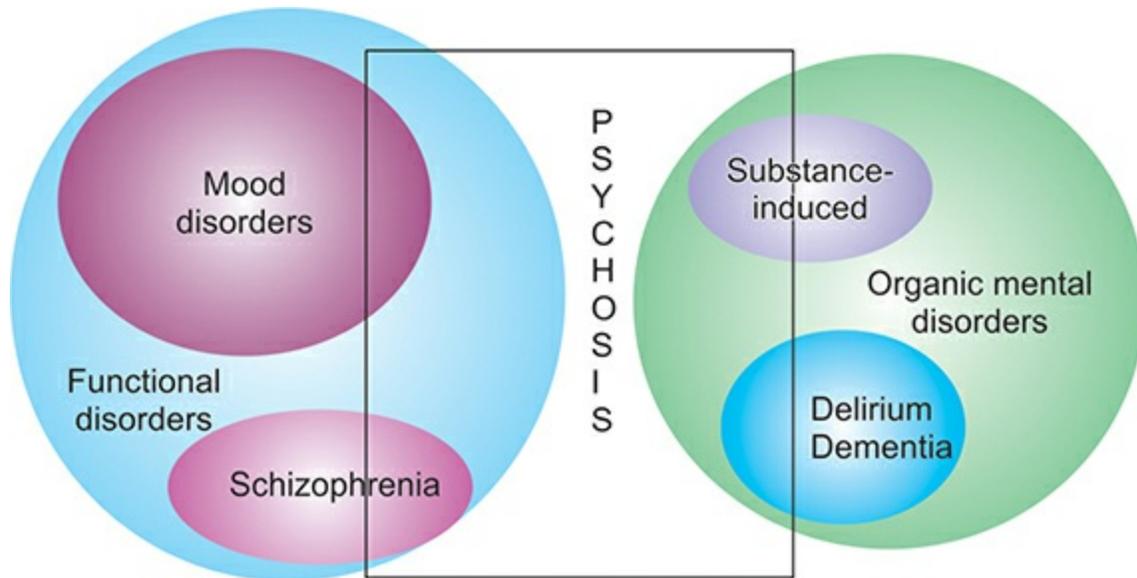

# PSYCHOTIC DISORDERS

**Q. Write short essay on distinction between an organic and functional psychosis.**

## Psychosis

- It is a symptom or feature of mental illness characterized by radical changes in personality, impaired functioning, and thoughts that are distorted or nonexistent.
- It is an abnormal condition of the mind described as involving a **‘loss of contact with reality’**.
- Psychosis is not pathognomonic of psychiatric disorder. It is a nonspecific cluster of signs and symptoms that may occur in medical, neurologic and surgical disorders or as a consequence of pharmacologic treatment, substance abuse or the withdrawal of drugs and alcohol.
- **Classification of psychoses:** Organic or functional mental disorders.
  - **Organic disorders with psychosis** are caused by structural defects or physiologic dysfunction of the brain, e.g. brain tumor.
  - **Functional disorders** have no identifiable cause, e.g. schizophrenia or bipolar disorder.
- **Lack of insight** is a failure to accept that one is ill and/or in need of treatment, and is characteristic of acute psychosis.
- Specific psychotic symptoms include delusions, hallucinations, ideas of reference, and disorders of thought.

Relationship of various psychological disorders is shown in Figure 18.3.

**Fig. 18.3:** Relationship of various psychological disorders.

## Neurosis

**Q. Write short essay on differences between psychosis and neurosis.**

Differences between psychosis and neurosis is presented in Table 18.8.

**Table 18.8:** Differences between psychosis and neurosis.

<i>Feature</i>	<i>Psychosis</i>	<i>Neurosis</i>
Contact with reality	Lost	Preserved
Interpersonal behavior	Marked disturbance in reality and behavior	Preserved
Empathy	Absent	Present
Insight	Absence of understanding current symptoms	Present symptoms are recognized as undesirable
Organic causative factor	Present	Absent
Symptoms	Delusions, illusions and hallucinations	Usually physical or psychic symptoms
Dealing with reality	Capacity is grossly reduced	Preserved
Examples	Schizophrenia	Anxiety, phobia, depression

## SCHIZOPHRENIA

**Q. Write short essay/note on schizophrenia.**

**Definition:** Schizophrenia is a heterogeneous group of disorders characterized by perturbations of language, perception, thinking, social activity, affect, and volition. It has no pathognomonic features.

- Schizophrenia occurs with regular frequency nearly everywhere in the world in **1% of population** and begins mainly in young age (mostly around 16 to 25 years).
- Schizophrenia has a 10% suicide rate (approximately one-third attempt suicide).

## Etiology

Many factors may predispose to, or precipitate, or sustain schizophrenia. These include:

- **Genetic factors:** Schizophrenia has a strong genetic contribution, probably involving many susceptibility genes, each of small effect, e.g. disrupted in schizophrenia-1 (DISC1) and neuregulin-1 (NRG1).
- **Environmental risk factors** include obstetric complications and urban birth. Winter born children more chances to develop schizophrenia.
- Family environment can influence the course of schizophrenia, e.g. a highly emotional family environment can produce relapses.
- **Psychological stresses:** Episodes of acute schizophrenia may be precipitated by social stress, adverse life events and cannabis (which increase dopamine turnover and sensitivity).
- **Others:** Viral vector or early developmental abnormalities.
- Brain imagings have found enlargement of lateral ventricle and accompanied by decrease in brain size (atrophy).
- *Schizophrenia syndrome:* It is characterized by temporal lobe epilepsy, Huntington's chorea, cerebral tumors and demyelinating diseases. This is known as **symptomatic schizophrenia**.
- Schizophrenia may be accompanied by functional overactivity in the dopaminergic neuronal systems in the **mesolimbic and mesocortical regions (responsible for positive symptoms)**.

## Physical and Psychiatric Symptoms

**Q. Write short essay/note on symptoms of schizophrenia.**

Typical stages of schizophrenia: Prodromal phase, active phase and residual

phase.

- **Diagnostic criteria for schizophrenia:** Patient must have at least two of positive or negative, symptoms mentioned in Table 18.9 for a 1-month period and continuous signs for at least 6 months.
- Bleuler’s criteria for the diagnosis of schizophrenia (Box 18.10)

**Box 18.10:** Bleuler’s criteria (4 As) for the diagnosis of schizophrenia.

- **Autism**—totally engorged in thinking not at all affected by external stimuli
- **Association loosening**
- **Ambivalence**—simultaneous opposite action/thought, do/do not (**Ambitendency**—Inability to choose between 2 opposite action)
- **Affective blunting**/(Snap prop) inappropriate facial expressions of mood

**Q. Write short note on Eugen Bleuler’s criteria for the diagnosis of schizophrenia.**

Schneider’s first rank symptoms of schizophrenia (Table 18.10)

**Q. Write short note on Schneider’s first rank symptoms of schizophrenia.**

## Types of Schizophrenia

**Q. Write short essay/note on paranoid schizophrenia and catatonia.**

**Major types of schizophrenic disorders (Table 18.11):** (1) paranoid, (2) disorganized, (3) catatonic and undifferentiated.

**Table 18.9:** Negative and positive symptoms of schizophrenia.

<i>Negative symptoms</i>	<i>Positive symptoms</i>
<b>Alogia:</b> ‘lack of words,’ including poverty of speech and of speech content in response to a question	<b>Hallucinations</b>
<b>Affective flattening</b> Decreased expression of emotion, such as lack of expressive gestures	<b>Delusions</b>
<b>Avolition-apathy</b> Loss of function Impaired concentration Diminished social engagement	Bizarre behavior Conceptual disorganization Aggressive/agitated, odd clothing or appearance, odd social behavior, repetitive stereotyped behavior

**Anhedonia-asociality**

*Few friends, activities, interests; impaired intimacy, little sexual interest*

**Formal thought disorder-** Loosening of association

**Attention impairment**

**Table 18.10:** Schneider's 11 first rank symptoms of schizophrenia.

**3 Thought phenomenon**

- Thought insertion
- Thought withdrawal
- Thought broadcasting

**3 Made phenomenon**

- Made volition
- Made affect
- Made impulse

**3 Disorders of thought perception**

Auditory hallucinations:

- 1st person ( Thought Echo),
- 2nd person (Command Hallucination)
- 3rd person (Running commentary)

**2 Special phenomenon**

- Somatic passivity phenomenon
- Primary delusions: of persecution, of reference, of infidelity, of control, somatic hypochondriac delusions

**Table 18.11:** Major types of schizophrenic disorders.

**1. Paranoid schizophrenia**

- Most common type of schizophrenia with best prognosis.
- Additional features include: (1) Delusions of persecution, reference, grandeur, control, infidelity, (2) Hallucinations have a persecutory or grandiose content, and (3) Disturbance of affect, volition, speech and motor behaviors.

**2. Disorganized (Hebephrenic) schizophrenia**

- Additional features include: (1) Marked thought disorder, incoherence, loosening of associations, and (2) Emotional disturbances-blunted affect, and **senseless giggling**.

**3. Catatonic schizophrenia**

- In addition has marked disturbance of motor behaviors.
- **Clinical forms:**
  - Excited catatonia: Increase in psychomotor activity (restlessness, agitation, excitement aggressiveness) and increase in speech production.
  - Stuporous (retarded) catatonia: Extreme retardation of psychomotor function.
  - Catatonia alternating between excitement and stupor: Features of both the above forms.

#### 4. Schizophrenia undifferentiated type

- Meets criteria for schizophrenia. Do not meet criteria for other schizophrenia types. Mainly has negative symptoms.

Course of Schizophrenia are indicated in Box 18.11.

Schizophrenic patients may also be classified as in Box 18.12:

Investigation of schizophrenia are presented in Box 18.13.

#### Other functional psychoses

- Delusional disorders
- Psychotic depression
- Schizoaffective disorder
- Manic episode
- Puerperal psychosis

#### Organic disorders

- Drug-induced psychosis/side effects of drugs
- Temporal lobe epilepsy
- Delirium
- Dementia
- Huntington's disease

### Box 18.11: Course of schizophrenia.

- Continuous without temporary improvement
- Episodic with progressive or stable deficit
- Episodic with complete or incomplete remission.

### Box 18.12: Two types of schizophrenia.

#### Type I (reactive or acute schizophrenia) patients

- They have 'positive' symptoms, normal ventricular size and a good response to antipsychotic drugs.
- It is usually sudden and seems to be a reaction to some life crisis.
- It is a more treatable form of the illness than process or chronic.

#### Type II (process schizophrenia) patients

- They have 'negative' symptoms, increased ventricular size and a poor response to antipsychotic drugs.
- Also referred to as poor premorbid schizophrenia
- It is characterized by lengthy periods of its development with a gradual deterioration and exclusively negative symptoms.
- It does not seem to be related to any major life change or negative event.
- Usually this type of schizophrenia is associated with "loners" who are rejected by society, tend not to develop social skills and do not excel out of high school.

### Box 18.13: Investigation of schizophrenia.

- Full neurological examination: Gait and motor
- Cognitive examination: MMSE
- Blood: Complete blood count, liver function tests, renal function tests, thyroid functions tests,

glucose

- Urine drug screen
- EEG if suspicion of temporal lobe epilepsy
- Brain imaging findings
  - CT: Lateral and third ventricular enlargement, reduction in cortical volume
  - MRI: Increased cerebral ventricles
  - PET: Hypoactivity of the frontal lobes.

**Q. Write short essay/note on management/treatment of schizophrenia/psychosis.**

**Q. Write short note on antipsychotic drugs.**

### **Management of Schizophrenia**

Hospital admission is necessary for a first episode to permit a full physical and psychiatric assessment.

**Indications for hospital admission:** Include suicide/violent, severe psychosis, severe depression, catatonic schizophrenia, non compliance and failure of outpatient treatment.

**Drug Treatment:** Antipsychotic drugs are discussed on page 1074.

#### ***Psychological Treatment***

It is an essential component of management.

- Psychoeducation can prevent relapse by enhancing insight.
- Cognitive behavioral therapy (CBT) to challenge delusions.
- Social skill training: Improve relationship.
- Behavioral: Positive reinforcement of desirable behavior.
- Family therapy: To reduce expressed emotion (EE). (High EE include hostility, overinvolvement, critical comments from family; hence reduce relapse rate).

#### ***Social Treatment***

After the control of an acute episode of schizophrenia, social rehabilitation may be needed.

Patients with chronic schizophrenia may need long-term, supervised accommodation.

#### ***Other Treatments***

- Rehabilitation to enhance self-care, compliance and insight.
- ECT (electroconvulsive therapy) is for catatonic schizophrenia.

**Prognosis: Rules of quarters:** Complete remission (25%), good recovery (25%), partial recovery (25%) and downhill course (25%).

## **Other Psychotic Disorders**

### ***Schizophreniform Disorder (>1 month but <6 months)***

- **Presenting symptoms:** Same as in schizophrenia (hallucinations, delusions, disorganized speech, grossly disorganized or catatonic behavior, negative symptoms, social and/or occupational dysfunction).

- **Difference from schizophrenia:** Symptoms are present > 1 month but < 6 months and most of the patients return to their baseline level of functioning.

#### Treatment

- Must assess whether the patient needs hospitalization, to assure safety of patient and/or others.
- Antipsychotic medication is indicated for a 3–6 month course.
- Individual psychotherapy.

## Schizoaffective Disorder

- **Presenting symptoms:** Mood disorders (major depressive episode, manic episode, or mixed episode) + psychosis (schizophrenia).
- Delusions or hallucinations for at least 2 weeks in the absence of mood symptoms
- **Prognosis:** Better prognosis than patients with schizophrenia. Worse prognosis than patients with affective (mood) disorders.

#### Treatment

Antidepressant medications and/or anticonvulsants to control the mood/symptoms. If these are not effective, consider the use of antipsychotic medications to help control the ongoing symptoms.

## ANXIETY DISORDERS

**Q. Write short notes on anxiety/anxiety neurosis diagnosis and treatment.**

- Definition: Anxiety disorders, as the term suggests, are characterized by unrealistic, irrational fear or anxiety of disabling intensity, worrisome thoughts, avoidance behavior and the somatic symptoms of autonomic arousal.
- Anxiety is a syndrome with psychological and physiologic components. Patients with anxiety may also have depression.

### Types of Anxiety Disorder

**Q. Write short notes on classification of anxiety disorders.**

**Q. Write short note on panic disorder.**

There are four main types:

## 1. Panic (paroxysmal) disorder

- Definition: Panic disorder is defined as the occurrence of recurrent unexpected attacks of intense anxiety that include marked physical symptoms, such as tachycardia, chest pain, hyperventilation, dizziness, trembling, numbness and sweating.
- Panic disorder may occur with or without agoraphobia (avoidance of situations where a person may feel trapped and unable to escape). A discrete period of intense fear or discomfort which develops abruptly and reaches a peak within 10 minutes. In between the attacks, patient is free from anxiety.
- Age of onset for panic disorder varies but lies between late adolescence and mid-30s.
- Patients have persistent concern of having attack and they worry about the implications of attack.

**Q. Write short notes on phobic disorders and its classification.**

## 2. Phobic anxiety disorder (Box 18.14): Specific phobias and social phobias

**Box 18.14:** List of phobias.

Claustrophobia: Fear of being in constricted, confined spaces

Aerophobia: Fear of flying

Arachnophobia: Fear of spiders

Zoophobia: Fear of animals

Aquaphobia: Fear of water

Acrophobia: Fear of heights

- A phobia is an *abnormal or excessive, persistent and disproportionate fear of an object or situation* that presents little or no actual danger to the person. It causes avoidance of it (e.g. excessive fear of dying in an air crash leading to avoidance of flying). Phobic responses can develop to general medical procedures, such as venipuncture.
- **Specific phobias:** It is characterized by clinically significant anxiety provoked by exposure of specific feared object or situation, often leading to avoidance.
- **Social phobia:** It is characterized by clinically significant anxiety provoked by exposure to certain types of social or performance situation, which people are exposed to unfamiliar people or to scrutiny by others.

- **Agoraphobia:** It is generalized phobia (marked fear) of going out alone or being in crowded places. Thus, avoid being alone or being in a public place (e.g. bridges, tunnels, crowds, etc).

**Q. Write short notes on generalized anxiety disorder (GAD).**

### 3. Generalized anxiety disorder (GAD)

- It is a chronic anxiety state associated with uncontrollable excessive anxiety and worry.
- **Symptoms:** It is associated with somatic symptoms of muscle tension and bowel disturbance, sleep disturbance and difficulty concentrating or mind going blank.

### Post-traumatic Stress Disorder (PTSD)

**Q. Write short notes on post-traumatic stress disorder (PTSD).**

- It is characterized by the re-experiencing (recurrent bouts) of an extremely traumatic event accompanied by the symptoms of increased arousal and by avoidance of stimuli associated with trauma.
- The traumatic event (e.g. a military experience, a physical or sexual assault, a motor vehicle accident, a natural disaster) involved may have caused death or near death experience, or serious injury to self or others.
  - Typically, patients re-experience the traumatic event (e.g. nightmares, flashbacks intrusive recollections), engage in avoidance of trauma or talk of trauma or recollections of stimuli associated with the sentinel trauma. Patients experience increased autonomic reactivity, such as hypervigilance, irritability, insomnia startle responses, etc.
- **Classification of PTSD:**
  - Acute PTSD: Symptoms begins within 3 months of trauma or the duration of symptoms is less than 3 months.
  - Chronic (or delayed) PTSD: Symptoms start more than 3 months after trauma (delayed) or persist for 3 months or longer.
  - With delayed onset: Six months have passed between the traumatic event and the onset of symptoms.

Differences between anxiety disorders are presented in Table 18.12.

**Table 18.12:** Differences between anxiety disorders.

<i>Characteristics</i>	<i>Panic disorder</i>	<i>Phobic anxiety disorder</i>	<i>Generalized anxiety disorder</i>
Occurrence	Paroxysmal	Situational	Persistent
Symptoms	Episodic	On exposure	Persistent
Cognitions	Fear of symptoms	Fear of situation	Worry
Behavior	Escape	Avoidance	Agitation

## Differential Diagnosis

### Q. Write short notes on treatment of anxiety disorders.

Physical illness which mimic anxiety disorder: Hyperthyroidism, pheochromocytoma, hypoglycemia, paroxysmal atrial arrhythmias, alcohol withdrawal, temporal lobe epilepsy.

#### Management of Anxiety Disorders

##### *Psychological treatment*

- Explanation and reassurance.
- Specific treatment may be necessary. Treatments include relaxation training, graded exposure (desensitization) to feared situations for phobic disorders, flooding and implosive therapy and CBT (Cognitive behavioral therapy).

**Drug treatment:** Discussed on page 1072.

- Drugs of choice are antidepressants. Benzodiazepines are useful in the short-term but long-term use can result in dependence. When somatic symptoms are prominent,  $\beta$ -blocker (e.g. propranolol) may be used.

## OBSESSIVE-COMPULSIVE DISORDER

### Q. Write short essay on obsessive-compulsive disorder.

Obsessive-compulsive disorder (OCD) is characterized by obsessive, recurrent, unwanted thoughts (which cause marked anxiety) and by compulsions (which serve to neutralize or relieve anxiety).

- **Obsessions:** These are persistent *thoughts, ideas, impulses, or images* that seem to invade a person's consciousness.
- **Compulsions:** Repetitive behaviors (eg, hand washing, ordering, checking) or mental acts (e.g. praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession.

### Types

People have symptoms like:

- **Cleaning:** Fears of contamination
- **Symmetry:** Arranging items symmetrically and repeating, ordering, and counting compulsions
- **Forbidden or taboo thoughts:** Aggressive, sexual, and religious obsessions.
- **Harm** (e.g. thoughts about harm on oneself or others).

#### Management

It usually responds to some degree to antidepressant drugs (SSRIs- paroxetine, citalopram, or escitalopram & SNRI -Clomipramine and to CBT (Cognitive Behavioural therapy). However, relapses are common and it often becomes chronic.

## Dissociative Disorder

### **Q. Write short note on dissociative disorder.**

- It was formerly called **hysteria** (dissociative disorder) and this old term was replaced in DSM IV and ICD-10 by new term dissociative disorder. More common in women and children.
- **Definition:** Dissociative disorder is a syndrome characterized by a loss or distortion of neurological function which cannot be fully explained by organic disease.
- Psychological functions commonly affected include conscious awareness and memory. Physical functions affected (conversion) include changes in sensory or motor function. These changes may resemble lesions in the motor or sensory nervous system.
- **Etiology.**
  - Unconscious psychological process: Patient lacks insight into nature of symptoms. It is maladaptive way of coping with an unresolved psychological conflict by becoming ill.
  - An association of this disorder with adverse childhood experiences, including physical and sexual abuse is being observed.

### ***Clinical Features (Box 18.15)***

- **Primary gain:** Keeps internal conflicts outside patient's awareness.
- **Secondary gain:** Benefits received from being 'sick'.
- ***La belle indifférence:*** Patient seems unconcerned about impairment.

#### Management/Treatment of dissociative disorder

- Physical and psychiatric examination to exclude organic disease.
- Explanation and reassurance.
- Resistant cases: Abreaction under hypnosis or small IV dose of penthanol.

**Box 18.15:** Common clinical features of dissociative disorder.

- Gait disturbance
- Loss of function in limbs
- Aphonia
- Pseudoseizures (non-epileptic seizures)
- Sensory loss
- Blindness

## SOMATIFORM DISORDERS

These disorders have somatic symptoms which are not explained by a medical condition (medically unexplained symptoms), nor better diagnosed as part of a depressive or anxiety disorder.

## PSYCHOSOMATIC DISORDER

**Q. Write a short note on psychosomatic disorder.**

Psychosomatic disorder is characterized by presence of organic pathology, but is altered by psychological influence. They include those disorders (Box 18.16) which are either initiated or exacerbated by the presence of meaningful psychosocial environmental stressors.

**Box 18.16:** Classical psychosomatic illnesses.

- Bronchial asthma
- Ulcerative colitis
- Peptic ulcer
- Neurodermatitis
- Thyrotoxicosis
- Rheumatic arthritis
- Essential hypertension

## CONVERSION DISORDER

It is a type of somatoform disorder (functional neurological symptom disorder under DSM 5).

**Etiology:** Unresolved psychological conflict is **converted** acutely and unconsciously into sensorimotor neurological symptoms → maladaptive coping mechanism.

**Treatment:** Psychodynamic therapy—resolution of psychological conflict.

## Symptom Production

- If **unconscious**—comes under **somatoform disorders**
- If **conscious with motive** to obtain benefit is called as **malinger**
- If conscious but **done without motive**—**factitious disorder/Munchausen syndrome**.

## FACTITIOUS DISORDER

It is an uncommon disorder characterized by the repeated and deliberate production of the signs or symptoms of disease to gain medical care, e.g. dipping of thermometers into hot drinks to fake a fever.

## Munchausen's Syndrome

**Q. Write short note on Munchausen's syndrome.**

- It is a rare, severe, chronic form of factitious disorder named after the *German Baron von Munchausen*, who was legendary for his inventive lying.
- They travel widely, sometimes visiting several hospitals in one day. Patient frequently changes his name, with history of 'doctor shopping'.
- These patients are memorable because they present so dramatically. They usually seek medical attention at night when junior doctors or residents are on duty. They fabricate a convincing history and present to the doctor with dramatic symptoms of a medical emergency. They persuade an inexperienced doctor to undertake investigations or initiate treatment including exploratory surgery.
- Abdomen may show several scar marks ('surgical battlefield') due to previous operations.

### Management

- Gentle and firm confrontation with clear evidence of the fabrication of illness.

- Psychological support.
- Recognition of the condition to avoid further iatrogenic harm.

## IMPULSE DISORDERS

### **Q. Write short essay/note on impulse disorders.**

- Impulsive disorder is defined as a sudden and irresistible force which compels a person to do some action without motive or forethought. A normal person always tries to analyze his actions whether they are consistent with law or not. Once he realizes that his action may be contrary to law he stops it.
- But in impulsive disorder, a person is not able to control himself. Examples:
  - Kleptomania: An irresistible desire to steal things usually of low value.
  - Pyromania: An irresistible desire to set things on fire.
  - Mutilomania: An irresistible impulse to maim animals.
  - Dipsomania: An irresistible impulse to drink at periodic intervals.
  - Sexual impulses: All sexual perversions.
  - Homicidal impulses: To kill some persons.
  - Suicidal impulses: To commit suicide. Impulses are quite commonly seen in various mental disorders like depression, schizophrenia, mania, etc.
  - Trichotillomania: It is an irresistible desire to pull out one's own hair.
  - Oniomania: Compulsive desire to shop (shopping addiction).

## DELIRIUM

### **Q. Write short essay/notes on definition, causes, clinical features (clinical recognition) and initial management of delirium.**

#### **Definition**

It is an acute organic mental disorder characterized by confusion, restlessness, incoherence, inattention, anxiety or hallucinations which may be reversible with treatment.

## Cardinal Features

- **Acute course:** Sudden onset, short episode.
- Global impairment of cognitive functions (memory, attention, orientation, thinking, etc.).
- Fluctuating course.
- **Cardinal feature:**
  - Clouding of consciousness, impaired alertness, awareness, attention.
  - Variability in state of arousal.
  - Reduced responsiveness is interspersed with periods of excited outbursts.
  - Sleep/wake cycle disrupted.
- Impaired perception: Misperceives surrounding and attendants, hallucinations.
- Disturbance of emotion: Agitation, fear, depression, anxiety.
- Psychomotor changes: Hyperactivity, restlessness, repetitive (plucking, tossing).

**Table 18.13:** Predisposing and precipitating factors of delirium.

<i>Predisposing</i>	<i>Precipitating</i>
<ul style="list-style-type: none"> <li>• Diseases of brain: Dementia, stroke, past severe head injury</li> <li>• Drugs: Sedatives, anticholinergics</li> <li>• Impairments of special senses: Sight, hearing</li> <li>• Multiple severe illnesses</li> <li>• Malnutrition</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Iatrogenic:</b> Unpleasant environmental change, invasive procedures, new medications, trauma, dehydration, ongoing malnutrition, elimination malfunction</li> <li>• <b>Illnesses:</b> Infections, intracranial pathologies, impaired organ function, abnormal metabolite function, pain, drug withdrawal</li> </ul>

Predisposing and precipitation factors of delirium (Table 18.13).

## Causes of Delirium (Table 18.14)

### Investigations

**If cause is not obvious:** Complete blood count, urine analysis, blood glucose, blood urea, serum electrolytes, liver and renal function tests, arterial blood gases, thyroid function test, X-ray chest, ECG, CSF, VDRL, HIV-testing, EEG, and Cranial CT scan or MRI scan.

### Management

Identify the cause and treat it accordingly.

**Drugs:**

- Chlorpromazine (50–100 mg 8th hourly) or Haloperidol (5–10 mg 8th hourly) are drugs of choices except in delirium tremens, where benzodiazepines (BZDs) or diazepam 10–20 mg 6th hourly is preferred.
- Also give supportive medical and nursing care.

**Table 18.14: Causes of delirium.**

<ul style="list-style-type: none"> <li>• Metabolic causes               <ul style="list-style-type: none"> <li>– Hypoxia, CO<sub>2</sub> narcosis</li> <li>– Hypoglycemia</li> <li>– Hepatic encephalopathy</li> <li>– H<sub>2</sub>O and electrolyte imbalance</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Endocrine causes               <ul style="list-style-type: none"> <li>– Hypo- and hyperpituitarism</li> <li>– Hypo- and hyperthyroidism</li> <li>– Hypo- and hyperparathyroidism</li> <li>– Hypo- and hyperadrenalism</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>• Drugs and poisons               <ul style="list-style-type: none"> <li>– Digitalis</li> <li>– Alcohol</li> <li>– Tricyclic antidepressants</li> <li>– Salicylates, penicillin, etc.</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Intracranial causes               <ul style="list-style-type: none"> <li>– Epilepsy</li> <li>– Head injury</li> <li>– Meningitis</li> <li>– Migraine</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>• Nutritional deficiencies               <ul style="list-style-type: none"> <li>– Thiamin, niacin</li> <li>– Proteins</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>• Miscellaneous               <ul style="list-style-type: none"> <li>– Postoperative states</li> <li>– Sleep deprivation</li> <li>– Acute and chronic systemic infections</li> <li>– Febrile delirium in children</li> </ul> </li> </ul>

Differences between delirium, dementia and psychosis are presented in Table 18.15.

**Table 18.15: Differences between delirium, dementia and psychosis.**

<b>Condition</b>	<b>Onset</b>	<b>Pattern</b>	<b>Orientation</b>	<b>Attention</b>	<b>Memory</b>	<b>Duration</b>
Delirium	Acute	Fluctuating	Usually impaired	Impaired/ fluctuating	Impaired	Hours or days
Dementia	Insidious	Progressive	Normal or impaired	~Normal	Impaired	Months or years
Psychosis	Variable	Variable	~Normal	Normal or impaired	Normal or impaired	Variable

Differences between delirium and dementia are presented in Table 18.16.

**Table 18.16: Differences between delirium and dementia.**

<b>Features</b>	<b>Delirium</b>	<b>Dementia</b>
Onset	Rapid (hours to days)	Gradual (years)
Course	Wide fluctuations; may continue for weeks if cause is not found	Slow but continuous decline
LOC (loss of consciousness)	Hyper-alert to difficult to arouse	Normal
Orientation	Disoriented, confused	Disoriented, confused
Attention	Always impaired	May be intact; may focus on one thing for long periods
Sleep	Always disturbed	Usually normal
Behavior	Agitated, restless	May be agitated or apathetic; may wonder
Memory	Especially recent memory impairment	Especially recent memory impairment
Cognition	Disordered reasoning Thought content: Incoherent, confused, delusional	Disordered reasoning and calculation
Perception	Illusions, hallucinations	No change
Judgment	Poor	Poor, socially inappropriate

## ALCOHOL MISUSE AND DEPENDENCE

Consumption of alcohol when associated with social, psychological and physical problems constitutes alcohol misuse.

### Etiology

Alcohol is a central nervous system depressant. It influences several neurotransmitter systems, mainly GABA (inhibition of behavior) but also glutamate system and serotonin system.

### Consequences of Chronic Alcohol Misuse (Table 18.17)

**Q. Write short notes on consequences of chronic alcohol misuse.**

**Table 18.17:** Consequences of chronic alcohol misuse.

<b>Acute alcohol intoxication</b>	<b>Features of alcohol withdrawal syndrome</b>
<ul style="list-style-type: none"> <li>• Disturbances in emotional and behavioral state</li> <li>• Medical symptoms: Due to hypoglycemia,</li> </ul>	<ul style="list-style-type: none"> <li>• Psychological: Restlessness, anxiety, panic attacks</li> </ul>

## Complications of Chronic Alcohol Misuse

- **Social problems:** Absenteeism from work, unemployment, marital tensions, child abuse, financial difficulties, violence and traffic offences.
- **Depression:** It is common. Alcohol has a direct CNS depressant and suicidal attempts may be observed with alcohol misuse.
- **Anxiety:** Alcohol relieves anxiety in the short term. Anxious individuals may use alcohol and may develop dependence. On the contrary, alcohol withdrawal increases anxiety.
- **Alcoholic hallucinosis:** It is a rare condition in which alcoholics experience auditory hallucination.
- **Alcohol withdrawal** (discussed below): Maximum symptoms usually develop 2–3 days after the last drink and can produce seizures ('rum fits').
- **Delirium tremens:** It is a form of delirium found with severe alcohol

withdrawal (refer below).

## ***Effects on the Brain***

### **Q. Write short notes on acute and chronic neurological complications of alcohol abuse.**

- Features observed in chronic alcoholics include ataxia, slurred speech, emotional incontinence and aggression.
- **Alcoholic blackouts:** It is amnesia for events that occurred during bouts of intoxication in very heavy alcoholic drinkers.
- **Alcoholic dementia:** It is a global cognitive impairment which may resemble Alzheimer's disease. It does not progress and may improve if the patient abstains from alcohol.
- **Indirect effects on brain:** It may be due to head injury subdural hematoma, hypoglycemia and encephalopathy.
- **Wernicke–Korsakoff syndrome:** (discussed on page 4)

### *Acute Alcoholic Intoxication*

- It is characterized by hypotension, gastritis, hypoglycemia, collapse, respiratory depression, coma and death.

### **Q. Write short note on treatment of acute alcoholic intoxication.**

#### **Treatment of acute alcoholic intoxication**

- Maintain patent airway and prevent aspiration of vomitus. Tracheal intubation and positive pressure respiration may be needed. Do not use analeptics because they may precipitate convulsions.
- Maintain fluid and electrolyte balance.
- Hypoglycemia is corrected by glucose infusion.
- Thiamine 100 mg in 500 mL glucose solution infused intravenously.

*Note:* Gastric lavage is helpful only when the patient is brought immediately after alcohol ingestion.

## **Alcohol Dependence (Alcohol Use Disorder)**

Alcohol use disorder, is characterized by a problematic pattern of alcohol use leading to clinically significant impairment or distress, as manifested by multiple psychosocial, behavioral, or physiologic features.

### ***Features of Alcohol Dependence***

- Loss of control: Engaging in risky behaviors while under the influence.

- Compulsive preoccupation: Worrying compulsively about getting a ‘fix’ and spending a lot of their time thinking about the drug.
- Continued use of alcohol despite negative consequences: Losing control of the ability to monitor how much and how often the user takes their drug.
- Loss of motivation: Losing interest in activities that the user enjoyed prior to addiction.
- Desire to stop drinking, but inability to do so.
- Excessive time spent getting or using alcohol, or recovering from its effects.
- Craving, or preoccupation with drinking.
- Problems stemming from alcohol use; ignoring those problems; drinking despite obvious hazards, including physical danger.
- Retreating from important work, family or social activities and roles.
- Tolerance: The need to drink more and more alcohol to feel the same effects, or the ability to drink more than other people without getting drunk.
- Withdrawal symptoms: After stopping or cutting back on drinking, symptoms are anxiety, sweating, trembling, trouble sleeping, nausea or vomiting, and, in severe cases, physical seizures and hallucinations. The person may drink to relieve or avoid such symptoms.

## ***Investigations and Diagnosis***

Diagnosis may be apparent from the history or may be made when the patient presents with a complication.

**CAGE questionnaire:** Affirmative answers to any two of the following questions (or to the last question alone) are suggestive of alcohol abuse.

- Have you ever felt that you should **Cut**down your drinking?
- Have you ever felt **Annoyed** by others criticizing your drinking?
- Have you ever felt **Guilty** about your drinking?
- Have you ever had a morning drink (**Eye**-opener) after hangover

### **Laboratory detection of alcohol abuse**

- **Breath, blood and urine examination:** Screen for alcohol.
- **Gamma-glutamyl transpeptidase (GGT):** It is most sensitive for alcohol abuse and is raised in patients with alcohol abuse.
- **MCV (mean corpuscular volume):** Raised, but is less sensitive than

GGT.

- **Carbohydrate-deficient transferrin level:** Elevated and is highly specific in the absence of liver disease.
- **Phosphatidylethanol(PEth)**-concentration greater than 20 ng/dL is evidence of intoxication; it can detect excessive alcohol intake within a two-week period.
- **Others:** Alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lactate dehydrogenase (LDH).

### Treatment

Alcohol dependence can be treated (Box 18.17) in two phases: (A) Detoxification and (B) Rehabilitation.

#### (A) Detoxification

**Box 18.17:** Drugs used for alcohol dependence.

**First line medications:** Naltrexone and acamprosate

**Second-line medications:** Disulfiram, topiramate, gabapentin, baclofen, nalmefene

#### • Disulfiram

- Disulfiram is **inhibitor of enzyme aldehyde dehydrogenase (ALDH)** and blocks the conversion of acetaldehyde (derived from alcohol) to acetic acid, thus increasing the levels of toxic substance, acetaldehyde in the body.
- When alcohol is consumed while on disulfiram, acetaldehyde accumulates in tissues and blood and produces distressing symptoms (aldehyde syndrome). These unpleasant symptoms include flushing, burning sensation, throbbing headache, perspiration, uneasiness, palpitations, nausea, postural faintness, and, in some cases, circulatory collapse. Duration of symptoms (1–4 hours) depends on the amount of alcohol consumed.
- **Side effects:** Infrequent and include rashes, metallic taste, nervousness and malaise. Very rarely myocardial infarction, congestive heart failure, respiratory depression, convulsions and death may develop.
- **Dosage:** Oral 250 mg–500 mg/daily.

#### • Naltrexone

- It is an opioid-receptor antagonist. It reduces alcohol craving, number of drinking days, chances of resumed heavy drinking.
- **Dose:** Oral 50 mg/day in a single dose.
- **Side effects:** Nausea decreased appetite, fatigue and headache.

#### • Acamprosate

- It is a weak N-methyl-D-aspartate (NMDA) receptor antagonist with modest GABA A receptor antagonist. It normalizes the dysregulated NMDA-mediated glutamatergic excitation that occurs in alcohol withdrawal and early abstinence. It reduces relapse of the drinking behavior.
- **Dose:** Oral 666 mg given thrice a day. It is available in 333 mg enteric-coated tablet.
- **Side effects:** Diarrhea, dizziness and headache.

#### (B) Rehabilitation

- To prevent relapse.
- Needs psychotherapeutic interventions.

## Alcohol Withdrawal

**Q.** Write short note on clinical features of alcohol withdrawal syndrome.

Alcohol withdrawal in chronic alcoholics is characterized by sudden exhibition of central nervous system excitation.

### *Clinical Features*

They occur 6 to 8 hours after the reduction of ethanol intake and may last for 2–7 days.

- **Minor withdrawal symptoms**
  - These include insomnia, tremors (the shakes), hyper-reflexia, restlessness, mild anxiety, gastrointestinal upset, headache, tachycardia, palpitations, sweating/diaphoresis, hypertension, anorexia, nausea, and vomiting.
  - They resolve within 24–28 hours.
- **Alcoholic hallucinosis**
  - These are hallucinations appear within 8–12 hours of abstinence and disappear within 48–72 hours.
  - Usually these hallucinations are visual. In contrast to delirium tremens, it is not associated with clouding of the sensorium.

**Q.** Write short note on causes and management of convulsions in alcoholics.

- **Withdrawal seizures**
  - These seizures (**‘rum fits’**) are generalized tonic-clonic convulsions. It develops usually 12–24 hours after the last drink, but may develop after only 2 hours of abstinence.
  - About 3% of chronic alcoholics develop withdrawal-associated seizures and, about 3% of them may develop status epilepticus.
  - About 30% of patients, who develop delirium tremens, give a history of preceding alcohol withdrawal seizures.
- **Delirium tremens**

**Q. Write short note on delirium tremens.**

- It usually develops between 24–72 hours after the last drink and last for about 1–5 days. If early alcohol withdrawal is not treated, about 5% will progress to delirium tremens.
- **Clinical features**
  - ◆ These include agitation, visual hallucinations (Lilliputian/macroscopic), illusions, delusions, tachycardia, hypertension, diaphoresis and dilated pupils.
  - ◆ Dehydration may occur as a result of diaphoresis, hyperthermia, vomiting and tachypnea.
  - ◆ **Other features:** Hypokalemia, hypomagnesemia and hypophosphatemia.
- Death occurs in about 5% of patients, usually due to arrhythmias, pneumonia or electrolyte imbalance.

**Management of alcohol withdrawal syndrome**

- Maintain patent airway and breathing.
- Thiamine 100 mg in 500 mL glucose solution infused intravenously after withdrawing appropriate blood samples since in alcoholics, the thiamine will be depleted and the TPP would not be present as a result, in patients with altered sensorium for prevention of progress to Wernicke Korsakoff's psychosis.
- Maintain fluid and electrolyte balance.
- **Mild cases of withdrawal:** Provide supportive care, such as reassurance and nursing care (monitoring of vital signs).
- **Benzodiazepines (nitrazepam, diazepam and lorazepam):** For patients with moderate to severe withdrawal. They also control seizures.
- **β-blockers:** It may reduce anxiety and tremors.
- **Anticonvulsants:** Such as phenytoin, valproic acid, carbamazepine and levetiracetam are of little value in treating or preventing alcohol withdrawal seizures.
- **Management of associated conditions:** Such as pneumonia, electrolyte imbalances, GI bleed, liver failure, pancreatitis, neurological injury and trauma.

## SUBSTANCE-RELATED DISORDERS

**Q. Write short notes on drug abuse, its effects and treatment.**

### Substance Misuse Disorder

#### *Substance Abuse*

- **Definition:** Substance abuse is defined as psychological dependence and heavy consumption of a substance. Substance dependence is similar impairment with increased tolerance or presence of physical signs on withdrawal of substance.
- Intoxication and withdrawal are disturbances that are a direct physiologic result of a substance abuse.

### ***Substance Intoxication***

- Reversible, substance-specific syndrome caused by the recent ingestion of or exposure to a substance.

**Tolerance:** It is defined by either of the following:

- A need for markedly increased amounts of the substance to achieve intoxication or desired effect.
- A markedly diminished effect with continued use of the same amount of the substance.

### ***Substance Withdrawal***

It is manifested by the following:

- The characteristic substance-specific, maladaptive behavioral change, with physiologic and cognitive concomitants, caused by the cessation of or reduction in heavy and prolonged substance use.

### **Risk Factors/Etiology**

- **Family history:** Parental drug/alcohol use, marital conflict, disturbed family environment.
- **Physiology:** Individuals who are innately more tolerant to alcohol.
- **Developmental history:** Poor parenting, childhood physical and sexual abuse.
- **Environmental:** Peer pressure, economic disadvantage and social isolation. Availability and access to drugs.
- **Psychiatric disturbances:** Conduct disorder, depression and bipolar disorder.

**Age group:** Highest prevalence of substance abuse is between 18 and 22 years of age. Experimentation with gateway drugs may start as early as preadolescence.

## Common Symptoms and Signs of Substance Abuse (Table 18.18)

**Table 18.18:** Common symptoms and signs of substance abuse.

<i>Symptoms</i>	<i>Signs</i>
<ul style="list-style-type: none"><li>• Frequent absences from school or workplace</li><li>• Depression/anxiety</li><li>• Epigastric distress, diarrhea</li><li>• Sleep disorders</li><li>• Sexual dysfunction</li><li>• Frequent trauma/injury</li></ul>	<ul style="list-style-type: none"><li>• Tremors</li><li>• Tachycardia</li><li>• Labile hypertension</li><li>• Conjunctival injection</li><li>• Odor of alcohol on breath in alcohol addiction</li><li>• Tender hepatomegaly</li></ul>

### Investigations and Diagnosis

Diagnosis may be apparent from the history or may be made when the patient presents with a complication.

#### *Laboratory Toxicology*

- **Breath, blood and urine examination:** Screen for types of substances of abuse and its concentrations.
- **Intravenous drug abuse workup:**
  - HIV, hepatitis B, hepatitis C and tuberculosis.
  - Drug screening of samples of urine or blood will help in confirming the diagnosis.
- Other laboratory studies for evidence of systemic damage from substance use.

### Treatment of Substance-related Disorders

**Biological Treatment:** Pharmacologic intervention to ameliorate psychological or physical symptoms.

- **Agonist substitution:** Safe drug with a similar chemical composition as the abused drug, e.g. methadone for heroin addiction.
- **Antagonistic treatment:** Drugs that block or counteract the positive effects of substances, e.g. naltrexone for opiate and alcohol problems.
- **Aversive treatment:** Drugs that make the injection of abused substances extremely unpleasant, e.g. disulfiram for alcoholism and silver nitrate for nicotine addiction.

## ***Psychosocial Treatment***

- Community support programs: These are strongly encouraged.
- Emotional reassurance and providing a structured and secure environment.
- Components of comprehensive treatment and prevention programs: Individual and group therapy, aversion therapy and covert sensitization, contingency management, community reinforcement, relapse prevention, preventative efforts via education.

## **Specific Drug-dependence Disorders**

### ***Main Categories of Substances***

- **Depressants:** Result in behavioral sedation (e.g. alcohol, sedative, anxiolytic drugs).
- **Stimulants:** Increase alertness and elevate mood (e.g. cocaine, nicotine, caffeine).
- **Opiates:** Primarily produce analgesia and euphoria (e.g. heroin, morphine, codeine).
- **Hallucinogens:** Alter sensory perception (e.g. marijuana, LSD).
- **Other drugs of abuse:** Include inhalants, anabolic steroids, and medications.

### ***Nicotine***

**Nicotine withdrawal:** Symptoms in chronic users appear about 30 minutes after every dose. These include confusion, anxiety, restlessness, insomnia, depression, frustration and anger, nightmares and headache.

### ***Treatment of Tobacco Use Disorder***

- **Smoking cessation**
- Cognitive behavioral therapy (CBT).
- Nicotine gum or lozenge, transdermal patch, nasal spray inhalers.
- Medication:
  - **Bupropion:** It is an antidepressant which is chemically unrelated to tricyclic antidepressants or SSRIs. Dose 150 mg po twice a day.
  - **Varenicline and cytisine:** It is an alpha-4 beta-2 nicotinic receptor partial agonist more effective than nicotine and bupropion. Dose 1 mg po bid.

# SLEEP DISORDERS

**Q. Write short notes on common sleep disorders.**

Disturbed sleep is one of the most frequent health complaints. Various sleep disorders are listed in (Box 18.18).

**Box 18.18:** Sleep disorders.

- Insomnia
- Circadian rhythm disorders
- Narcolepsy
- Parasomnias
- Obstructive sleep apnea
- Restless leg syndrome
- Upper airway resistance syndrome

DSM-IV recognizes three major categories of sleep disorders (Box 18.19).

## Insomnia

Insomnia is the complaint of inability to sleep long enough or maintain sleep despite the patient having adequate amount of time to devote to sleep. It is associated with impairment of daytime functioning or mood symptoms.

Insomnia can be classified according to the nature of sleep disruption and the duration of the complaint. Most insomnia patients present with two or more of these symptoms.

**Box 18.19:** Major categories of sleep disorders.

- **Dyssomnias:** Sleeping disorder that make it difficult to get to sleep, or to stay sleeping.
- **Parasomnias:** It consists of various uncommon disruptive sleep-related disorders. They are intense, infrequent physical acts that occur during sleep. Some common parasomnias include sleepwalking, sleep talking, sleep terrors, nightmares, and teeth grinding
- **Neurological/psychiatric disorders**

**Box 18.20:** Common causes of insomnia.

### *Primary sleep disorders*

- Idiopathic insomnia
- Periodic leg movements
- Restless legs syndrome

### *Secondary sleep disorders*

- **Psychiatric or psychological problems:** Mood disorders (e.g. mania, depressive and anxiety

disorders); delirium and dementia

**Use or misuse of drug/substance abuse:** Consumption or discontinuation of drugs/substances. Withdrawal of addictive drug (e.g. alcohol, benzodiazepines); stimulant drugs (e.g. caffeine, nicotine, amphetamines); prescribed drugs (corticosteroids, dopamine agonists)

- **Physical/medical disorders:** Chronic pain (e.g. Carpal tunnel syndrome); nocturia (e.g. prostatism); malnutrition, chronic obstructive pulmonary disease, asthma, menopause, and neurologic disorders.

- **Sleep onset insomnia:** Difficulty falling asleep.
- **Sleep maintenance insomnia:** Frequent or sustained awakenings
- **Sleep offset insomnia:** Early morning awakenings or frequent nocturnal awakenings.

## ***Causes of Insomnia (Box 18.20)***

### ***Consequences***

- Depression may cause insomnia, and insomnia may cause depression.
- Can heighten the perception of pain.
- May be associated with:
  - Development of endocrine disturbances.
  - Increased risk for hypertension or cardiovascular disease.
  - Increased risk for motor vehicle accidents and occupational errors.

### **Q. Write short notes on behavioral therapy.**

#### **Treatment**

- **Behavioral therapy** effective but may be time-consuming. These include: Relaxation techniques, cognitive behavior therapy. Other measures include: Decreasing alcohol intake, to have early supper, daily exercise, and hot bath prior to going to bed and routine going to bed at the same time.
- **Pharmacologic treatment**
  - Benzodiazepines (e.g. temazepam, triazolam, estazolam and eszopiclone) for sleep-maintenance insomnia.
  - Nonbenzodiazepines (e.g. zolpidem, zolpidem controlled release zaleplon, zopiclone or eszopiclone) for both sleep-onset and sleep-maintenance insomnia.
  - Melatonin agonist (e.g. ramelteon) for sleep onset insomnia.
  - Antihistamines (e.g. diphenhydramine and promethazine) and antidepressants (e.g. amitriptyline, trimipramine, trazodone, mirtazapine).

## **Narcolepsy**

## ***Definition***

- Excessive daytime sleepiness and REM abnormalities for >3 months.
- REM sleep occurs for less than 10 minutes.
- Patients feel refreshed upon awakening.

## ***Etiology***

- Loss of orexin (hypocretin) signaling is believed to be the cause.
- Strong genetic/HLA association: HLADQB1\*0602 haplotype is present in 95% of patients with cataplexy and in 96% of those with orexin deficiency.

## ***Clinical Features***

The classic '**narcolepsy tetrad**' consists of four main clinical features. These consist of:

1. **Excessive daytime sleepiness (EDS)** occurring almost daily for at least 3 months that interferes with functioning **plus three specific symptoms** related to an intrusion of REM sleep characteristics. Sleep attack is the most common symptom.
2. **Cataplexy** (*pathognomonic sign*): Sudden weakness or loss of muscle tone without loss of consciousness, usually precipitated by loud noise, laughter or other intense emotions.
3. **Hypnagogic/hypnopompic hallucinations**: **Hypnagogic hallucinations** (hallucinations occur as the patient is going to sleep) or **hypnopompic hallucinations** (hallucinations upon awakening).
4. **Sleep paralysis**: Muscle paralysis upon awakening. It consists of episodes up to several minutes in duration of inability to move and occasionally feeling unable to breathe despite being awake. Fragmented sleep is classically seen in patients.

## ***Diagnosis***

- **Electrographic evidence**
  - **Multiple sleep latency test**: Demonstration of rapid transition from wakefulness to sleep and short time to onset of REM sleep confirmatory for the diagnosis. A mean sleep latency of  $\leq 8$  minutes and two or more sleep onset REM periods (SOREMPs) on a multiple

sleep latency test (MSLT) performed using standard techniques.

- HLA testing may also be useful.
- Cerebrospinal fluid (CSF) hypocretin-1 concentration is low.

### Treatment

The treatment is symptomatic.

- Forced naps at a regular time of day is usually the treatment of choice.
- **Psychostimulants**
  - **Wake-promoting therapeutics: Modafinil** is the drug of choice, principally because it has few side effects and has low addiction potential. Older drugs such as methylphenidate or methamphetamine or dextroamphetamine are used as alternatives, particularly in refractory patients.
  - **Tricyclic antidepressants** (TCAs) to help suppress the REM sleep [e.g. protriptyline, imipramine and clomipramine or the selective serotonin reuptake inhibitors (SSRIs) [e.g. fluoxetine (10–20 mg/d)] or selective norepinephrine reuptake inhibitors (e.g. venlafaxine) can improve cataplexy.
  - **Gamma hydroxybutyrate** (GHB) is effective in reducing daytime cataplectic episodes.
  - **Sodium oxybate** (a sodium salt of  $\gamma$ -hydroxybutyrate alone or combined with modafinil, can reduce sleep disruption significantly. It is administered at night to help consolidate REM sleep and increase slow-wave sleep. It significantly reduces day time sleepiness and also improves cataplexy.
  - **Pitolisant**, a histamine H3 receptor inverse agonist, is effective treatment for cataplexy and daytime sleepiness.
  - Others: Selegiline, clomipramine, fluoxetine and venlafaxine.

## Circadian Rhythm Sleep Disorders

- Circadian rhythm sleep disorders (CRSD) are mainly due to alterations of the circadian time-keeping system or asynchrony between the endogenous circadian rhythm and external factors that affect the timing or duration of sleep.
- Wake-sleep schedule disorders fall into two categories:
  - Primary malfunction of the biologic clock per se
  - Secondary malfunction due to environmental effects on the underlying clock.
  - Shift work type:
    - ◆ Night shift or shift changes.
  - **Jet Lag Disorder** associated with excessive daytime sleepiness, sleep onset insomnia, and frequent arousals from sleep, especially in the latter half of the night. Transient symptoms of difficulty falling asleep at the appropriate time and daytime sleepiness following rapid change

in time zones altering the timing of exogenous light stimuli.

## Diagnosis

- Made by **history** and a **sleep diaries**.
- **Actigraphy**: Based on a wrist-mounted motion detector worn as an outpatient for at least 7 days. It can help in quantify time spent asleep.

### Treatment of the Primary Circadian Rhythm Disorders

- **Chronotherapy**
  - Useful in delayed sleep phase type of circadian rhythm disorders.
  - Patient delays the onset of sleep by a few hours everyday and sleeps only the predetermined number of hours until the onset of sleep occurs at the desired time.
- **Phototherapy**: Bright light therapy
  - Patient sits at a prescribed distance from a bright light with an illuminance of greater than 2500 lux at that distance for 2–3 hours in the mornings.
- **Pharmacologic Therapy**
  - **Melatonin** 3 mg given 4–5 hours before the desired time of sleep onset. Useful in patients with delayed sleep phase.
- **For jet lag**
  - Behavioral strategies (good sleep hygiene), shifting sleep and wake times gradually before travel to conform to the destination's time zone and avoiding bright light exposure before bedtime).
  - Melatonin administered before bedtime in the new time zone.

## Parasomnias

**Definition:** Abnormal unpleasant or undesirable behaviors or experiences that occur during sleep, entry to sleep, or arousal from sleep.

**Table 18.19:** Types and features of parasomnias.

Type of parasomnias	Features
<b>Non-REM sleep parasomnias</b>	
Confusional arousals	Sudden arousals, associated with confusion and disorientation
Sleep terrors	Sudden arousal with fearful agitated behavior, often with screaming or crying; patients may be disoriented, unresponsive to the environment and typically do not remember the event afterward.
Sleepwalking	Arousal with complex motor behavior, walking, running, talking, and eating.
<b>REM sleep-associated parasomnias</b>	
Nightmare disorder	Recurrent, disturbing dreams not associated with autonomic activity or amnesia.

REM sleep behavior disorder (RBD)

Abnormal persistence of muscle tone during REM sleep, permitting vigorous movements while dreaming. Also includes screaming, punching and kicking for up to several minutes, sometimes resulting in injury to the patient or bed partner.

## ***Types and Features of Parasomnias (Table 18.19)***

### **Treatment**

- **Avoid:** Caffeine or alcohol and drugs, such as serotonin reuptake inhibitors and MAO inhibitors.
- **Remove dangerous objects** from the environment of sleep.
- **Pharmacologic therapy:** These include clonazepam, tricyclic antidepressants, dopamine agonists or levodopa, melatonin and carbamazepine.

## **Sleep-related Movement Disorders**

These include restless leg syndrome and periodic limb movement disorder.

### ***Restless Leg Syndrome (Willis-Ekbom Disease)***

It is a common sleep-related movement disorder.

#### *Clinical manifestation*

- It is characterized by urge to move legs and patient usually complains of a variety of uncomfortable sensations in the legs (e.g. pins and needles, creeping or crawling sensations, aching, itching, stabbing, heaviness, tension, burning, or coldness).
- Symptoms are usually experienced during periods of prolonged rest or inactivity.
- Symptoms are typically relieved only by movement or stimulation of the legs.
- The discomfort appears more prominent during evening and between midnight and 4 AM.
- May disrupt sleep initiation.

#### *Types*

- **Primary or idiopathic:** Inherited as an autosomal dominant disorder.
- **Secondary:** To other causes, including **iron deficiency**, pregnancy, varicose vein or venous reflux, uremia, or folate deficiency, peripheral neuropathy, radiculopathy rheumatoid arthritis, etc. It often develops suddenly and may be daily from the very beginning.

### **Treatment**

- Treatment of the underlying condition.
- **First-line drugs:** Dopamine agonists (e.g. pramipexole, carbidopa/levodopa or pergolide and ropinirole) are the treatments of choice.
- **Other drugs** include quinine levodopa preparations, gabapentin, opiate agonists (e.g. oxycodone, codeine, propoxyphene oxycodone, or methadone), benzodiazepines (e.g. clonazepam which often assist in staying asleep and reducing awakenings from the movements) may also be effective. Anticonvulsants, such as gabapentin, often helpful in patients with painful sensations

### ***Periodic Limb Movement Disorder (PLMD)***

- It is a repetitive, stereotyped limb movement and consists of 0.5- to 5.0-s extensions of the great toe and dorsiflexion of the foot.
- It occurs/recurs every 20–40 seconds during NREM sleep and each episode lasts from minutes to hours.
- Movements often disrupt sleep and lead to daytime sleepiness.
- **Treatment:** Dopaminergic medications or benzodiazepines.

## **EATING DISORDERS**

### **Anorexia Nervosa (AN)**

**Q. Write short note on anorexia nervosa and its management.**

#### ***Diagnostic Criteria***

- **Marked weight loss:** Refusal to maintain body weight at or above a minimally normal weight for age and height.
- **Avoidance of high-calorie foods:** Weight loss arising from food avoidance because of intense fear of gaining weight or becoming fat, even though underweight.
- **Distortion of body image** so that patients regard themselves as fat even when they appear grossly underweight.
- In postmenarcheal females, **amenorrhea**, i.e. the absence of at least 3 consecutive menstrual cycles (or 3 months).

#### ***Major Subtypes***

- **Restricting type:** Fasting, introverted, decreased risk of substance abuse, family conflict is covert.
- **Bulimic type:** Binge eating or purging, more volatile, family frequently

disengaged, prone to substance abuse.

### ***Etiology***

Unknown but probably includes genetic, environmental, psychologic and cultural factors.

### ***Clinical Features***

- **Onset:** Average age is 17 years. Very late-onset anorexia nervosa has a poorer prognosis.
- Onset is often associated with emotional stressors, particularly conflicts with parents about independence and sexual conflicts.

### ***Symptoms***

- Restricted food intake and maintaining diets of low-calorie foods and exercises.
- **Purging:** Self-induced vomiting or the use of laxatives, diuretics or enemas.
- Great concern with appearance.
- Significant amount of time spent examining and denigrating self for perceived signs of excess weight.
- Denial of emaciated condition.
- Excessive interest in food-related activities (other than eating).
- Obsessive-compulsive symptoms and depressive symptoms.

### ***Physical Examination***

- **Signs of malnutrition:** Emaciation, hypotension, bradycardia, lanugo (i.e. fine hair on the trunk) and peripheral edema.
- **Signs of purging:** Eroded dental enamel caused by emesis and scarred or scratched hands from self-gagging to induce emesis. Parotid abscess and dental caries-because of keeping food in mouth for long time.
- Evidence of medical conditions due to abnormal diets, starvation and purging.

### ***Course and Outcome***

- About 20–30% of restricting anorexics eventually develop binge eating

within the first 5 years of onset.

- These illnesses have a chronicity of 5–10%.
- Generally favorable outcome is achieved in 60–70% of patients at 5–7-year outcome.
- Long-term mortality rate of individuals hospitalized for anorexia nervosa is 10%, due to the effects of starvation and purging or suicide.

### ***Diagnostic Tests***

- **Signs of malnutrition:** Normochromic normocytic anemia, abnormal electrolytes, elevated liver enzymes, low estrogen and testosterone levels.
- **Signs of purging:** Metabolic alkalosis, hypochloremia and hypokalemia due to emesis. Metabolic acidosis caused by laxative abuse.
- **Hormonal abnormalities:**
  - Elevated growth hormone and plasma cortisol levels and reduced gonadotropin levels (along with low FSH, LH, and estrogen).
  - T3 may be reduced, but T4 and TSH are often normal.
  - Increased corticotrophin CSF levels.

#### **Treatment**

- Initial treatment should be correction of significant physiologic consequences of starvation with hospitalization if necessary.
- Behavioral therapy should be initiated, with rewards or punishments based on absolute weight, not on eating behaviors.
- Family therapy designed to reduce conflicts about control by parents.
- Antidepressants when comorbid depression is present.

## **Bulimia Nervosa**

**Q. Write a short note on bulimia nervosa.**

### ***Diagnostic Criteria***

- Recurrent episodes of **binge eating**.
- Absence of self-control over eating during binges.
- **Self-induced vomiting, purgation** or dieting after binges.
- **Weight maintained** within normal range.

### ***Major Subtypes***

- **Purging type:** Self-induced vomiting or use of laxatives, diuretics, or enemas.
- **Nonpurging type:** Use of other compensatory mechanisms, such as fasting or excessive exercise.

Occurs at 1: 9 male-to-female ratio.

### ***Etiology***

- Psychologic conflict regarding guilt, helplessness, self-control and body image may be predisposing factor.
- **Onset:** During late adolescence or early adulthood and often follows a period of dieting.
- **Course:** It may be chronic or intermittent.

### ***Symptoms***

- Recurrent episodes of binge-eating.
- Obsession with dieting but followed by binge-eating of high-calorie foods.
- Binges are associated with emotional stress and followed by feelings of guilt, self-recrimination and compensatory behaviors.
- Recurrent, inappropriate compensatory behavior.
- Self-castigation for mild weight gain or binges. Attempts to conceal binge-eating or purging, or lies about behaviors.

### ***Physical examination***

- Calluses on the dorsal surface of their hands (self-induced vomiting), dental erosion and caries, esophageal erosion, lanugo hair, enlarged parotid glands (chipmunk face secondary to increased amylase), bradycardia, hypotension, and arrhythmias (secondary to hypokalemia).
- **Associated problems:** Depression, substance abuse and impulsivity (Kleptomania).
- **Comorbid disorders:** Borderline personality disorder is present in 50% of patients.

### ***Outcome***

- Prognosis of bulimia is better than anorexia.
- Favorable prognostic indicators: Younger age at onset, higher social class,

and family history of alcohol abuse.

Diagnostic tests: Evidence of laxative or diuretic abuse.

#### Treatment

- Antidepressants (SSRI).
- Cognitive and behavioral therapy.
- Psychodynamic psychotherapies are useful for borderline personality traits.

Differences between anorexia and bulimia are listed in Table 18.20.

**Table 18.20:** Differences between anorexia and bulimia.

<i>Anorexia</i>	<i>Bulimia</i>
<ul style="list-style-type: none"><li>• Denies abnormal eating behavior</li><li>• Introverted</li><li>• Turns away food in order to cope</li><li>• Preoccupation with losing more and more weight</li></ul>	<ul style="list-style-type: none"><li>• Recognizes abnormal eating behavior</li><li>• Extroverted</li><li>• Turns to food in order to cope</li><li>• Preoccupation with attaining an 'ideal' but often unrealistic weight</li></ul>

## PUERPERAL DISORDERS

### **Q.** Write a short note on puerperal psychosis.

Three common psychiatric disorders occur after childbirth.

1. **Postpartum blues:** These are characterized by irritability, labile mood and tearfulness. Symptoms start soon after childbirth, and peak by about the fourth day and then resolve.
2. **Postpartum depression:** It develops in 10–15% of women within a month of delivery.
3. **Puerperal psychosis:** It is a rare disorder occurring in perhaps less than 1 or 2 per 1000 deliveries. It is more common in primiparous than multiparous women. Symptoms generally appear abruptly within about 3 days to several weeks after delivery. Rarely serious complication, such as a manic or depressive psychosis may develop. It may be associated with a personal or familial history of bipolar disorder. Management depends on the type of psychosis. Hospitalization is generally indicated. Most women recover but have an increased (25%) risk of developing puerperal psychosis in the next pregnancy, and a 50% lifetime risk.

# EMERGING NEUROINFECTION

## NIPAH VIRUS ENCEPHALITIS

**Q. Write a short note on Nipah virus encephalitis.**

### Etiology

- It is caused by a **RNA virus** of the family *Paramyxoviridae*, genus Henipavirus first identified in 1999 outbreak, has caused annual outbreaks in Bangladesh, Malaysia and India. Recent Indian outbreak has occurred in north Kerala in May 2018 has claimed lives.

### Transmission

- The Nipah virus is a zoonotic virus, which means it spreads to humans from either air or through saliva. The fruit bats is the primary carriers of Nipah virus. The virus is usually transferred through fluids from the bat. Close contacts with infected pigs and cattle can transmit the disease.

### Clinical Features

- The incubation period ranges from 5 to 14 days. The illness presents with high grade fever and headache, followed by drowsiness, disorientation and mental confusion. This can progress to encephalitis with brain stem dysfunction and coma within 24-48 hours.
- Other neurological signs include seizures, myoclonus, meningismus, autonomic dysfunction and cerebellar involvement. One third of patients develop pulmonary signs (ARDS), gastrointestinal and renal involvement is seen in 5% of cases.

### Investigations

- Thrombocytopenia, leucopenia and elevated transaminases is seen in majority of patients.
- Diffuse bilateral lung infiltrates with basal atelectasis are seen in many cases.
- CSF shows lymphocytic pleocytosis.
- Serum/CSF immunoglobulin (Ig) M capture enzyme immunoassay (EIA) for detection of Nipaha IgM antibodies and an indirect EIA for Nipah IgG antibodies are done for the specific diagnosis.

### Treatment and Prognosis

- Treatment is supportive only.
- The disease has a fatality rate of around 40%.

### Prevention

- Stay away from pigs, bats or domestic animals in endemic areas.
- Do not drink raw date, palm sap.
- Avoid fruits that have fallen from trees on the ground.

# Genetics

# CHAPTER 19

## COMMON GENETIC AND CHROMOSOMAL DISORDERS

**Q.** Write short essay/note on various types (classification) of chromosomal disorders/aberrations.

### Classification of Chromosomal Disorders (Box 19.1)

#### *Numerical Chromosomal Aberrations*

Normal cells are **diploid** containing 46 chromosomes, 22 pairs of autosomes and 1 pair of sex chromosomes. The 23 chromosomes (22 autosomes and one sex chromosome) constitute a **haploid**. Any exact multiple of the haploid number is called **euploid**.

#### *Types of numerical aberrations*

**Aneuploidy:** It is defined as a **chromosome number that is not a multiple of 23** (the normal haploid number). It is caused by either loss or gain of one or more chromosomes. Aneuploidy may result from **nondisjunction or anaphase lag**.

- **Trisomy:** Numerical abnormalities with the presence of **one extra chromosome** are referred to as trisomy ( $2n + 1$ ). It may involve either **sex chromosomes or autosomes**. *Examples:* Down syndrome (patients have three copies of chromosome 21, i.e. 47 XX, +21, hence Down syndrome is often known as trisomy 21, Patau syndrome (trisomy 13; 47 XY, +13) and Edward's syndrome (trisomy 18; 47XY, +18).
- **Monosomy:** Numerical abnormalities with the **absence or loss of one chromosome** ( $2n - 1$ ) are referred to as monosomy. It may involve autosomes or sex chromosomes. Monosomy of autosomes is almost

incompatible with survival. Example for monosomy of sex chromosomes is Turner's syndrome (**45 XO**) instead of normal XX (46 XX).

**Polyploidy:** It is chromosome number that is a multiple greater than two of the haploid number (**multiples of haploid number 23**). Triploidy is three times the haploid number (69), tetraploidy is four times the haploid number (92). Polyploidy is incompatible with life and usually results in spontaneous abortion.

### **Box 19.1:** Types of chromosomal abnormality.

#### ***Numerical abnormalities***

- Aneuploidy
  - Monosomy
  - Trisomy
  - Tetrasomy
- Polyploidy
  - Triploidy
  - Tetraploidy

#### ***Structural abnormalities***

- Translocations (exchange)
- Deletions (loss)
- Duplications
- Insertions
- Inversions
- Nondisjunction
- Ring chromosome

#### ***Isochromosomes***

#### ***Mixoploidy***

- Mosaicism
- Chimerism

### *Causes of numerical aberrations*

Numerical aberrations can occur during meiosis and/or mitosis. These errors are nondisjunction and anaphase lag.

- **Nondisjunction:** It is failure of paired chromosomes to separate during meiosis or mitosis. Meiotic nondisjunction is the most common cause.
- **Anaphase lag:** Anaphase lag results in the loss of a chromosome during meiosis or mitosis.

### **Structural Chromosomal Aberration (Box 19.1)**

**Q. Discuss chromosomal translocations with examples.**

- What is reciprocal translocation?
- Write a note on Robertsonian translocation.

Structural chromosomal aberrations may occur either during **mitosis** or **meiosis**.

**Causes of structural alterations:** It may occur spontaneously at a low rate and is increased by exposure to environmental mutagens, such as chemicals and ionizing radiation.

***Types of Structural/Chromosomal Aberrations (Fig. 19.1)***

**Translocations:** It is a structural alteration between two chromosomes in which **segment of one chromosome gets detached and is transferred to another chromosome**. There are two types of translocations.

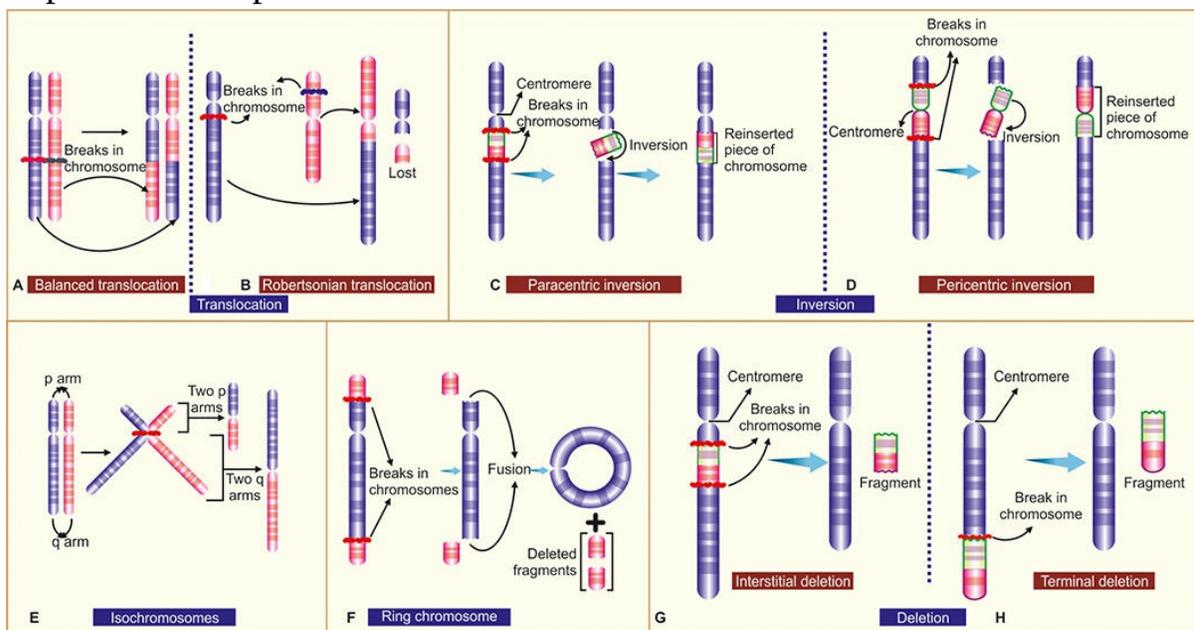

1. **Balanced reciprocal translocations:** It is characterized by single breaks in each of two chromosomes with exchange of genetic material distal to the break. There is no loss of genetic material. A balanced reciprocal translocation between the long arm of chromosome 5 and the short arm of chromosome 10 would be written *46, XX, t (5; 10) (q31; p14)*.
  - **Simple translocation:** In this case, terminal segment of a chromosome is integrated at one end of a non-homologous region. Simple translocations are rather rare.
  - **Shift:** In shift, an intercalary segment of a chromosome is integrated within a non-homologous chromosome.
2. **Robertsonian translocation/centric fusion:**
  - This results from the breakage of two acrocentric chromosomes (i.e. chromosome **13, 14, 15, 21, 22**) at or close to their centromeres and subsequent fusion of their long arms.
  - The short arms of each chromosome are lost, this being of no clinical importance as they contain genes only for ribosomal RNA, for which there are multiple copies on various other chromosomes.
  - The total chromosome number is reduced to **45**.
  - The overall incidence of this translocation is 1 in 1000, the most common being 13q14q.
  - The major practical importance is that this can predispose to the birth of babies with Down syndrome.

**Inversion:** When a segment of chromosome is oriented in the reverse direction, such segment said to be inverted and the phenomenon is termed as inversion.

**Isochromosome:** They are formed **due to faulty centromere division**. Normally, centromeres divide in a plane parallel to long axis of the chromosome. If a centromere divides in a plane transverse to the long axis, it results in pair of isochromosomes. One pair consists of two short arms and the other of two long arms.

**Deletion:** It is **the loss of a part of a chromosome**. It is of two types namely: interstitial (middle) and terminal (rare).

- **Interstitial deletion:** It occurs when there are two breaks within a chromosome arm. This is followed by loss of the chromosomal material between the breaks and fusion of the broken ends of the remaining portion of the chromosome. It has to be specified in which region(s) and at what bands the breaks have occurred. For example, *46, XY, del (16) (p11.2p13.1)* describes breakpoints in the short arm of chromosome 16 at 16p11.2 and 16p13.1 with loss of material between breaks.

**Fig. 19.1:** Types of structural abnormalities of chromosome.

- **Terminal deletion:** It results from a single break at the terminal part in a chromosome arm, producing a shortened chromosome bearing a deletion and a fragment with no centromere. The fragment is then lost at the next cell division.

**Ring chromosome:** It is a **special form of deletion**. Ring chromosomes are formed by a break at both the ends of a chromosome with fusion of the damaged ends.

**Insertion:** It is a form of **nonreciprocal translocation** in which a fragment of chromosome is transferred and inserted into a nonhomologous chromosome.

## Mixoploidy

**Mosaicism:** Defined as the presence in an individual, or in a tissue, of two or more cell lines that differ in their genetic constitution but are derived from a single zygote, i.e. they have the same genetic origin. Seen Down (1–2%) syndrome and Duchenne muscular dystrophy.

**Chimerism:** Defined as the presence in an individual, or in a tissue, of two or more cell lines that are derived from more than one zygote, i.e. they have different genetic origin.

## DOWN SYNDROME (TRISOMY 21)

**Q.** Write short essay/note on Down syndrome and its clinical features.

- The best known and most common chromosome related syndrome. Formerly known as ‘Mongolism’.
- It is the most common chromosomal disorder and is a leading cause of *mental retardation*. The incidence of Down syndrome in newborns is about 1 in 700 live births.

### Etiology and Pathogenesis

- **Maternal age:** It has a **strong influence** on the incidence of trisomy 21. Children of older mothers have much greater risk of having Down syndrome. The risk for mothers less than 25 years of age to have the trisomy is about 1 in 1500 births. At 40 years of age, 1 in 100 births. At 45 years, 1 in 40 births.
- **Other factors:** Increased incidence may be associated with exposure of mother to pesticides, electromagnetic fields, anesthetic drugs, alcohol and caffeine.

**Mechanism of trisomy 21:** The three copies of chromosome 21 in somatic cells cause Down syndrome. It may be due to:

1. About 95% of these individuals have *non-disjunction* during the first meiotic division of gametogenesis.
2. *Robertsonian translocation* of an extra-long arm of chromosome 21 to

another acrocentric chromosome causes about 5% of cases.

3. About 1% *mosaicism* having two different cell lines, one with normal chromosomal constitution and the other with an extra chromosome 21.

## Clinical Features (Fig. 19.2)

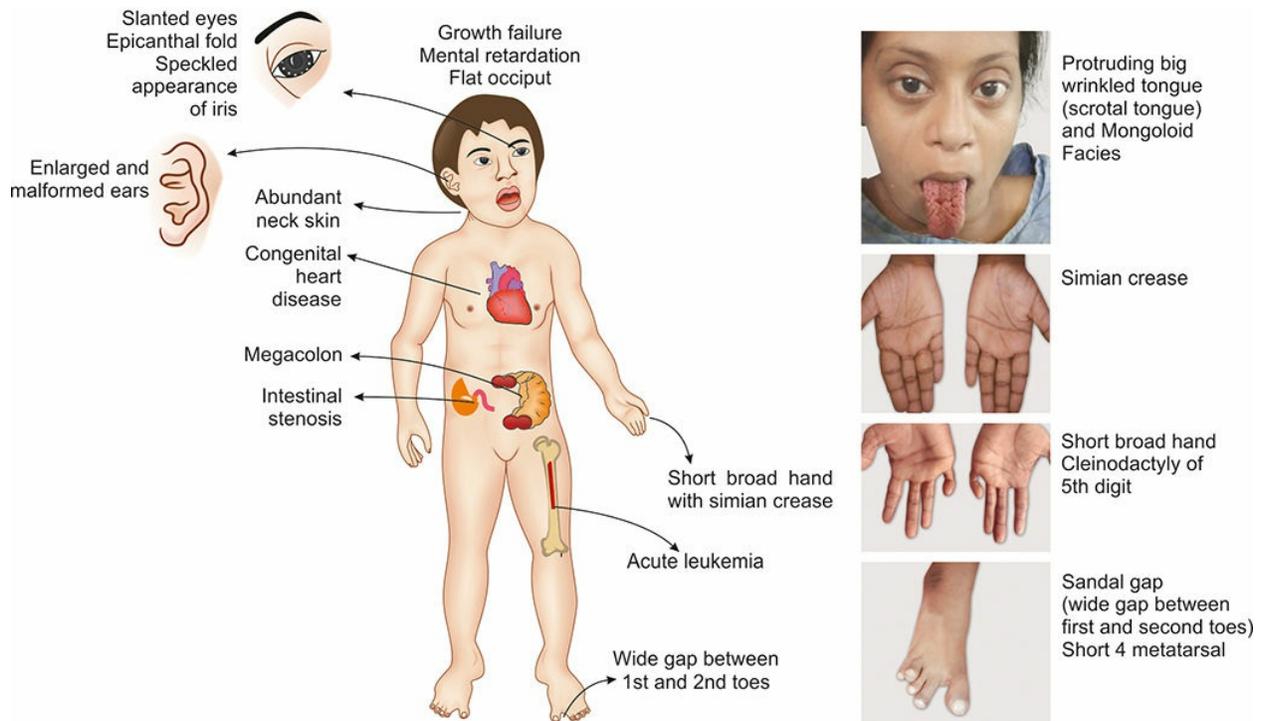

### Craniofacial and Skeletal Features:

- Flat face and occiput, with a low-bridged nose, reduced interpupillary distance and oblique palpebral fissures.
- Epicanthal folds of the eyes impart an almond shape to the eyes and an oriental appearance (obsolete term mongolism).
- A speckled appearance of the iris (Brushfield spots), enlarged and malformed ears.
- A protruding furrowed tongue (macroglossia), which typically lacks a central fissure and protrudes through an open mouth (scrotal tongue).
- Broad, short neck, brachycephaly, simian crease-single palmar flexion crease (50% cases), clinodactyly-incurved fifth finger with hypoplastic mid phalanx (60%), short stature, hypotonia and space between the first and second toes (sandal gap).

**Brain:** Mental retardation, attention-deficit hyperactivity disorder, autism, dementia, atlantoaxial dislocation.

**Heart:** Congenital **cardiac anomalies** are responsible for the majority of the deaths in infancy and early childhood. The genetic band in 21q22 critical region is considered responsible for the cardiac anomalies. Complete atrioventricular septal defect (CAVSD)—37%, ventricular septal defect (VSD)—31%, atrial septal defect (ASD)—15%, partial atrioventricular septal defect (PAVSD)—6%, and patent ductus arteriosus (PDA)—4%.

**Gastrointestinal tract:** It may show esophageal/duodenal stenosis or atresia, imperforate anus and Hirschsprung disease (megacolon).

**Fig. 19.2:** Major clinical features of Down syndrome.

**Reproductive system:** Men are sterile because of spermatogenesis arrest.

**Immune system:** Affected children are susceptible to infections due to defective immunity.

**Endocrine system:** Antithyroid antibodies may cause hypothyroidism Type 1 diabetes.

**Hematologic disorders:** They have increased risk of acute myeloid or lymphoblastic leukemia. Polycythemia, macrocytosis, leukopenia, and leukemia (acute megakaryoblastic, and acute lymphoblastic).

**Other features:** Refractive errors, strabismus, sensory neural hearing loss, obesity, obstructive sleep apnea.

Down syndrome screens are mentioned in Box 19.2.

**Box 19.2:** Down syndrome screens.

- **Triple screen (75% sensitive):** Maternal serum alpha fetoprotein, estriol, and human chorionic gonadotropin.
- **Quad screen (79% sensitive):** Maternal serum alpha-feto- protein, estriol, human chorionic gonadotropin and high inhibin-alpha (INHA).
- **Nuchal translucency/free beta-hCG>/PAPPA screen (91% sensitive):** Ultrasound to measure Nuchal Translucency in addition to the free Beta-hCG and PAPPA (pregnancy-associated plasma protein A).

- **The full integrated test** (first-trimester nuchal translucency, and pregnancy-associated plasma protein-A [PAPP-A] plus second-trimester quadruple markers) detects 85% of Down syndrome fetuses.

## KLINFELTER'S SYNDROME

### **Q. Write short essay/note on Klinefelter's syndrome.**

It is an important genetic cause of male hypogonadism and is associated with reduced spermatogenesis and male infertility.

### Pathogenesis

- Most patients with Klinefelter's syndrome have one extra X-chromosome (47, XXY karyotype). It is due to *non-disjunction* of X chromosome during meiosis.
- A minority is mosaic (e.g. 46, XY/47, XXY) or has more than two X-chromosomes (e.g. 48, XXXY) and one or more Y- chromosomes.

### Clinical Features (Fig. 19.3)

- Klinefelter's syndrome is usually diagnosed after puberty.
- Most patients are **tall and thin** with relatively long legs (eunuchoid body habitus). Mental retardation is uncommon, although average IQ is reduced.
- At puberty, **testes and penis remain small with lack of secondary male characteristics**.
  - Female characteristics develop which include a **high-pitched/deep voice, gynecomastia**, and a **female pattern of pubic hair**. Sparse facial, body and sexual hair.
  - **Azoospermia** results in infertility.
  - All of these changes are due to hypogonadism and reduced levels of testosterone.

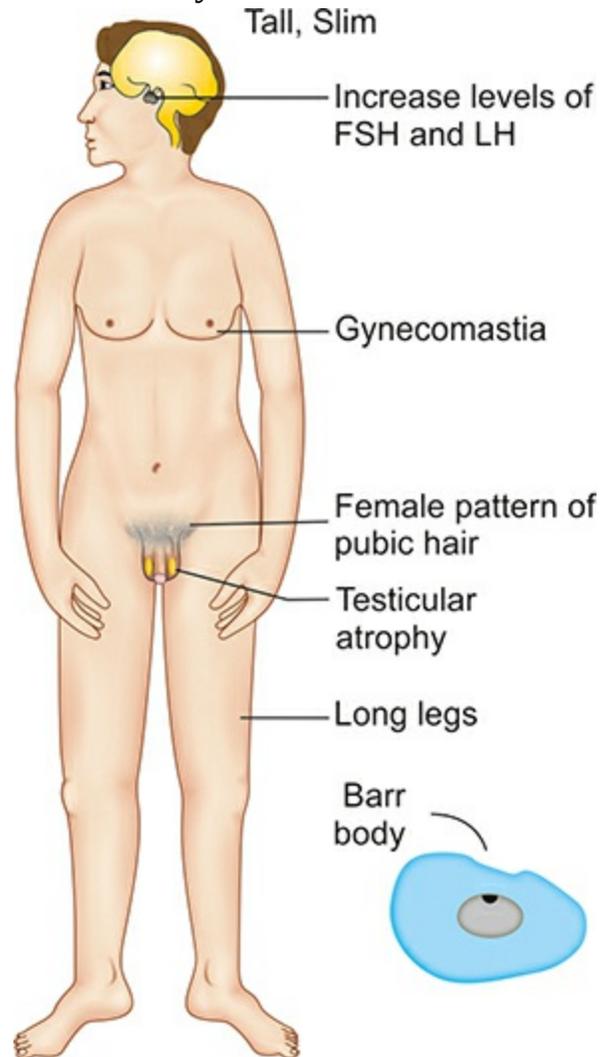

### Diagnosis

- **Buccal smear for Barr body:** Extra X-chromosome may be seen as a Barr body on buccal smears.
- **Leukocytes-nuclear sexing:** **Neutrophils** in the peripheral smear may also be examined for nuclear sexing. In a normal female (XX), the neutrophils in a peripheral smear show a drumstick which is counterpart of

Barr body in buccal smear. One extra drumstick is found in males with *Klinefelter's syndrome* (XXY).

- Chromosomal analysis
- *Hormonal status*:
  - Follicle-stimulating hormone and LH are remarkably high.
  - *Testosterone*: Low to low-normal level.
  - The ratio of estrogens and testosterone determines the degree of feminization.

Complications of Klinefelter's syndrome are listed in Box 19.3.

**Fig. 19.3:** Features of Klinefelter's syndrome.

## Management

- *Testosterone*: It should be started at puberty (round age 12 years) and increasing its dosage sufficient to maintain serum concentrations of testosterone, estradiol, FSH and LH appropriate to the age. It promotes normal body proportions and development of normal secondary sex characteristics. However, it does not affect infertility, gynecomastia and atrophy of testis. It decreases the long-term complications such as breast cancer, autoimmune disease and osteoporosis.
- Speech therapy.
- Physiotherapy for hypotonia or delayed motor skills.

### Box 19.3: Complications of Klinefelter's syndrome.

- Increased **risk of breast carcinoma** in 47, XXY (relative risk exceeding 200 times).
- **Endocrine complications**: Diabetes mellitus, hypothyroidism and hypoparathyroidism.
- **Autoimmune diseases**: Systemic lupus erythematosus, Sjögren's syndrome and rheumatoid arthritis.
- Development of varicose veins.
- Decreased bone density.

## TURNER'S SYNDROME

### Q. Write short essay/note on Turner's syndrome.

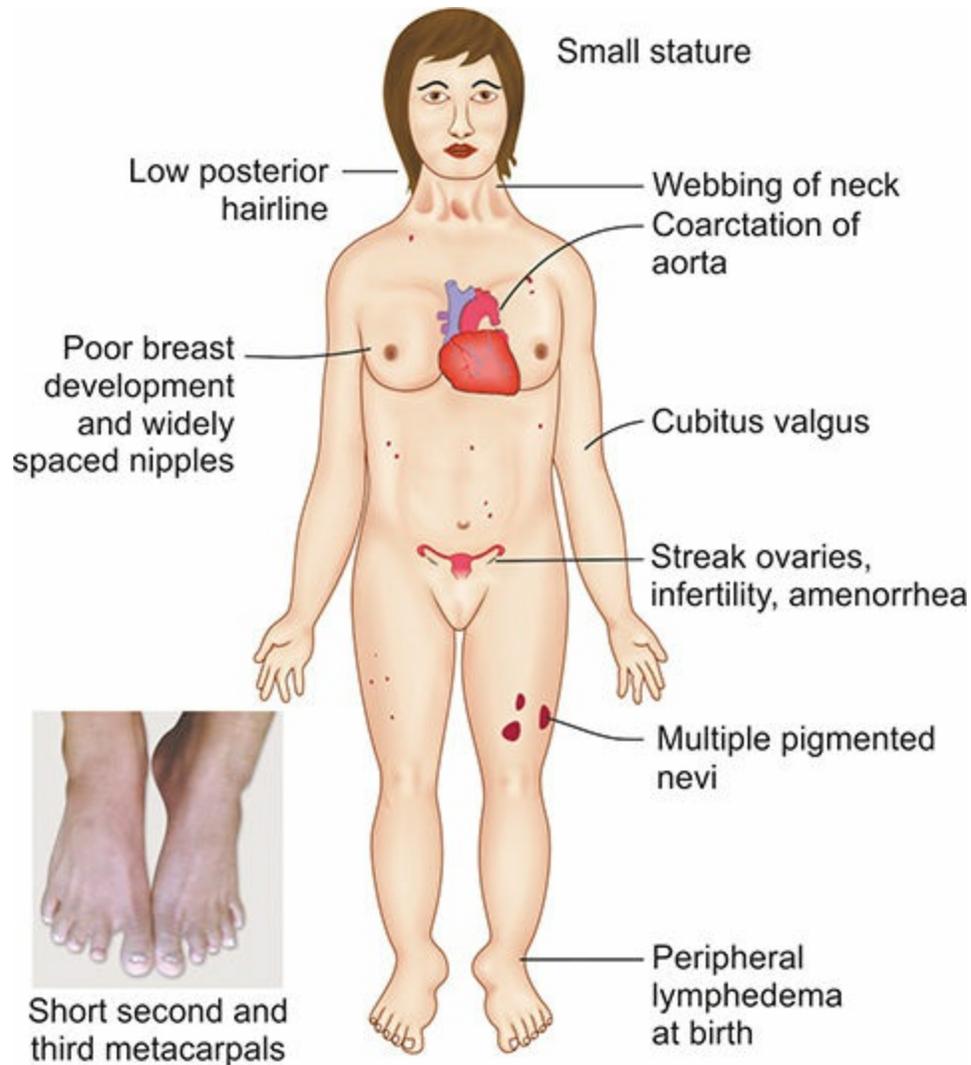

- Turner's syndrome is a sex chromosomal abnormality. Turner's syndrome is characterized by a spectrum of abnormalities due to **complete or partial monosomy of the X-chromosome** in a phenotypic female.
- It is characterized by hypogonadism and is the **most common sex chromosome abnormality in females**.

### Karyotypic Abnormalities

- *Missing of an entire X-chromosome*: This resulting in a 45, X karyotype Due to *non-disjunction* of X-chromosomes during meiosis. Genetic constitution hence becomes 45 XO.
- *Structural abnormalities of the X-chromosomes*: These includes isochromosome of the long arm, translocations, ring chromosome, and deletions.
- *Mosaics*: The mosaic patients have combination of a 45, X cell population along with one or more karyotypically normal or abnormal cell types. *Examples*: (1) 45, X/46, XX; (2) 45, X/46, XY. It is known as mosaic Turner's syndrome.

### Clinical Features (Fig. 19.4)

Turner's syndrome is usually not discovered before puberty. It presents with **failure to develop normal secondary sex characteristics**. Important diagnostic features are:

**Fig. 19.4:** Features of Turner's syndrome.

- **Adult women** with **short stature** (less than 5 feet tall) **primary amenorrhea and sterility**. Raised follicle-stimulating hormone (FSH)
- *Other features are:*
  - **Webbed neck**, and **low posterior hairline**, wide/increased carrying angle at the elbows (cubitus valgus), Madelung deformity of the forearm and wrist, broad chest (shield chest) with widely spaced nipples and hyperconvex fingernails.
  - The **genitalia remain infantile**, **breast development is inadequate**,

and there is little pubic hair. The ovaries are converted to fibrous streaks. Lack of secondary sexual characteristics.

- Pigmented nevi become prominent as the age advances.
- **Cardiovascular anomalies** such as congenital heart disease particularly **coarctation of the aorta** or **bicuspid aortic valve** may be present. Aortic dissection or rupture is a common cause of death. The severely affected may present during infancy with peripheral edema (of the dorsum of the hand and foot) due to lymph stasis. Systemic hypertension is seen in 30% of cases. No mental retardation.

#### Box 19.4: Causes of mental retardation.

- Genetic and chromosomal disorders, e.g. Down syndrome and fragile X syndrome
- *CNS lesions:*
  - Hydrocephalus
  - Microcephaly
  - Cerebral palsy
  - Post-traumatic, postmeningitic and postencephalitic states
  - Birth trauma, kernicterus
- *Environmental causes:*
  - *Associated intrauterine infections:* Congenital infections, congenital rubella syndrome, cytomegalovirus and other viruses
  - *Intrauterine exposure to toxins and other insults:* Alcohol, hypoxia or malnutrition
  - *Postnatal causes:* Exposure to toxins, infection and heavy metals
- Metabolic disease, e.g. cretinism, phenylketonuria, mucopolysaccharides, inborn errors of metabolism (e.g. Glycogen storage diseases)

## MENTAL RETARDATION/INSUFFICIENCY

**Q.** Write short note on mental retardation and its causes.

**Definition:** Mental retardation is defined statistically as tested cognitive performance that is two standard deviation below the mean of the general population (roughly below the 3rd percentile).

### Causes of Mental Retardation

See Box 19.4.

### Assessment of Degree of Mental Retardation (Table 19.1)

**Table 19.1:** Mental retardation by IQ range.

<i>Severity of mental retardation</i>	<i>IQ Range</i>
Mild	50–55 to 70
Moderate	35–40 to 50–55
Severe	20–25 to 35–40
Profound	Below 20–25

It is assessed by IQ (Intelligence quotient) testing.

$$IQ = \frac{\text{Mental age}}{\text{Chronological age}}$$

## INHERITANCE

**Q. Write short note on Mendelian disorders.**

### Single-Gene or Monogenic Disorders/Mendelian Disorders

Genetic disorders that result from mutations in single genes are called as single gene or monogenic (Mendelian) disorders. This type of inheritance is called *Mendelian inheritance*.

**Q. Write short note on autosomal dominant inheritance and diseases transmitted by autosomal dominant method.**

### *Autosomal Dominant Pattern of Inheritance*

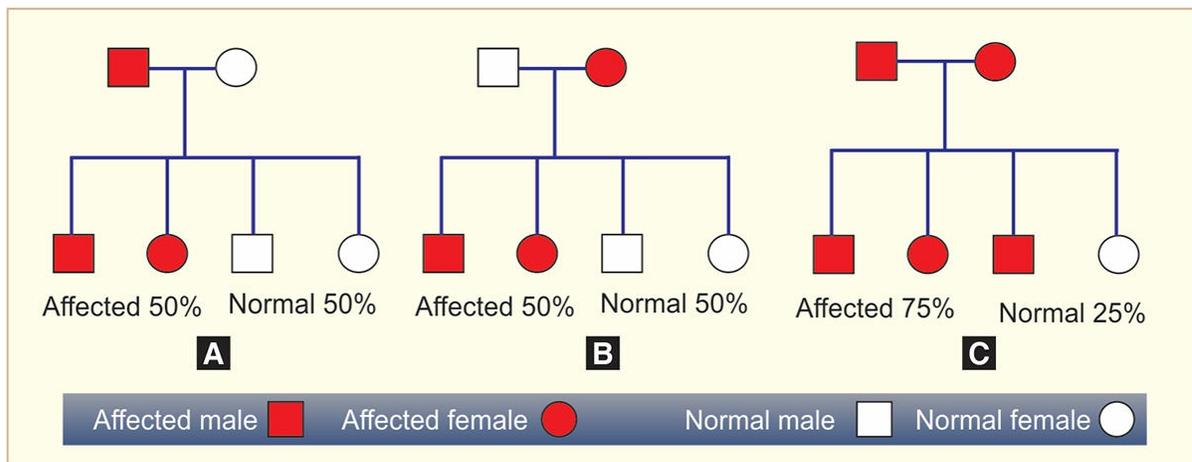

- It is determined by the presence of one abnormal gene on one of the autosomes (chromosomes 1–22)
- Disease is in **heterozygotes** (These disorders generally manifest when one of the two homologous (paired) chromosomes carries a mutant gene).

The general characteristics of autosomal dominant inheritance:

- **Location of mutant gene:** These are found on **autosomes**.
- **Required number of defective genes:** Only **one copy of the mutant (abnormal) gene** is required for effects.
- The disorder is **transmitted in a vertical (parent to child) pattern, appearing in multiple generations**
- **Sex affected:** Males and females are equally affected.
- **Pattern of inheritance:** **Every affected individual has one affected**

parent.

- Unaffected individuals (family members who do not manifest the trait) do not pass the disorder to their children.
- **Risks of transmission** (Figs. 19.5A to C) **to children (offspring):** Affected males and females have an equal risk of passing on the disorder to children.

**Figs. 19.5A to C:** Pedigree illustrating autosomal dominant transmission. (A and B) One parent is affected; (C) Both parents are affected. Note that both males and females are affected equally.

- **When only one parent is affected and other is normal:** An affected individual has a 50% (1 in 2) chance of passing on the deleterious genes for *each* pregnancy, and therefore of having a child affected by the disorder. This is called as the **recurrence risk** for the disorder.
- **When both parents are affected:** It has 75% chance of children being affected and a 25% chance to be normal.
- Finding of **male-to-male transmission** essentially confirms autosomal dominant inheritance.
- Examples of autosomal dominant and autosomal recessive disorders are listed in Table 19.2.
- **Additional properties:**
  - **Penetrance:** Penetrance is the percentage of individuals with the mutation who present with clinical symptoms.
    - ◆ **With complete penetrance,** all individuals show clinical symptoms.
    - ◆ **With incomplete penetrance or reduced penetrance,** only some individuals show disease and in **nonpenetrance** (gene is not

expressed at all) individuals may not show any symptoms.

- ◆ For example, *retinoblastoma*: AD malignant eye tumor is a good example of reduced penetrance. About 10% of the obligate carriers of the RB susceptibility gene (affected parent and affected child or children) do not have the disease.
- **Variable expressivity**: It refers to variations in expression (qualitatively or quantitatively) of severity of the same disorder among individuals (even within the same family), who have the abnormal gene. In some, the disorder may be mild and in others it may show significant symptoms. Penetrance may be complete, but severity of disease can vary greatly. Well-studied example is **neurofibromatosis type 1, or von Recklinghausen disease**.

**Q. Write short note on autosomal recessive inheritance and examples of transmitted by autosomal recessive mode.**

### ***Autosomal Recessive Pattern of Inheritance***

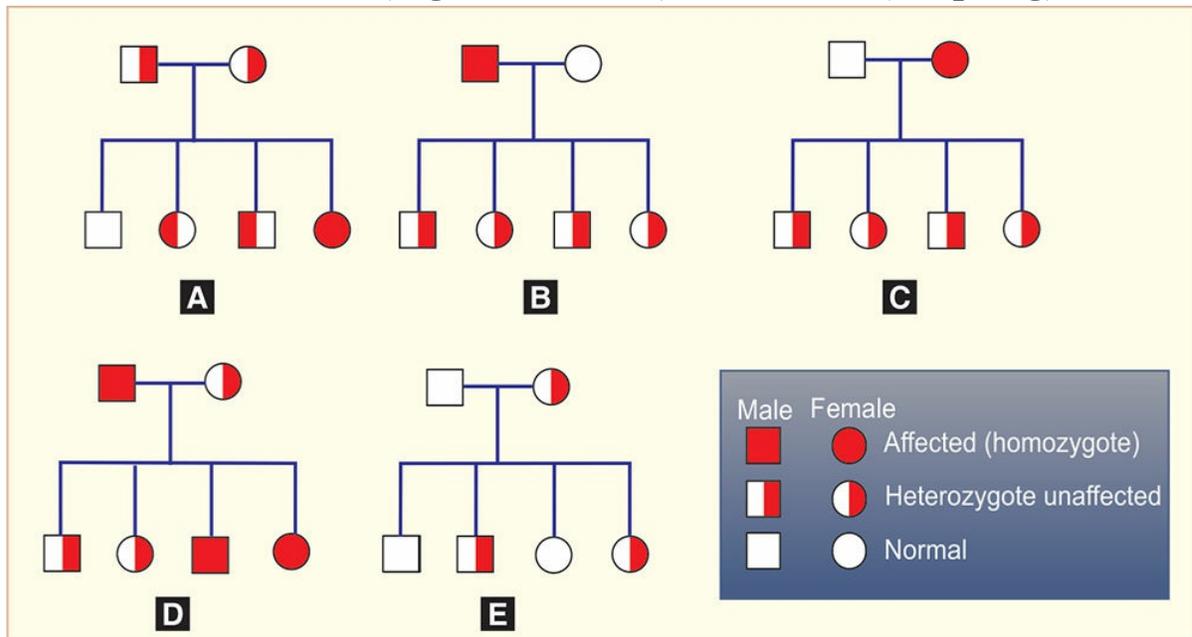

- Autosomal recessive inheritance involves mutations in both copies of a gene.
- These disorders generally manifest when both the homologous chromosomes carry mutant genes (**homozygous** state).

The general features of these disorders are:

- **Location of mutant gene**: These genes are located on **autosomes**.
- **Required number of defective gene**: Symptoms of the disease appear only when an individual has **two copies** of the mutant gene. The heterozygote state is called as a carrier. In the carrier state, the product of the normal gene is able to compensate for the mutant allele and is hence the patients are asymptomatic.
- **Horizontal transmission**: The observation of multiple affected members of kindred in the same generation, but no affected family members in other generations.
- **Pattern of inheritance**: For a child to be at risk, both parents must be having at least one copy of the mutant gene. *Almost all inborn errors of metabolism are autosomal recessive disorders.*
- **Sex affected**: Males and females being equally affected, though some traits exhibit different expression in males and females (ovarian cancer,

hypospadias).

- **Consanguineous marriage:** It is common predisposing factor.
- Recurrence risk of 25% for parents with a previous affected child.
- **Risks of transmission (Figs. 19.6A to E) to children (offspring):**

**Figs. 19.6A to E:** Pedigree illustrating mechanism of autosomal recessive transmission. (A) Both parents are unaffected heterozygotes; (B and C) One parent is sufferer (homozygous) and other is normal; (D) One parent is sufferer and other is unaffected heterozygote; (E) One parent is normal and other is an unaffected heterozygote.

- **When both parents are heterozygous for the condition:** Heterozygous parents carry one mutated gene and normal gene. When two **heterozygotes** mate, 25% of the children will be affected, 50% will be unaffected heterozygotes and 25% will be normal.
- **When one parent is affected and the other is normal:** All the children will be unaffected heterozygote.
- **When one parent is affected and the other is heterozygote:** The chances are that 50% of children will be unaffected heterozygote and 50% homozygous affected.
- **When one parent is normal and the other is heterozygote:** This may result in 50% unaffected heterozygote carriers and 50% normal children.
- If the frequency of an autosomal recessive disease is known, then frequency of the heterozygote or carrier state can be calculated from the

*Hardy-Weinberg formula:  $p^2 + 2pq + q^2 = 1$* , where p is the frequency of one of a pair of alleles and q is the frequency of the other.

Examples of autosomal dominant and autosomal recessive disorders are listed in Table 19.2.

**Table 19.2:** Examples of autosomal dominant and autosomal recessive disorders.

<i>System</i>	<i>Autosomal dominant disorder</i>	<i>Autosomal recessive disorder</i>
Nervous	Huntington disease Neurofibromatosis Tuberous sclerosis	Neurogenic muscular atrophies Friedreich's ataxia Spinal muscular atrophy
Skeletal	Marfan syndrome Achondroplasia Noonan syndrome	Alkaptonuria Ehlers-Danlos syndrome
Metabolic	Familial hypercholesterolemia Intermittent porphyria	Cystic fibrosis, phenylketonuria, lysosomal storage diseases, galactosemia, hemochromatosis, glycogen storage diseases
Hematopoietic	Hereditary spherocytosis von Willebrand disease	Sickle cell anemia, thalassemia
Renal	Polycystic kidney disease	Congenital adrenal hyperplasia
Gastrointestinal	Familial polyposis coli	Wilson's disease

## X-Linked Pattern of Inheritance

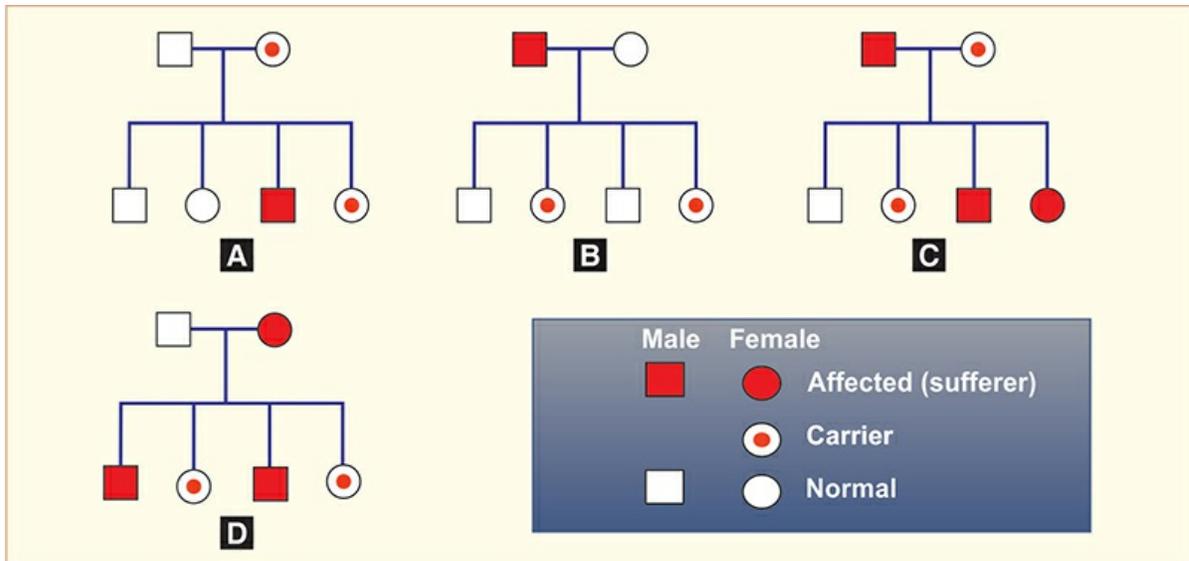

**Q. Write short note on X-linked inheritance and examples of diseases transmitted by X-linked method.**

Almost all sex-linked Mendelian disorders are X-linked. Males with mutations affecting the Y-linked genes are usually infertile.

**Expression of an X-linked disorder** is different in males and females. Though X-linked disorders may be inherited either as dominant or recessive, almost all X-linked disorders have recessive pattern of inheritance.

- **Characteristics of X-linked inheritance:**

- Males are more commonly and more severely affected than females.
- **Female carriers** are generally unaffected, or if affected, they are affected more mildly than males.
- Affected males will have only carrier daughters.

**Figs. 19.7A to D:** Mode of X-linked recessive transmission. Note the absence of male-to-male transmission. (A) Male is normal and female is a carrier; (B) Male is sufferer and female is normal; (C) Male is a sufferer and female is a carrier; (D) Male is normal and female is a sufferer.

- Carrier women have a 25% risk for having an affected son, a 25% risk for a carrier daughter, and a 50% chance for a child that does not inherit the mutated X-linked gene.

### ***X-linked Recessive Traits***

- **Location of mutant gene:** Mutant gene is on the X chromosome and there is no male-to-male transmission.
- **Required number of defective gene:** One copy of mutant gene is required for the manifestation of disease in males, but two copies of the mutant gene are needed in females.
- **Sex affected:** Males are more frequently affected and manifest disease than females; daughters of affected male are all asymptomatic carriers. In many diseases, males do not survive.
- **Pattern of inheritance (Figs. 19.7A to D):** Transmission is through female carrier (heterozygous). Mothers are always carriers and all their sons are affected. The disease is never passed from father to son.
- Very rarely, a female can develop the disease due to:
  - Female having Turner's syndrome (XO) with only one X-chromosome.
  - Presence of testicular feminization syndrome.

- Father with mutation in X-chromosome and a carrier female.
- Affected father and carrier mother.
- Inactivation of normal X-chromosome in most cells (Lyon hypothesis).

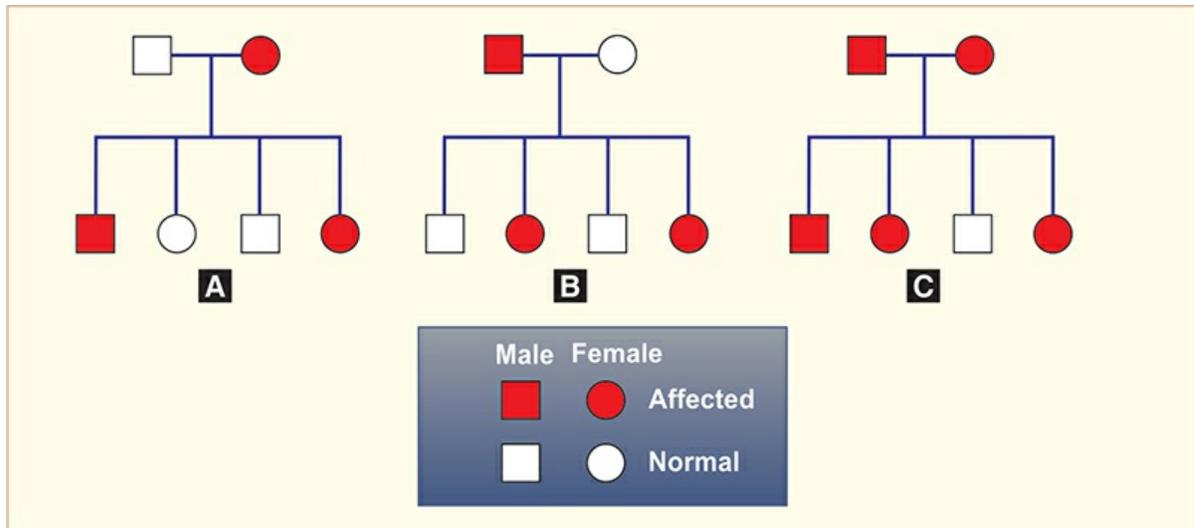

Examples of X-linked recessive disorders are shown in Table 19.3.

**Table 19.3:** Examples of X-linked recessive disorders.

<i>System</i>	<i>Related X-linked recessive disease</i>
Musculoskeletal	Duchenne muscular dystrophy
Blood	Hemophilia A and B
	Glucose-6-phosphate dehydrogenase deficiency
Immune	Agammaglobulinemia
Metabolic	Diabetes insipidus
Nervous	Fragile-X syndrome

### ***X-linked Dominant Conditions***

- Disorders are relatively uncommon (very rare). For example, vitamin D resistance rickets, Alport’s syndrome
- **Location of mutant gene:** It is located on the X-chromosome and there is no transmission from affected male to son. This is because the son’s ‘normal’ X-chromosome is from mother.
- **Required number of defective gene:** One copy of mutant gene is required for its effect.
  - Often lethal in males and so may be transmitted only in the females line.
  - Often lethal in affected males and they have affected mothers.
  - There is no carrier state as the disease will manifest, even if single chromosome has abnormal gene.
  - These are more frequent in females than in males.
- **Risks of transmission to children (offspring) (Figs. 19.8A to C):**

**Figs. 19.8A to C:** X-linked dominant transmission. Only females are affected. Usually males who inherit the mutant allele die *in utero*. (A) Normal male and female affected (sufferer); (B) Affected male and normal female; (C) Both male and female are affected.

- **When female is affected and the male is normal:** They transmit the disorder to 50% of their sons and 50% of their daughters.
- **When male is affected and the female is normal:** They transmit to all their daughters but none to their sons. All daughters of an affected father develop disease because the daughter gets abnormal X from the father.
- **When both male and female are affected:** All the females will be affected and half of males will be affected.

### ***Y-linked diseases***

Characterized by:

- Only males are affected.
- An affected male transmits the disorder to all his sons but not to his daughters.
- Most Y-linked genes are related to male sex determination and reproduction, and are associated with infertility. Therefore, it is rare to see familial transmission of a Y-linked disorder.
- For example, Leri-Weill dyschondrosteosis, Langer mesomelic dwarfism.

### ***Digenic inheritance***

- Digenic inheritance explains the occurrence of **retinitis pigmentosa (RP)**

in children of parents who each carry a different RP-associated gene.

- Both parents have normal vision, but the offspring who were **double heterozygotes** developed RP.
- Digenic pedigrees exhibit characteristics of both autosomal dominant (vertical transmission) and autosomal recessive inheritance (1 in 4 recurrence risk).

### ***Mitochondrial inheritance***

- An individual’s mitochondrial genome is entirely derived from the mother.
- Examples include **MELAS** (*myopathy, encephalopathy, lactic acidosis, and stroke-like episodes*), **MERRF** (*myoclonic epilepsy associated with ragged red fibers*), and **Kearns-Sayre syndrome** (*ophthalmoplegia, pigmentary retinopathy, and cardiomyopathy*).

### **Triplet Repeat Expansion Disorders**

- Caused by expansion in the number of three-base-pair repeats.
- An error in replication can result in expansion of that number, referred to as **premutation**.
- There is a clinical correlation to the size of the expansion, with a greater expansion causing more severe and/or earlier age of onset for the disease. The observation of increasing severity of disease and early age of onset in subsequent generations is termed **genetic anticipation** and is a defining characteristic of triplet repeat expansion disorders.
- Examples of triplet repeat expansion disorders are listed in Table 19.4.

**Table 19.4:** Examples of triplet repeat expansion disorders.

<b><i>Disease</i></b>	<b><i>Triplet repeated</i></b>	<b><i>Disease</i></b>	<b><i>Triplet repeated</i></b>
Huntington	CAG	Fragile X syndrome (FRAXA)	CGG
Myotonic dystrophy	CTG	FXTAS (Fragile X-associated tremor/ataxia syndrome)	CGG
X-linked spinal and bulbar muscular atrophy	CAG	Machado-Joseph disease (MJD)	CAG
Spinocerebellar ataxia type I	CAG	Friedreich’s ataxia	GAA

---

## Simple Tandem Repeat Mutation

- Variations in the length of simple tandem repeats of DNA are thought to arise as the result of slippage of DNA during meiosis and are termed microsatellite (small) or minisatellite (larger) repeats.
- These repeats are unstable and can expand or contract in different generations. This instability is related to the size of the original repeat, in that longer repeats tend to be more unstable.
- For example, Huntington disease, sickle cell anemia, MJD, Fragile X, myotonic dystrophy.

## Genetic Imprinting

- The two copies of most genes are functionally equivalent. In a small number, only one of the pair is transcribed.
- The active gene will be that inherited from a specific parent, and the other copy is silenced associated with methylation of DNA (**epigenetic modification** of a gene not due to a DNA mutation).

## *Conditions Associated with Genetic Imprinting*

- **Prader-Willi syndrome** with paternal chromosome deletion.
- **Angelman syndrome** with maternal chromosome deletion.
- Uniparental disomy (UPD): Rare occurrence of a child inheriting both copies of a chromosome from the same parent is another genetic mechanism that can cause Prader-Willi and Angelman syndromes.
- Other conditions associated with imprinting are Beckwith-Wiedemann syndrome and Russell-Silver syndrome, Duchenne muscular dystrophy (DMD) in females and epigenetic silencing in oncogenesis, e.g. colon cancer 3p21 MLH1.

## Pleiotropy

- Genes that exert effects on multiple aspects of physiology or anatomy are pleiotropic.
- *For example:* Marfan syndrome (affects eye, the skeleton and the cardiovascular system), cystic fibrosis (affects sweat glands, lungs, pancreas, and genitourinary system), osteogenesis imperfecta: Affects bones, teeth and sclera, sickle cell anemia (affects RBCs, bone and spleen).

## Locus Heterogeneity

- Disease that can be caused by mutations at different loci in different families is said to exhibit locus heterogeneity.
- *Osteogenesis Imperfecta (OI)*: Subunits of procollagen triple helix are encoded by two genes, one on chromosome 17 and the other on chromosome 7. Mutation in either of these genes can alter the structure of the collagen molecules and lead to OI, disease states are often indistinguishable.

## Polymorphisms

- A polymorphism is defined as one that exists with a population frequency of  $> 1\%$ .
- Most common polymorphisms are neutral but some cause subtle changes in gene expression or in protein structure and function. For example, cystic fibrosis, hemochromatosis, alpha 1 AT deficiency, spinomuscular dystrophy.

## GENE THERAPY

**Q.** Write short note on gene therapy.

**Definition:** Gene therapy is the insertion of genes into an individual's cells and tissues to treat a disease, such as a hereditary disease in which a deleterious mutant allele is replaced with a functional one.

To be effective, the gene therapy requires methods that ensure the safe, efficient and stable introduction of genes into human cells. Gene therapy uses genes to treat or prevent disease. First done on September 14, 1990 for Ashanthi DeSilva suffering from SCID where the missing gene introduced through processed WBC.

### Approaches for Correcting Faulty Genes

- A normal gene may be inserted into a nonspecific location to replace a nonfunctional gene.
- An abnormal gene could be swapped through homologous recombination.
- Repair through selective reverse mutation.
- The regulation of a particular gene could be altered.

## Types of Gene Therapy

The cells in the body can be divided into two main categories somatic cells and germ cells.

- **Somatic cell therapy:** It involves delivering a correcting gene to somatic cells in the affected tissues. Somatic cells are the non-reproductive cells and its therapeutic effect ends with the individual receiving it and is not passed on to the future generations. Hence, somatic cell therapy is considered as a safer approach. This type of gene therapy is used for disorders such as cystic fibrosis, muscular dystrophy, cancers and certain infectious diseases.
- **Germ cell therapy:** In germ cell therapy, germ cells (egg or sperms) are used and it results in permanent changes that are passed on to the future generations. Thus it offers the possibility of permanently eliminating some diseases from a particular family and ultimately from the population. It is not accepted at present due to ethical reasons.

## Arguments for Germline Gene Therapy

- *Medical utility:* The potential of a true 'cure'
- *Medical necessity:* May be only way to cure some diseases
- *Prophylactic efficacy:* Better to prevent a disease rather than to treat pathology
- *Parental autonomy:* Parents can make choices about what is best for their children
- Easier, more effective than somatic gene therapy
- Eradication of disease in future generations
- *Part of being human:* Supporting human improvement.

## Forms of Genetic Therapy

There are two basic forms of somatic gene therapy: (i) *ex vivo* and (ii) *in vivo*.

- **Ex vivo:** Transfer of gene in cultured cells and finally these cultured cells are reintroduced into patients.
- **In vivo:** Delivery of genes into cells of particular tissues. The gene may be transferred by a viral vector or by a nonviral method. This is most often used technique.

## Vectors in Gene Therapy

The most common form of gene therapy involves insertion of normal gene into the genome with the help of certain carriers called **vectors**. These vectors can be divided into two main types, viral and nonviral vectors.

**Viral vectors:** The various viruses include retroviruses, adenoviruses, adenoassociated viruses and herpes simplex viruses.

**Nonviral methods:** Gene delivery can also be carried by nonviral methods. These have some advantages. They do not elicit an immune response, safer and simpler to use and allow large-scale production. The nonviral methods include: direct inoculation/naked DNA, liposomal-mediated DNA transfer, gene gun method and dendrimers.

### Problems/Limitations of Gene Therapy

- **Short-lived nature of gene therapy.** Hence, patients will have to undergo multiple rounds of gene therapy.
- **Immune response:** Gene therapy may stimulate the immune response against introduced gene and reduce the effectiveness of gene therapy.
- **Problems with viral vectors:** Viral vectors may sometimes cause potential problems to the patient like: toxicity and inflammatory responses. In addition, the viral vector, once inside the patient, may recover its ability to cause disease.
- **Multifactorial disorders:** Genetic disorders due to single gene mutations are usually show best response to gene therapy. Unfortunately, some the most commonly occurring disorders (e.g. atherosclerosis, hypertension, diabetes, Alzheimer's disease and rheumatoid arthritis) are multifactorial and are difficult to treat effectively using gene therapy.
- **Risk of inducing a tumor (insertional mutagenesis):** If the gene is integrated in the wrong place in the genome (e.g. in a tumor suppressor gene), it could induce a tumor.
- **Risk of death:** Deaths have occurred due to gene therapy.

### Therapeutic Applications (Table 19.5)

- Not been approved for clinical use.
  - Trials are being conducted on using gene therapy in the treatment of various genetic disorders, cancers, infectious diseases and other diseases such as Alzheimer's disease and atherosclerosis.
- 

**Table 19.5:** Gene therapy in medicine.

<i>Cancers</i>	<i>Parkinson disease</i>
Vascular diseases	Metastatic melanoma
Thalassemia	Hemophilia
Cystic fibrosis	Infectious diseases
SCID	Muscular dystrophy
Sickle-cell anemia	Leber's congenital amaurosis

## HUMAN GENOME PROJECT

**Q.** Write short note on human genome and human genome project.

### Introduction

**Genome:** A **genome** is the entire DNA in an organism, including its genes. The human genome is estimated to contain 30,000–40,000 genes that are divided among the 23 chromosomes. The 23 different chromosomes 22 are autosomes (numbered 1–22) and 1 pair sex chromosomes (X and Y). The functions of over 50% of discovered gene is not known.

**Gene mapping:** It is the process of identifying and sequencing each and every human gene of the human genome. The map of the human genome provides a picture of locations, and structures of genes.

- **Genetic mapping** (linkage analysis): A genetic map describes the order of genes and defines the position of a gene relative to other loci on the same chromosome.
- **Physical Mapping:** Physical mapping indicates the position of genes in a chromosome, which is determined by physical distances (measured in base pairs) between genes.

Organism and their genomic size are presented in Table 19.6.

**Table 19.6:** Organism and their genomic size.

<i>Organism</i>	<i>Genomic size in base pairs</i>
Epstein–Barr virus	$0.172 \times 10^6$
Bacteria ( <i>E. coli</i> )	$4.6 \times 10^6$
Yeast	$12.1 \times 10^6$
Nematode worm ( <i>C. elegans</i> )	$95.5 \times 10^6$

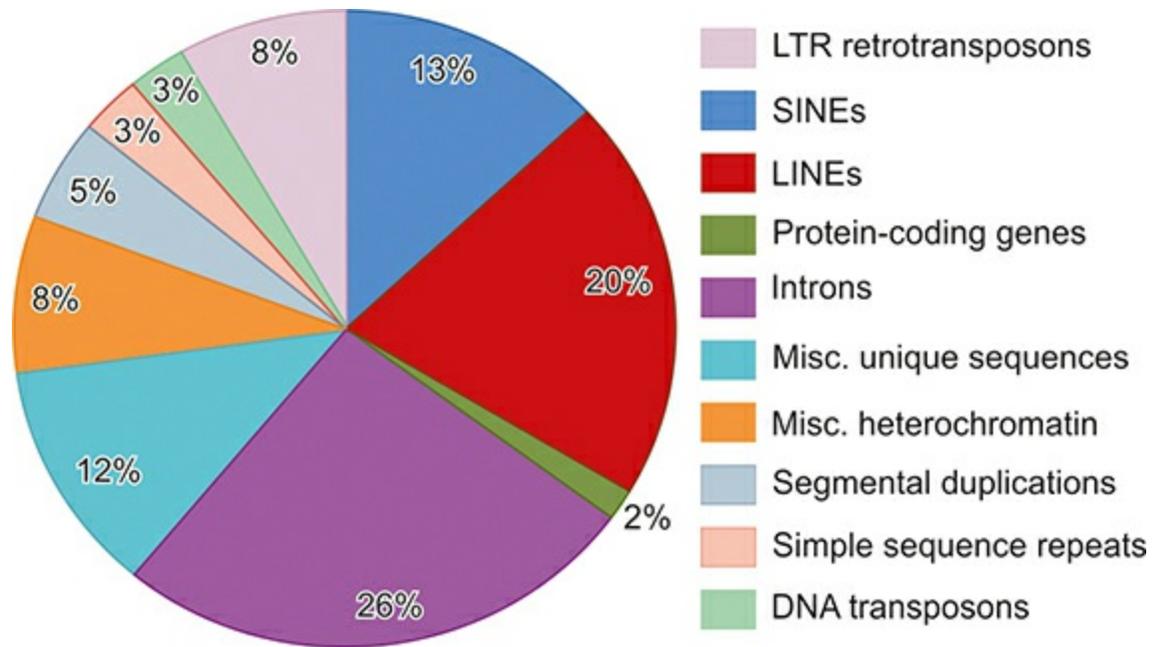

Fruit fly	$180 \times 10^6$
Human	$3200 \times 10^6$

The **human genome project (HGP)** is an international scientific research project to understand the genomes of humans and other organisms. It was started in 1990 under **Dr James D Watson** at the United States National Institute of Health. In addition to the United States, the international consortium comprised geneticists in the United Kingdom, France, Germany, Japan, China and India.

### Goals of Human Genome Project

- Understand and **identify all genes** of the human genome.
- Determine the **human DNA sequence**: The primary focus of the HGP was to obtain DNA sequence for the entire human genome. HGP goal was to map all genes of the human genome and also to map human inherited diseases. Thus, it includes creation of genetic maps, development of physical maps, and determination of the complete human DNA sequence.
- **Develop software for large-scale DNA analysis**, store all found information in databases and improve tools for data analysis.
- Transfer-related technologies to the private sector
- **Collect and distribute data**
- **Study the ethical, legal, and social issues (ELSI) of genetic research** that may arise from the project.

Components involved in human genome are diagrammatically shown in Figure 19.9.

**Fig. 19.9:** Components of human genome.

All humans have unique gene sequences. Therefore, the data published by the HGP does not represent the exact sequence of each and every individual's genome. It is the combined genome of a small number of anonymous donors. The HGP genome is a scaffold for future work in identifying differences among individuals.

## Uses of Human Genome Project

Human genome project will shed light on a wide range of basic questions, to identify the number of genes in humans, how cells work, how living things evolved, how single cells develop into complex creatures, and what exactly happens when we become ill. The understanding of the genome provides clues for

1. **Etiology** of cancers, Alzheimer's disease, etc.
2. Defining the **pathogenesis** of a disease and to study the disease processes at molecular level.
3. **Susceptibility** of an individual to a variety of illnesses, e.g. carcinoma breast, disorders of hemostasis, liver diseases, cystic fibrosis, etc.
4. Precise new ways **to prevent** a number of diseases that affects the human beings.
5. To **diagnose and treat** disease. Target genes for treatment and management of diseases.

5. *Human development and anthropology*: Analysis of similarities between DNA sequences from different organisms helps to **study evolution**.
7. **Researcher**: By visiting the human genome database on the Worldwide Web, researcher can examine what other scientists have written about the gene.

### Ethical Issues (Box 19.5)

HGP helps to identify disease-causing genes, thereby can lead to improvements in diagnosis, treatment, and prevention. It is estimated that most individuals harbor several serious recessive genes. However, completion of the human genome sequence and determination of the association of genetic defects with disease has raised many new issues with implications for the individual and mankind.

#### Box 19.5: Ethical issues in human genome project (HGP).

- Fairness in the use of genetic information
- Privacy and confidentiality
- Psychological impact and stigmatization
- Genetic testing
- Reproductive issues
- Education, standards, and quality control
- Commercialization
- Conceptual and philosophical implications.

## MISCELLANEOUS

**Q. Write short note on proteomics/proteome.**

### Proteome

- The term proteome is derived from proteins expressed by a genome. It refers to all the proteins produced by an organism and proteins are the functional units. Thus, proteome represents full sets of proteins produced by the body and is similar to the term genome for the entire set of genes. Human body contains more than 2 million different proteins, each having different functions.
- Proteomics is the study of the proteome (full set/entire library of proteins in a cell type or tissue) and its variation/relationship to disease.

- Amino acids are the basic units of proteins and are very small. Each amino acid consists of atoms ranging from 7 to 24 and cannot be identified under even the powerful microscopes.
- *Uses:* Proteomic technologies play an important role in drug discovery, diagnostics and molecular medicine. When a defective protein causing particular diseases are founded, new drugs can be developed to either alter the shape of a defective protein or mimic a missing one.

## Epigenetics

### **Q. Write a short note on epigenetics.**

**Definition:** Epigenetics is a **reversible, heritable change/alteration** in gene expression which occurs without mutation and is unrelated to gene nucleotide sequence. Epigenomics is the study of epigenetics. Epigenetic alterations are associated with cancers and other diseases. Unlike genetic changes in cancer, epigenetic changes are reversible.

- In normal cells, the majority of the genome is not expressed. Some portions of the genome are silenced by DNA methylation and histone modifications.
- In some tumors, epigenetic changes may directly contribute to tumor development. Epigenetic changes involve post-translational modifications of histones and DNA methylation, both of which affect gene expression.
- In cancer cells, there is global DNA hypomethylation and selective promoter-localized hypermethylation.

### Examples

1. **Silencing genes by hypermethylation** (epigenetic mechanism)
  - a. *Tumor suppressor genes:* Examples: p53 can be indirectly inactivated through silencing ARF by hypermethylation. This hypermethylated ARF prevents inhibition of the MDM2 oncogenic protein and the enhancement of p53 degradation; *BRCA1* in breast cancer and *VHL* in renal cell carcinomas.
  - b. *DNA repair genes:* Mismatch-repair gene *MLH1* in colorectal cancer.
2. **Hypomethylation:** The genome of cancer cells may also undergo global DNA hypomethylation. Gene hypomethylation can cause chromosomal instability, derepression of growth regulatory genes, and overexpression of antiapoptotic genes, which may induce tumors.

## ***Clinical Applications***

- Use of epigenetic tumor markers
- Use of epigenetic therapeutic agents (e.g. azacitidine, decitabine, vorinostat) in the treatment of myelodysplastic syndromes (MDS) and lymphoma.

## **Pharmacogenomics**

### **Q. Write short note on pharmacogenomics and pharmacogenetics.**

- Pharmacogenetics or pharmacogenomics is the study of interaction between genetics and therapeutic drugs.
- Pharmacogenetics is the study of unexpected drug response result and to look for a genetic cause.
- Pharmacogenomics is the study of identifying genetic differences within a population that explain certain observed responses to a drug or susceptibility to a health problem.

## ***Applications***

- To develop a drug that has maximum therapeutic effect and produces least damage to adjacent healthy cells.
- To prescribe drugs depending on the patient's genetic profile so as to reduce the adverse reactions.
- To determine the accurate dosage.
- To determine drug responses in the treatment of cardiac, respiratory and psychiatric conditions.
- To develop targeted therapy (e.g. psychiatry, dementia, cardiac conditions) and in the treatment of breast cancer (testing for HER2 receptor for response to trastuzumab) and other cancers (e.g. testing for BCR-ABL for response to imatinib in CML; testing for epidermal growth factor receptor response to gefitinib and erlotinib in lung cancer).

## **Prevention of Genetic Disease**

### **Q. Write short note on prevention of genetic disease.**

- **Preimplantation diagnosis:** Before conception (i.e. when one or two of the parents are carriers of a certain trait). The human embryos can be produced using assisted reproductive techniques such as *in-vitro*

fertilization (IVF). *In vitro* fertilization involves removing egg cells from a woman's ovaries and fertilizing them with sperms outside the body and culture to blastomere stage. One cell is then studied by PCR or gene probe technique to detect genetic markers of diseases.

- **Prenatal testing:** These tests are performed on fetus or embryo before it is born to detect changes in a fetus's genes or chromosomes. These include: amniocentesis, biochemical, cytogenetic and DNA studies and transcervical chorionic villous biopsy (chorionic villous sampling, CVS).
- **Newborn or neonatal, childhood screening**
- **Screening test in adolescence and adulthood**
- **Genetic counseling.**

List of chromosomal disorders are presented in Table 19.7.

**Table 19.7:** List of chromosomal disorders.

<i>Chromosome</i>	<i>Abnormality</i>	<i>Disease Association</i>
X	XO	Turner's Syndrome
Y	XXY	Klinefelter syndrome
Y	XYY	Double Y syndrome
Y	XXX	Trisomy X syndrome
Y	Xp21 deletion	Duchenne's/Becker syndrome congenital adrenal hypoplasia, chronic granulomatus disease
1	1p (somatic) monosomy trisomy	Neuroblastoma
2	Monosomy trisomy 2q	Growth retardation, developmental and mental delay, and minor physical abnormalities
3	Monosomy trisomy (somatic)	Non-Hodgkin's lymphoma
4	Monosomy trisomy (somatic)	Acute nonlymphocytic leukemia (ANLL)
5	5p deletion	Cri du chat; Lejeune syndrome
5	5q (somatic) monosomy trisomy	Myelodysplastic syndrome
6	Monosomy trisomy (somatic)	Clear-cell sarcoma
7	7q 11.23 deletion	William's syndrome
8	Monosomy trisomy	Myelodysplastic syndrome; Warkany syndrome; chronic myelogenous leukemia
9	Trisomy	Complete trisomy 9 syndrome: mosaic trisomy 9 syndrome
10	Monosomy trisomy (somatic)	ALL or ANLL
11	11p-	Aniridia; Wilms tumor

11	Monosomy (somatic) trisomy	Myeloid lineages affected (ANLL, MDS)
12	Monosomy trisomy (somatic)	CLL, Juvenile granulosa cell tumor (JGCT)
13	13q14 deletion	Retinoblastoma
13	Monosomy trisomy	Patau's syndrome
14	Monosomy trisomy (somatic)	Myeloid disorders (MDS, ANLL, atypical CML)
15	15q11-q13 deletion monosomy	Prader-Wili, Angelman's syndrome
15	Trisomy (somatic)	Myeloid and lymphoid lineages affected, e.g. MDS, ANLL, ALL, CLL
16	16q13.3 deletion monosomy trisomy (somatic)	Rubinstein-Taybi, papillary renal cell carcinomas (malignant)
17	17p-(somatic)	17p syndrome in myeloid malignancies
17	Monosomy trisomy (somatic)	Renal cortical adenomas
18	Monosomy trisomy	Edwards syndrome
19	Trisomy, deletion	
20	20p-	Trisomy 20p syndrome
20	20q-	MDS, ANLL, polycythemia vera, chronic neutrophilic leukemia
20	Monosomy trisomy (somatic)	Papillary renal cell carcinomas (malignant)
21	Monosomy trisomy	Down's syndrome
22	22q11.2 deletion	DiGeorge's syndrome, velocardiofacial syndrome, conotruncal anomaly face syndrome, CML-reciprocal translocation 9:22 Opitz G/BBB syndrome, Caylor cardiofacial syndrome
22	Monosomy trisomy	Complete trisomy 22 syndrome

## POLYMERASE CHAIN REACTION AND ITS APPLICATIONS

### **Q. Write short essay/note on polymerase chain reaction (PCR).**

Kary Mullis in 1983 discovered polymerase chain reaction (PCR). PCR is a method employed to amplify minute amount of DNA within a few hours. This technique consists of selective amplification of specific target nucleic acid sequences from total DNA by using primers specific for the target region to be amplified.

### **Basic Steps**

- **Denaturation:** In this step, the double-stranded template DNA is

denatured by heat (temperature of around 92–96 °C) into single-stranded DNA.

- **Annealing:** DNA primers of interest are added along with the four basic deoxynucleotides and the solution is cooled. It causes binding of DNA probes to their specific target regions of the single-stranded DNA at a temperature of around 50–65°C.
- **Extension:** The primers are extended at a temperature of around 68–78°C in the presence of DNA polymerase, dNTPs and Mg<sup>2+</sup> ions. The newly synthesized DNA strand acts as a template for the next cycle. This cycle is repeated several times (around 25 to 30 times) and produces millions of copies of the original specific target DNA. To retain the activity of DNA polymerase enzyme at such high denaturation temperature, *Taq* DNA polymerase, extracted from a microorganism (*Thermus aquaticus*) is used in the PCR reaction.

## Applications of PCR

PCR is the starting test used in most of the molecular genetic tests.

- *Diagnosis of hereditary/genetic diseases:* In genetic disorders, genetic mutations can be detected by PCR alone (e.g. Huntington disease), PCR followed by digestion with restriction endonucleases (e.g. diagnosis of spinal muscular atrophy), PCR followed by dot-blot hybridization (e.g. thalassemia mutation detection), PCR followed by capillary electrophoresis for genotyping (e.g. detection of triplet repeat disorders).
- *Sequencing:* It is used as first step for DNA amplification for all methods of DNA sequencing.
- *Detection of pathogens:* To detect small quantities of pathogen DNA (e.g. PCR for *Mycobacterium tuberculosis*), to detect viruses, (including use of reverse transcriptase enzyme for RNA viruses), and real-time PCR (RT-PCR) for quantification of viral load, e.g. hepatitis B and C, human immunodeficiency virus (HIV).
- *Forensic genetics:* To identify DNA sequences that are unique to each individual.

**Reverse transcriptase PCR (RT-PCR):** Initial step is to convert RNA to complementary DNA and rest of the process is same as PCR. It is used to quantify the amount/number of copies of input DNA/RNA.

**Real-time PCR:** This technique, quantifies the PCR product in ‘real-time’. It

is used to quantify the amount/number of copies of input DNA/RNA.

### Immunoblot (Western Blot)

It is a test to detect antibodies. According to molecular weight, the microbial proteins are separated by polyacrylamide gel electrophoresis (PAGE). They are transferred (blotted) on to a nitrocellulose membrane, which is incubated with serum of patient. Binding of specific antibody is detected with an enzyme–anti-immunoglobulin conjugate (similar to in ELISA), and specificity is confirmed by its location on the membrane. The test is a highly specific and can be used to confirm the results of less specific tests such as ELISA.

## INBORN ERRORS OF METABOLISM

### Lysosomal Storage Disorders

#### *Classification of Lysosomal Storage Disorders (Table 19.8)*

**Table 19.8:** Classification of lysosomal storage disorders.

<i>Disorder</i>	<i>Underlying defect</i>
Mucopolysaccharidoses	Defective metabolism of glycosaminoglycans
Sphingolipidoses and sulfatidoses	Defective degradation of sphingolipids and their components
Glycogen storage diseases	Defective degradation of glycogen
Oligosaccharidoses	Defective degradation of the glycan portion of glycoproteins
Mucolipidoses	Defective degradation of acid mucopolysaccharides, sphingolipids and/or glycolipids

#### *Mucopolysaccharidoses (Table 19.9)*

**Table 19.9:** Various types of mucopolysaccharidoses.

<i>Type of disorder</i>	<i>Enzyme deficiency</i>
MPS I Hurler syndrome, Hurler-Scheie syndrome, Scheie syndrome	$\alpha$ -L-iduronidase
MPS II Hunter syndrome	Iduronate 2 sulfatase
MPS III Sanfilippo disease	Heparan N-sulfatase

<ul style="list-style-type: none"> <li>• Type A</li> <li>• Type B</li> <li>• Type C</li> </ul>	$\alpha$ -N-acetylglucosaminidase $\alpha$ -glucosaminide N-acetyltransferase
MPS IV Morquio disease <ul style="list-style-type: none"> <li>• Type A</li> <li>• Type B</li> </ul>	Acetylgalactosamine-6-sulphatase $\beta$ -galactosidase
MPS VI Maroteaux–Lamy disease	Arylsulfatase B
MPS VII Sly disease	$\beta$ -Glucuronidase

## MPS I Hurler Syndrome

- **Head/face:** Prominence of the forehead, broad nose with a flattened nasal bridge enlargement and protrusion of the tongue, chronic hearing loss, corneal clouding, retinal degeneration or glaucoma; tonsillar/adenoidal hypertrophy predispose the child to URI, sleep apnea.
- **Heart:** Cardiomyopathy with asymmetric hypertrophy of the ventricular septum, thickening of the aortic and mitral valves, which progress to valvular insufficiency.
- **Abdomen:** Hepatosplenomegaly results in a protuberant abdomen
- **Neurological:** Mental retardation

## MPS II Hunter Syndrome

- Initial symptoms starts at two to four years of age with progressive growth delays, resulting in short stature.
- **Head/face:** Macrocephaly, delayed tooth eruption, progressive hearing loss, thickening of the lips, tongue, and nostrils.
- **Heart:** Thickening of the heart valves leading to a decline in cardiac function
- **Lungs:** Obstructive airway disease
- **Abdomen:** Hepatosplenomegaly
- **Skeletal:** Short neck and broad chest, joint stiffness, with restriction of movements
- **Neurological:** Hydrocephalus, mental retardation and seizures.

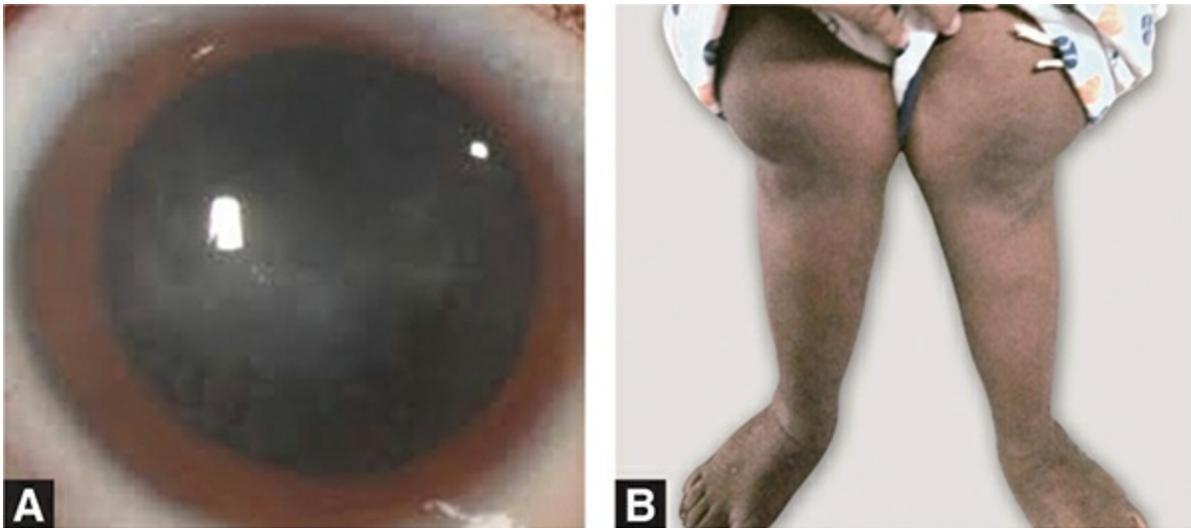

## MPS IV Morquio Syndrome

- Widely spaced teeth, corneal clouding (Fig. 19.10A), hearing loss, enlarged heart

- **Abnormal skeletal development:** Scoliosis, hypermobile joints, large fingers, knock-knees (Fig. 19.10B), short trunk with pectus carinatum, bell-shaped chest (ribs flared), severe growth retardation (82–115 cm), odontoid hypoplasia, compression of spinal cord (cervical myelopathy) and dwarfism.

## Phenylketonuria (PKU)

- Autosomal recessive disease, due to deficiency of enzyme *phenylalanine hydroxylase* with failure to convert phenylalanine to tyrosine.
- Development delay, mental retardation, seizures, eczema, blue eyes, hyperactivity, aggressive behavior, blond hair and musty/mousy odor.

**Figs. 19.10A and B:** (A) Corneal clouding seen in Hurler and Morquio syndrome; (B) Knock knees in Morquio syndrome.

## Galactosemia

Autosomal recessive disease due to deficiency of the enzyme *Galactose 1-phosphate uridyl-transferase*. It is due to ingestion of galactose (lactose).

- Liver failure (hypoglycemia, bilirubinemia), hepatosplenomegaly
- Renal tubular disorder (acidosis, glycosuria, albuminuria)
- Lethargy, feeding intolerance, failure to thrive, cataracts
- Learning disorders in older children—mental retardation
- About 25% will develop sepsis (*E. coli*) in first 1–2 weeks, if untreated → death

# **Immunology**

# CHAPTER 20

## INTRODUCTION

Immune system is defined as the body's defense system that protects against pathogenic microorganisms and noninfectious foreign substances.

Immune system is the third line of defense against infection (Fig. 20.1). Innate and adaptive are the two types of immune response.

### Duality of Immune System

- ***Humoral (antibody-mediated) Immunity***
  - It involves production of antibodies against foreign antigens, by a subset of lymphocytes called B-cells. These B cells are stimulated to form plasma cells and they secrete antibodies.
  - Humoral immunity is involved in defense against bacteria, bacterial toxins, and viruses that circulate freely in body fluids, before they enter cells. They are also responsible for certain reactions against transplanted tissue.
- ***Cell-mediated Immunity***

#### **Q. Write short note on cell-mediated immunity.**

- Involves specialized set of lymphocytes called T-cells that recognize foreign antigens on the surface of cells, organisms, or tissues: Helper T-cells and cytotoxic T-cells
- Defense against:
  - ◆ Bacteria and viruses which lie inside the host cells and are not accessible to antibodies.
  - ◆ Fungi, protozoa, and helminthes, cancer cells, transplanted tissue.

### ***Antigens***

Most of the antigens are proteins or large polysaccharides from a foreign microbes or nonmicrobes.

- **Microbes:** The antigens may be capsules, cell walls, toxins, viral capsids, flagella, etc.
- **Nonmicrobes:** These antigens include pollen, egg white, serum proteins, and surface molecules of red blood cell and transplanted tissue.
  - Lipids and nucleic acids become antigen only when combined with proteins or polysaccharides.

### ***Hapten***

These are small foreign molecule which are not antigenic by themselves. They become antigenic when coupled to a carrier molecule. Once antibodies are formed they will recognize hapten.

### ***Epitope***

Epitope represents a small part of an antigen that interacts with an antibody. Each antigen may have one to several epitopes. Each epitope is recognized by a different antibody.

Nonspecific defense mechanisms		Specific defense mechanisms (immune system)
First line of defense	Second line of defense	Third line of defense
<ul style="list-style-type: none"> <li>• Skin</li> <li>• Mucous membranes</li> <li>• Secretions of skin and mucous membranes</li> </ul>	<ul style="list-style-type: none"> <li>• Phagocytic white blood cells</li> <li>• Antimicrobial proteins</li> <li>• The inflammatory response</li> </ul>	<ul style="list-style-type: none"> <li>• Lymphocytes</li> <li>• Antibodies</li> </ul>

**Fig. 20.1:** Nonspecific and specific defense mechanisms.

### ***Antibodies***

**Q. Briefly discuss immunoglobulins and its functions.**

- Antibodies (immunoglobulins) are proteins which recognize and bind to a particular antigen with very high specificity.
- These are produced in response to exposure to the antigen.
- One virus or microbe may have several antigenic determinant sites. Each site may bind to different antibodies.

- Each antibody possess at least two identical sites which bind antigen. These sites are called as antigen binding sites.
- Valence of an antibody: It is the number of antigen binding sites in antibody and most antibodies are bivalent.

### ***Antibody structure***

- **Monomer:** It is an antibody molecule having a flexible Y-shape with four protein chains, i.e. 2 identical light chains and 2 identical heavy chains.
- **Variable regions:** These are two sections at the end of Y's arms. They contain the antigen binding sites (Fab). They are identical on the same antibody, but vary from one antibody to another.
- **Constant regions:** They represent the stem of monomer and lower parts of Y arms.
  - **Fc region:** They are regions on the stem of monomer and are important because they can bind to complement or cells.
  - **Fab region:** For antigen binding.

### *Immunoglobulin classes (Table 20.1)*

#### *Functions of immunoglobulins/antibodies*

- **Acts as opsonins:** Immunoglobulins coat bacterial surface and act as opsonins. This facilitates phagocytosis by cells possessing Fc receptor (e.g. neutrophils).
- **Antibody-dependent cell-mediated cytotoxicity (ADCC):** In this, antibodies bind to microbes via their Fab region. Cytotoxic NK cells attach via Fc receptors and kill these organisms by release of toxic substances called perforins.
- **Activation of complement system:** Binding of antibodies to antigen can trigger activation of the classical complement pathway. Complement components can function as opsonins (C3b component and aid in phagocytosis), chemotaxis (recruitment of leukocytes by C3a and C5a) and cause death of microbes (by MAC-membrane attack complex C5-9).
- **Neutralization:** Some antibodies may directly neutralize the biological activity of their antigen target or toxins released by bacteria. This is an important feature of IgA antibodies at mucosal surfaces.
- **Processing of antigen:** Antibodies present on B lymphocytes helps in

internalization of antigen and further processing it for presentation to other cells.

- **Agglutination:** Antibodies (e.g. IgM) help in agglutination of particulate matter including bacteria and viruses.
- **Immobilization of microbes:** Antibodies against bacterial cilia or flagellae may immobilize their movement and ability to escape the phagocytosis.
- **Protection of mucosal surface:** This is observed with IgA type of antibodies.
- **Immune-complex formation:** Antibodies combine with antigen to form immune complexes. The size of immune complexes vary depending upon the ratio between antigen and antibody. Larger immune complexes can be removed by the phagocytic cells in the reticuloendothelial (RE) system.
- **Transplacental passage:** Maternal antibodies can pass through placenta from mother to fetus conferring immunity to the fetus.

**Table 20.1:** Features of immunoglobulin classes.

<i>Features</i>	<i>IgG</i>	<i>IgM</i>	<i>IgA</i>	<i>IgD</i>	<i>IgE</i>
Structure	Monomer	Pentamer, hexamer	Dimer	Monomer	Monomer
Subtypes	G1, G2, G3, G4	Other chains : J chain	A1, A2		
Percentage serum antibodies	75—85% (IgG1=45–53%, IgG2=11-15%)	5–10%	7–15%, (IgA1=11–14% IgA2 =1–4%)	0.04 %	0.003%
Location	Blood, lymph, intestine	Blood, lymph, B cell surface (monomer)	Secretions (tears, saliva, intestine, milk), blood and lymph	B-cell surface, blood, and lymph	Bound to mast cells and basophils throughout body
Half-life in serum	23 days	5 days	6 days	3 days	2.5 days
Complement fixation	Yes (classical, alternate)	Yes (classical )	No	Alternate pathway	No
Placental transfer	Yes	No	No	No	No

neutralizes toxins and viruses, protects fetus and newborn	infection. Effective against microbes and agglutinating antigens	of mucosal surfaces. Provides immunity to infant digestive tract	unknown. On B-cell surface, initiate immune response. Marker of mature B-cell	and antiparasitic action
--	--	--	---	--------------------------

## CYTOKINES

### Q. Write a short note on cytokines.

The immune response involves multiple interactions among many cells. These cells are lymphocytes, dendritic cells, macrophages, other inflammatory cells (e.g. neutrophils), and endothelial cells. Few of these interactions are cell-to-cell contact. However, many interactions and effector functions of leukocytes are mediated by short-acting soluble proteins, multipurpose chemical messengers called **cytokines**. Cytokines which mediate communications between leukocytes are called **interleukins**.

- **Mode of action:** Cytokines exert their effect by binding to specific receptors on target cells. They may act by three ways.
  - Autocrine when the cytokines act on the same cells which secretes them.
  - Paracrine when cytokines are produced by one cell type which acts on adjacent/nearby target cells.
  - Endocrine when the cytokine secreted into the circulation act on target cells at a site distant from their site of synthesis.

#### Interleukins:

- They are produced by and signal between white cells which mediate endocrine communication at a site distant from their site of synthesis.
- **Source:** Activated macrophages.
- **Effects:** Fever, bone marrow release of neutrophils into circulation (leukocytosis), B-cell proliferation, antibody production, and production of IL-2 by T-cells. Interleukin-2 (IL-2) stimulates the proliferation of activated B-cells, T-cells and NK cells.

#### Tumor necrosis factor- $\alpha$ :

- **Source:** TNF- $\alpha$  is produced by activated macrophages in response to infection by bacteria and other microbes.
- **Effects:** Fever, cachexia (pathologic state characterized by weight loss and anorexia seen in neoplastic diseases and some chronic infections) anorexia, shock, enhanced leukocyte cytotoxicity, enhanced NK-cell function, acute phase protein synthesis, proinflammatory cytokine induction, increases apoptosis and expression of cytokines and adhesion molecules.

## Interferons

### Q. Write short note on interferons.

- They are critical cytokines that play a key role in defense against viral infections and other intracellular microbes (e.g. *Toxoplasma gondii*). This group includes interferon- $\alpha$  (IFN- $\alpha$ ), interferon- $\beta$  (IFN- $\beta$ ) and interferon- $\gamma$  (IFN- $\gamma$ ).
- **Source:**
  - Produced by a wide range of cells when attacked by viruses and other non-self-pathogenic antigens.
  - IFN- $\gamma$  is mostly released by T cells and NK cells.

## Erythrocyte Sedimentation Rate (ESR)

### Q. Write a short note an erythrocyte sedimentation rate.

- It is the rate at which RBCs settle down when anticoagulated whole blood is allowed to stand.
- RBCs have net negative charge on their surface and do not aggregate but tend to repel each other. Plasma proteins have positive charge and neutralize the surface negative charge called Zeta potential of red cells.

### ***Factors Affecting ESR***

**Plasma factors:** Increase in plasma proteins (especially fibrinogen), reduces the repulsive forces of red blood cells and cause them to stack together like tyres, or rouleaux. Rouleaux have more mass/surface area ratio than single red cells, and therefore sediment faster and increase the ESR.

- An accelerated ESR is favored by elevated levels of fibrinogen, globulins and cholesterol (which increase the positive charge of plasma) whereas

albumin and lecithin retard ESR.

- Elevated fibrinogen and raised ESR is also observed in pregnancy, old age, end-stage renal disease.
- In acute inflammation ESR and acute phase reactants are raised.
- ESR is increased in conditions associated with monoclonal (multiple myeloma) or polyclonal (chronic infections like tuberculosis) increase in immunoglobulins. In systemic lupus erythematosus (SLE) ESR is raised but CRP may be normal.

**Red cell factors:** The sedimentation rate is directly proportional to the weight of the cell aggregates and inversely proportional to the surface area. ESR may be low if plasma proteins are low or red cell morphology is abnormal making rouleaux formation impossible.

- Anemia increases the ESR and polycythemia decreases.
- Microcytes sediment slower than macrocytes.
- Red cells with an abnormal or irregular shape, such as sickle cells or spherocytes, do not exhibit rouleaux formation and have low ESR.

**Normal range:** For men 1–10 mm 1st hour and for women 5–20 mm 1st hour.

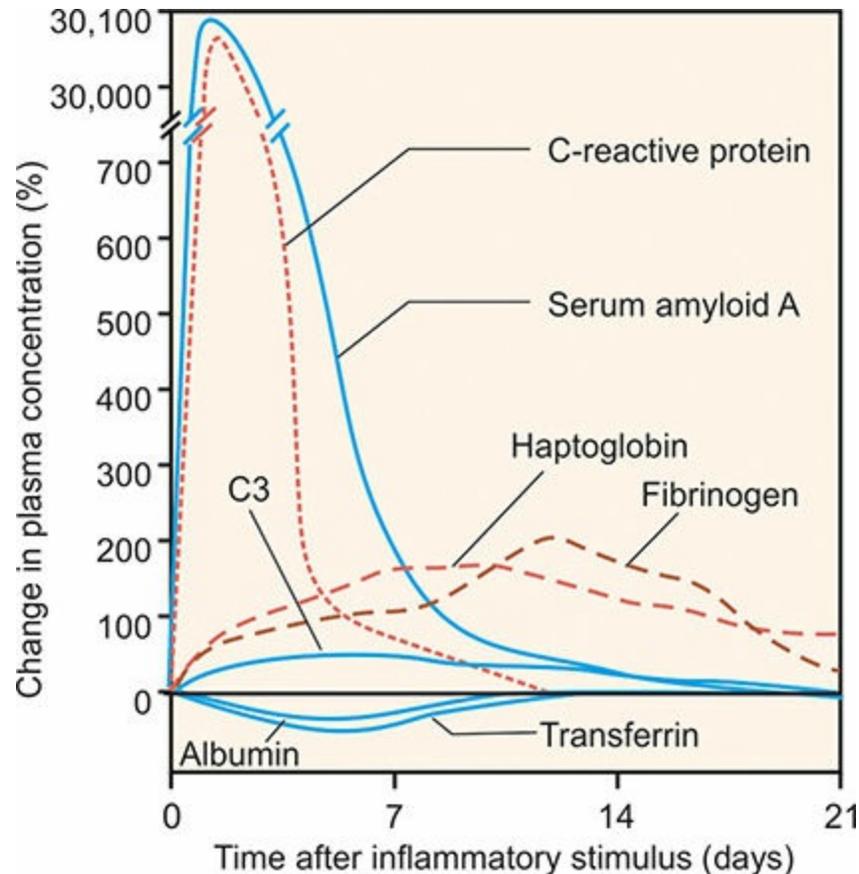

Fig. 20.2: Various acute phase reactants and their levels in inflammation.

## Acute Phase Reactants (Fig. 20.2)

### Q. Write short notes on acute phase reactants.

Acute phase proteins are produced by liver in response to inflammatory stimuli. They have a wide range of activities.

- **C-reactive protein:** C-reactive protein (CRP) plays an important role in host defense and stimulates repair and regeneration. C-reactive protein is an acute phase reactant produced in the liver.
  - It opsonizes invading pathogens.
  - CRP increase (may be up to 1000-fold) within 6 hours of acute inflammation. Levels fall within a few days after the inflammation subsides. Sequential measurement of CRP is useful in monitoring disease activity.
  - In some inflammatory diseases there may be normal or slight elevations of CRP concentration despite unequivocal evidence of active

inflammation. These include SLE, systemic sclerosis, ulcerative colitis and leukemia. However, existing infection in these conditions is associated with significantly raised levels of CRP.

- It is to be noted that intercurrent infection does not cause a significant CRP response in these conditions.
- **Serum amyloid A** plays a role in host defense and stimulates repair and regeneration. In chronic inflammation, it may contribute to the development of amyloidosis.
- **Fibrinogen** plays an essential role in wound healing.
- **$\alpha_1$ -antitrypsin and  $\alpha_1$ -antichymotrypsin:** They control inflammation by neutralizing the enzymes produced by activated neutrophils and prevent tissue destruction.
- Antioxidants such as haptoglobin and manganese superoxide dismutase scavenge for oxygen free radicals.

## COMPLEMENT SYSTEM

**Q. Write a short note on the complement system.**

- The complement system is a group of plasma proteins ( $\beta$  globulins) major source being the liver. C1q produced mainly by bone marrow derived cells like macrophages and dendritic cells.
- They are proteases and are important in both inflammation and immunity.

### Pathways of Complement System Activation (Fig. 20.3)

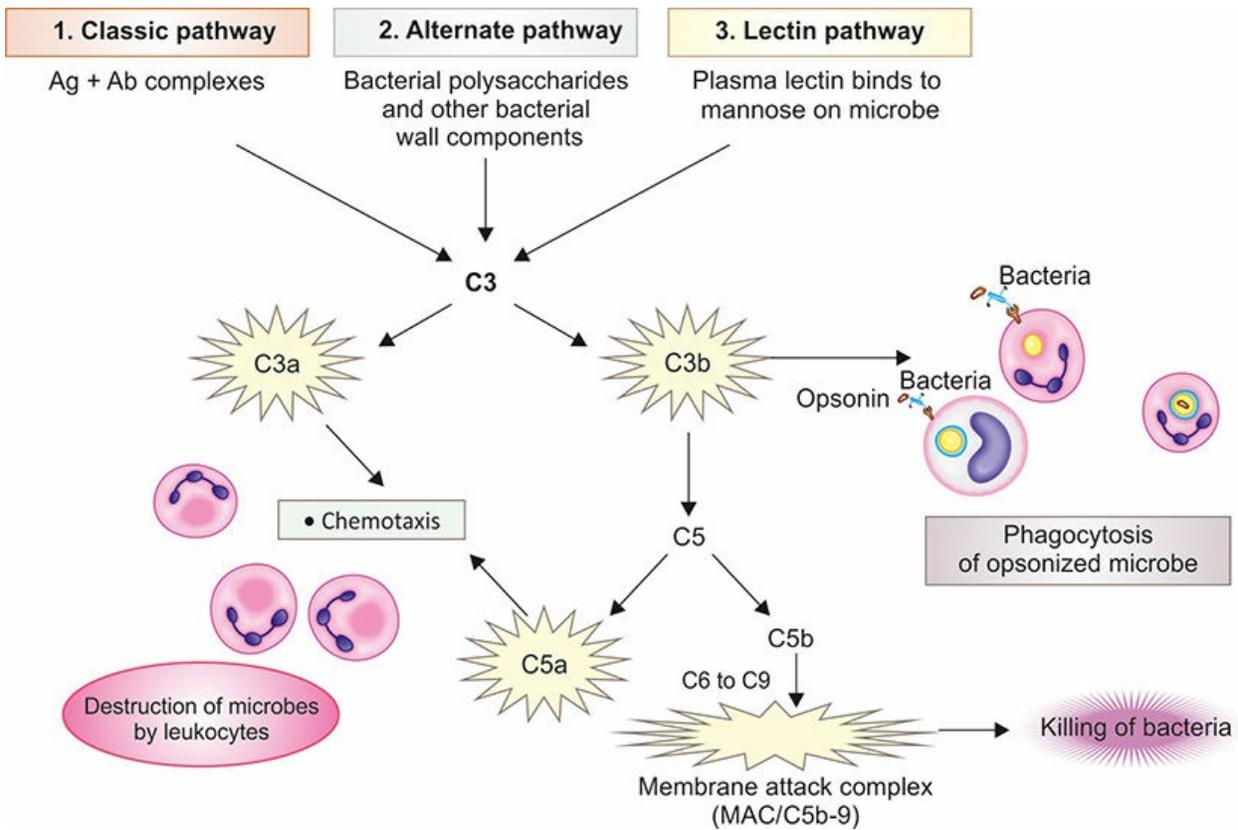

The decisive step in complement activation is the proteolysis of the third component, C3. Cleavage of C3 can occur by any one of three pathways:

- **Classical pathway:** It is activated by **antigen-antibody** (Ag-Ab) complexes in which C1 binds to antibody (IgM or IgG), acute phase proteins, charged molecules, and apoptotic or necrotic cell debris.
- **Alternative pathway:** This pathway is antibody-independent.
  - It is activated by binding of C3 directly to microbial surface molecules [e.g. endotoxin, or lipopolysaccharides (LPS)], complex polysaccharides, cobra venom, and ‘altered self’ such as tumor cells, **in the absence of antibody**. They **cleave C3 to C3b**.
  - **C3b** in the presence of **factors B and D** generates **C3bBb** (alternative

pathway C3 convertase).

- **C3bBb is labile** and **degraded by factors I and H**, but **stabilized by properdin** and can subsequently activate C3.
- This results in persistent and prolonged C3 activation and hypocomplementemia. In addition, decreased synthesis of C3 by the liver, is also responsible for hypocomplementemia.

- **Lectin pathway:** It directly activates C1 when plasma mannose-binding lectin (MBL) binds to mannose on microbes.

**Fig. 20.3:** Different pathways of activation and functions of the complement system. All pathways of activation lead to cleavage of C3.

## Complement System and Disease (Table 20.2)

**Table 20.2:** Genetic deficiencies of plasma complement components and associated clinical findings.

Deficiency	Infection	Autoimmune disease
<b>Classical Pathway</b>		
C1q	Pneumococcal B/M, Other pyogenic	SLE, GN, DV/DLE

C1rs	Other pyogenic Pneumococcal B/M, DGI	SLE GN
C4	Other pyogenic	SLE, GN, Other AD
C2	Other pyogenic, pneumococcal B/M, meningococcal M	SLE, GN, DV/DLE, Other AD
C3	Other pyogenic Pneumococcal B/M, meningococcal M	GN, DV/DLE, SLE, Other AD
C5, C6, C7, C8, C9	Meningococcal M, DGI, Other pyogenic	SLE, GN Other AD
<b>Lectin Pathway</b>		
MBL	Other pyogenic, fungal, HIV	SLE
MASP-2	Pneumococcal pneumonia	SLE
<b>Alternative Pathway</b>		
Factor D	DGI, meningococcal M, Other pyogenic	
<b>Control Proteins</b>		
C1 INH	Hereditary angioedema	SLE
Factor I	Other pyogenic, Meningococcal M Pneumococcal B/M	
Factor H	Meningococcal B/M, Other pyogenic	GN, HUS, SLE
Properdin	Meningococcal M, Pneumococcal B/M, Other pyogenic	DV/DLE
C4-binding protein		Other AD

(B/M: bacteremia or meningitis; DGI: disseminated gonococcal infection; DV/DLE: dermal vasculitis or typical discoid lupus erythematosus; GN: glomerulonephritis in various forms, often membranoproliferative; HIV: human immunodeficiency virus; HUS: hemolytic-uremic syndrome; M: meningitis; MASP: MBL-associated serine protease; MBL: mannose-binding lectin; other AD: autoimmune disease (almost all possible diagnoses have been reported); other pyogenic: serious deep or systemic infection due to, or typically caused by, a pyogenic bacterium (abscess, osteomyelitis, pneumonia, bacteremia other than pneumococcal, meningitis other than meningococcal or pneumococcal, cellulitis, myopericarditis, and peritonitis); SLE: typical systemic lupus erythematosus or an SLE-like syndrome without characteristic serologic findings).

## Major Histocompatibility Complex (MHC)

**Q. Write short note on HLA system/major histocompatibility complex**

## (MHC).

All human cells express a series of molecules on their surfaces that are recognized by other individuals as foreign antigens. It was found that major histocompatibility antigens are the important antigens involved in the rejection of transplanted organs. These antigens are encoded by a segment of **chromosome 6 (6p21.3)** known as the major histocompatibility complex.

### *Significance of MHC/HLA System*

**Q. Write short note on HLA associated diseases. List diseases associated with HLA-B27.**

- **In transplantation:** HLA typing is prerequisite in selecting appropriate donor and recipient combinations for transplantation.
- **Regulations of cell-to-cell interaction:** During immune response (immune response genes).
- Defense against viral infections.
- **HLA and disease association (Table 20.3):** HLA alleles confer a state of susceptibility, or risk, for disease. Many diseases are known to be associated with certain HLA alleles. The diseases associated with the HLA locus can be broadly categorized as mentioned in Table 20.3.

**Table 20.3:** Diseases showing positive HLA antigen association.

<i>System</i>	<i>Disease</i>	<i>HLA antigen</i>	<i>Relative risk</i>
<i>Rheumatologic</i>	• Ankylosing spondylitis	B27	90.0

## IMMUNODEFICIENCY

Immunodeficiency may be primary or secondary.

### Primary Immunodeficiency Diseases (Box 20.1)

#### *Classification of Primary Immunodeficiency Diseases*

**Q. Classify primary immunodeficiency disorders.**

Primary immunodeficiency diseases (PIDs) are classified into eight major categories according to the component of the immune system primarily involved (Box 20.1). Common components, their frequency, and their susceptibility in primary immunodeficiency are presented in Table 20.4.

**Box 20.1:** Classification of primary immunodeficiency diseases.

- Combined T-cell and B-cell immunodeficiencies
- Predominantly antibody deficiencies
- Other well defined immunodeficiency syndromes
- Diseases of immune dysregulation
- Congenital defects of phagocyte number and function
- Defects in innate immunity
- Autoinflammatory disorders
- Complement deficiencies

**Table 20.4:** Common components, their frequency, and their susceptibility in primary immunodeficiency.

<i>Class (Deficiency)</i>	<i>Relative frequency</i>	<i>Susceptibility</i>	<i>Treatment</i>
B lymphocytes	50%	Bacterial infections	Immunoglobulin injection
Combined B and T T lymphocytes	20% 10%	Viral, bacterial, fungal and protozoal	Bone marrow transplant
Phagocytes	18%	Bacterial infections	Antibiotics and cytokines
Complement	2%	Bacterial infections and autoimmunity	Infusion of complement components

**Warning Signs for Suspicion of Primary Immunodeficiency Disorders (Table 20.5)**

**Table 20.5:** Warning signs for suspicion of primary immunodeficiency disorders (PID).

- |   |   |
|---|---|
| <ul style="list-style-type: none"> <li>• Four or more new ear infections within 1 year</li> <li>• Two or more serious sinus infections within 1 year</li> <li>• Two or more months on antibiotics with little effect</li> <li>• Two or more pneumonias within 1 year</li> <li>• Failure of an infant to gain weight or grow normally</li> </ul> | <ul style="list-style-type: none"> <li>• Recurrent, deep skin or organ abscesses</li> <li>• Persistent thrush in mouth or fungal infection on skin</li> <li>• Need for intravenous antibiotics to clear infections</li> <li>• Two or more deep-seated infections including septicemia</li> <li>• A family history of PID</li> </ul> |
|---|---|

## Box 20.2: Main types of antibody deficiencies

- X-linked and autosomal recessive agammaglobulinemia
- Common variable immunodeficiency
- IgA deficiency
- IgG subclass deficiency
- Transient hypogammaglobulinemia of infancy
- Selective antibody deficiency
- Associated to other immunodeficiencies (Job syndrome, hyper-IgM)

## Antibody Deficiencies

### Q. Write short note on B-cell (antibody) immunodeficiency disorders.

- Constitute 70% of PIDs.
- Recurrent pyogenic infections starting after 6–12 months. Main types of antibody deficiencies are listed in Box 20.2

### X-linked agammaglobulinemia (XLA) (Bruton agammaglobulinemia)

#### Q. Write short note on XLA (X-linked agammaglobulinemia).

- Described as the ‘prototypical antibody deficiency’ and is the first immunodeficiency described.
- **Bruton tyrosine kinase** (*Btk*) is necessary for the growth and the maturation of B-cell precursors.
- **Xq21.3-22** (> 300 mutations).
- **B-lymphocytes are decreased**, <1% CD19 or CD20-positive lymphocytes.
- Tonsils are small, no palpable lymph node.
- **Autosomal recessive transmission** due to mutation in the genes of the surface bound  $\mu$  heavy chain,  $\lambda 5$  and  $Ig\alpha$ .

#### Clinical features: Little Boys With Big Infections!

- Symptoms appear at 6–9 months of age (after loss of maternal Ig).
- **Sites of infection:** Mucous membranes, ear (otitis media), lungs (bronchitis/pneumonia), blood (sepsis), gut (giardia, or enterovirus), skin, eyes, meningitis.
- Typical bacterial infections include *Haemophilus influenzae* and

*Streptococcus pneumoniae*.

- Also seen: Neutropenia, malignancy in older patients, renal and joint involvements.

Prevention of infections in patients with PID involves avoidance measures, vaccination, prophylactic antibiotics, immune globulin therapy.

## **Common Variable Immunodeficiency (CVID)**

**Q. Write short note on common variable immunodeficiency (CVID).**

- Diagnosis depends on the exclusion of other causes of antibody deficiencies.
- Incidence: 1/10 000-1/50 000 (second or third decade).
- Decrease in IgG, A +/-M. B-Cells are normal or decreased.

### *Clinical features*

- CVID has a tendency to autoantibody formation.
- Chronic pulmonary infections, chronic giardiasis, intestinal malabsorption, atrophic gastritis and pernicious anemia.
- T-cell immunity may be deficient
- Increased risk of lymphoreticular and gastrointestinal malignancies.

## **IgA Deficiency**

- Incidence: 1/700 Caucasians but symptoms in < 33%.
- Presents with recurrent respiratory infections and chronic diarrhea. Associated conditions with IgA deficiency are listed in Box 20.3

## **IgG subclass deficiencies**

- Normal total serum IgG levels with subnormal levels of one or more IgG subclasses.
- Mutations in heavy chain genes on 14q32.3 ( $\gamma$ 1, 2, 3, 4).
- IgG1: Lead to a decrease in total serum IgG.
- IgG2: Most common IgG subclass deficient in children. Frequently associated with poor response to polysaccharide antigens and IgA deficiency.
- IgG3: Most common IgG subclass deficient in adults.
- IgG4: Levels vary widely in normal people.

### **Transient hypogammaglobulinemia of infancy**

- Decrease of the maternal IgG transferred to the fetus during pregnancy but delayed Ig production (IgM, IgG, and IgA).
- Normal range after 36 months.
- Normal response to vaccination.

### **Selective antibody deficiencies**

- Normal total serum levels of IgG and IgM but failure to respond to certain antigens (polysaccharide antigens).
- Asymptomatic or recurrent sinopulmonary infections.
- Found in sickle cell anemia, asplenia, Wiskott-Aldrich syndrome and DiGeorge syndrome.

### **Hyper-IgM syndrome**

- Deficit in IgM: IgG switch. IgM ↑ but IgG and IgA ↓.
- The most frequent deficit concerns CD154 on CD4<sup>+</sup> T-cell (Xq26.3-27.1).

### **The hyper-IgE syndrome (Job syndrome)**

- Recurrent abscesses, eczema, dysmorphism, eosinophilia and high serum levels of IgE.
- Autosomal dominant and sporadic cases.

### **Box 20.3:** associated conditions with IgA deficiency.

- CVID (common variable immunodeficiency)
- Deficit in IgG2 (IgG4, E) and poor response to polysaccharide antigens
- Ataxia-telangiectasia
- Risk of asthma and autoimmune diseases (RA, vitiligo, thyroiditis)
- Auto and allo anti IgA antibodies (IVIG!).

### **Box 20.4:** T-cell (cell mediated) immunodeficiency disorders.

- DiGeorge syndrome
- Defect in CD3/TCR
- Defect in signaling
- Defect in cytokine production as IL-2 and IFN gamma.
- Defect in cytokine response

### **Box 20.5:** Combined immunodeficiency disorders.

- Severe combined immunodeficiency (SCID)

- Omenn syndrome
- ADA (adenosine deaminase deficiency)
- Ataxia-telangiectasia syndrome (AT)
- Wiskott-Aldrich syndrome (WAS)
- EBV associated immunodeficiency (Duncan's syndrome)

## ***Cell Mediated (T-cell) Immunodeficiency (Box 20.4)***

**Q. Write short notes on T-cell (cell mediated) immunodeficiency disorders.**

## ***Combined Immunodeficiencies (Box 20.5)***

### **Severe combined immunodeficiency (SCID)**

**Q. Write short note on severe combined immunodeficiency (SCID).**

- Failure to thrive.
- Onset of infections in the neonatal period.
- Opportunistic infections, chronic or recurrent thrush, chronic rashes, chronic or recurrent diarrhea.
- Lack of lymphoid tissue including thymus, tonsils and lymph nodes.
- Characteristic abnormality in ADA deficient SCID includes cupping at the end of the ribs demonstrated on a chest radiograph and an absent thymic shadow.
- Common *Pneumocystis jirovecii* infection, or persistent oral or diaper candidiasis.

#### **Treatment**

- Pneumocystis prophylaxis with trimethoprim-sulfamethoxazole
- Replacement IgG therapy. Enzyme replacement therapy (e.g. polyethylene glycol-adenosine deaminase [PEG-ADA]).
- Patients should only be transfused with irradiated blood products and should not receive any live vaccines.

Features of DiGeorge syndrome (congenital thymic aplasia) are mentioned in Box 20.6).

**ADA (adenosine deaminase deficiency) SCID:** The most profound lymphopenia ( $<500/\text{mm}^3$ ); skeletal abnormalities, including chondro-osseous dysplasia (flared costochondral junctions and bone-in-bone anomalies in

vertebrae); and deficiency of all types of lymphocytes.

### **Box 20.6:** DiGeorge syndrome (congenital thymic aplasia)

- Defective development in thymus and parathyroid that develop from third and fourth pharyngeal pouch.
- Thymic hypoplasia leading to variable immunodeficiency.
- Characteristic facies. Deletion in 22q11 in > 80%.
- **Acronym -- CATCH 22**
  - Cardiac abnormality (commonly interrupted aortic arch, truncus arteriosus and tetralogy of Fallot)
  - Abnormal facies
  - Thymic aplasia
  - Cleft palate
  - Hypocalcemia/hypoparathyroidism

**Omenn syndrome** is a rare autosomal recessive disease usually presenting in neonatal period, characterized by symptoms of SCID associated with other findings like erythroderma, lymphadenopathy, hepatosplenomegaly and eosinophilia.

### **Wiskott-Aldrich syndrome (WAS)**

#### **Q. Write short note on Wiskott Aldrich syndrome.**

- X-linked recessive disease.
- Immunodeficiency, microplatelet thrombocytopenia, and eczema.
- Mutations of the gene encoding WASP at X11p.
- **Low IgM, normal IgA and IgG and high IgE.**

### ***Ataxia-Telangiectasia***

#### **Q. Write short note on ataxia telangiectasia.**

- Autosomal recessive
- Progressive cerebellar ataxia, abnormal eye movements, oculocutaneous telangiectasias, and immune deficiency. Also characterized by recurrent sinopulmonary infections, bronchiectasis and Interstitial lung disease.
- Vascular malformations (telangiectasia), neurologic defects, tumors and ID.
- IgA and IgG2 deficiency
- T-cell function is variably depressed

- Gene responsible on chromosome 11q22.3
- Increased serum alfa feto protein is diagnostic
- Prone for various malignancies (lymphomas, breast cancer and acute leukemias).

## Diseases of Immune Dysregulation

Four groups of diseases are included in this category.

1. Familial hemophagocytic lymphohistiocytosis (FHL) that includes perforin deficiency. HLH secondary to autoimmune diseases is called Macrophage Activation Syndrome.
2. UNC13D (Munc13-4) deficiency
3. Syntaxin 11 deficiency and STXBP2 (Munc18-2) deficiency
4. Autoimmune lymphoproliferative syndrome (ALPS)

### ***Diagnostic Criteria for HLH Proposed by Histiocyte Society (HLH-2004 trial)***

#### **Q. List the diagnostic criteria for hemophagocytic lymphohistiocytosis (HLH).**

Molecular identification of an HLH-associated gene mutation (e.g. PRF1, UNC13D, STX11, STXBP2, Rab27A, SH2D1A, BIRC4, LYST, ITK, SLC7A7, XMEN, HPS). Children require documentation of homozygosity or compound heterozygosity for HLH-associated gene mutations. By comparison, heterozygosity may be sufficient for adults if they have clinical findings associated with HLH.

OR

Five of the following eight findings:

1. Fever  $\geq 38.5^{\circ}\text{C}$
2. Splenomegaly
3. Peripheral blood cytopenia, with at least two of the following: hemoglobin  $< 9$  g/dL (for infants  $< 4$  weeks, hemoglobin  $< 10$  g/dL); platelets  $< 100,000/\text{microL}$ ; absolute neutrophil count  $< 1000/\text{microL}$ .
4. Hypertriglyceridemia (fasting triglycerides  $> 265$  mg/dL) and/or hypofibrinogenemia (fibrinogen  $< 150$  mg/dL)
5. Hemophagocytosis in bone marrow, spleen, lymph node, or liver.
6. Low or absent NK cell activity.
7. Ferritin  $> 500$  ng/mL (the author prefers to consider a ferritin  $\geq 3000$  ng/mL is more indicative of HLH).
8. Elevated soluble CD25 (soluble IL-2 receptor alpha) two standard deviations above age-adjusted laboratory-specific norms.

## HYPERSENSITIVITY REACTIONS

### **Q. What are the different types of immune reactions?**

Immunologically mediated reactions (hypersensitivity reactions) that may produce in tissue damage are summarized in Figure 20.4 and Table 20.6.

### Urticaria ('Hives')

#### **Q. Write short essay/note on urticaria or hives or nettle rash.**

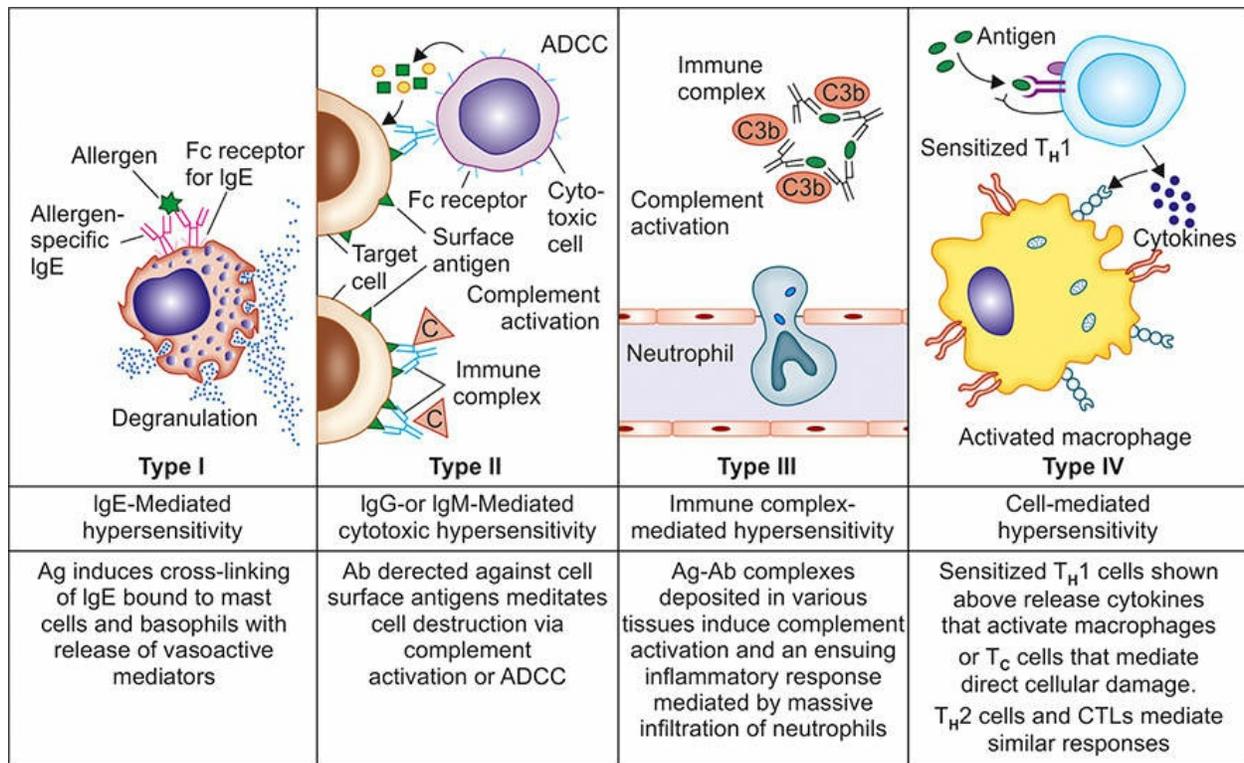

- Urticaria (also known as hives) is produced due to localized edema of dermis secondary to a temporary increase in capillary permeability. The term angioedema is used if edema involves subcutaneous or submucosal layers. Classification (causes) of urticaria and/or angioedema is presented in Table 20.7.

### *Etiology and Pathogenesis (Fig. 20.5)*

#### **Q. Write short answer on causes of urticaria.**

**Types:** Acute urticaria is the presence of urticaria for less than 6 weeks and chronic if it persists for more than 6 weeks.

- Urticaria may be brought out by either immunologic or non-immunologic mechanisms (Table 20.7). Urticaria is triggered by a wide variety of antigens or by physical stimuli, including cold, pressure, and sunlight. They produce local degranulation of mast cells by various mechanism such as (1) type I hypersensitivity, (2) spontaneous mast cell degranulation (chronic urticarial), (3) chemical mast cell degranulation, (4) autoimmunity (chronic urticaria).

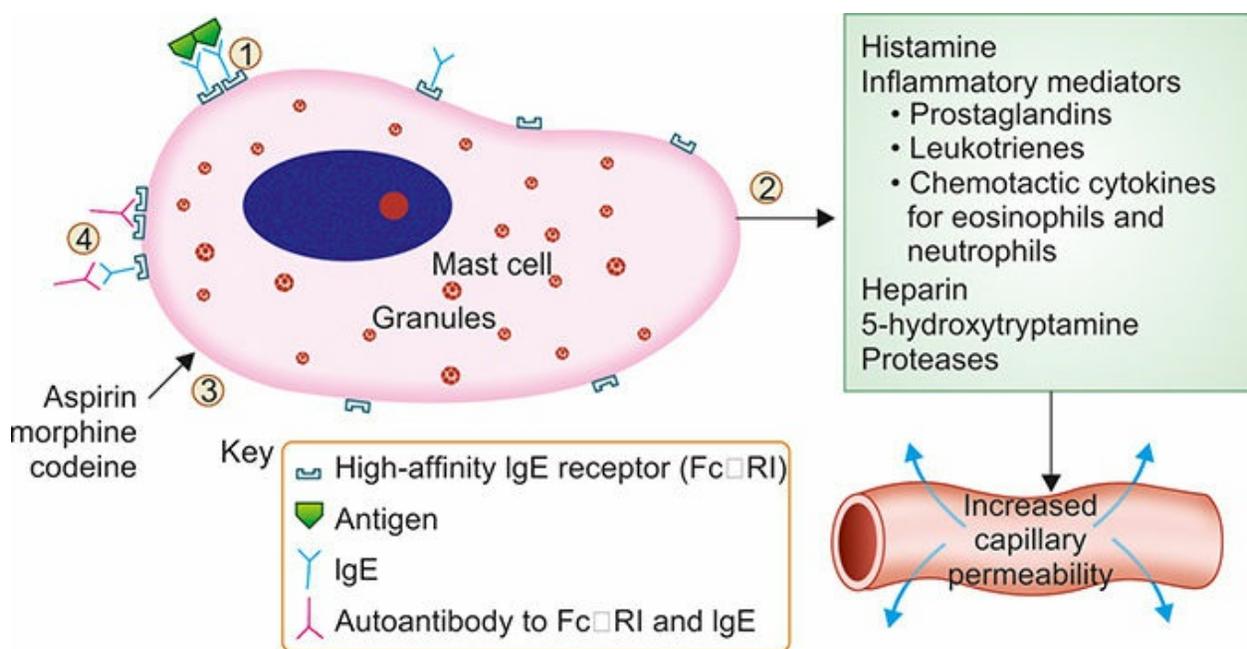

**Fig. 20.4:** Features of hypersensitivity reactions (Gell and Coomb's classification).

**Table 20.6:** Characteristic features of hypersensitivity reactions.

Type	I (immediate)	II (cytotoxic)	III (immune complex)	IV (cell-mediated)
Antigens	Pollens, moulds, mites, food drugs and parasites	Cell surface or tissue bound	Exogenous (virus, fungi, parasites) Autoantigens	
Mediators	IgE and mast cells	IgG, IgM and complement	IgG, IgM, IgA and complement	
Time taken for reaction to develop	5–10 minutes	6–36 hours	4–12 hours	
Pathological feature	Edema, vasodilatation, mast cell degranulation, eosinophils	• Antibody-mediated damage to target cells	Acute inflammatory response (neutrophils), vasculitis	
Prototype disorder/diseases produced	• Asthma (extrinsic) • Anaphylaxis (systemic and localized) • Urticaria, eczema	• Autoimmune hemolytic anemia, transfusion reactions, hemolytic disease of newborn • Goodpasture's syndrome	Autoimmune disease (glomerulonephritis, arthritis) Serum sickness, A	

	<ul style="list-style-type: none"> <li>• Angioedema</li> <li>• Allergic rhinitis</li> <li>• Food allergies</li> </ul>	<ul style="list-style-type: none"> <li>• Pernicious anemia</li> <li>• Myasthenia gravis</li> </ul>	
Diagnostic tests	<ul style="list-style-type: none"> <li>• Skin-prick tests</li> <li>• Specific IgE in serum</li> </ul>	<ul style="list-style-type: none"> <li>• Coombs' test</li> <li>• Indirect immunofluorescence</li> </ul>	Immune complex levels

<b>Idiopathic</b>	<b>Drugs:</b> Salicylates, opiates, NSAIDs, antibiotics

## ***Clinical Manifestation***

- Urticaria is common and can be seen in persons of all ages.
- Urticarial eruptions may involve any area of the body from the scalp to the soles of the feet.
- Urticarial lesions represent local area of edema involving only the superficial portions of the dermis. On certain body sites (e.g. the lips, hands), the edema spreads deeper into subcutaneous tissue and is referred to as angioedema.
- They are well-circumscribed wheals, pink to light red in color, with erythematous raised serpiginous borders blanching center. Size of the lesions vary from one millimeter to several centimeters.
- Almost always pruritic and individual wheals come and go within 24 hours and those lesions lasting up to 6 weeks are called as acute urticaria. If the urticaria recurs over a period of 6 weeks or more it is known as chronic urticaria.
- When individual lesions last more than 36 to 48 hours and leave post-inflammatory hyperpigmentation or palpable purpura, it is called as urticarial vasculitis.
- Urticaria may be associated with headache, dizziness, nausea, vomiting, abdominal pain, diarrhea and arthralgias.

## **Management**

- Management of urticaria depends on its severity and the duration.
- Mild urticaria limited to the skin: Antihistamines (diphenhydramine) or the newer nonsedating agents (terfenadine, cetirizine, loratadine).
- Severe urticaria: Short-term corticosteroids (up to 1 mg/kg).
- Chronic urticaria: Finding the cause and remove the causative antigen. Antihistamines and cyclosporine at doses of 3 mg/kg or higher for 8 to 16 weeks may be beneficial.

## Allergy

### **Q. Define allergy. List atopic disorders.**

- Allergy is defined as a hypersensitivity reaction induced by exposure to an otherwise harmless exogenous substance (known as an allergen), generally environmental.
- In an allergic reaction, initial exposure to allergen triggers the production of specific IgE antibodies by activated B-cells. These IgE antibodies bind to the surface of mast cells via high-affinity IgE receptors.
- The first dose of allergen (priming dose) which sensitizes the immunologic system (B lymphocyte). On re-exposure, the allergen (shocking dose) binds to membrane-bound IgE which activates the mast cells, releasing vasoactive mediators (the early phase response) and causing a type I hypersensitivity reaction and the symptoms of allergy. This may be followed by late phase reaction and is mediated by basophils, eosinophils and macrophages.
- Examples: Asthma, anaphylaxis, rhinitis, urticaria, angioedema, eczema, and food hypersensitivity.

## Angioedema

### **Q. Write short essay/note on the clinical features and treatment of angioedema.**

Angioedema is defined as a well-demarcated localized edema involving the deeper layers of the skin, including the subcutaneous tissue and submucosal tissues.

### ***Etiology***

It is an IgE-mediated reaction that causes direct release of histamine from the mast cells. It follows a variety of allergens. It may develop due to insect sting, drug reaction, food allergy and exposure to other biological products. Rarely, angiotensin-converting enzyme (ACE) inhibitors may produce angioedema due to increased levels of bradykinin. Most of the cases are idiopathic.

### ***C1-esterase Inhibitor Deficiency***

C1 esterase (C1INH) inhibitor is a complement protein that inhibits

spontaneous activation of classical complement pathway. C1 esterase inhibitor also regulates kinin cascade, activation of which increases local bradykinin levels and produces local pain and swelling. Both C1-esterase inhibitor and C1 levels are low. C1INH deficiency produces bradykinin. Deficiency of C1INH may be hereditary or acquired disorder.

- **Hereditary angioedema:** It is an autosomal dominant disorder, is due to C1 esterase inhibitor (C1INH) deficiency. Angioedema develops either spontaneously or following infection or injury (e.g. dental injury). Onset is usually in early childhood. The attacks become worse at puberty and usually its frequency and severity decreases after the age of 50 and may even disappear totally. Diagnosis confirmed by low levels of C1-esterase inhibitor (in 85% cases) or dysfunctional C1-esterase inhibitor (in 15% cases).
- Mutations in chromosome 11; Autosomal dominant inheritance.
  - Type I C1ID: 85% patients no detectable protein.
  - Type II C1ID: 15% patients dysfunctional protein
- **Acquired C1INH deficiency:** It presents in a manner similar to the hereditary angioedema but the onset occurs in the fifth and sixth decades of life. It is due to appearance of an autoantibody. It may occur with B-cell lymphoma, multiple myeloma, Waldenstrom's macroglobulinemia and chronic lymphocytic leukemia.

### ***Clinical Features***

- May occur at any age but most common in young adults.
- It presents with well-defined, non-pitting swelling, usually non-pruritic. It may be associated with urticaria lesions.
- Angioedema up to 6 weeks is called acute and if it lasts beyond 6 weeks is called chronic.
- May involve any area of the body but often affects periorbital, lips (Fig. 20.6) and genital areas.
- Angioedema of the upper respiratory tract may cause laryngeal obstruction which may be life-threatening.
- Involvement of gastrointestinal system may produce abdominal colic, with or without nausea and vomiting.
- Angioedema does not produce residual discoloration unless there is

extravasation of RBCs.

**Fig. 20.6:** Angioedema.

#### **Treatment**

- Identification of the etiologic factor(s) and remove the offending agent if possible.
- Antihistamines to control the lesions, e.g. diphenhydramine cetirizine, des- loratidine.
- Observe for any evidence of airway obstruction and if present manage in a fashion similar to those with anaphylaxis.
- Acute attack should be controlled with epinephrine.
- Chronic angioedema not responding to maximal dosages of antihistamines, glucocorticosteroids and other immunomodulating agents (e.g. methotrexate, cyclosporine) may be considered.
- During severe attacks of hereditary angioedema due to C1INH deficiency, fresh frozen plasma is lifesaving as it provides C1-esterase inhibitor. Danazol is useful to prevent episodes of hereditary angioedema.
- Newer therapy for hereditary angioedema: Purified C1 inhibitor concentrate, recombinant C1INH —**Conestat alfa**, Bradykinin receptor antagonist—**Icatibant** and kallikrein inhibitor —**Ecallantide**.

## **Systemic Anaphylaxis**

**Q. Write a short note on anaphylactic reactions (anaphylaxis).**

**Q. Discuss the causes and treatment/management of anaphylactic shock.**

**Definition:** Systemic anaphylaxis is a life-threatening form of immediate (appears within minutes after systemic exposure to specific antigen) type 1 hypersensitivity reaction mediated by IgE. It is a systemic response that develops when mast cells (possibly basophils) are provoked to secrete

mediators with potent vasoactive and smooth muscle contractile activities.

## **Causes**

It occurs in sensitized individuals and requires prior sensitization occurs to inciting antigen, either alone or in combination with a hapten. It usually occurs when allergen is administered parenterally and it is less likely after oral ingestion, inhalation, or cutaneous or ocular topical contact. The causes of systemic anaphylactic reactions are listed in Box 20.7

Anaphylaxis may be triggered by extremely small doses of antigen. Example, the minute dose used in skin testing for various forms of allergies.

## **Mechanism (Fig. 20.7)**

- **Initial exposure to antigen:** The sensitizing antigen (allergen) from its site of entry is presented to T-cells which differentiate into T<sub>H</sub>2 cells. IL-13 secreted by T<sub>H</sub>2 cells **enhances IgE production by B-cells. IgE gets attached to mast cells and basophils.**
- **During subsequent exposure to antigen,** the antigen (allergen) binds to the IgE antibodies previously bound to the mast cells and produces IgE induced degranulation of mast cells and basophils. It results in the liberation of a number of mediators (Table 20.8). Mediators released by mast cells include preformed mediators (stored in secretory granules), secondary mediators (newly synthesized products). They are responsible for the pathogenesis of an anaphylactic reaction (Table 20.8).

## **Box 20.7:** Causes of systemic anaphylactic reactions.

### *Anaphylaxis: IgE-Mediated Mast Cell Degranulation*

#### 1. **Proteins**

- Foreign proteins (e.g. antisera),
- Foods (peanuts, fish and shellfish, egg, milk, soya products)
- Food additives (aspartame, monosodium glutamate)

#### 2. **Drugs**

- Antibiotics (penicillins, cephalosporins tetracyclines, trimethoprim-sulfamethoxazole, cancomycin, nitrofurantoin)
- Chemotherapeutic agents
- Hormones (e.g. insulin, vasopressin, parathormone),
- Enzymes (chymotrypsin, penicillinase, streptokinase).
- Intravenous anesthetic agents (suxamethonium, propofol)
- Latex

### 3. Biological agents

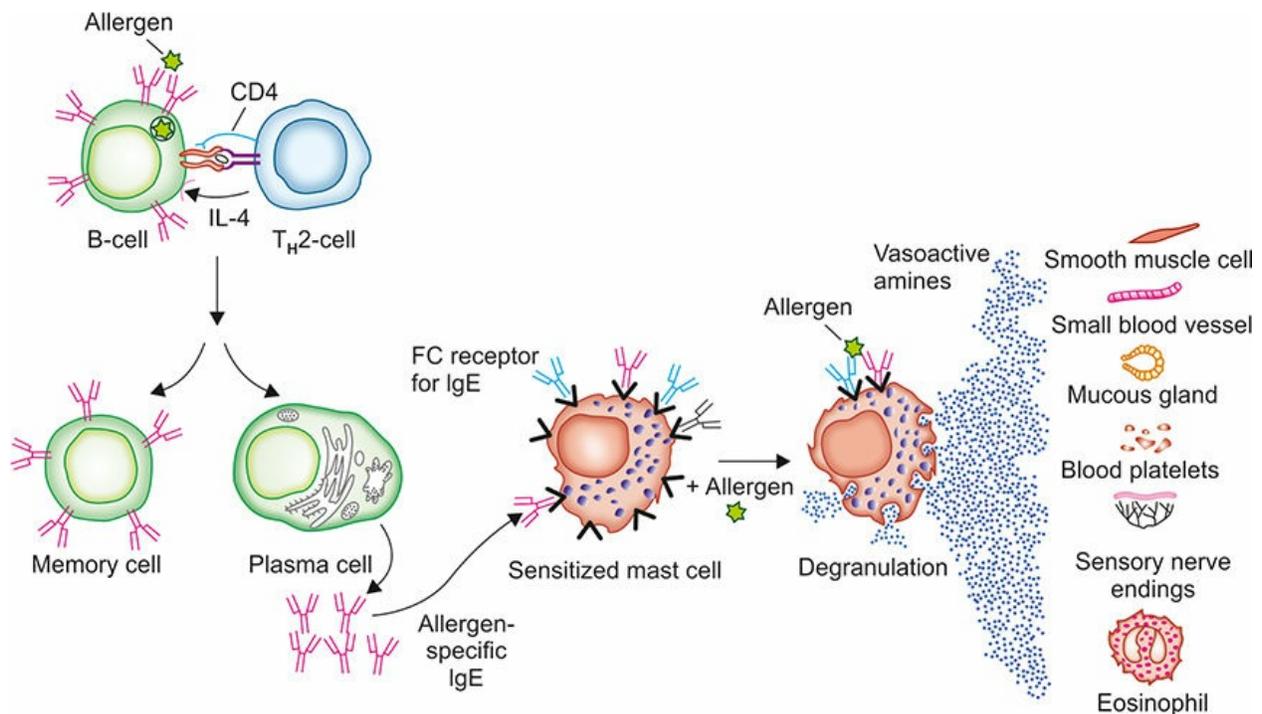

- Blood
- Tetanus, rabies and diphtheria antitoxins
- Antithymocyte globulin
- Vaccines

### 4. Insect bites and stings

- Honey bee (bee venom)
- Wasps (wasp venom)

**Table 20.8:** Mast cell mediators in anaphylactic reactions.

<i>Preformed mediators (primary mediators)</i>	<i>Secondary (newly synthesized) mediators</i>
<ol style="list-style-type: none"><li>1. Vasoactive amines: Histamine</li><li>2. Enzymes: Neutral proteases (chymase, tryptase) and several acid hydrolases</li><li>3. Proteoglycans: These include heparin (anticoagulant), and chondroitin sulfate</li><li>4. Eosinophil chemotactic factor</li><li>5. Neutrophil chemotactic factor</li></ol>	<ol style="list-style-type: none"><li>1. Lipid Mediators:<ul style="list-style-type: none"><li>• Leukotrienes B<sub>4</sub>, C<sub>4</sub> and D<sub>4</sub>.</li><li>• Prostaglandin D<sub>2</sub></li><li>• Platelet-activating factor (PAF)</li></ul></li><li>2. Cytokines: TNF, IL-1, IL-4 and chemokines</li></ol>

**Fig. 20.7:** Mechanism of systemic anaphylaxis.

### *Anaphylactoid Reactions (Pseudo-allergic Reactions/non-IgE Mediated)*

**Q. Write a short note on anaphylactoid reaction.**

- They are indistinguishable from anaphylactic reactions.
- Most non-IgE-dependent foreign agents do not require antigen processing (sensitization) and can elicit a mast cell activation response on first antigenic exposure itself. However, they may be associated with IgG and IgM antibodies and not IgE. These antibodies activate the complement system through classical pathway and produce activated complement components and may cause direct release of preformed mediators from mast cells and basophils.
- Short lived because involves only degranulation of mast cells and not cytokine synthesis.
- Causes: (Box 20.8).

***Clinical Features (Tables 20.9 and 20.10)***

The anaphylactic response appears within minutes after systemic exposure to specific antigen.

**Box 20.8:** Anaphylactoid reactions (Pseudo-allergic reactions/non-IgE mediated).

***Anaphylactoid: Non-IgE-Mediated Mast Cell Degranulation***

1. **Drugs**
  - Aspirin and non-steroidal anti-inflammatory drugs (NSAIDs)
  - Vancomycin
  - Narcotics (e.g, codeine, morphine, opiates)
  - Radiocontrast media/dye
2. **Physical**
  - Exercise
  - Exposure to cold
3. **Autoimmune**
4. **Narcotics/vancomycin**
5. **Idiopathic**

**Table 20.9: Clinical features of systemic anaphylaxis.**

<b><i>Cutaneous</i></b>	<b><i>Respiratory</i></b>
<ul style="list-style-type: none"><li>• Itching (pruritus)</li><li>• Hives (urticaria)</li><li>• Skin erythema with or without angioedema</li></ul>	<ul style="list-style-type: none"><li>• Intense bronchospasm resulting in respiratory distress</li><li>• Dyspnea and wheeze</li></ul>

<ul style="list-style-type: none"> <li>• Flushing</li> <li>• Insect stings</li> </ul>	<ul style="list-style-type: none"> <li>• Laryngeal edema resulting in hoarseness and laryngeal obstruction</li> <li>• Pulmonary edema</li> </ul>
<b><i>Gastrointestinal</i></b>	<b><i>Cardiovascular</i></b>
<ul style="list-style-type: none"> <li>• Nausea</li> <li>• Vomiting</li> <li>• Abdominal cramps</li> <li>• Diarrhea</li> </ul>	<ul style="list-style-type: none"> <li>• Tachycardia</li> <li>• Hypotension</li> <li>• Arrhythmias</li> <li>• Shock and collapse</li> </ul>
<b><i>Central nervous system</i></b>	
<ul style="list-style-type: none"> <li>• Confusion</li> <li>• Feeling of impending doom</li> <li>• Apprehensionx</li> <li>• Metallic taste</li> <li>• Altered levels of consciousness</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Biphasic anaphylaxis</b> is recurrence of symptoms that develops following the apparent resolution of the initial anaphylactic episode with no additional exposure to the causative agent.</li> </ul>

**Table 20.10:** Clinical features of systemic anaphylaxis depending on severity.

<b><i>Severity</i></b>	<b><i>Features</i></b>
Mild	Cutaneous features only: pruritus, erythema, urticaria or mild angioedema
Moderate	The above plus more severe angioedema and/or vomiting, abdominal pain and/or mild dyspnea or tightening of throat
Severe	The above plus respiratory difficulty (laryngeal edema or asthma) and/or hypotension

**Q. Write short note on treatment of anaphylaxis. List life-saving drugs used in anaphylactic shock.**

### **Treatment**

Anaphylaxis is an acute medical emergency and its early recognition is mandatory, since death occurs within minutes to hours after the first symptoms.

- **Prevent further contact with allergen**, e.g. removal of bee sting.
- **Ensure airway patency:** Fatal outcomes in anaphylaxis are mainly due to either airway constriction or hypotension.
- **Oxygen alone via a nasal catheter or with nebulized salbutamol/albuterol**, oxygen 4–6 L/minute.
  - If progressive hypoxia develops, either endotracheal intubation or tracheostomy with intermittent positive ventilation is mandatory for oxygen delivery.
- **Administer adrenaline (epinephrine) intramuscularly** into the thigh and is the most critical drug to administer. Earlier administration during the course of an anaphylactic event is better.
  - Adult dose: 0.3.1.0 mL 1:1000 solution and it acts within minutes [0.01 mg/kg (up to 0.3 mg) for children].

- Repeat at 5.10 minutes intervals, if the response is inadequate.
- In severe cases, 1 mL of 1:100,000 of solution is given intravenously.
  - ◆Patients on  $\beta$ -blocker may be resistant to epinephrine and glucagon (1 mg IV, or 1 to 5 mg/hour IV) or vasopressin (5 to 40 IU IV) may be used.
- **Administer antihistamines:** They may prevent the progression of urticaria and pruritus, but does not reverse hypotension or tissue edema by directly opposing effects of mast cell activation, e.g. chlorphenamine 10 mg IM or slow IV injection, diphenhydramine, 50.100 mg IM or IV.
- **Administer corticosteroids:** Hydrocortisone 200 mg IV stat (not effective for the acute event as takes 4 hours to act; but alleviate recurrence of bronchospasm, urticaria and hypotension).
- **Provide supportive treatments**
  - Bronchodilators: They relieve bronchospasm, e.g. nebulized  $\beta$ 2-agonists/salbutamol and aminophylline, 0.25.0.5 g IV.
  - Hypotension: Immediately assume the Trendelenburg position (prevent progression to anaphylactic shock). Shock is treated with intravenous fluids (if needed with dopamine) to restore or maintain blood pressure. **ECMO** has been tried.

**Non-IgE mediated (Idiopathic) anaphylaxis:** Usually presents slowly over a few hours. Begins with pruritus of the palms and soles, then progresses to general pruritus, erythema, and urticaria, with diarrhea, abdominal pain, and hypotension. Respiratory symptoms are rare.

### ***Allergen Immunotherapy or Desensitization***

- Subcutaneously incremental doses of allergen are given at 1 to 2 weekly intervals until the top dose is reached.
- Useful for prevention of atopy/anaphylaxis.

### **Acute Serum Sickness**

#### **Q. Write short note on serum sickness.**

- It is a systemic immune complex mediated disease (type III hypersensitivity immune reaction).
- It was a frequent sequelae to the administration of large amounts of foreign serum (e.g. serum from immunized horses used for protection against diphtheria). But nowadays it is infrequent.
- IgG is produced when a foreign antigen is injected in large quantities. They form soluble immune (antigen-antibody) complexes.

**Mechanism:** Introduction of antigen  $\rightarrow$  body's immune system responds by synthesizing antibodies after 4–10 days  $\rightarrow$  antibody reacts with antigen, forming soluble complexes that may diffuse into vascular walls and may initiate activation of complement  $\rightarrow$  complement-containing immune

complexes generate influx of leukocytes into vessel walls → proteolytic enzymes that can mediate tissue damage are released → immune complex deposition + inflammatory response are responsible for vasculitic lesions seen.

### ***Clinical Features***

Fever, urticarial (at the site of injection), joint pains (arthralgias), lymph node enlargement, and proteinuria appear during this phase. Wherever immune complexes deposit the tissue damage is similar (Box 20.9).

**Treatment (Box 20.10).**

## **AUTOIMMUNITY**

**Q. Write short essay/note autoimmunity.**

**Definition:** Autoimmunity is defined as immune reactions in which body produces autoantibodies and immunologically competent T-lymphocytes against self-antigens.

**Box 20.9:** Lesion produced in acute serum sickness.

- Vasculitis-inflammatory lesion in blood vessels.
- Glomerulonephritis-inflammatory lesion in renal glomeruli.
- Arthritis-inflammatory lesion in the joints.

**Box 20.10:** Treatment of acute serum sickness.

- Corticosteroid creams or ointments: Relieve discomfort from itching and rash.
- Antihistamines: May reduce the length of illness and itching.
- NSAIDS: May relieve joint pain.
- Paracetamol: Helpful in relieving fever and muscle pain.
- Medications causing problem should be stopped and future use should be avoided.

### **Mechanisms of Autoimmunity (Fig. 20.8)**

#### ***Genetic Factors***

**Role of Susceptibility Genes:** Most autoimmune diseases are complex multigenic disorders and genetic factors have an important role.

- **Runs in families:** The incidence is greater in monozygotic than in

dizygotic twins.

- **Association with HLA genes:** Most significant.

## ***Environmental Factors***

### *Role of infections*

A variety of microbes may trigger autoimmunity by several mechanisms.

- **Molecular mimicry:** Few viruses and microbes may express antigens that have the antigenic structure similar to self-antigens. Immune responses against them may cross-react with self-tissue and this phenomenon is known as molecular mimicry. Example: **Rheumatic heart disease**, in which antibodies formed against streptococcal bacterial proteins cross-react with myocardial proteins and cause myocarditis. Molecular mimicry between microbial proteins and host tissues is also found in Klebsiella and HLA-B27 in ankylosing spondylitis, Coxsackie and glutamic acid decarboxylase in insulin-dependent (type 1) diabetes mellitus, rheumatoid arthritis, and multiple sclerosis.
- **Breakdown of anergy:** Tissue necrosis and inflammation produced by microbial infections can cause **up-regulation of costimulatory molecules** on APCs. This may favor breakdown of anergy and activation of T-cells.
- **Immune dysregulation:** Normally, T-cells regulate any autoreactive T and B-cells that have survived clonal deletion. Dysregulation of T-cell function can lead to loss of control and the development of autoimmune disease. Examples: immunodeficiency diseases such as hypogammaglobulinemia and HIV infection are commonly associated with autoimmune phenomena.

### ***Other environmental factors***

- **Ultraviolet radiation**
- **Cigarette smoking**
- **Local tissue injury/damage:** Some autoantigens are hidden within the cells or tissues in immunologically privileged sites (e.g. brain or the anterior chamber of the eye). Therefore, the lymphoid cells remain in a state of immunologic ignorance. In this state, lymphoid cells are neither activated nor anergized to proteins expressed by these immunologically privileged sites. If the tissue in the privileged site is damaged by trauma or inflammation or tumor, the antigens may be and released. These antigens

can evoke an autoimmune response. Examples, Dressler’s syndrome is an acute pericarditis developing in a patient with myocardial infarction secondary to the production of anti-myocardial antibodies, development of insulin-dependent diabetes in association of Coxsackie virus infection, multiple sclerosis and sympathetic ophthalmia.

- **Drugs:** T-cell bypass is a mechanism by which T-cells help auto-reactivation of B-cells instead of suppressing them. Examples include drug-induced autoimmune responses such as quinine induced thrombocytopenia.
- **Hormones.**

Classification of autoimmune disorders are presented in Table 20.11.

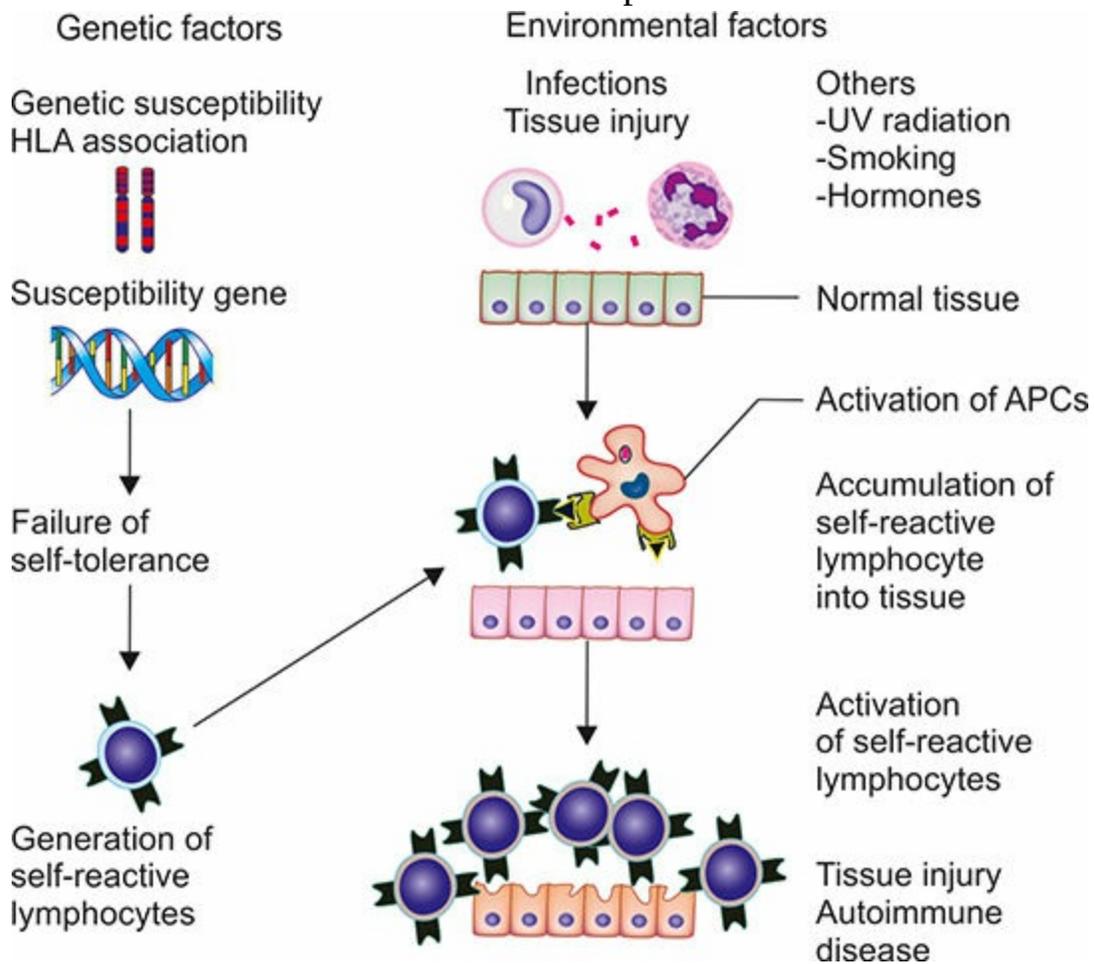

Fig. 20.8: Pathogenesis of autoimmunity.

Table 20.11: Classification of autoimmune disorders.

Organ specific autoimmune diseases	Systemic autoimmune diseases
------------------------------------	------------------------------

- Type I diabetes mellitus
- Goodpasture syndrome
- Multiple sclerosis
- Grave's disease
- Hashimoto's thyroiditis
- Autoimmune pernicious anemia
- Autoimmune Addison's disease
- Vitiligo
- Myasthenia gravis
- Rheumatoid arthritis
- Scleroderma
- Systemic lupus erythematosus
- Primary Sjögren syndrome
- Polymyositis

### Q. List autoimmune diseases.

#### Therapy of Autoimmune Disease

- Control of symptoms (e.g. non-steroidal anti-inflammatory drugs for joint pains, fever, etc. in SLE; b-blockers in patients with thyrotoxic features).
- Specific replacement therapy where the organ has been completely destroyed (e.g. thyroid hormone replacement in hypothyroidism).
- Immunosuppressive therapy including corticosteroids, cytotoxic drugs in different forms, different regimens and different routes.
- Newer and experimental forms of therapy including immunomodulation, e.g. plasmapheresis, intravenous immunoglobulin therapy, cyclosporin.

## TRANSPLANTATION IMMUNOLOGY

### Transplantation

#### Q. Write short note on transplantation and its types.

Organ transplant is the moving of an organ from one body to another (or from a donor site on the patient's own body) for the purpose of replacing the recipient's damaged or failing organ with a working one from the donor site.

#### *Graft Types*

- **Autograft:** Tissue transfer within the same individual (e.g. skin graft).
- **Isograft:** Tissue transfer between genetically identical individuals (e.g. identical twins).
- **Allograft:** Tissue transfer between genetically non-identical members of the same species (includes living-related donor and cadaver donor human transplants). Immunosuppression is required.
- **Xenograft:** Tissue transfer between different species. Immunosuppression is required for transplantation.

## Donors

1. **Cadaver donors** are individuals with severe brain injury resulting in brain death, which is defined as complete irreversible cessation of all brain function, including the brainstem.
  - Table 20.12 lists criteria for cadaver donor selection and exclusion.
2. **Living donors:**
  - Living-unrelated donors on average share no more genes with a recipient than a cadaver donor. An example is the patient's spouse.
  - Living-related donors share a substantial portion of their genomes with the recipient.
  - **Requirements**
    - Living donors must be in almost perfect health.
    - Normal function of the organ under consideration.
    - Be good candidates for anesthesia and the operative procedure.
  - **Workup:** (refer *Factors Determining the Success* on page 912).
  - **Risk**
    - Perioperative mortality for living kidney donors is 0.03%.
    - A living donor provides one kidney, and the remaining kidney hypertrophies and achieves 80% of creatinine clearance before donation.

## Surgical Position

- Orthotopic: The old organ is removed, and the new one is placed in the same position.
- Heterotopic: The new organ is placed in a different position.

## Rejection

The three types of rejection are: (i) hyperacute, (ii) acute and (iii) chronic; and details discussed on pages 913-4.

**Table 20.12:** Criteria for cadaver donor selection and exclusion.

<i>Donor selection</i>	<i>Exclusion</i>
<ul style="list-style-type: none"><li>• Donor must be normothermic</li></ul>	<ul style="list-style-type: none"><li>• Disseminated or uncured extracranial cancers</li></ul>
<ul style="list-style-type: none"><li>• Donor must not on depressant drugs</li></ul>	<ul style="list-style-type: none"><li>• Sepsis</li></ul>

(especially barbiturates)	
<ul style="list-style-type: none"> <li>• An apnea test result must be negative (i.e. no respiratory effort despite a high arterial carbon dioxide level)</li> </ul>	<ul style="list-style-type: none"> <li>• Poor organ function</li> </ul>
<ul style="list-style-type: none"> <li>• Electroencephalogram (EEG) and cerebral blood flow studies are optional</li> </ul>	<ul style="list-style-type: none"> <li>• Hepatitis C/B, CMV, HIV</li> </ul>

## IMMUNOMODULATORS

**Definition:** Immunomodulators are drugs which either suppress the immune system, i.e. immunosuppressants or stimulate the immune system, called immunostimulants.

### Immunosuppressants (Box 20.11)

#### *Glucocorticoids (refer page 68)*

#### *Calcineurin Inhibitors*

Calcineurin (CN) is a protein phosphatase activates the T-cells of the immune system and can be blocked by drugs.

- **Cyclosporine**
  - It binds to the cytosolic protein cyclophilin of immunocompetent lymphocytes, especially T-lymphocytes.
  - This complex of ciclosporin and cyclophilin inhibits the phosphatase calcineurin, which under normal circumstances induces the transcription of interleukin-2.
  - The drug also inhibits lymphokine production and interleukin release, leading to a reduced function.
  - Uses and toxicity of cyclosporine is presented in Table 20.13.
- **Tacrolimus**
  - It binds to the immunophilin FKBP1A and the complex inhibits calcineurin. This in turn inhibits its phosphatase activity and prevents the progression of cell from the  $G_0$  into  $G_1$  phase of the cell cycle.
  - Tacrolimus is more potent and has less side-effect compared to cyclosporine. Toxicity of tacrolimus are listed in Box 20.12.
  - **Use**
    - ◆ Prophylaxis of solid-organ allograft rejection.

◆ Topical preparation available for use in atopic dermatitis and psoriasis.

• **Sirolimus (rapamycin)**

**Q. Write short note on sirolimus.**

- They affect the first phase of T lymphocyte activation unlike cyclosporine and tacrolimus.
- Sirolimus affects the signal transduction and lymphocyte clonal proliferation.
- It binds to FKBP1A (similar to tacrolimus) and mTOR (mammalian target of rapamycin). However, it does not inhibit calcineurin. Toxicity of sirolimus are listed in Box 20.13.
- It indirectly inhibits many T lymphocyte-specific kinases and phosphatases. T cel prevents their progression from G<sub>1</sub> to S phase of the cell cycle.
- Sirolimus inhibits B-cell differentiation into plasma cells and reduces the production of IgM, IgG, and IgA antibodies.
- Uses: Prophylaxis of organ transplant rejection with other drugs.

**Table 20.13:** Uses and toxicity of cyclosporine.

<i>Uses</i>	<i>Toxicity</i>
<ul style="list-style-type: none"> <li>• Organ transplantation: Kidney, liver, heart</li> <li>• Rheumatoid arthritis, IBD (inflammatory bowel disease), uveitis</li> <li>• Psoriasis</li> <li>• Aplastic anemia</li> <li>• Skin conditions: Atopic dermatitis, alopecia areata, pemphigus vulgaris, lichen planus, pyoderma gangrenosum</li> </ul>	<ul style="list-style-type: none"> <li>• Renal dysfunction</li> <li>• Tremor</li> <li>• Hirsutism (hypertrichosis)</li> <li>• Hypertension</li> <li>• Hyperlipidemia</li> <li>• Gum hyperplasia</li> <li>• Hyperuricemia – worsens gout</li> <li>• Calcineurin inhibitors + glucocorticoids = Diabetogenic</li> </ul>

**Box 20.11:** Various categories of immunosuppressants.

- Glucocorticoids-Prednisolone
- Calcineurin inhibitors
  - Cyclosporine
  - Tacrolimus
  - Sirolimus

- Everolimus
- Antiproliferative/antimetabolic agents
  - Azathioprine
  - Mycophenolate mofetil
- Others: Methotrexate, cyclophosphamide, thalidomide and chlorambucil, Interferon
- Antibodies
  - Antithymocyte globulin
  - Anti CD3 monoclonal antibody: Muromonab
  - Anti-IL-2 receptor antibody: Daclizumab, basiliximab
  - Anti TNF alpha: Infliximab, etanercept

---

### Box 20.12: Toxicity of tacrolimus.

- Nephrotoxicity
- Neurotoxicity: Tremor, headache, motor disturbances, seizures
- GI side effects
- Hypertension
- Hyperglycemia
- Risk of tumors, infections

---

### Box 20.13: Toxicity of sirolimus.

- Increase in serum cholesterol, triglycerides
- Anemia
- Thrombocytopenia
- Hypokalemia
- Fever
- Gastrointestinal effects
- Risk of infection, tumors

---

## *Antiproliferative/Antimetabolic Agents*

### **Q.** Write short note on azathioprine.

- **Azathioprine**
  - It is nonenzymatically converted to mercaptopurine which acts as a purine analogue and inhibits DNA synthesis.
  - The clonal expansion of lymphocytes in the induction phase of the immune response is prevented and thereby affects both the cell and the humoral immunity. Toxicity of azathioprine are listed in Box 20.14.
  - Uses
    - ◆ Prevention of organ transplant rejection

- ◆ Rheumatoid arthritis
- **Mycophenolate Mofetil**
  - Prodrug: Mycophenolic acid.
  - Inhibits IMPDH: Enzyme in guanine synthesis (Inosine monophosphate dehydrogenase (IMPDH)).
  - Selectively inhibits lymphocyte proliferation, function, Antibody formation, cellular adhesion, migration
  - Uses:
    - ◆ Prophylaxis of transplant rejection
    - ◆ Combination: Glucocorticoids, calcineurin inhibitors.

### ***Antibodies (Box 20.15)***

- **Anti-TNF agents**
  - **TNF is a cytokine released at the site of inflammation.** Anti-TNF agents and their uses is listed in Table 20.14.

### **LFA-1 inhibitor (lymphocyte function associated)**

- Efalizumab
  - Monoclonal Ab targeting lymphocyte function associated antigen. Blocks T-cell adhesion, activation, trafficking
- Uses
  - Organ transplantation
  - Psoriasis.

### ***Glatiramer acetate***

- The only immunosuppressant agent used for the treatment of multiple sclerosis (MS).
- Used to reduce the frequency of MS relapses (exacerbations) in relapsing-remitting multiple sclerosis (RRMS).

### **Complications of Immunosuppression**

- Infections:
  - The immunosuppression impairs host defenses against a diverse group of pathogens (e.g. opportunistic infections).
  - Wide range of bacterial, fungal, and protozoal organisms can cause

opportunistic infections. They can be lethal. Hence, they need prompt diagnosis and treatment.

- Neoplasia: The three major areas of increased risk are:
  1. Skin cancer
  2. Post-transplant lymphoproliferative disorders (PTLDs)
  3. Oral squamous cell cancers or female genital tract cancers.

**Box 20.14: Toxicity of azathioprine.**

- Bone marrow suppression: Leukopenia, thrombocytopenia, anemia
- Increased susceptibility to infection
- Hepatotoxicity
- Alopecia
- Diarrhea

**Box 20.15: Antibodies used as immunosuppressants.**

- Antithymocyte Globulin
- Monoclonal antibodies
- Anti-CD3 Monoclonal antibody (Muromonab-CD3)
- Anti-IL-2 Receptor antibody (Daclizumab, Basiliximab)
- Campath-1H (Alemtuzumab)

**Table 20.14: Anti-TNF agents and their uses.**

<i>Anti-TNF agents</i>	<i>Uses</i>	<i>Adverse reactions</i>
<ul style="list-style-type: none"> <li>• Infliximab</li> <li>• Etanercept</li> <li>• Adalimumab</li> <li>• Infliximab</li> <li>• Certolizumab pegol, golimumab</li> </ul>	<ul style="list-style-type: none"> <li>• Rheumatoid arthritis</li> <li>• Crohn’s disease – fistulae</li> <li>• Psoriasis, rheumatoid arthritis</li> <li>• Psoriatic arthritis</li> <li>• Ankylosing spondylosis</li> <li>• RA, SLE, vasculitis, inflammatory myopathy, uveitis</li> </ul>	<ul style="list-style-type: none"> <li>• Cytopenias</li> <li>• Infusion reactions</li> <li>• Demyelinating disorders</li> <li>• Infections</li> <li>• Tuberculosis</li> <li>• Heart failure</li> <li>• Hepatotoxicity</li> </ul>

**Immunostimulants (Box 20.16)**

***Levamisole***

*Uses*

- Adjuvant therapy with 5FU in colon cancer

## ***Thalidomide***

- Used in multiple myeloma, graft versus host disease, myelodysplastic syndrome, colon and prostate cancer.
- Contraindicated in women with childbearing potential: Phocomelia.

## ***Bacillus Calmette-Guerin***

- Used as intravesical therapy for superficial bladder cancer.

## ***Interferons (Box 20.17)***

### *Interferon alfa-2b*

Uses and adverse reactions of interferon alfa -2b is listed in Table 20.15.

### **Interleukin-2 (aldesleukin)**

- Uses: Metastatic renal cell carcinoma, melanoma.
- Toxicity: Cardiovascular—capillary leak syndrome, hypotension.

## **Plasmapheresis**

**Q. Write short note on indications for plasmapheresis.**

Plasmapheresis is a process that filters the blood and removes harmful antibodies. Its indications are listed in Box 20.18.

## **ADULT IMMUNIZATION**

**Q. Write short note on adult immunization schedule.**

Screening tools to be checked before vaccination is listed in Box 20.19.

### **Contraindications for Immunization**

- Previous anaphylaxis to a specific vaccine
- History of anaphylaxis to egg protein, neomycin (MMR)
- Live vaccines in pregnancy
- Live vaccines in patients with impaired immunity.

### **Adverse Effects of Active Immunization**

- Mild fever
- Infection (live vaccines)

- Local reaction
- Allergy/anaphylaxis
- SSPE, demyelination, brachial neuritis.

## Documentation

Provide copy of vaccine information statement (VIS) to patient/documents to be maintained

- Date vaccination and next dose
- Vaccine manufacturer
- Lot number
- Dose and site of vaccine
- Vaccinator's initials

ACIP adult immunization, age-based recommendations in India is presented in Table 20.16.

### Box 20.16: List of immunostimulants.

Levamisole  
 Thalidomide  
 BCG (Bacillus Calmette-Guerin)  
 Recombinant cytokines

- Interferons
- Interleukin-2

Other drugs  
 – Inosiplex, azimexon, imexon, thymosin, methylinosine monophosphate

Immunization  
 Vaccines, immunoglobulin, Rho (D) immunoglobulin

### Box 20.17: Features of interferon.

- Antiviral
- Immunomodulatory activity
- Bind to cell surface receptors: Initiate intracellular events
- Enzyme induction
- Inhibition of cell proliferation
- Enhancement of immune activities
- Increased phagocytosis

**Table 20.15: Uses and adverse reactions of interferon alfa-2b.**

<i>Uses</i>	<i>Adverse reactions</i>
<ul style="list-style-type: none"> <li>• Hairy cell leukemia</li> </ul>	<ul style="list-style-type: none"> <li>• Flu-like symptoms: Fever, chills, headache</li> </ul>

- |                      |                                |
|----------------------|--------------------------------|
| • Malignant melanoma | • CVS: Hypotension, arrhythmia |
| • Kaposi sarcoma     | • CNS: Depression, confusion   |
| • Hepatitis B        |                                |

**Box 20.18:** Indications for plasmapheresis.

- Guillain-Barré syndrome
- Myasthenia gravis
- Thrombotic thrombocytopenic purpura, hemolytic uremic syndrome
- Hyperviscosity syndromes (e.g. Waldenstrom’s macroglobulinemia)
- Rapidly progressive glomerulonephritis. Wegeners granulomatosis, Goodpasture syndrome
- Fulminant hepatitis, chronic inflammatory demyelinating polyradiculoneuropathy, Sydenhams chorea

**Box 20.19:** Utilize screening tools; H-A-L-O.

- **H**ealth condition
- **A**ge
- **L**ifestyle
- **O**ccupation

**Table 20.16:** Shows ACIP adult immunization, age-based recommendations in India.

Vaccine/Age group	19–26 years	27–49 years	50–59 years	60–64 years	> 65 years
Tetanus, Diptheria, Pertussis (Tdap)	Substitute one time dose of Tdap with Td, then booster with Td every 10 years				Td booster every 10 years
Human papilloma vaccine	3 doses				
Varicella	2 doses				
Zoster				1 dose	
Measles, mumps, rubella	1 or 2 doses		1 dose		
Influenza	1 dose annually				
Pneumococcal (Polysaccharide)	1 or 2 doses				1 dose
Hepatitis A	2 doses				
Hepatitis B	3 doses				
Hepatitis C	1 or more doses				

Recommended if some risk factor is present
All persons who meet the age criteria
No recommendation

**Table 20.16:** Shows Acip adult immunization, age-based recommendations in India.

Adult immunization based on medical and other indications in India is presented in Table 20.17.

**Table 20. 17:** Shows adult immunization based on medical and other indications in India.

Vaccine	Pregnancy	Indication	HIV infection with CD4 count		Diabetes, heart disease, chronic lung disease	Asplenia (excluding elective splenectomy disease)	Chronic liver disease	Kidney failure, end stage renal disease, on hemodialysis	Health care professionals
			<200 cells/uL	≥ 200 cells/uL					
Tetanus, Diphtheria, Pertussis (Tdap)	Td	Substitute one time dose of Tdap with Td, then booster with Td every 10 years							
Human Papilloma Vaccine		3 doses for females through age 26 years							
Varicella	Contraindication	2 doses							
Zoster	Contraindication	1 dose							
Measles, mumps, rubella	Contraindication	1 or 2 doses							
Influenza		1 dose annually							1 dose
Pneumococcal (Polysaccharide)		1 or 2 doses							
Hepatitis A		2 doses							
Hepatitis B									
Meningococcal		1 or more doses							

  Recommended if some risk factor is present  
   All persons who meet the age criteria  
   Contraindication

**Table 20.17 Shows adult immunization based on medical and other indications in India.**

Vaccination details are presented in Table 20.18.

**Table 20.18:** Vaccination details.

Vaccine	Recommendation	Booster	Route	Dose	Special population/efficacy
Diphtheria, tetanus, pertussis	18–64 years Three dose series at 0 and 4 weeks, the third 6–12 months after second	Tdap every 10 years	Intramuscular	0.5 mL	92% efficacy. Pregnant women—1 dose in second or third trimester
Measles, mumps and rubella	>18 years of age should receive at least one dose of MMR if there is no serologic proof of immunity	No	Subcutaneous		Pregnancy to be avoided for at least 4 weeks after vaccination
Influenza	Annual, single dose	Annual	Intramuscular Nasal spray	0.5 mL, 0.25	<ul style="list-style-type: none"> <li>• People aged &gt; 50 years</li> <li>• Chronic obstructive</li> </ul>

				mL into each nostril	<p>pulmonary disease (COPD).</p> <ul style="list-style-type: none"> <li>• Cardiac diseases</li> <li>• Diabetes mellitus, cancer</li> <li>• immunodeficiency, renal disease</li> <li>• Hemoglobinopathies</li> <li>• Pregnant women</li> <li>• Health care providers</li> <li>• Adult household contacts</li> <li>• Travelers to endemic area</li> </ul>
Pneumococcal polysaccharide vaccine (PPSV23) and conjugate vaccine (PCV13)	Single dose Aged above 65 years	Can be repeated after 5 years	Intramuscular	0.5 mL	<ul style="list-style-type: none"> <li>• Anatomic asplenia</li> <li>• Sickle cell disease</li> <li>• Immunocompromised persons</li> <li>• Pregnant women with high-risk conditions</li> </ul>
Hepatitis B	For immunocompetent adults, administered at 0, 1, and 6 months	A booster if anti-HBs levels decline to less than 10 mIU/mL and <100 mIU/mL in patients on dialysis	Intramuscular	1mL (20 µg)	<p>Protection (anti-HBs antibody titer of 10 mIU/mL or higher) after recombinant vaccine</p> <p>After first dose—20–30%</p> <p>After second dose—75–80%</p> <p>After third doses—90–95%</p>
Hepatitis A	Two doses of 1 mL at 6 month interval		Intramuscular	1 mL	<p>Only recommended in:</p> <ul style="list-style-type: none"> <li>• People who travel to endemic area of Hep A</li> <li>• Persons who work with HAV-infected primates or with HAV in a laboratory</li> <li>• Who receive clotting factor concentrates</li> <li>• Food handlers</li> </ul>

					<ul style="list-style-type: none"> <li>• Chronic liver disease/CKD awaiting transplant</li> <li>• Men who have sex with men</li> </ul>
Varicella	<p>&lt; 13 years - 1 dose -</p> <p>&gt; 13 years - 2 doses</p> <p>Interval between 2 doses should be 4–8 weeks</p>		Subcutaneous	0.5 mL	<p>Health care workers</p> <p>Family contacts of immunocompromised persons</p> <p>High risk of exposure (e.g. teachers, day care employees, military personnel, and international travelers)</p>
Human papilloma virus	<p>Gardasil vaccine, 3 doses- at 0, 2, and 6 months.</p> <p>Cervarix vaccine, 3 doses IM at 0, 1 and 6 months</p>		Intramuscular	0.5 mL	<p>Woman age 26 years or younger or a man age 21 years or younger</p> <p>The immunization must precede the sexual debut.</p> <p>Age for initiation for vaccination to be 10–12 years (females) and 9–12 years (males)</p>
Meningococcal meningitis	Single dose	Nil	Intramuscular	0.5 mL	<p>During an outbreak (HCW, Lab. worker, close contacts)</p> <p>During inter-epidemic period</p> <p>To travelers, pilgrims (Quadrivalent) people attending fairs and festivals. (bivalent 10–14 days prior)</p>
Herpes zoster	Single dose	Nil	Subcutaneous	0.65 mL	<ul style="list-style-type: none"> <li>• Recommended for persons &gt;60 years.</li> <li>• High risk for developing recurrent herpes zoster, such as</li> <li>• Patients with chronic medical conditions (CKD, diabetes mellitus, rheumatoid arthritis, and chronic pulmonary disease)</li> <li>• Persons who are likely to have severe</li> </ul>

					immunosuppression in near future.
Haemophilus influenzae type b (Hib)			Intramuscular	0.5 mL	Not recommended for routine practice
Typhoid <ul style="list-style-type: none"> <li>• Live oral Ty21a vaccine,</li> <li>• Injectable Vi polysaccharide vaccine, and</li> <li>• Vi-rEPA vaccine</li> </ul>		Every five years			Not recommended for routine practice
Cholera	Two separate doses, 1–6 weeks apart for those aged over 6 years	No	Oral		85–90% protection

## AMYLOIDOSIS

**Definition:** Amyloidosis is a group of acquired and hereditary disorders characterized by extracellular deposition of insoluble polymeric **proteins** fibrils in tissues and organs.

### Classification of Amyloidosis (Table 20.19)

**Table 20.19:** Classification of amyloidosis.

<i>Category</i>	<i>Precursor protein</i>	<i>Fibril protein</i>	<i>Associated disease/(s)</i>
<b>A. Systemic (generalized) amyloidosis</b>			
1. Immunocyte dyscrasias with amyloidosis (primary amyloidosis)	Immunoglobulin light chains (mainly $\lambda$ )	AL	Multiple myeloma, other plasma cell dyscrasias
2. Reactive systemic amyloidosis (secondary amyloidosis)	Serum amyloid associated (SAA)	AA	Chronic inflammatory process
3. Hemodialysis-associated amyloidosis	$\beta_2$ -microglobulin	A $\beta_2$ m	Chronic renal failure
<b>B. Hereditary or familial amyloidosis</b>			
	SAA	AA	

1. Familial Mediterranean fever			
2. Familial amyloidotic neuropathies	Transthyretin	ATTR	
3. Systemic senile amyloidosis			
<b>C. Localized amyloidosis</b>			
1. Senile cerebral	Amyloid precursor protein (APP)	A $\beta$	Alzheimer disease
2. Endocrine			
• Thyroid	Calcitonin	A Cal	Medullary's carcinoma
• Islets of Langerhans	Islet amyloid peptide	AIAPP	Type 2 diabetes

## Clinical Features

- It is usually a rapidly progressive disease. The clinical features depends on the organs involved.
- **Nonspecific symptoms:** These include fatigue and weight loss.
- **Renal amyloidosis:** Kidneys are affected in about 70% of patients. It usually presents with proteinuria (often in the nephrotic range), hypoalbuminemia, secondary hypercholesterolemia, and edema or anasarca.
- **Cardiac amyloidosis:** The heart is the second most commonly (50%) affected organ and may show concentric thickening of ventricles and diastolic dysfunction, leading to a restrictive cardiomyopathy. It may present with heart failure.
- **Neuropathies:** Autonomic dysfunction with gastrointestinal motility disturbances (diarrhea, constipation) and peripheral sensory neuropathies are relatively common. Carpal tunnel syndrome with weakness and paresthesia of the hands may be an early presenting feature.
- **Macroglossia (Fig. 20.9A):** Enlarged tongue, is pathognomonic of AL amyloidosis that may be found in ~10% of patients.
- **Amyloidosis of liver:** Causes cholestasis and hepatomegaly.
- **Amyloidosis of spleen:** May produce functional hyposplenism in the absence of significant splenomegaly.
- **Cutaneous amyloidosis:** It can produce:
  - Easy bruising due to amyloid deposits in capillaries or to deficiency of

clotting factor X, which can bind to amyloid fibrils.

- Cutaneous ecchymosis especially around the eyes and can produce “raccoon-eye” sign (Fig. 20.9B).
- **Other findings:** These include nail dystrophy, alopecia, and amyloid arthropathy with thickening of synovial membranes in wrists and shoulders.

**Figs. 20.9A and B:** (A) Macroglossia; (B) Raccoon eyes in amyloidosis.

## Diagnosis

- Key feature for diagnosis of AL amyloidosis is the identification of the underlying B-lymphoproliferative process and clonal light chain.
- Serum protein electrophoresis (SPEP) and urine protein electrophoresis (UPEP) are NOT useful screening tests. However, more than 90% of cases, show serum or urine monoclonal LC or whole immunoglobulin by immunofixation electrophoresis of serum (SIFE) or urine (UIFE).

## Hereditary Amyloidosis

## 1. *Familial Mediterranean Fever*

- **Autosomal recessive** disorder.
- Characterized by recurrent attacks of fever accompanied with inflammation of serosal surfaces (peritoneum, pleura, and synovial membrane).

## 2. *Familial Amyloidotic Neuropathies*

- Familial amyloidotic neuropathies are characterized by **deposition of amyloid in peripheral and autonomic nerves** and the **fibrils are made up of mutant TTRs**.
- **ATTR (transthyretin associated)** amyloidosis are transmitted as autosomal dominant diseases.
- Clinically, they present with peripheral sensorimotor and autonomic neuropathy and symptoms of autonomic dysfunction, diarrhea and weight loss. Renal involvement is less common than with AL amyloidosis. Macroglossia does not develop.

## Hemodialysis-associated (Dialysis Related) Amyloidosis

- Patients with **chronic renal failure (ESRD) on long-term hemodialysis** have high **levels of  $\beta_2$ -microglobulin** in the serum because it cannot be filtered through dialysis membranes → gets deposited as amyloid. Its incidence appears to be decreasing with newer high-flow dialysis techniques.
- It produces rheumatologic manifestations and usually presents with carpal tunnel syndrome, persistent joint effusions, spondyloarthropathy, or cystic bone lesions.

## Other Amyloids

- **Cerebral amyloidosis:** Brain is a common site of amyloid deposition, though it is not directly affected in any form of acquired systemic amyloidosis.
- **Alzheimer's disease:** Intracerebral and cerebrovascular amyloid deposits are found in Alzheimer's disease. Most cases are sporadic.
- **Transmissible spongiform encephalopathy:** In hereditary spongiform encephalopathies, several amyloid plaques are observed.

## Treatment

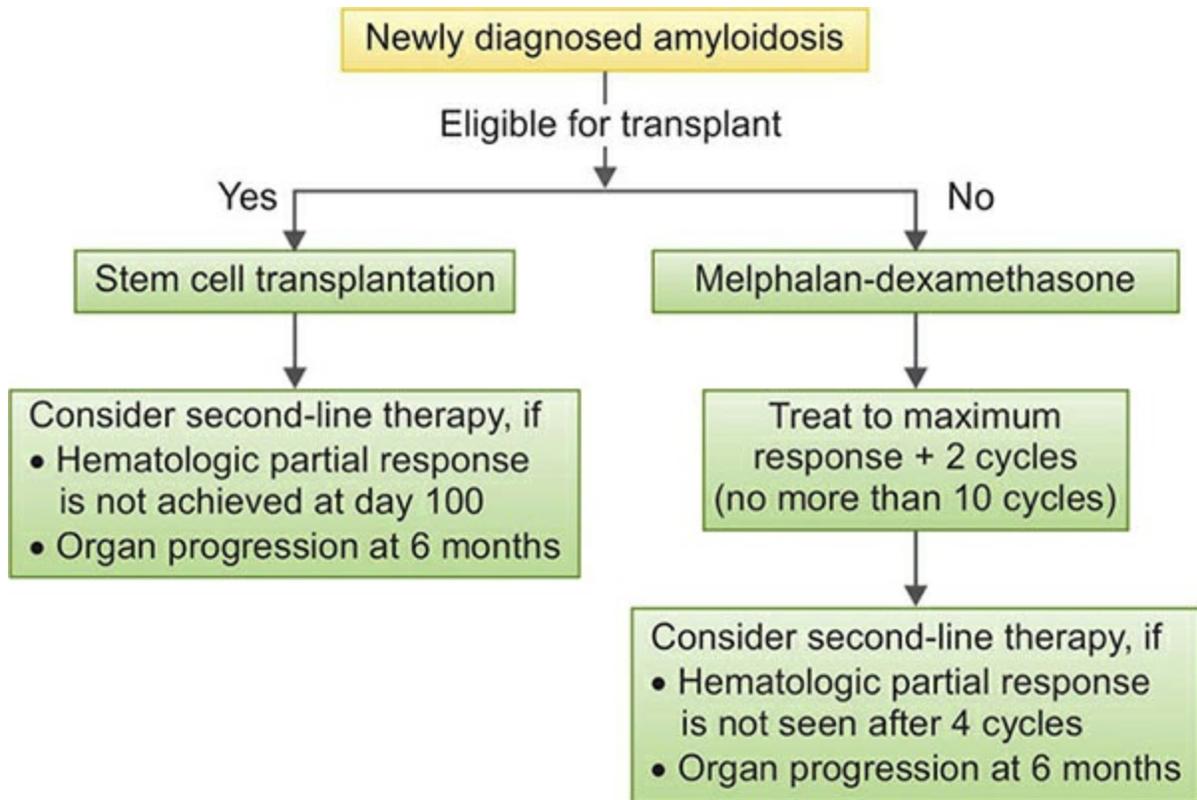

- **Aim of treatment:** To support the function of affected organs and, in acquired amyloidosis, treatment of the associated primary disorder to prevent further amyloid deposition.
- **Treatment of underlying disorder:** Treatment of any underlying inflammatory source or infection may produce regression of existing amyloid deposits. Chemotherapy with melphalan plus dexamethasone or stem cell therapy is useful in AL amyloidosis. Guidelines for the treatment of newly diagnosed primary amyloidosis is presented in Flowchart 20.1.
- Second-line chemotherapy includes thalidomide/lenalidomide, bortezomib, carfilzomib plus dexamethasone.
- Colchicine may be useful in familial Mediterranean fever.
- Nephrotic syndrome and congestive cardiac failure are treated with the relevant therapies.
- Hereditary transthyretin amyloidosis: In ATTR amyloidosis, where transthyretin is mainly produced in the liver, liver transplantation is the definitive therapy.

## Immunoblot (Western Blot)

### **Q. Write short note on Western blot.**

It is a test to detect antibodies. According to molecular weight, the microbial proteins are separated by polyacrylamide gel electrophoresis (PAGE). They are transferred (blotted) on to a nitrocellulose membrane, which is incubated with serum of patient. Binding of specific antibody is detected with an enzyme–anti-immunoglobulin conjugate (similar to in ELISA), and specificity is confirmed by its location on the membrane. The test is a highly specific and can be used to confirm the results of less specific tests such as ELISA.

**Flowchart 20.1:** Guidelines for the treatment of newly diagnosed primary amyloidosis.

# CHAPTER 21

## BIOLOGY OF AGING

### Aging

#### Q. What is aging?

**Definition:** Aging can be defined as gradual, insidious, and progressive decline in structure and function which begins to unfold after the achievement of sexual maturity. Various mechanisms that cause and counteract cellular aging are shown in Figure 21.1.

**Fig. 21.1:** Mechanisms of cellular aging and that counteract cellular aging. (IGF: insulin-like growth factor; TOR: target of rapamycin)

## Changes in Physiologic Function with Age (Table 21.1)

**Table 21.1:** Changes in physiologic function with age.

<b>Organ system</b>	<b>Age-related change</b>
Cardiovascular	<ul style="list-style-type: none"> <li>• Impaired contractile function and baroreceptor function</li> <li>• Decreased conductivity and ventricular filling</li> <li>• Increased systolic blood pressure</li> </ul>
Respiratory	<ul style="list-style-type: none"> <li>• Decreased lung elasticity, decreased maximal breathing capacity, decreased number of cilia and diminished mucus clearance, decreased arterial PO<sub>2</sub></li> <li>• Diminished cough reflex and diminished number of functional alveoli</li> </ul>
Gastrointestinal	Decreased esophageal and colonic motility
Renal	<ul style="list-style-type: none"> <li>• Decreased renal blood flow and glomerular filtration rate</li> <li>• Kidney size decreases by 20–30% by age 90</li> </ul>
Bladder	<ul style="list-style-type: none"> <li>• Decline in bladder capacity from about 500–600 mL to about 250 mL</li> </ul>
Immune	<ul style="list-style-type: none"> <li>• Decreased cell-mediated immunity, decreased T-cell number, decreased T-helper cells</li> <li>• Increased T-suppressor cells, increased autoimmunity</li> <li>• Loss of memory cells</li> <li>• Decline in antibody titers to known antigens</li> </ul>
Endocrine	<ul style="list-style-type: none"> <li>• Decreased hormonal responses to stimulation and decreased androgens and estrogens</li> <li>• Impaired glucose tolerance and impaired norepinephrine responses</li> </ul>
Autonomic nervous	<ul style="list-style-type: none"> <li>• Impaired response to fluid deprivation</li> <li>• Decline in baroreceptor reflex</li> <li>• Increased susceptibility to hypothermia</li> </ul>
Neurologic	<ul style="list-style-type: none"> <li>• Decreased vibratory sense and decreased proprioception</li> <li>• Slowed neuronal transmission</li> </ul>
Special senses	<ul style="list-style-type: none"> <li>• Presbyopia</li> <li>• Lens opacification</li> <li>• Decreased hearing, taste, and smell</li> </ul>
Musculoskeletal	Sarcopenia (reduced muscle mass and contractile force)
Integumentary changes	<ul style="list-style-type: none"> <li>• Decreased skin elasticity-wrinkling, senile purpura</li> <li>• Increased dryness</li> <li>• Thickened nails</li> <li>• Thinning of hair (baldness)</li> <li>• Decreased subcutaneous fat</li> </ul>

Factors which makes assessment/treatment of elderly different is presented in Box 21.1

**Box 21.1:** What makes the assessment/treatment of elderly different?

- Individuals become more dissimilar as they grow.
- Abrupt decline in any system is always due to disease and not due to normal aging.

- Multiple pathology
- Missing symptoms (e.g. angina in an elderly patient with osteoarthritis—may not manifest)
- Masking symptoms (e.g. history of fall and fracture neck of femur in an elderly female-masked a coexistent hemiparesis due to a internal capsule infarct.)

## Atypical Disease Presentations in Older Adults (Table 21.2)

**Table 21.2:** Atypical disease presentations in older adults.

<i>Diagnosis</i>	<i>Potential presenting symptoms and signs</i>	<i>Diagnosis</i>	<i>Potential presenting symptoms and signs</i>
Myocardial infarction	<ul style="list-style-type: none"> <li>• Altered mental status</li> <li>• Fatigue</li> <li>• Fever</li> <li>• Functional decline</li> </ul>	Malignancy	<ul style="list-style-type: none"> <li>• Altered mental status</li> <li>• Fever</li> <li>• Pathologic fracture</li> </ul>
Infection	<ul style="list-style-type: none"> <li>• Altered mental status</li> <li>• Functional decline</li> <li>• Hypothermia</li> </ul>	Pulmonary embolus	<ul style="list-style-type: none"> <li>• Altered mental status</li> <li>• Fatigue</li> <li>• Fever</li> <li>• Syncope</li> </ul>

## COMPREHENSIVE GERIATRIC ASSESSMENT

### **Q.** What is comprehensive geriatric assessment?

- Comprehensive geriatric assessment (CGA) is a multi-dimensional, multi-disciplinary diagnostic and therapeutic process conducted to determine the

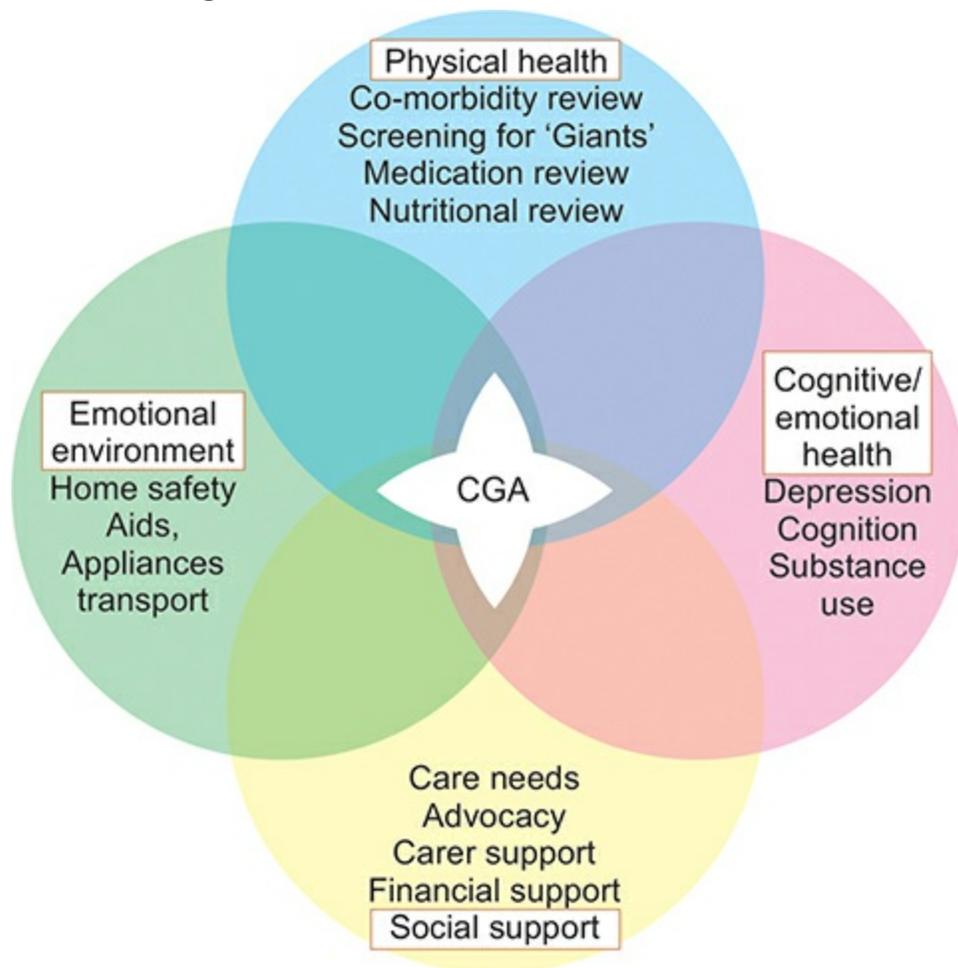

medical, mental, and functional problems of older people with frailty so that a co-ordinated and integrated plan for treatment and follow-up can be developed (Table 21.3).

Domains assessed and considered in the multidimensional approach of comprehensive geriatric assessment (CGA) are shown in Figure 21.2.

Basic activities of daily living (BADL) and instrumental activities of daily living (IADL) are presented in Table 21.4.

- Such assessments may be done by a Geriatrician working independently, or as part of an interdisciplinary team that often include specially trained nurses (RNs), occupational therapists (OT), physical therapists (PT), social workers (SW), dieticians, speech language pathologists (SLP) and specialty pharmacists.

How to identify elderly patients who would benefit from such an assessment (i.e. the frail elderly)? Strongly consider if they have three or more of the 'Red Flags' listed in Box 21.2.

**Fig. 21.2:** Components of comprehensive geriatric assessment (CGA).

**Table 21.3:** Systematic comprehensive geriatric evaluation of an older person.

<b>Medical evaluation PLUS</b>	<b>Additional assessment</b>
Standard medical history PLUS	<ul style="list-style-type: none"> <li>• Slow the pace of history taking</li> <li>• Ensure the patient can hear</li> <li>• Obtain collateral history</li> <li>• Ask about functional independence</li> <li>• Ask a full drug history</li> </ul>

**Table 21.4:** Basic activities of daily living (BADL) and instrumental activities of daily living (IADL)

<b>Basic activities of daily living (BADL)</b>	<b>Instrumental activities of daily living (IADL)</b>
<ul style="list-style-type: none"> <li>• Toileting, self-hygiene, bathing, grooming, dressing, feeding, and ambulation (stairs too).</li> </ul>	<ul style="list-style-type: none"> <li>• Tasks and roles you do at home</li> </ul>
<ul style="list-style-type: none"> <li>• <i>For each of the questions, enquire whether the person can perform it independently, whether he/she needs assistance or he/she is completely caregiver dependent</i></li> </ul>	<ul style="list-style-type: none"> <li>• Shopping, meal planning and preparation, housekeeping, laundry, transit, financial management, using a telephone, medication management and driving</li> </ul>

### **Objective Measures of Physical Function (Table 21.5)**

## **COMMON CLINICAL PROBLEMS OF AGING**

### **Gerontology**

Gerontology is the study of aging from a multidisciplinary perspective. It examines specific changes common to older adults as well as the broader social issues. Both the normal and the problematic aspects of aging are considered. In addition to education and research about adulthood and aging, practice is emphasized in order to provide services more effectively to older adults and their families.

### **Box 21.2:** Red flags in the comprehensive geriatric assessments.

- >75 years
- Needs help with ADLs/IADLs by caregiver
- Lives alone

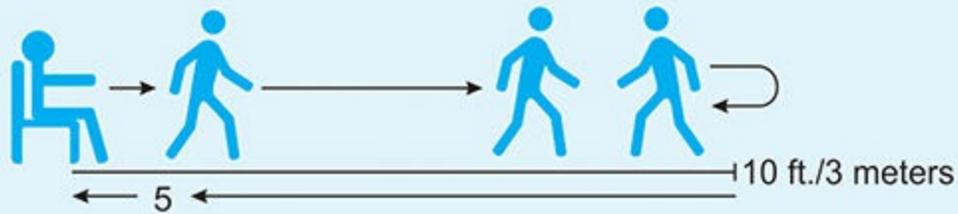

- Falls
- Delirium/confusion
- Incontinence
- >2 admissions to acute care hospital/year
- ‘Failure to thrive.’

## Geriatric Giants (Fig. 21.4)

- It is a term coined by Bernard Isaacs.
- It refers to the principal chronic disabilities of old age that have an impact on physical, mental and social domains of older adults. Many of these conditions are often wrongly perceived to be an unavoidable part of old age. However, they can be improved.

**Table 21.5: Objective measures of physical function.**

• Timed Get-Up-and-Go (TUG- test) (Fig. 21.3)	>30 sec: fall risk
• 6 meter walk	<5.8 sec
• Gait speed	>6.0 sec
• 6 minute walk	<300 m: mortality
	<400 m: functional impairment

The patient starts in a seated position

1. Instruct the patient:

When I say "Go", I want you to:

- a. Stand up from the chair
- b. Walk to the line on the floor at your normal pace for 3 meters
- c. Turn around
- d. Walk back to the chair at your normal pace
- e. Sit down again

2. On the word "Go", begin timing

3. Stop timing after patient sits back down

4. Record time

**Fig. 21.3:** Timed Get-Up-and-Go (TUGTest).

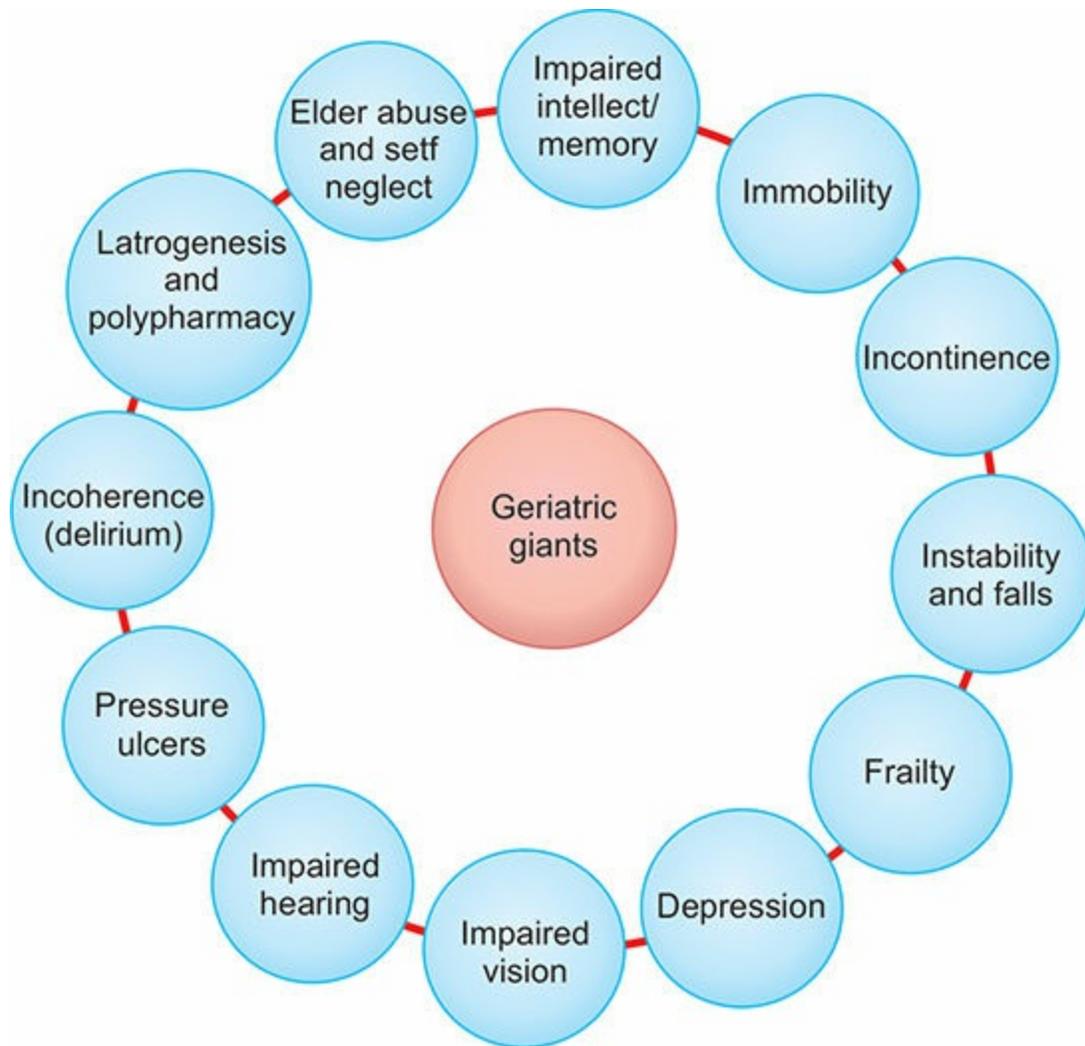

Fig. 21.4: Modern geriatric giants.

## Dementia

**Q. Write short notes on dementia and its causes.**

Dementia is typically progressive and nonreversible. It affects 5–10% of those above 65 years and 20–25% over 85 years.

**Box 21.3:** Diagnostic Criteria for Dementia (DSM-IV).

- **Memory impairment:** Impaired ability to learn new information or to recall old information.
- **One or more of the following:**
  - Aphasia (language disturbance); apraxia (impaired ability to carry out motor activities despite intact motor function); agnosia (failure to recognize or identify objects despite intact sensory function); disturbance in executive functioning-impaired ability to plan, organize, sequence, abstract.
- Cognitive deficits result in functional impairment (social/occupational).

- Cognitive deficits do not occur exclusively solely during a delirium.
- NOT due to other medical or psychiatric conditions.

### ***Diagnostic Criteria for Dementia (DSM-IV) (Box 21.3)***

The old dementia terminology required the presence of memory impairment for all of the dementias. It has been recognized that memory impairment is not the first domain to be affected. Hence, DSM 5 has subgrouped neurocognitive disorder into minor or major (Table 21.6).

**Table 21.6: DSM 5 subgroups of neurocognitive disorder.**

Minor neurocognitive disorder ( DSM-5)	Major neurocognitive disorder (DSM-5)
Modest cognitive decline from a previous level of performance in one or more of the domains	Substantial cognitive decline from a previous level of performance in one or more of the domains
Deficits are insufficient to interfere with independence, but greater effort, compensatory strategies, or accommodation may be required to maintain independence	Deficits are sufficient to interfere with independence
The cognitive deficits do not occur exclusively in the context of a delirium. The cognitive deficits are not primarily attributable to another mental disorder.	

### ***Classification of Dementia***

- **Cortical**
  - Disorder affecting the cortex, the outer portion or layers of the brain.
  - Alzheimer’s and Creutzfeldt-Jakob are two forms of cortical dementia.
  - Memory and language difficulties (aphasia) are most pronounced symptoms.
- **Subcortical**
  - Dysfunction in parts of the brain that are beneath the cortex.
  - Memory loss and language difficulties not present or less severe than cortical.
  - Huntington’s disease and AIDS dementia complex.
  - Changes in their personality and attention span. Thinking slows down.

### ***Mild Cognitive Impairment (MCI)/Prodromal Dementia***

- It is a condition in which there is mild memory impairment alone (1.5 standard deviations below that of age matched controls) in the absence of global cognitive decline or functional disabilities; it

can only be diagnosed by sophisticated neuropsychiatric testing. **It does not meet criteria for dementia.**

- Dementia will develop about 30% of those with MCI within three years. The remainder have stable, mild cognitive impairments that do not appear to progress.

## ***Causes of Dementia (Table 21.7)***

**Table 21.7:** Causes of dementia.

<b>Degenerative/inherited</b> <ul style="list-style-type: none"><li>• Alzheimer's disease (60–70%)</li><li>• Neurodegenerative disorders: Frontotemporal dementia (including Pick's disease), Lewy body disease, Parkinson's disease, Huntington's disease.</li></ul> <b>Vascular dementia (10–20%):</b> Diffuse small vessel disease	<b>Traumatic:</b> Chronic subdural hematoma, posthead injury <b>Infections:</b> Creutzfeldt–Jakob disease, HIV, syphilis <b>Toxic/nutritional:</b> Alcohol, thiamine deficiency, vitamin B12 deficiency <b>Prion diseases</b> <b>Reversible dementia</b>
<b>Neoplastic:</b> Primary/secondary deposits	

## **ALZHEIMER'S DISEASE**

**Q. Write a short essay/note on Alzheimer's disease.**

### **Introduction and Definition**

- Alzheimer's disease (AD) is the most common cause of dementia in the world. It is the most common cause of dementia above the age of 40.
- In India: Most common cause of dementia is AD (50–60%) followed by vascular and dementia with Lewy bodies (DLB).

### **Etiology**

- **Genetic factors**
  - Genetic factors play an important role and about 15% of AD is familial. Familial cases may be of two main groups: 1. early-onset disease with autosomal dominant mode of inheritance and 2. a later-onset group with polygenic inheritance.
  - **Mutations:** It can occur in several genes.
    - ◆ Point mutation in **amyloid precursor protein (APP)** can cause AD.
    - ◆ Mutations in the gene **presenilin-1 (PS1) and presenilin-2 (PS2)**. PS1 mutations are implicated in over 50% of families with familial

AD.

- ◆ The inheritance of one of the alleles of apolipoprotein  $\epsilon_4$ (apo  $\epsilon_4$ ) is associated with an increased risk of AD.
- **Environmental risk factors**
  - **Age:** It is the main risk factor and incidence of AD increases exponentially with age.
  - **Female gender** may also be a risk factor independent of the greater longevity of women.
  - **Head trauma and vascular risk factors.**
  - According to some studies long-term consumption of **NSAIDs** and acetaminophen have shown protection.

## Clinical Feature

**Q. Write a short essay/note on clinical features of Alzheimer's disease.**

The main clinical features are:

- **Memory impairment/loss:** Early recent (short-term) memory loss is key feature of AD.
- **Language problem:** It is the next common symptom, common being anomia and difficulty with word finding is characteristic.
- **Apraxia:** It is impaired ability (inability) to carry out (perform) skilled, complex, organized motor activities.
- **Agnosia:** It is failure to recognize objects (e.g. clothing, places or people).
- **Frontal executive function:** It is impairment of organizing, planning and sequencing.
- **Parietal presentation:** Visuospatial difficulties and difficulty with orientation in space.
- **Myoclonic jerks** (sudden brief contractions of various muscles or the whole body) may occur spontaneously or in response to physical or auditory stimulation. This phenomenon raises the possibility of Creutzfeldt-Jakob disease (CJD), but the course of AD is much more prolonged.
- **Generalized seizures** may also occur.
- Death usually results from malnutrition, secondary infections, or heart disease.

- The typical duration of AD is 8 to 10 years, but the course can range from 1 year to 25 years.

## Diagnostic Criteria for AD (Box 21.4)

**Box 21.4:** Diagnostic criteria for Alzheimer's disease.

- Memory impairment
- One or more of the following
  - Aphasia
  - Apraxia
  - Agnosia
  - Disturbance in executive functioning.

## Investigations

Investigation is aimed at excluding other treatable causes of dementia.

- Neuroimaging studies (computed tomography (CT) and magnetic resonance imaging (MRI)) are not specific for AD and may be normal early in the course of the disease. As AD progresses, diffuse cortical atrophy becomes apparent, and detailed MRI scans show atrophy of the hippocampus.
- PET–Scan: It is the test of choice. It shows hypoperfusion in bilateral perietotemporal cortex.
- CSF markers: (1) Raised tau proteins, (2) low B42 amyloid, and (3) elevated ceremides level.
- Routine investigations: Blood chemistry, a complete blood count, tests for syphilis, serum levels of vitamin B12 and thyroid functions.

### Treatment for Alzheimer's Disease

There is no specific treatment and the primary focus is on long-term amelioration of associated behavioral and neurologic problems. Supportive therapy for AD is listed in Box 21.5.

**Box 21.5:** Supportive therapy for AD.

- Rehabilitation
  - Cognitive rehabilitation
  - Exercise programs
  - Occupational therapy

**Drugs used** (Table 21.8): Donepezil, rivastigmine, galantamine and tacrine are cholinesterase inhibitors. Patients with Alzheimer disease (AD) have reduced cerebral content of choline acetyl transferase, which leads to a decrease in acetylcholine synthesis and impaired cortical cholinergic

function.

- Memantine appears to act by blocking overexcited N-methyl-D-Aspartate NMDA channels.
- Statins may have protective effect on dementia especially vascular. Antioxidants (vitamin E, selegiline), estrogen replacement, Ginkgo biloba have been tried.
- Mild to moderate depression is common in the early stages of AD and responds to antidepressants. Selective serotonin reuptake inhibitors SSRIs are commonly used due to their low anticholinergic side effects.

Newer developmental agents:

- Immunization against  $\beta$ -amyloid.
- Huprine X-acetylcholinesterase inhibitor.
- Xanomeline patch-m1/m4 muscarinic receptor agonist.
- AIT-082 (purine hypoxanthine derivative)-increases neurotransmission.
- COX 2 inhibitors-neuroinflammation therapy.
- Protease inhibitors-target gamma-secretases to prevent amyloid formation.

## Vascular dementia (Multi-infarct dementia)

### **Q. Discuss the clinical features of vascular dementia.**

- Second most common cause of dementia. Found in 15–30% of patients with dementia.
- **Risk factors:** Male sex, advanced age, diabetes, hypertension and/or other cardiovascular disorders.
- **Abrupt onset** of symptoms followed by **stepwise deterioration**.
- Findings on neurologic examination consistent with prior stroke(s), infarcts on cerebral imaging.
- **Focal neurologic symptoms:** Pseudobulbar palsy, dysarthria and dysphagia are most common.

**Table 21.8:** Drugs used for Alzheimer's disease and their adverse reactions.

<i>Drug and dosage</i>	<i>Adverse drug reactions</i>
Tacrine: 80 to 160 mg/day	Liver toxicity, nausea, vomiting, diarrhea
Donepezil: 5 and 10 mg/day	Nausea, vomiting, diarrhea, muscle cramps
Rivastigmine: 6 to 12 mg/ day	Nausea, vomiting, diarrhea, headache, dizziness
Galantamine: 20 to 50 mg/ day	Nausea, vomiting, agitation, sleep disturbances

### *NINDS-AIREN criteria for vascular dementia*

All the following criteria should be present:

- Dementia.
- Focal signs on examination + evidence of cerebrovascular disease by CT or MRI.

A relationship of the two above, with dementia within 3 months of a recognized stroke and or abrupt deterioration in fluctuation, or fluctuating stepwise progression of cognitive deficits.

### *Physical examination*

- May show increased tone (especially in the legs), exaggerated deep tendon reflexes, and Babinski responses.
- Examination may reveal carotid bruits, fundoscopic abnormalities and enlarged heart.
- Gait apraxia ('magnetic' gait) may be seen.
- MRI may reveal hyperintensities and focal atrophy suggestive of old infarctions.

### **Treatment**

- Control of risk factors such as hypertension, smoking, diabetes, hyperlipidemia.
- Antiplatelets/statins.
- Correction of sources of emboli, endarterectomy and anticoagulant therapy.

## **Frontotemporal dementia (FTD)**

### **Q. Write short essay on the clinical features of frontotemporal dementia.**

- Characterized by focal atrophy of the frontal and temporal lobes in the absence of Alzheimer pathology.
- **Pick's disease** was the first recognized subtype of FTD, one that is characterized pathologically by the presence of Pick bodies (silver staining intracytoplasmic inclusions) in the neocortex and hippocampus.
- Clinically, presents initially with **language abnormalities** and **behavioral disturbances**.
- Occurs between the ages of 35 and 75 years, and only rarely after age 75; the mean age of onset is the sixth decade.
- Both sexes are equally affected.

### **Box 21.6:** Core diagnostic features of FTD.

- Insidious onset and gradual progression
- Early decline in social interpersonal conduct
- Early impairment in regulation of personal conduct
- Early emotional blunting
- Early loss of insight

## Genetics of FTD

- 45% of patients have a family member affected.
- Up to 18% of these have an abnormality on the short arm of chromosome 17 localized near gene for the microtubule associated protein, *tau*.

Box 21.6 lists the core diagnostic features and of Table 21.9 lists the supportive diagnostic features of frontotemporal dementia.

**Table 21.9:** Supportive diagnostic features of frontotemporal dementia.

<b>Behavioral disorder</b>	<b>Speech and language deficits</b>
<ul style="list-style-type: none"><li>• Decline in personal hygiene and grooming</li><li>• Mental rigidity and inflexibility</li><li>• Distractibility and impersistence</li><li>• Utilization behavior hyperorality and dietary changes</li><li>• Perseverations and stereotyped behavior</li></ul>	<ul style="list-style-type: none"><li>• Altered speech output (spontaneity and economy of speech).</li><li>• Stereotype speech</li><li>• Echolalia</li><li>• Perseverations</li><li>• Mutism</li></ul>
<b>Physical signs</b>	<b>Investigations</b>
<ul style="list-style-type: none"><li>• Primitive reflexes; at least one of grasp, snout and sucking</li><li>• Incontinence</li><li>• Akinesia, rigidity and tremor (rarely)</li><li>• Low and labile blood pressure</li></ul>	<ul style="list-style-type: none"><li>• <b>Neuropsychology:</b> Significant impairment on frontal lobe tests in the absence of severe amnesia, aphasia or perceptuospatial disorder</li><li>• <b>EEG:</b> Normal despite clinically evident dementia</li><li>• <b>Brain imaging</b> (structural or functional) predominant frontal and/or temporal abnormality</li></ul>

## Normal-pressure hydrocephalus

It is a condition of pathologically enlarged ventricular size with normal opening pressures on lumbar puncture, clinically presents with a triad of dementia, gait disturbance, and urinary incontinence (**Adam's triad**—The 'Wet, Wobbly, and Wacky' Triad) reversible by the placement of a ventriculoperitoneal shunt.

## Dementia with lewy bodies

- Most common dementia syndrome associated with Parkinsonism.
- Second most common form of neurodegenerative dementia after Alzheimer disease (AD).
- For a probable diagnosis (Box 21.7) of Lewy body disease need at least two of the following:
  - Fluctuating cognition with pronounced variations in attention and

alertness.

- Recurrent **visual hallucinations** which are typically well-formed and detailed.
- Spontaneous motor features of parkinsonism.

**Box 21.7:** Features supporting the diagnosis dementia with Lewy bodies.

- Syncope or transient loss of consciousness (LOC)
- Neuroleptic sensitivity (i.e. new shuffling gait, tardive dyskinesia)
- Systematized delusions
- Hallucinations in other modalities (i.e. smell, hearing, taste)
- Falls

***Parkinson’s disease (refer pages 1008-13)***

Salient features of Pick’s disease and Creutzfeldt-Jacob disease are presented in Table 21.10.

**Table 21.10:** Salient features of Pick’s disease and Creutzfeldt-Jacob disease.

<b><i>Pick’s disease</i></b>	<b><i>Creutzfeldt-Jacob disease</i></b>
<ul style="list-style-type: none"><li>• Subtype of frontal lobe dementia</li><li>• Pick bodies (silver staining intracytoplasmic inclusions in neocortex and hippocampus)</li><li>• Language abnormalities</li><li>• Logorrhea (abundant unfocused speech)</li><li>• Echolalia (spontaneous repetition of words/phrases)</li><li>• Palilalia (compulsive repetition of phrases)</li></ul>	<ul style="list-style-type: none"><li>• Rapid onset and deterioration</li><li>• Motor deficits</li><li>• Seizures</li><li>• Slowing and periodic complexes on EEG</li><li>• Myoclonic activity</li></ul>

***Modifiable/Reversible Causes of Dementia (Table 21.11)***

**Q. List the reversible causes of dementia.**

**Table 21.11:** Modifiable causes of dementia.

<ul style="list-style-type: none"><li>• Depression so-called ‘Pseudodementia’</li><li>• Electrolyte disorders (hyponatremia, hypercalcemia, etc.)</li><li>• Hypothyroidism</li><li>• Late onset psychosis</li></ul>	<ul style="list-style-type: none"><li>• Vitamin deficiencies (B12, folate)</li><li>• Obstructive sleep apnea</li><li>• Normal pressure hydrocephalus (reverse with shunting)</li><li>• Brain tumor (post resection)</li></ul>
---	---

- Medication side effects (e.g. sedatives, anticonvulsants, antihypertensives, anticholinergics, first generation neuroleptics)
- Ethanol overuse/misuse
- Subdural hematoma (SDH)
- Sub-acute CNS infections (i.e. meningitis, encephalitis, syphilis)

## Cognitive Testing

Mini-Mental State Examination tests a broad range of cognitive functions including orientation, recall, attention, calculation, language manipulation, and constructional praxis. Scores can be classified as: no cognitive impairment = 24–30; mild cognitive impairment = 18–23; severe cognitive impairment = 0–17. **Montreal Cognitive Assessment (MoCA)** is a 30-point test that is more sensitive for the detection of mild cognitive impairment, and it includes items that sample a wider range of cognitive domains, including memory, language, attention, visuospatial, and executive functions.

## Frailty Syndrome

- Frailty is defined as the loss of an individual's ability to withstand minor stresses because of decreased functional reserve of several organ systems.
- The functional decline is so severely reduced that even a trivial illness or adverse drug reaction may result in organ failure and death.
- In a fit person of the same age, the same stresses would cause little upset.
- Frailty indicates increased vulnerability to loss of function.

Characterized by multisystem dysregulation involving four main domains that includes: (1) chronic inflammation, (2) sarcopenia, (3) osteoporosis and (4) alteration in neuroendocrine function.

### Box 21.8: Conditions required for the diagnosis of frailty.

1. Unexplained weight loss (>5% over a year)
2. Poor endurance and energy (self-reported)
3. Poor strength (in lowest 20th percentile)
4. Slow walking speed (Poor 'Get up and Go' test)
5. Low physical activity (lowest 20th percentile)

## Clinical Criteria

Five key elements form the core of the frailty cycle, including the following; *Frailty* is defined as the presence of three or more of conditions listed in Box 21.8.

Two main criteria used in diagnosing frailty are Linda Fried/Johns

Hopkins Frailty Criteria and the Rockwood Frailty Index.

## Delirium in the Elderly

*Definition:* It is an acute syndrome of transient, reversible cognitive dysfunction (*details discussed on pages 1086-7*).

### Management

Prevention is the best medicine.

- Eliminate extra medications, reverse metabolic abnormalities, hydration, and nutrition.
- Education of patients and family.
- Re-orientation by staff, family, sitters, clocks, calendars.
- Remove nonessential lines and tubes.
- Drug therapy:
  - Delirium that causes injury to the patient or others should be treated with medications.
  - The most common medications used are neuroleptics (Haloperidol, risperidone, olanzapine).
  - Benzodiazepines (lorazepam) often are used for withdrawal states.
  - Thiamine, cyanocobalamine supplementation.

## Depression

- Depression is the most common psychiatric illness in the elderly. Although common, it is NOT a natural part of aging.
- The prevalence in community dwelling elders range from 8% to 15%; it raises to as much as 30% of those in long-term care facilities. Depression and suicide are common in the elderly (especially older males; those over 75, have the same risk of suicide as 20–24 years old depressed males).
- Depression is NOT present in ALL older adults, but is under recognized and under treated.

**Bereavement or grief reaction** is commonly misdiagnosed as depression. A normal grief reaction after the death of a spouse or a loved one lasts about 2 months in time, with the mourning process being complete in <2 years. Feelings of sadness and preoccupation with the deceased are not helped by anti-depressant medications during this time of mourning.

Treatment of depression in the elderly is discussed on pages 1076-8.

**Box 21.9:** Potentially reversible causes (**‘DIAP-PERS’** mnemonic).

D - Delirium

I - Infection

A - Atrophic vaginitis or urethritis

P - Pharmaceuticals  
P - Psychological disorders  
E - Endocrine disorders  
R - Restricted mobility  
S - Stool impaction

---

## Incontinence

Involuntary loss of urine or stool in sufficient amount or frequency to constitute a social and/or health problem.

### *Urinary Incontinence*

- Urinary incontinence is defined as the involuntary loss of urine. It is a heterogeneous condition that ranges in severity from dribbling small amounts of urine to continuous urinary incontinence.
- The prevalence increases with age, but it is not a part of normal aging. It affects about 25–30% of community dwelling older women and 10–15% of community dwelling older men, 50% of nursing home residents; often associated with dementia, fecal incontinence, inability to walk and transfer independently.
- Bladder record or diary needs to be maintained.

### *Reversible Conditions Associated with Urinary Incontinence (Box 21.8)*

Potentially reversible causes urinary incontinence are listed in Box 21.9.

#### **Box 21.10:** Medications causing incontinence.

---

- Diuretics
  - Anticholinergics: Antihistamines, antipsychotics, antidepressants
  - Sedatives/hypnotics
  - Alcohol
  - Narcotics
  - $\alpha$ -adrenergic agonists/antagonists
  - Calcium channel blockers
- 

Medications causing incontinence are listed in Box 21.10.

### *Categories of Incontinence*

- **Urge incontinence:** Other Names: Detrusor hyperactivity, detrusor

instability, irritable bladder, spastic bladder.

- Most common cause of UI >75 years of age.
- Abrupt desire to void cannot be suppressed.
- Usually idiopathic.
- **Causes:** Infection, tumor, stones, atrophic vaginitis or urethritis, stroke, Parkinson's disease, dementia.

- **Stress incontinence**

- Most common type in women <75 years old.
- Occurs with increase in abdominal pressure; cough, sneeze, etc.
- Hypermotility of bladder neck and urethra; associated with aging, hormonal changes, trauma of childbirth or pelvic surgery (85% of cases).
- Intrinsic sphincter problems; due to pelvic/incontinence surgery, pelvic radiation, trauma, neurogenic causes (15% of cases).

- **Overflow incontinence**

- Over distention of bladder.
- Bladder outlet obstruction; stricture, BPH, cystocele, fecal impaction.
- Non-contractile bladder (hypoactive detrusor or atonic bladder); diabetes, MS, spinal injury, medications.

- **Functional incontinence**

- Does not involve lower urinary tract.
- Result of psychological, cognitive or physical impairment.

A recently defined syndrome, **overactive bladder**, includes urinary frequency (more than eight voids per 24 hours), nocturia (awakening at night from sleep to void), and urgency (the acute need to void), with or without incontinence is prevalent in around 31% women 75 years and older and 42% men 75 years and older.

### ***Treatment Options in Urinary Incontinence (Flowchart 21.1)***

General treatment options in urinary incontinence are mentioned in Table 21.12.

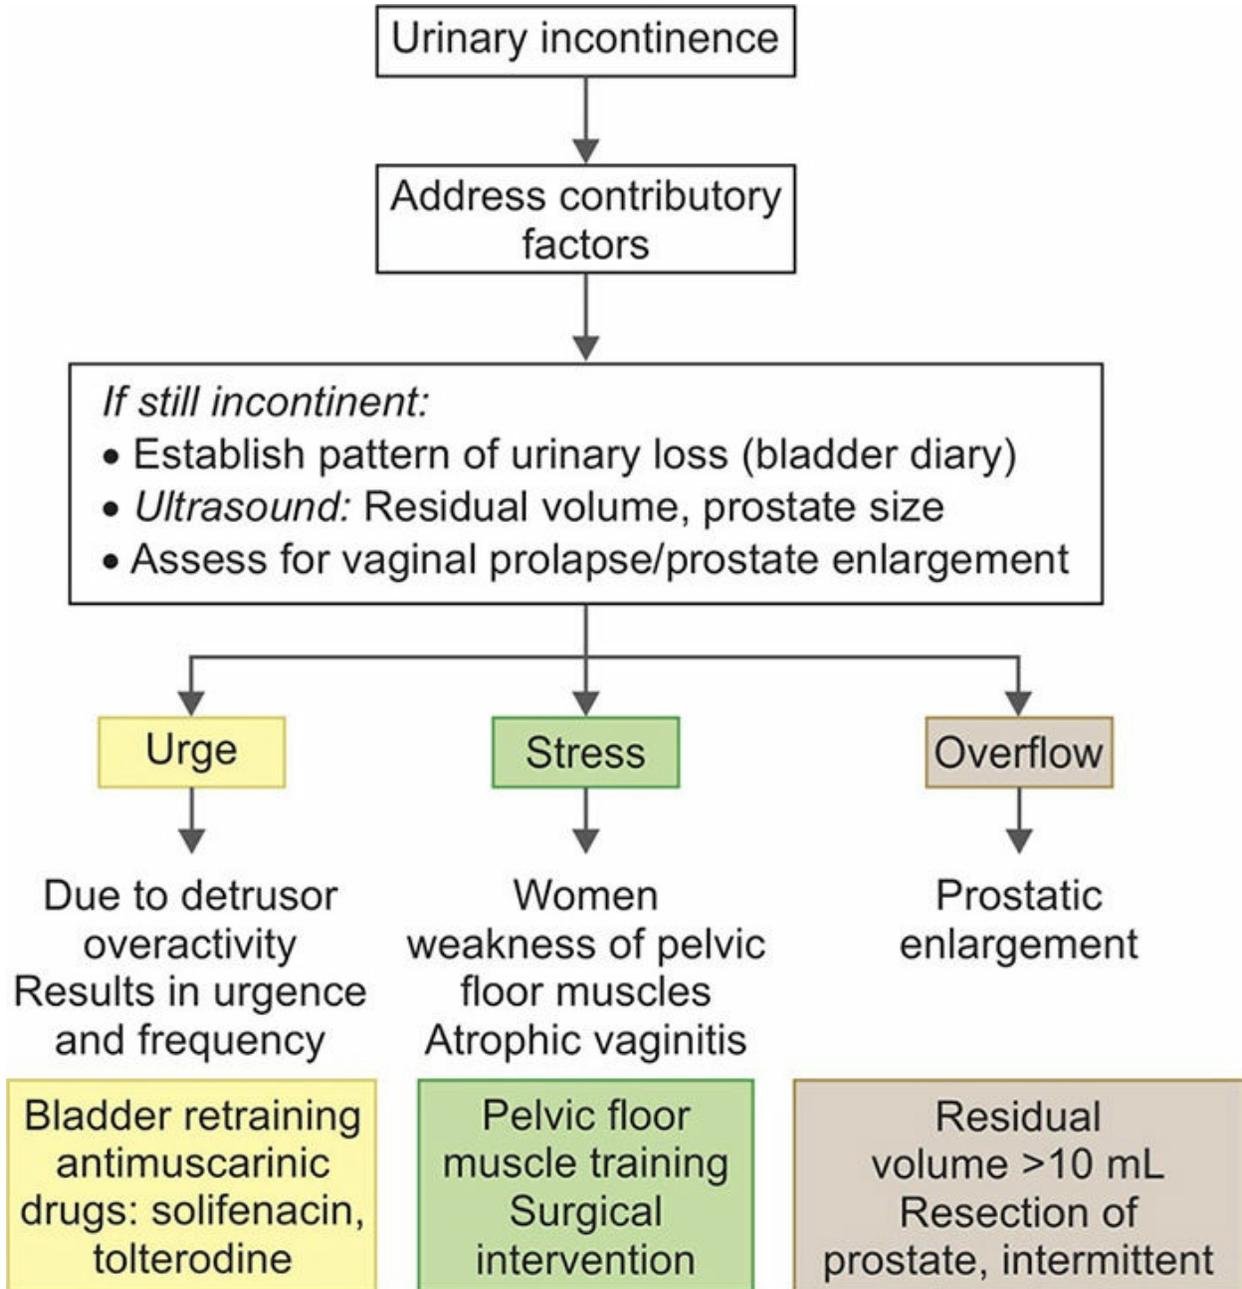

#### **Pharmacological interventions**

- **Urge incontinence:** Oxybutynin, Propantheline, Imipramine.
- **Stress incontinence:** Phenylpropanolamine, Pseudo-Ephedrine, Estrogen (orally, trans-dermally or transvaginally).

#### **Surgical interventions**

- **Urethral hypermotility:** Marshall-Marchetti-Krantz procedure, needle neck suspension.
- **Intrinsic sphincter deficiency:** Sling procedure.

**Other interventions (Box 21.11)**

**Flowchart 21.1:** Approach to urinary incontinence.

**Box 21.11:** Other interventions in urinary incontinence.

- Pessaries
- Periurethral bulking agents (periurethral injection of collagen, fat or silicone)
- Diapers or pads

- Chronic catheterization
  - Per urethral or suprapubic
  - Indwelling or intermittent

**Table 21.12: General treatment options in urinary incontinence.**

<ul style="list-style-type: none"> <li>• Reduce amount and timing of fluid intake</li> <li>• Avoid bladder stimulants (caffeine)</li> <li>• Use diuretics judiciously (not before bed)</li> <li>• Reduce physical barriers to toilet (use bedside commode)</li> <li>• Bladder training</li> <li>• Patient education</li> </ul>	<ul style="list-style-type: none"> <li>• Scheduled voiding</li> <li>• Positive reinforcement</li> <li>• Pelvic floor exercises (Kegel exercises)</li> <li>• Biofeedback</li> <li>• Caregiver interventions: Scheduled toileting, habit training, prompted voiding</li> </ul>
--	--

**Table 21.13: Falls in elderly.**

<i>Intrinsic factors</i>	<i>Extrinsic factors</i>
<ul style="list-style-type: none"> <li>• Medical conditions</li> </ul>	<ul style="list-style-type: none"> <li>• Medications</li> </ul>
<ul style="list-style-type: none"> <li>• Impaired vision and hearing</li> </ul>	<ul style="list-style-type: none"> <li>• Improper use of assistive devices</li> </ul>
<ul style="list-style-type: none"> <li>• Age-related changes</li> </ul>	<ul style="list-style-type: none"> <li>• Environment</li> </ul>

## Falls in the Elderly

### **Q. Write short note on falls in elderly.**

About 30% of individuals over 65 years of age fall each year. About 10–15% of falls result in serious injury and they are the cause of >90% of hip fractures in this age group. Factors causing falls in elderly are listed in Table 21.13.

### ***Normal Changes with Aging (Table 21.14)***

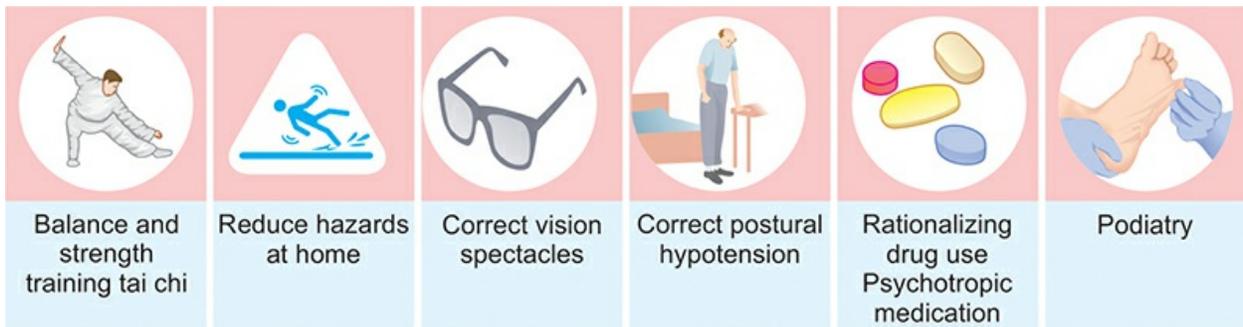

**Table 21.14: Normal changes with aging.**

<p><b>Neurologic changes</b></p> <ul style="list-style-type: none"> <li>• Increased reaction time</li> <li>• Decreased righting reflexes</li> <li>• Decreased proprioception</li> </ul>	<p><b>Changes of gait</b></p> <ul style="list-style-type: none"> <li>• Slower gait</li> <li>• Decreased stride length and arm swing</li> <li>• Forward flexion at head and torso</li> <li>• Increased flexion at shoulders and knees</li> <li>• Increased lateral sway</li> </ul>
<p><b>Vision changes</b></p> <ul style="list-style-type: none"> <li>• Decreased accommodation and dark adaptation</li> <li>• Decreased muscle mass</li> </ul>	

Fall risk factors and targeted interventions (Table 21.15 and Fig. 21.5)

**Table 21.15:** Fall risk factors and targeted interventions.

<i>Risk factor</i>	<i>Targeted intervention</i>
Postural hypotension	Behavioral recommendations, such as hand clenching, elevation of head of bed; discontinuation or substitution of high-risk medications
Use of benzodiazepine or sedative-hypnotic agent	Education about sleep hygiene; discontinuation or substitution of medications
Use of multiple prescription medications	Review of medications
Environmental hazards	Appropriate changes; installation of safety equipment (e.g. grab bars)
Gait impairment	Gait training, assistive devices, balance or strengthening exercises
Impairment in transfer or balance	Balance exercises, training in transfers, environmental alterations (e.g. grab bars)
Impairment in leg or arm muscle strength or limb range of motion	Exercise with resistance bands or putty, with graduated increases in resistance

**Fig. 21.5:** Multidisciplinary approach to prevent falls

Box 21.12 lists the common pathologies associated with fall.

There are several reasons for the greater incidence of iatrogenic drug reactions in the elderly, the most important of which is the high number of medications that are taken by elders, especially those with multiple comorbidities.

### **Guidelines for Drug Therapy in the Elderly (Box 21.13)**

#### ***Elder Abuse***

- More than a million people world over aged 65 or older have been injured,

exploited, or otherwise mistreated by someone on whom they depended for care or protection. Neglect is the most common form of abuse followed by financial and emotional abuse.

- Elder abuse can be suspected when the patient exhibits behavioral changes in the presence of the caregiver, delays between occurrence of injuries and sought treatment, inconsistencies between an observed injury and associated explanation, lack of appropriate clothing or hygiene, and not filling prescriptions.
- Many elders with cognitive impairment become targets of financial abuse.
- Abuse and self-neglect has increased risk of mortality.

### ***Major Forms of Abuse***

1. **Physical and sexual abuse:** Any act of violence or rough treatment, whether or not actual physical injury results. For example, slapping, punching, kicking, pinching, burning, restraints.
2. **Emotional and psychological abuse:** Any act that diminishes dignity and self worth. For example, confinement, isolation, verbal assault, humiliation and infantilization.
3. **Financial abuse and material exploitation:** Any improper conduct that results in monetary or personal loss for the older adult.
4. **Abandonment and neglect**
  - Active neglect: Intentional (deliberate) withholding of basic necessities and/or care for physical or mental health.
  - Passive neglect: Not providing basic necessities and care. There is no conscious attempt to inflict distress.
5. **Medical abuse:** Any medical procedure or treatment done without the permission of the older person or their Power of Attorney or substitute decision maker.

### **Box 21.12:** Common pathologies associated with fall.

- Ophthalmologic diseases
- Arthritis
- Foot problems
- Neurologic illness
- Parkinson's and related disorders
- Strokes

- Peripheral neuropathy
- Dizziness and disequilibrium

---

### **Box 21.13:** Guidelines for drug therapy in the elderly.

---

#### **Recommended approach**

Use nonpharmacologic approaches whenever possible.

Avoid *routine* use of 'as needed' drugs for sleep, anxiety, pain.

Choose the drug with the least toxic potential. Substitute less toxic alternatives whenever possible (antacid or sucralfate for an H<sub>2</sub>-blocker or proton pump inhibitors, Metamucil or Kaopectate for Imodium, scheduled acetaminophen regimen for pain management).

Reduce the dosage.

'Start low and go slow.'

Start with 25–50% of the standard dose of psychoactive drugs in the elderly.

Titrate the drug slowly.

Set realistic end points: Titrate to improvement, not elimination of symptoms.

Keep the regimen simple.

Regularly reassess the medication list.

Re-evaluate long-time drug use because the patient is changing.

Review over-the-counter medication use.

---

# **Dermatology**

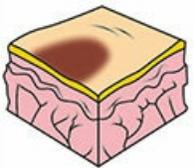

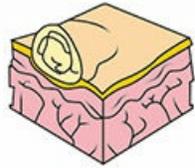

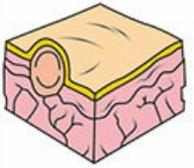

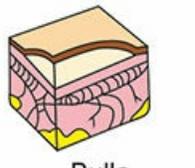

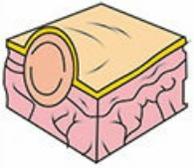

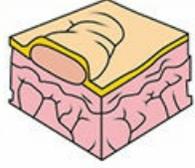

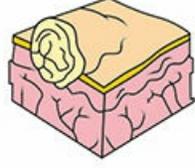

# CHAPTER 22

## INTRODUCTION

### Description of Primary Skin Lesions (Fig. 22.1)

**Q. Write short note on:**

- Macule and causes of macular lesions.
- Plaque and its common causes.
- Papule and causes of papular lesions.

 <p>Macule, patch</p>	 <p>Vesicle</p>
 <p>Papule, plaque</p>	 <p>Bulla</p>
 <p>Nodule, tumor</p>	 <p>Wheal</p>
	 <p>Pustule</p>

**Fig. 22.1:** Schematic representation of common primary skin lesions.

## Description of Secondary Skin Lesions (Fig. 22.2)

 <p>Erosion</p>	<p>Description: Partial loss of epidermis, which will heal without scarring</p>	 <p>Ulcer</p>	<p>Description: Full thickness loss of epidermis and some dermis, which will heal with scarring</p>
 <p>Atrophy</p>	<p>Description: Depression of the surface due to thinning of the epidermis or dermis</p>	 <p>Fissure</p>	<p>Description: Linear split in the epidermis or dermis at an orifice (angle of the mouth or anus)</p>
 <p>Scale</p>	<p>Description: Dry/flaky surface due to abnormal stratum corneum with accumulation of or increased shedding of keratinocytes Example: Psoriasis</p>	 <p>Lichenification</p>	<p>Description: Thickening of the epidermis with exaggerated skin markings. Example: Lichen planus</p>

Fig. 22.2: Schematic representation of common secondary skin lesions.

## PSORIASIS

**Q. Write short essay/answer on etiology, clinical manifestations, and management of psoriasis.**

It is a non-infectious, chronic papulosquamous T cell mediated inflammatory skin disorder and is one of the most common skin diseases. It usually follows a relapsing and remitting course.

- **Gender:** It equally affects males and females.
- **Age:** It occurs in two peaks of age.
  - Early onset (age 16–22) is commoner and is often with a positive family history. It has an increased prevalence of the **HLA group Cw6**.
  - Late onset (peaks at age 55–60 years) and no HLA association.

### Etiology

The exact etiology of psoriasis is not known.

- **Genetic factors:** The genetic component is complex and polygenic. There is a clear genetic predisposition (with a positive family history in more than 50% of patients) in association with certain environmental triggers. Nine susceptibility genes have been identified (*PSORS1* to *PSORS9*), most important being *PSORS1* (on chromosome 6p21.3).
- **Environmental factors:** Several environmental triggers produce psoriasis in a genetically predisposed individual. These include infections, stress, physical injury, trauma, smoking, alcohol and drugs.

## Pathogenesis

- Psoriasis results from **interactions of genetic and environmental factors**. There is a shortened cell cycle time for keratinocytes (36 hours compared with 311 hours in normal skin) and a decreased turnover time of the epidermis (four days from basal cell layer to stratum corneum, compared with 27 days in normal skin).
- Available evidence suggests that in genetically susceptible individuals, triggering factors activate the antigen-presenting cells (dendritic/Langerhans) which in turn activate CD4<sup>+</sup> T<sub>H</sub>1 and T<sub>H</sub>17 cells via IL-12 and IL-23 respectively and these T cells enter the skin and accumulate in the epidermis. These T cells secrete mediators (TNF- $\alpha$  and interferon- $\gamma$  by T<sub>H</sub>1; IL-17A, 17F and 22 by T<sub>H</sub>17) which activate keratinocytes to produce antimicrobial peptides (e.g.  $\beta$ -defensins), cytokines (e.g. TNF- $\alpha$ , IL-1 $\beta$ , IL-6) and chemokines.

## Pathology

- Increased epidermal cell proliferation (hyperproliferation of keratinocytes).
- Proliferation of the subepidermal vasculature leads to dilated, tortuous blood vessels within the dermal papillae surrounded by a mixed neutrophilic and lymphohistiocytic perivascular infiltrate.
- Dense inflammatory cell infiltrate. Polymorphonuclear abscesses may be seen within mildly spongiotic foci of the superficial epidermis (**spongiform pustules**) and within the parakeratotic stratum corneum (**Munro microabscesses**).

## Clinical Features

- Psoriasis can involve the **skin, scalp, and nails** and can present in

different clinical patterns.

- Clinically skin lesions are characterized by well-defined pink-red, sharply demarcated macules, papules, or rounded plaques, that are usually covered by silvery scales with a whitish halo around lesions (**Woronoff's sign**). On removal of the scales, by scrapping using a microscopic slide, multiple, minute, pin-point bleeding points may be observed (**the Auspitz sign/Grattage test**). This finding reflecting the proliferation of blood vessels in the superficial dermis. It predominantly affects **extensor surfaces** and scalp, and has a chronic fluctuating course. *There is increased association of psoriasis with HIV infection.*

### Box 22.1: Types of psoriasis.

- Plaque psoriasis (psoriasis vulgaris), chronic plaque psoriasis
- Guttate psoriasis (small rain drop like psoriatic lesions)
- Inverse psoriasis (flexural psoriasis)
- Localized pustular psoriasis
- Generalized pustular psoriasis
- Erythrodermic psoriasis
- Von Zumbasch psoriasis-pustular+erythroderma

## Types of Psoriasis (Box 22.1)

**Q.** Write short essay/note on types and diagnosis of psoriasis.

### ***Plaque Psoriasis (Psoriasis Vulgaris), Chronic Plaque Psoriasis***

- Most common form and accounts for 90% of cases.
- Lesions (Figs. 22.3A and B):
  - Symmetrically distributed plaques involving the scalp, extensor surfaces of the elbows, knees, gluteal cleft, and lower back, ears, scalp and back. Plaques 1–10 cm in diameter with raised, well-defined margins.
  - Thick silvery scale frequently present (although bathing may remove scale).
  - Classically asymptomatic, although some patients report pruritis, irritation, or pain.
  - Pitting of nail plates and involvement of intertriginous areas (umbilicus and intergluteal cleft) may occur.

- Psoriatic lesions can be induced in susceptible individuals by minor local injury/trauma, a process known as the **Koebner phenomenon** (Fig. 22.4).
- Exacerbating factors: Drugs (lithium, beta-blockers, chloroquine, NSAIDs, ACE inhibitors, terbinafine), infections (bacterial and viral), and ethanol abuse.

**Figs. 22.3A and B:** Skin lesion of psoriasis.

**Fig. 22.4:** Koebner phenomenon in psoriasis.

## Associated Features of Psoriasis

- **Nails (Fig. 22.5):** Involvement is common and may be observed up to 50% of patients with psoriasis. These include (a) ‘thimble pitting’ of the nail plate; (b) distal separation of the nail plate from the nail bed (onycholysis); (c) yellow-brown discoloration underneath the nail plate (‘oil drop’ sign), (d) subungual hyperkeratosis and (e) thickening of the nail (onychodystrophy).

**For diagnosis of nail involvement:** > 6 nails should be involved with each nail should have >20 pits.

- **Psoriatic arthropathy:** It may be seen in 5–10% of psoriatic patients. It usually develops several years after appearance of skin lesions and most of these will have nail changes. It is a form of chronic sero-negative spondyloarthropathy (discussed on page 668).
- **Others:** It may be associated with the co-morbidities such as ulcerative colitis, Crohn’s disease, coronary artery disease, metabolic syndrome and lymphoma.

**Fig. 22.5:** Nail changes in psoriasis.

## Investigations and Diagnosis

In most cases, the diagnosis can be made based on the history and physical examination alone. Biopsy is seldom necessary.

### Management of Psoriasis

Treatment depends on the type, location, and extent of disease.

#### General Management

- Education, explanation reassurance and instruction are important.
- Instructed to avoid excess drying or irritation of skin and to maintain adequate hydration of skin.

**Treatment** can be divided into four broad categories namely (1) topical agents, (2) UV therapies, (3) systemic agents, and (4) biological therapies.

**Treatment of psoriasis vulgaris:** A three step approach.

#### **Step 1: Topical treatments**

- **Emollients/moisturizers:** Petroleum jelly and thick creams, especially effective when applied after hydrating bath or shower.
- **Topical corticosteroids:** Mainstay for treatment. Moderate to high potency ointments (e.g. betamethasone 0.5%) +/- occlusion by tape or plastic wrap recommended for thick plaques on extensor surfaces, whereas low potency (e.g. 0.05% fluocinonide) usually sufficient for face and intertriginous areas.
- **Coal tar:** Usually used in conjunction with steroids, although may be used alone.
- **Calcipotriene and Calcitriol:** Vitamin D3 analog that affects growth and differentiation of keratinocytes.

- **Tazarotene:** Topical retinoid (vitamin A derivative).
- Topical calcineurin inhibitors: Topical **tacrolimus and pimecrolimus**.
- Salicylic acid: Keratolytic that softens and removes scale from plaques, allowing topical meds to penetrate.
- Topical anthralin

**Q. Write short note on PUVA therapy in psoriasis.**

**Step 2: Phototherapy:** *Effect likely through immunomodulatory properties*

- Sunlight: Careful sun exposure may improve psoriasis, but sunburn may exacerbate it.
- **UVB (295–320 nm) radiation:** Erythema inducing doses (3–5x/week until remission) used for moderate to extensive disease, alone or in combination with topical tar.
- UVB narrow band (311nm): Has been shown to be more effective than the broader band in some studies, inducing more apoptosis of T-cells.
- **PUVA:** Photochemotherapy with oral psoralen (8-methoxypsoralen) followed by exposure to UVA (320–400 nm) radiation used for moderate-severe disease when UVB fails. Effective (75% of patients note marked improvement), but increases risk for cataract, pigmentation, premature skin aging and skin cancer. Psoralens are natural photosensitizers found in many plants. Psoralen molecules intercalate between the two strands of DNA and, on excitation with ultraviolet A (UVA), photons cross-link the DNA strands. It is thus a pro-drug which after oral administration is distributed throughout the body, but only activated in skin that is exposed to UVA. Other uses of PUVA include vitiligo, mycosis fungoides, atopic dermatitis and senile pruritis.
- High Energy 308 nm excimer laser: Treats only involved skin, allows higher doses to be delivered to the plaques, compared with traditional phototherapy.
- Two regimens used commonly are:
  1. *Goeckerman regimen:* UVB + coal tar.
  2. *Ingram regimen:* coal tar+UVB+ dithranol.

**Step 3: Systemic therapy**

- **Methotrexate:** Effective in severe psoriasis, psoriatic arthritis, and psoriatic nail disease.
- **Acitretin:** Vitamin A analog used for treatment of severe psoriasis, especially pustular and erythrodermic variants. It is a teratogen and pregnancy is contraindicated for three years after discontinuing the drug. May be used in combination with UVB or PUVA.
- **Cyclosporine:** T-cell suppressor indicated for severe psoriasis not responsive to other agents.

**Biologics, Immunomodulatory Drugs**

- Etanercept: Recombinant TNF-alpha inhibitor, approved for treatment of psoriatic arthritis and for adults with moderate-severe plaque psoriasis.
- Alefacept: Recombinant protein that binds to CD2 receptor on T-lymphocytes.
- Efalizumab: Monoclonal antibody to CD11a. Approved for moderate-severe plaque psoriasis.
- Infliximab: TNF-alpha inhibitor.
- Human interleukin12/23 monoclonal antibody: Ustekinumab, a fully human monoclonal antibody against the p40 subunit of IL-12 and IL-23 is effective. Guselkumab is a human immunoglobulin G1 (IgG1) lambda monoclonal antibody that binds to the p19 subunit of IL-23.
- Monoclonal antibody against the p40 molecule shared by IL12 and IL23: For example, brikinumab is effective in moderate and severe psoriasis.

Others: Brodalumab (an antiIL17 receptor antibody) and ixekizumab (an anti IL17 monoclonal antibody) can also be effective in psoriasis.

Newer treatment options: (i) **Climatotherapy** (bathing in sea water in combination with sun

exposure) and (ii) **Balneophototherapy** (salt water baths with artificial UV exposure).

## LICHEN PLANUS (LP)

### **Q.** Write short essay on lichen planus.

Lichen planus is a pruritic inflammatory dermatosis that is commonly associated with mucosal involvement. Rarely, it may be associated with involvement of nail (nail dystrophy) and hair (scarring alopecia).

### **Etiology**

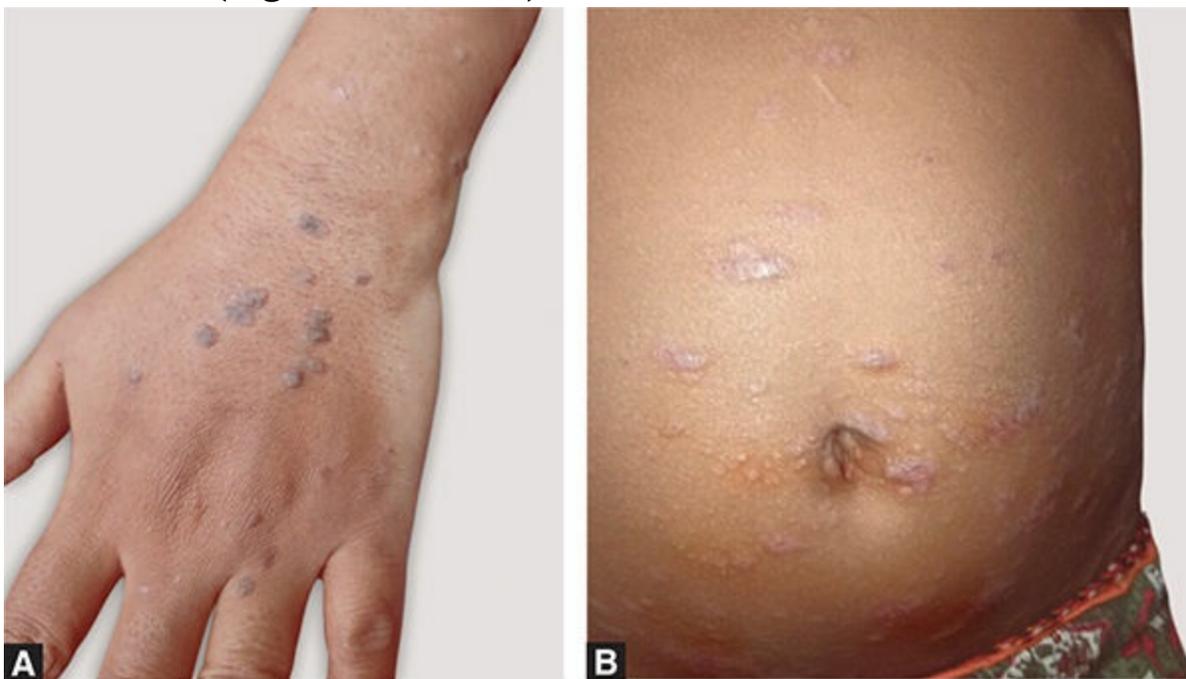

**Autoimmune:** An autoimmune mechanism is suspected, because of its association with inflammatory bowel disease, primary biliary cirrhosis, autoimmune hepatitis, hepatitis B and C, alopecia areata, myasthenia gravis and thymoma. There are similarities with graft-versus-host disease (GVHD). Drugs like thiazides, INH can produce lichenoid eruptions.

### **Clinical Features**

**Age and gender:** Lichen planus affects women more than men (at a ratio of 3:2), and occurs most often in middle-aged adults.

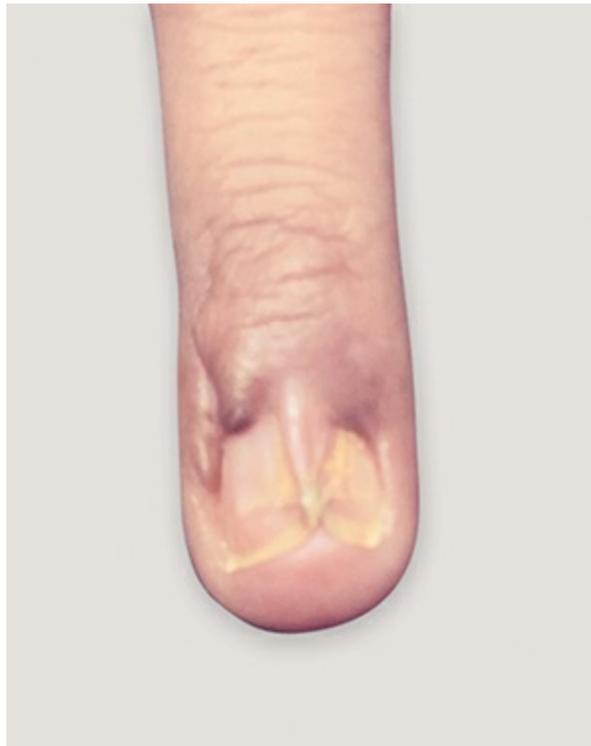

### **Characteristics of Lesion**

- **Skin lesions (Figs. 22.6A and B):**

**Figs. 22.6A and B:** Skin lesions in lichen planus.

- The typical rash of lichen planus is well-described by the ‘5 P’s’: Well-defined **pruritic, planar, purple, polygonal papules or plaques**.
- **Sites involved:** Flexor surfaces especially wrists, flanks, medial thighs, shins of tibia, glans penis, nails, scalp and oral mucosa.
- There may be a characteristic fine lacy white pattern (network) on the surface of lesions (**Wickham’s striae**).
- **Koebner’s phenomenon**.
- After lesions subside, post lichen hyperpigmentation occurs.
- **Mucous membrane:** Involvement is common (30–70%) and prominent symptom is of severe pain rather than itch. The mouth is the most commonly affected. It can also affect genital and other mucosal surfaces.
- **Nail involvement:** Occurs in about 10% and causes a thinning of the nail with longitudinal ridges and may progress to complete loss of the nail plate (**pterygium formation**) (Fig. 22.7).

**Fig. 22.7:** Nail changes (pterygium formation) in lichen planus.

- **Scalp involvement:** Lichen planopilaris is the specific name given to lichen planus on the scalp that may cause permanent, scarring alopecia.

## Diagnosis

**Histological changes:** Characteristic histological changes include: (1) hyperkeratosis with thickening of the granular cell layer, (2) basal cell degeneration and (3) dense, band-like T-lymphocyte infiltrate at the dermal-epidermal junction, with affinity for the epidermis (epidermotropism). The dermoepidermal junction becomes ragged and appears ‘saw-toothed’. The basal layer shows liquefactive degeneration with colloid (apoptotic) bodies, **Colloid or Civatte bodies** in the upper dermis.

## Prognosis

It is usually self-limiting and often clears by 18 months but can recur at intervals.

## Complications of Lichen Planus (Box 22.2)

**Box 22.2:** Complications of lichen planus.

- Squamous cell carcinoma in oral ulcerative lesions
- Cicatricial alopecia in scalp LP
- Postinflammatory hyperpigmentation.

### Management

- Treatment is symptomatic.
- Topical corticosteroids: Potent local corticosteroids (e.g. 0.05% clobetasol propionate, 0.1% triamcinolone ointment, twice daily for 2 to 4 weeks) are helpful in patients with limited disease. Oral lesions may require high potency steroids given as an ointment, gel or mouth wash. Topical 0.1% tacrolimus ointment or pimecrolimus may be very useful for painful oral disease unresponsive to steroids.
- Oral therapy: Short courses of systemic corticosteroids (oral prednisolone 30 mg daily for 2–4 weeks) are sometimes required for extensive disease.
- Widespread lichen planus may require UVB, PUVA or UVA1 and in resistant cases retinoids or immunosuppressants such as azathioprine and ciclosporin may be helpful.
- Hydroxychloroquine and dapsone have also been tried.

## ACANTHOSIS NIGRICANS (AN)

**Q. Write short note on acanthosis nigricans.**

It is a skin lesion marked by thickened, verrucous (warty) hyperpigmentation of the skin with a velvety texture (Fig. 22.8) predominantly of the flexural areas (axillae, skin folds of the neck, groin, and anogenital regions) including

the lips.

- In 80% of cases, it is associated with benign conditions (most commonly with obesity, **insulin resistance** and diabetes, drugs like nicotinic acid, fusidic acid, stilbestrol, OCPs), develops gradually, usually during childhood or puberty. They are associated with very high levels of insulin owing to insulin resistance. Obesity associated AN is sometimes termed 'pseudo-acanthosis nigricans'.
- In the remaining cases, it arises in association with underlying cancers (most commonly *gastrointestinal adenocarcinomas*), usually in middle-aged and older individuals. In this setting, it occurs as a paraneoplastic phenomenon caused by growth factors released from tumors. Other tumors producing this are Wilm's tumor malignant tumors of bronchus, pancreas, ovary, bile duct, gallbladder, breast and thyroid.

Associated thickening of palms with accentuated dermatoglyphics is called **Tripe palms**. **Acrochordons (skin tags) may be present.**

**Fig. 22.8:** Skin lesions of acanthosis nigricans.

#### **Treatment**

- Treat any underlying disease/malignancy.

- Weight loss is advised in the obese.
- Topical or oral retinoids (0.5 mg/kg per day) may be helpful.

Few may benefit from metformin, oral isotretinoin, topical retinoic acid, topical salicylic acid and oral fish oil.

## ECZEMA

### Q. Write short essay/answer on:

- Types of eczema and outline their clinical features and general management.
- Give a brief account of dermatitis.

Eczema is catarrhal inflammation of a sensitive skin, synonymous with the term dermatitis. Eczema is not a specific disease entity and may develop as a final common response of the skin to several causes. These causes may be either exogenous or endogenous in origin. It presents with spectrum of clinical presentation from acute through to chronic. Acute type is histologically characterized by spongiosis (intercellular edema of the epidermis) and intra-epidermal vesiculation (producing multilocular blisters). Chronic eczema shows more epidermal thickening (acanthosis).

### Classification of Eczema (Table 22.1)

#### *Atopic Dermatitis*

### Q. Write short essay/answer on atopic dermatitis.

Atopic dermatitis (AD) is an endogenous type of eczema that develops in individuals who are 'atopic' and is the cutaneous expression of the atopic state. Atopic state is characterized by a family history of asthma, allergic rhinitis, or eczema.

**Table 22.1:** Classification of eczema.

<i>Endogenous</i>	<i>Exogenous</i>
<ul style="list-style-type: none"> <li>• Atopic eczema</li> <li>• Discoid eczema (nummular eczema)</li> <li>• Seborrheic eczema</li> <li>• Hand eczema</li> <li>• Venous ('gravitational')/Asteatotic eczema</li> </ul>	<ul style="list-style-type: none"> <li>• Contact eczema               <ul style="list-style-type: none"> <li>– irritant</li> <li>– allergic</li> </ul> </li> <li>• Photosensitive eczema</li> <li>• Lichen simplex/nodular prurigo</li> </ul>

## ***Etiology***

The exact pathophysiology is partially defined in atopic dermatitis.

- **Genetic factors:** Atopic eczema is a genetically complex familial disease and often associated with positive family history of atopic disease (90% concordance in monozygotic twins but only 20% in dizygotic twins).
- **Environmental allergens:** Atopy is characterized by generalized, prolonged hypersensitivity to common environmental antigens (e.g. pollen, food, animal hair and house dust mite). Atopic individuals develop one or more of a group of diseases such as asthma, hay fever, food and other allergies, and atopic eczema.
- **Epidermal barrier impairment:** It is a major and perhaps primary factor in atopic eczema. It was observed in Caucasian individuals that loss of function mutations in the epidermal barrier protein filaggrin can predispose to atopic eczema. *Filaggrin* is coded by *FLG* gene on chromosome 1q21.

**Exacerbating factors:** Factors that can exacerbate eczema include:

- **Infection:** Infection in the skin or systemic infection can exacerbate atopic eczema. Paradoxically, lack of infection (in infancy) may allow eczema to develop ('**hygiene hypothesis**').
- **Irritants:** Such as strong detergents, chemicals and woollen clothes.
- **Severe anxiety or stress** in some individuals.
- **Others:** Cat and dog fur, food allergens, dairy products or eggs.

## ***Clinical Features (Box 22.3)***

**Box 22.3:** Clinical features of atopic dermatitis.

- Family history of atopy (asthma, allergic rhinitis, food allergies, or eczema)
- Itching and scratching
- Lichenification of skin (in adults)
- Dry skin (xeroderma)
- Course
  - Characterized by exacerbations and remissions
  - Lasts for more than 6 weeks

**Age:** Atopic eczema is most commonly seen among young children. About

50% present within the first year of life, and 80% present by 5 years of age.

**Character of lesion (Fig. 22.9):**

**Fig. 22.9:** Skin lesions of atopic dermatitis.

- Primary lesions include erythematous macules, papules, and vesicles, which can coalesce to form patches and plaques. **Commonest presentation** is extremely **itchy erythematous scaly patches** accompanied by scratching.
- The symptom of itch is so central in the pathogenesis that atopic dermatitis is described as **‘the itch that rashes and not the rash that itches’**.
- It may also present as widespread cutaneous dryness (roughness).
- **Acute lesions** can produce small vesicles. In severe cases, secondary lesions from infection or excoriation (due to scratching) may be marked by weeping and crusting.
- **In chronic lesions**, repeated rubbing produces lichenification.

**Distribution of lesion:** Vary with age:

- Lesions are usually found in the periorbital area and the **flexor areas such as in front of the elbows and ankles**, behind the knees (popliteal fossae) and around the neck.
- In **infants eczema** usually starts on the **face** before spreading to the body.

**Table 22.2:** Cutaneous and vascular stigmata of atopic dermatitis.

<i>Cutaneous stigmata</i>	<i>Vascular stigmata</i>
<ul style="list-style-type: none"><li>• <b>Dennie-Morgan</b> infraorbital fold</li><li>• Pityriasis alba</li><li>• Keratosis pilaris</li><li>• <b>Hertoghe's sign</b>—thinning of the lateral eyebrows</li></ul>	<ul style="list-style-type: none"><li>• <b>Headlight sign</b>—perinasal and periorbital pallor</li><li>• <b>White dermographism</b> (Fig. 22.10)—blanching of the skin at the site of stroking with a blunt instrument—cause edema and obscure color of underlying vessels</li></ul>

**Box 22.4:** Complications of atopic eczema.

**Secondary infection**

- Bacterial: *Staphylococcus aureus* most common
- Viral: For example, viral warts and *Molluscum contagiosum* especially if treated with topical corticosteroids. Herpes simplex virus (HSV) can cause severe widespread eruption (eczema herpeticum).

**Increased susceptibility to irritants due to defective barrier function**

**Increased susceptibility to allergy**

- Food allergy mainly in infants, e.g. egg, cow's milk, protein, fish, and wheat may cause an urticarial eruption.

**Fig. 22.10:** Dermographism seen in urticaria and atopic dermatitis.

## *Cutaneous and vascular stigmata of atopic dermatitis (Table 22.2)*

**Diagnosis:** It is made based on (1) morphologic features, (2) the distribution of the lesions, and (3) a family and personal history of atopy. About 80% of patients may have high serum IgE levels or high specific IgE levels to certain ingested or inhaled antigens and a blood eosinophilia. Hanifin and Rajka Criteria is used for diagnosis.

## ***Complications of Atopic Eczema (Box 22.4)***

### **Management**

General measures

**Box 22.5:** Classification of topical corticosteroids by potency.

1. Mild: 1% hydrocortisone or 2.5% hydrocortisone
2. Moderately potent: 0.05% clobetasone butyrate or 0.05% alclometasone dipropionate
3. Diluted potent: 0.025% betamethasone valerate or 0.00625% fluocinolone acetonide
4. Potent: 0.1% betamethasone valerate or 0.025% fluocinolone acetonide
5. Very potent: 0.05% clobetasol propionate or 0.3% diflucortolonevalerate

### ***Atopic eczema***

1. Education, explanation and reassurance.
2. Avoidance of contact with skin irritants (especially soaps or furry animals), heat and dryness. Advised to wear cotton clothes.
3. **Emollients for moisturizing:** Emollients are used to moisturize, lubricate, protect and soften skin.
4. **Topical anti-inflammatory agents:**
  - a. **Topical corticosteroid ointments:** They should be used judiciously. Depending on the potency, topical corticosteroids can be divided into five groups (Box 22.5). Mid potency topical glucocorticosteroids are used in most treatment regimens.
  - b. **Topical immunomodulators:** These include two macrolide immunosuppressant namely tacrolimus ointment (0.1% for 3–4 weeks), and pimecrolimus cream (1% for 3–4 weeks).  
*The 'triple' combination of topical steroid, emollients and bath oil and soap substitute (e.g. aqueous cream) is usually helpful.*
5. **Adjunct therapies**
  - a. **Oral antihistamines:** Control of pruritus is most often achieved by use of antihistamines. These include fexofenadine, 180 mg every morning, and hydroxyzine hydrochloride 10–25 mg at nighttime.
  - b. **Bandaging:** Paste bandaging may be used for lichenified eczema of the limbs. It helps absorption of topical treatment and also acts as a barrier to prevent scratching.
  - c. **Prompt treatment of secondary infection by antibiotics:** Secondary infection of eczema may lead to exacerbation of atopic dermatitis. The causative agent for secondary infection should be identified by culture and treated with appropriate systemic antibiotics.
6. **Phototherapy**
  - **Narrow-band-UVB phototherapy:** Ultraviolet radiation (UVR) treatment: Most commonly narrowband ultraviolet B is used.

- **Psoralen and ultraviolet A (PUVA).**

**7. Systemic therapy:**

- a. Systemic glucocorticosteroids should be given to severe exacerbations that do not respond to topical therapy. Generally, oral prednisolone is given in the dose of 0.5–1 mg/kg/day.
- b. Use of cyclosporin: Cyclosporin is an immunosuppressant that inhibits production of interleukin2 by T lymphocytes.

## Contact Dermatitis

### ***Allergic Contact Eczema (Figs. 22.11A and B)***

This develops as a manifestation of delayed hypersensitivity reaction following contact with antigens or haptens. Many agents can cause allergic contact eczema and common agents include nickel in costume jewellery and buckles (e.g. eczema of the earlobes and umbilicus); chromate in cement (eczema of the hands and foot) and latex in surgical rubber gloves (eczema of the hands and wrist). Allergy persists indefinitely and eczema develops at sites of contact of allergen.

During the acute phase, lesions show edema, erythema and vesicle formation. Later, vesicles rupture producing oozing and papules and plaques appear. In the chronic phase, scaling, lichenification and excoriations predominate.

**Figs. 22.11A and B:** (A) Skin lesions of symmetrical atopic dermatitis; (B) Chronic contact dermatitis.

### ***Irritant Contact Eczema***

This type of eczema can occur in any individual and the injury is due to an inherent characteristic of compound-irritant contact dermatitis. It usually develops on the hands after repeated exposures to irritants (e.g. detergents, soaps or bleach, alkalis, acids) and is common in housewives, cleaners, hairdressers, mechanics and nurses. The lesions may be acute (wet and edematous) with strong irritants or chronic (dry, thickened, and scaly) with weak irritants.

#### **Treatment of Contact Dermatitis**

- Identify and avoid the contact with causative agent/irritants and use of protective gloves or clothing. In extreme cases even changing of occupation or hobbies may be needed.
- Treatment with high-potency topical glucocorticoids.
- In cases where systemic therapy is indicated, daily oral prednisone beginning at 1 mg/kg, but usually 60 mg/day is given. It should be tapered over 2 to 3 weeks.

### **Seborrheic Dermatitis**

Seborrheic dermatitis is a common, chronic disorder, characterized by red scaly patches or plaques.

**Etiology:** It is due to *Pityrosporum ovale* (also called *Malassezia furfur* in its hyphal form).

**Sites of involvement:** Seborrheic dermatitis affects body sites rich in sebaceous glands.

- **Scalp:** It most commonly affects the scalp (recognized as severe dandruff).
- **Facial region:** On the face, it affects the nasolabial folds, eyebrows, eyelids, and glabella. Scaling of the external auditory canal and the postauricular areas often show maceration and tenderness.
- Other sites include central chest, axilla, groin, submammary folds, and gluteal cleft.

**Clinical features:** Three age groups are affected by seborrheic dermatitis.

- In neonates: Presents as yellowish thick crusts on the scalp (**cradle cap**), face, or groin. Normally, it improves spontaneously after a few weeks.
- In young adults (especially males): The rash is more persistent and presents as an erythematous scaling along the sides of the nose, in the eyebrows, around the eyes and in the scalp (dandruff). It is more common in patients with **Parkinson's disease**, in those who have had cerebrovascular accidents, and in those with **HIV infection** (especially with CD4 cell count  $<400/\text{mm}^3$ ).
- In elderly people: It can be more severe and progress to involve large areas of the body.

**Treatment of Seborrheic Dermatitis: Treatment is suppressive rather than curative.**

- A **combination of low-potency topical glucocorticoids** (e.g. 1% hydrocortisone applied twice daily) with a **topical antifungal cream** (e.g. miconazole or ketoconazole or Ciclopirox olamine cream applied twice daily) is often effective. Topical 0.1% tacrolimus ointment or pimecrolimus cream can also be effective.
- **Antipityrosporal agents**, such as ketoconazole shampoo and arachis oil are useful for the scalp and beard areas. Emollients and a soap substitute may be used as adjuncts. High-potency topical glucocorticoids (betamethasone or clobetasol) are effective in cases with severe scalp involvement. However, they should not be used on the face because they may be associated with steroid-induced rosacea or atrophy.

## Pityriasis Versicolor (Tinea Versicolor)

**Q. Write short essay/note on pityriasis versicolor (tinea versicolor).**

- Pityriasis versicolor is a relatively common persistent, superficial skin condition caused by a common commensal lipophilic yeast, **Malassezia furfur** (also known as pityrosporum ovale). The yeast is a normal inhabitant of the skin.
- **Predisposing factor:** Infection is more frequent in warmer, humid climates, and is usually more severe and persistent in the immunocompromised individuals.
- **Appearance of skin lesion (Fig. 22.12):** Typical lesion is round, scaly, oval macules on the upper trunk. It is usually hypopigmented (on dark skin) but occasionally hyperpigmented (on light skin). Hypopigmentation is more obvious after sun exposure and tanning. Sometimes it may have raised erythematous margins. Inappropriate use of topical steroids causes spread the lesion.
- **Sites affected:** Upper back, shoulders and chest but also affects upper arms, neck and rarely on the face. The lesions are more extensive in patients in tropics.
- **Other diseases associated with tinea versicolor:** Cushing's syndrome, hyperhidrosis and altered immune status (e.g. HIV).

**Fig. 22.12:** Skin lesions of pityriasis versicolor (tinea versicolor).

**Diagnosis:** The diagnosis can be confirmed by

- **Skin scrapings:** Shows characteristic '*spaghetti and meatballs*' appearance.
- **Wood's light examination:** Shows some pigment (yellow fluorescence)

in skin regions involved by tinea versicolor whereas in vitiligo, there is total loss of pigment in the affected areas.

#### **Treatment**

##### **Topical antifungals**

- Selenium sulfide or 2% ketoconazole shampoo to be applied to the affected areas of the body and removed after 30–60 minutes and repeated daily for 1 week. In resistant cases, overnight application may be useful.
- Topical imidazole (miconazole, clotrimazole, ketoconazole) cream twice daily for 10 days.

##### **Oral antifungals**

Oral itraconazole (100 mg twice daily for 1 week) in resistant cases. The pigmentation takes months to recover even after successful treatment. Others include ketoconazole (200 mg daily for 10 days or 400 mg/day for 2 days, though less effective), and fluconazole (150–300 mg weekly for 2–4 weeks). The condition may recur but can be re-treated.

## **BLISTERING (BULLOUS) DISORDERS OF SKIN**

Blistering skin disease (BSD) are skin conditions characterized by blister formation. A blister is an accumulation of fluid between cells of the epidermis or upper dermis (Fig. 22.13). Causes of blister formation may be genetic, physical, inflammatory, immunologic and as a reaction to drugs. Blistering disorders are mostly due to autoimmune mechanism.

### **Types of Blistering Diseases (Box 22.6)**

#### ***Pemphigus Vulgaris***

**Q. Write short essay/note on etiology, clinical features, diagnosis and treatment of pemphigus vulgaris.**

Pemphigus vulgaris (PV) is a potentially fatal mucocutaneous blistering disease.

##### *Etiology*

- **Autoimmunity:** It is thought to be an autoimmune disorder. Patients with PV have IgG 4 autoantibodies directed against desmosomal protein desmoglein 1 and 3 (belong to the cadherin family of calcium-dependent adhesion molecules). Desmoglein 1 and 3 is expressed in skin and mucosal surfaces. IgG 4 autoantibodies are responsible for blister formation and their titer correlates with disease activity.

- **Drug-induced:** Pemphigus may also be drug-induced (e.g. sulfonamides, penicillins and antiepileptic drugs).

### *Clinical features*

- **Age and gender:** It predominates in patients between the fourth and sixth decades of life and both sexes are affected equally.
- **Lesions:** They typically begin on mucosal surfaces and often progresses to involve the skin. Lesions consist of fragile, flaccid blisters that rupture to produce erosions in mucous membranes and skin.

### **Box 22.6:** Types of blistering diseases.

**Genetic blistering diseases:** (1) Epidermolysis bullosa, (2) Hailey-Hailey disease (Benign familial pemphigus)

#### **Immunobullous diseases:**

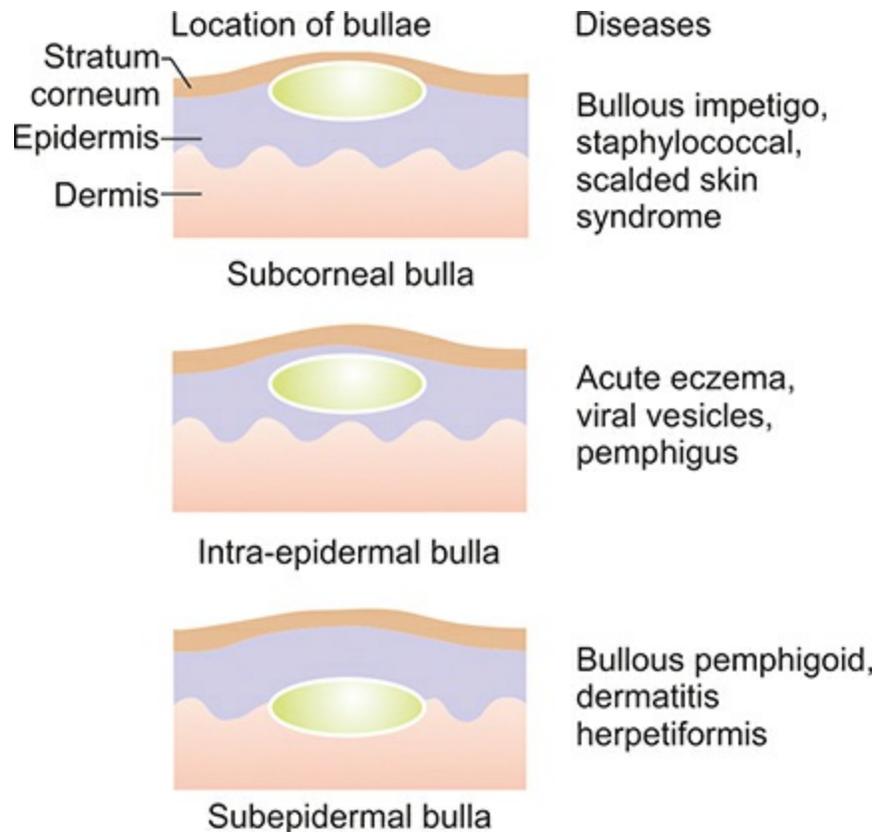

- **Intraepidermal immunobullous diseases:** (1) Pemphigus vulgaris (PV), (2) Pemphigus vegetans, (3) Pemphigus foliaceus, (4) Pemphigus erythematosus, (5) Paraneoplastic PV
- **Subepidermal immunobullous diseases:** (1) Bullous pemphigoid, (2) Pemphigoid gestations, (3) Linear IgA disease, (4) Epidermolysis bullosa acquisita and (5) Dermatitis herpetiformis

### *Oral cavity*

- **Characteristic of lesion:** Mucosal involvement (especially oral ulceration) is the most common (up to 75% of cases) presenting sign. Lesions consist of fragile, flaccid blisters that rupture to produce erosions in mucous membranes.
- **Sites:** Lesions within the oral cavity can be seen anywhere and are most often found in areas subjected to friction trauma (e.g. cheek mucosa, tongue, palate and lower lip).

### *Skin lesions*

- **Sites:** Typically involves scalp, face, neck, trunk and intertriginous areas (axilla, groin).
- Skin lesions follow oral lesion and appear as **non-itchy flaccid blisters filled with clear fluid** that arises on normal skin. Blistering usually becomes widespread and is fragile. They **rapidly denude/rupture** giving rise to painful **erythematous, weeping erosions**. Erosions are often large. Intact blisters may be sparse.

**Fig. 22.13:** Location of bullae and few associated diseases.

**Q. Write short essay/note on Nikolsky's sign.**

**Nikolsky's sign:** It is positive. It is elicited by applying gentle manual sliding pressure to the affected skin (e.g. where a blister is located), or rub sideways the perilesional skin or normal skin with a cotton swab or finger). A positive response is indicated by extension of the blister and/or separation of the epidermis in the area immediately and is known as Nikolsky's sign. This sign is not specific to pemphigus but is also seen in toxic epidermal necrolysis (TEN), Stevens-Johnson syndrome, staphylococcal scalded skin syndrome, bullous impetigo and epidermolysis bullosa. This sign is usually negative in bullous pemphigoid.

**Diagnosis**

Skin biopsy: Microscopically, it shows suprabasal blister due to suprabasilar (immediately above the basal cell layer) acantholysis (the dissolution or lysis of the intercellular bridges that connect squamous epithelial cells). Acantholytic cells separate from one another, lose their polyhedral shape and appear round (tombstone appearance).

- **Direct immunofluorescence:** Lesions show a characteristic net-like pattern of intercellular IgG deposits. IgG is usually seen at all levels of the epithelium.

#### Treatment

- Anesthetic mouth lozenges to reduce the pain of mouth ulcers.
- Fluids and electrolytes balance, and nutritional support if required.
- Antibiotics to control secondary infections.

*Patients with moderate to severe PV:*

- **Systemic glucocorticoids:** Mainstay of treatment to inhibit production of the autoantibodies. Usually started on oral prednisone, 1 mg/kg/day as an early morning dose.
- **Immunosuppressive agents:** If new lesions continue to appear after 1–2 weeks of treatment with prednisone, the dose is to be increased and/or combined with other immunosuppressive agents such as azathioprine, mycophenolate mofetil, or cyclosporin, or cyclophosphamide.
- **Immunoglobulins:** One course of intravenous immunoglobulin (400 mg/kg/day for 5 days) may be a safe and effective treatment for cases resistant to steroids.

*Severe/treatment-resistant disease:*

**Plasmapheresis** [six high-volume exchanges (i.e. 2–3 L per exchange) over ~2 weeks], **IV immunoglobulin** (IVIg) (2 g/kg over 3–5 days every 6–8 weeks), or **rituximab** (375 mg/m<sup>2</sup> per week x 4, or 1,000 mg on days 1 and 15). The duration of therapy varies according to the level of disease activity.

## Bullous Pemphigoid

### Q. Write short essay/note on:

- Bullous pemphigoid or pemphigoid
- Etiology, clinical features, diagnosis and treatment of bullous pemphigoid.

Bullous pemphigoid (BP) is the most common autoimmune subepidermal blistering disease. Mucosal involvement is rare.

**Age and gender:** It occurs in elderly in the fifth to seventh decades, with an average age of onset of 65 years. Males and females are equally affected.

### *Etiopathogenesis*

Bullous pemphigoid is caused by autoantibodies against specialized proteins that are involved in adherence of basal keratinocytes to the basement membrane. These linking proteins are called **hemidesmosomes** and the so-called bullous pemphigoid antigens (BPAGs) are components of these hemidesmosomes.

## ***Clinical Features***

**Bullae (Fig. 22.14):** Patient usually presents with large tense bullae anywhere on the skin but often involve flexor surfaces of the arms and legs, axilla, groin, and abdomen. The bullae may be centered on an erythematous or urticated skin. The bullae may contain hemorrhagic fluid. Pemphigoid can be very itchy. Mucosal ulceration is uncommon and when seen, it is of minor clinical significance. Nontraumatized bullae usually heal without scarring.

## ***Diagnosis***

**Skin biopsy:** Biopsies of skin lesion shows subepidermal blisters with an eosinophil-rich inflammatory infiltrate at sites of vesicle formation and in perivascular areas.

**Direct immunofluorescence:** Shows linear deposits of **IgG and C3 at the dermoepidermal junction.**

**Fig. 22.14:** Bullous pemphigoid.

## **Treatment**

- Patients with local or mild disease can sometimes be controlled with the application of very potent topical steroids to all sites in frail elderly patients. Occasionally it can be controlled by oral dapsone or high-dose oral minocycline or tetracyclines.
- The mainstay of treatment is systemic **glucocorticoids** (oral prednisolone 30–60 mg daily).

Patients with more extensive lesions respond to systemic glucocorticoids either alone or in combination with immunosuppressive agents. Immunosuppressive agents include azathioprine, mycophenolate mofetil, or cyclophosphamide.

Intravenous immunoglobulin as a steroid-sparing therapy in BP may also be useful.

## Dermatitis Herpetiformis (DH)

### **Q. Write short note on dermatitis herpetiformis.**

- Characterized by intensely itchy, chronic papulovesicular eruption distributed symmetrically on extensor surfaces.
- **Age:** It may start at any age. Most commonly it occurs in 2nd, 3rd, and 4th decades of life.
- **Skin biopsy:** If a vesicle can be biopsied before it is scratched away, the microscopic examination shows a subepidermal blister, with dermal papillary collections of neutrophils (microabscesses).
- **DIF (direct immunofluorescence):** Granular **IgA** deposits in normal-appearing skin are diagnostic for DH.
- Most DH patients (not all) have an associated **gluten-sensitive enteropathy**. So associated anti-endomysial antibodies are positive.

### **Treatment**

- The rash responds rapidly to **dapsone** therapy.
- Gluten-free diet works very slowly.

## REACTIVE DISORDERS OF SKIN

### Erythema Multiforme

### **Q. Write short essay/note on precipitating causes, clinical manifestations and management of erythema multiforme.**

- Erythema multiforme (EM) is an uncommon acute, self-limiting, recurrent cutaneous and/or mucocutaneous blistering eruption that occurs in individuals of any age.
- Eruptions are characterized by target-shaped plaques commonly over extremities and face.

### *Causes*

Erythema multiforme can be triggered by variety of factors (Box 22.7).

**Box 22.7:** Precipitating factors in erythema multiforme.

1. **Infections**

- Viral, e.g. herpes simplex, Orf, infectious mononucleosis, hepatitis B, HIV
- *Mycoplasma* and other bacterial infections (e.g. typhoid)
- Fungal, e.g. histoplasmosis, coccidioidomycosis
- Rickettsia

2. **Exposure to drugs**

For example, sulfonamides, penicillins, barbiturates salicylates, hydantoins, antimalarials and carbamazepine

3. **Systemic disease**

- Sarcoidosis
- Malignancy (carcinomas and lymphomas),
- Collagen vascular diseases [Systemic lupus erythematosus (Rowell's syndrome), Wegener's granulomatosis, dermatomyositis, and polyarteritis nodosa].

4. **Other**

Radiotherapy, pregnancy

## ***Pathogenesis***

Immune mediated disease: It is characterized by keratinocyte injury caused by CD8+ cytotoxic T lymphocytes in the skin. The CD8+ cytotoxic T cells are found in the central portion of the lesions, and CD4+ helper T cell and Langerhans cells are found in the peripheral portions. The epidermal antigens causing the disease are not known.

**Box 22.8:** Classification of erythema multiforme (EM).

- EM Minor: Cutaneous without mucous involvement
- EM Major (EMM): Cutaneous + mucous involvement
- Mucosal EM: Fuch's ectodermosis pluriorificialis
- HAEM: Herpes associated EM
- MPAEM: Mycoplasma associated EM

## ***Classification (Box 22.8)***

### ***Clinical Features of Erythema Multiforme***

- Male:Female = 3:2.
- Occurs in the young/adolescents.
- About 50% of patient give history of preceding herpetic infection.

- Associated with HLA – DQB1 \* 0301 Allele.

### ***Elementary skin lesions***

**Multiforme:** As the name implies, it presents with a diverse array of lesions (multiforme), including macules, papules, vesicles, bullae.

#### *Distribution of skin lesions (topography)*

- Lesions are symmetrical, acral, centripetal in distribution
- Extensor aspect: Extremities > face > neck > trunk
- Predilection to sun-exposed areas/Koebnerization present.

**Fig. 22.15:** Erythema multiforme with target lesion.

#### *Characteristic lesion*

**Q.** Write short essay/note on target lesions, iris lesions and bull's eye lesions of erythema multiforme.

- **Classic target lesion (Fig. 22.15):** Consists of **three concentric distinct zones/rings** of different colors: a **dark central circular dusky red** (darker red) zone is surrounded by an **intermediate light rim** (white), which in turn is encircled by a **outermost red zone** (iris lesions). Central circular zone may show bulla formation or crust. The lesion may resemble

a ‘bull’s eye’.

- Larger lesions show central bulla and marginal ring of vesicles: **Herpes iris of Bateman.**

### Mucosal lesions

Mucosal (oral mucosa) involvement is usually absent and, when present, lesions are few in number and mildly symptomatic.

## Stevens-Johnson Syndrome (Figs. 22.16A to C)

### Q. Write short essay/note on Stevens-Johnson syndrome.

- Stevens-Johnson syndrome (SJS) is a rare, acute and life-threatening mucocutaneous disease with systemic involvement and is nearly always drug-related.

- SJS is a ‘minor form of TEN’ with less than 10% body surface area (BSA) detachment
- Overlapping Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN): Detachment of 10–30% BSA.
- Toxic epidermal necrolysis (TEN): **Detachment of more than 30% BSA.**

Clinical features of Stevens-Johnson syndrome are listed in Table 22.3.

Mortality rate in SJS: 1–5%.

**Table 22.3:** Clinical signs and symptoms of Stevens–Johnson syndrome/toxic epidermal necrolysis.

Cutaneous	Mucous membrane <sup>a</sup>	Extracutaneous
<p><i>Initial phase:</i></p> <ul style="list-style-type: none"> <li>• Erythematous, dusky red, flat, atypical targetoid macules</li> <li>• Symmetrical lesions distributed on the face/trunk/proximal part of limbs. It can spread to entire body</li> </ul> <p><i>Later phase:</i></p> <ul style="list-style-type: none"> <li>• Lesions progressively coalesce and evolve into flaccid blisters</li> <li>• Detachment of epidermis</li> </ul>	<ul style="list-style-type: none"> <li>• <i>Ocular:</i> Edema of eyelid, redness, photophobia, discharge, lacrimation, corneal scarring</li> <li>• <i>Buccal:</i> Erosive hemorrhagic lesions, grayish-white pseudomembranes and crust on lips</li> <li>• <i>Genital:</i> Erosive hemorrhagic lesions, painful urination</li> </ul>	<ul style="list-style-type: none"> <li>• <i>Nonspecific:</i> Fever, pain, weakness</li> <li>• <i>Respiratory<sup>b</sup>:</i> Respiratory distress</li> <li>• <i>Gastrointestinal:</i> Diarrhea, nausea, malabsorption, perforation of colon, melena</li> <li>• <i>Renal<sup>b</sup>:</i> Proteinuria, hematuria, microalbuminuria</li> </ul>

a. Normally involves at least two sites. b. Lower occurrence in SJS compared to TEN.

**Figs. 22.16A to C:** (A) Stevens-Johnson syndrome (SJS)-toxic epidermal necrolysis (TEN); (B) Toxic epidermal necrolysis; (C) Oral lesions in SJS/TEN.

## Toxic Epidermal Necrolysis (Lyell's Syndrome)

### **Q. Write short essay/note on toxic epidermal necrolysis.**

- Toxic epidermal necrolysis is characterized by diffuse necrosis and sloughing of skin and mucosal epithelial surfaces. It begins with severe mucosal erosions and progresses to diffuse, generalized detachment of the skin epidermis.
- Nikolsky sign often positive, i.e. sliding pressure from a finger on normal-looking epidermis dislodges the epidermis.
- No target lesions seen.
- Mortality rate in TEN: High (30%).

### **Management**

#### ***Treatment of Erythema Multiforme***

- Management of the precipitating factors/causes. If a drug is suspected, it must be discontinued and precipitating infection should be treated.
- Treatment of EM otherwise is nonspecific.
- Severe cases may require systemic corticosteroids.
- Oral acyclovir early reduces the number and duration of lesions.
- Chronic antiviral treatment with acyclovir (400 mg twice daily for 6 months) in herpes-associated outbreaks in patients with recurrent erythema multiforme.

#### ***Treatment of SJS (Stevens-Johnson syndrome) and TEN (Toxic epidermal necrolysis)***

- Maintain the fluid and electrolyte balance.
- Manage oral mucosal lesions with mouthwashes. Topical anesthetics may reduce pain and allow the patient to take in fluids.

- Area of denuded skin should be covered with compresses of saline.
- **Systemic corticosteroid is contraindicated** in Stevens-Johnson syndrome.
- Treatment of toxic epidermal necrolysis is very difficult, but intravenous immune globulin (2–3 g/kg over a period of 2–5 days) may improve the prognosis.

## PIGMENTARY DISORDERS OF SKIN

### Hypopigmentation

#### *Causes of Hypopigmentation (Box 22.9)*

**Q.** Write short note on causes and differential diagnosis of hypopigmented cutaneous lesions/hypopigmentation.

**Box 22.9:** Causes of hypopigmentation and/or depigmentation.

- Generalized loss of pigmentation: Albinism
- Patchy loss of pigmentation: Vitiligo
- Localized loss of pigmentation: Piebaldism, pityriasis alba, pityriasis versicolor, idiopathic guttate hypomelanosis, leprosy, leukoderma
- Other rare causes: Phenylketonuria and hypopituitarism

### Vitiligo

**Q.** Write short note on etiology, clinical features and treatment of vitiligo.

Vitiligo is a common, slowly progressive acquired condition caused by focal loss of melanocytes within the skin resulting in the development of well circumscribed patches of hypopigmentation (Figs. 22.17A to C).

**Figs. 22.17A to C:** (A) Vitiligo; (B) Acral vitiligo; (C) Koebner phenomenon in vitiligo.

#### *Classification (Box 22.10)*

## Clinical Features

### Non-segmental vitiligo

- It presents as small, depigmented macule that may enlarge and coalesce into larger patches. It is often symmetrical and occurs mainly around body orifices (around the eyes, nose, lips, genitalia), hands, feet, flexor surface of the wrists, ankles, elbows, knees, and major body folds.
- The hair of the scalp, beard, eyebrows and lashes (leukotrichia) may also show depigmentation.
- **Vitiligo fulminans/galloping vitiligo:** Rapid downhill course with rapid progression of skin lesions.
- Patients are very susceptible to sunburn.
- Non-segmental vitiligo can spread by **Koebner phenomenon (Fig. 22.17C)**. *Other skin conditions that spread by Koebner phenomenon include psoriasis, molluscum contagiosum, warts, EM and lichen planus.*

### Box 22.10: Classification of vitiligo.

#### Localized

- **Focal vitiligo:** One or more macules in one area not clearly in a segment
- **Segmental vitiligo:** Number of macules in unilateral segment of the body (stops abruptly at midline)
- **Mucosal vitiligo:** Affects lips, oral cavity and genitalia

#### Generalized

- **Acrofacial vitiligo:** Lesions on the acral (hand and feet) and face (perioral)
- **Vitiligo vulgaris:** Multiple macules bilaterally symmetrically scattered.
- **Lip-tip vitiligo:** Tips of digits and lips only
- **Mixed:** Any combination of the above
- **Universal vitiligo:** Complete or near complete depigmentation of the body.

### Segmental vitiligo

It is **restricted to one part** of the body. The patches of depigmentation are sharply defined. Spotty perifollicular pigment may be seen within the depigmentation. **Sensation in the depigmented patches is normal** (unlike in tuberculoid leprosy). Wood's light examination shows the contrast between pigmented and nonpigmented skin.

**Trichrome vitiligo (vitiligo gradate):** Presence of tan colored zone in between normal skin and the depigmented macule. Sometimes a fourth color dark brown is present at sites of perifollicular repigmentation-**quadrichrome**

## **vitiligo.**

### *Association of vitiligo with other diseases (Box 22.11)*

#### **Box 22.11:** Vitiligo association with other diseases.

- Autoimmune thyroiditis
- Addison's disease
- Pernicious anemia
- Diabetes mellitus
- Vogt Koyanagi Harada syndrome: Vitiligo, poliosis, uveitis, alopecia and hearing difficulties.

#### **Management**

- Protect the patches from excessive sun exposure with clothing or sunscreen to avoid sunburn.
- **Treatment:** Often unsatisfactory

#### **Topical treatment**

Includes the use of potent topical corticosteroids, topical immunomodulators (e.g. calcineurin-inhibitors tacrolimus 0.1% ointment especially on the face).

#### **Phototherapy**

- Topical psoralen plus ultraviolet-A (UV-A) phototherapy (PUVA therapy) is a most effective repigmentary treatment available for non-segmental generalized vitiligo.
- Narrow-band UV-B (NB-UVB) phototherapy: It is the treatment of choice for active, generalized vitiligo. Cosmetic results are better and side effects are less than PUVA.
- Topical application of corticosteroids along with UV-A exposure is often effective.
- Autologous melanocyte transfer is effective for treating stable, focal vitiligo
- Extensive vitiligo may be treated with removal of pigment from the remaining normally pigmented skin by using bleaching creams (e.g. monobenzylether of hydroquinone and 4-methoxy-phenol).
- Human placental extract and calcipotriol have been tried.
- **Systemic treatment (Box 22.12)**
- **Surgical treatment (Box 22.13)**

#### **Box 22.12:** Systemic treatment for vitiligo.

- Psoralen and UVA
- Corticosteroids
- Immunomodulators (Cyclosporine, levamisole, azathioprine)
- Phenylalanine plus UVA
- Khellin
- Antioxidants

#### **Box 22.13:** Surgical treatment for vitiligo.

- Punch grafting

- Split skin thickness grafting
- Blister grafting
- Melanocyte culture and transplantation
- Tattooing

## Pityriasis Alba

### **Q. Write short note on pityriasis alba.**

- Common skin disorder in children that is usually evident before puberty.
- **Cause:** Not known, however there is often a history of atopy.

### ***Clinical Features***

Hypopigmented patches or macules with slight scale, mainly on the face and less frequently on the neck, trunk and extremities. No permanent damage to the skin. Often improves after puberty.

**Treatment:** Use of lubricants and mild topical steroids.

## Inherited Hypopigmentation Disorders

### **Q. Write short note on inherited hypopigmentation disorders.**

#### **Albinism**

- Autosomal recessive inherited disorder.
- Genetic defect in melanin synthesis and normal melanocyte number and structure.
- Mutation in tyrosinase gene.
- Affected individual will be born with white hair and skin and blue eyes (retinal pigment epithelium involved).
- Selenium deficiency in the setting of total parental nutrition can lead to **pseudoalbinism**.

#### **Piebaldism**

- Rare autosomal dominant disease
- Congenital **white forelock**
- Hyperpigmented macules within the amelanotic macules and normally pigmented skin is characteristic.

#### **Waardenburg syndrome**

Autosomal dominant disorder characterized by white forelock, heterochromia iridis, and hypomelanotic macules.

## Conditions Associated with Increased Pigmentation (Box 22.14)

**Box 22.14:** Conditions associated with increased pigmentation.

- Melasma
- Freckles (Ephelides)
- Lentiges (NAME syndrome, Leopard syndrome)
- Peutz Jegher syndrome

**Q.** Write short note on conditions associated with increased pigmentation.

## Systemic Diseases Causing Hyperpigmentation (Table 22.4)

**Table 22.4:** Systemic diseases causing hyperpigmentation.

- |  |   |
|--|---|
| <ul style="list-style-type: none"><li>• Post inflammatory</li><li>• Syphilis, malaria</li><li>• Pellagra, scurvy, vitamin A deficiency, vitamin B<sub>12</sub> deficiency</li><li>• Addison's disease: Diffuse melanosis pronounced in the axillae and palmar creases, and nipples and genitals, and buccal mucosa</li><li>• Diabetes produces diffuse bronzing of the skin</li><li>• Nelson's syndrome (a pituitary MSH-producing tumor)</li><li>• Pheochromocytoma</li><li>• Hemochromatosis</li><li>• Amyloidosis</li></ul> | <ul style="list-style-type: none"><li>• Scurvy</li><li>• Pregnancy</li><li>• Menopause</li><li>• Porphyria cutanea tarda</li><li>• Vitamin B<sub>12</sub> deficiency</li><li>• Kwashiorkor</li><li>• Vitamin A deficiency</li><li>• Primary biliary cirrhosis (triad = hyperpigmentation, pruritis, xanthomas)</li><li>• Industrial hyperpigmentation: Occurs in coal miners, anthracene workers, pitch workers, etc.</li></ul> |
|--|---|

## SKIN TUMORS

**Q.** Write short essay/answer on benign, premalignant conditions of the skin.

## Benign and Premalignant Lesions of Skin (Table 22.5)

**Table 22.5:** Benign and premalignant lesions of skin.

<i>Benign conditions</i>		<i>Premalignant conditions</i>
<ul style="list-style-type: none"> <li>• Ephelide</li> <li>• Melanotic naevi</li> <li>• Granuloma telangiectaticum</li> <li>• Hemangioma of skin</li> <li>• Dermatofibroma</li> <li>• Papilloma</li> </ul>	<ul style="list-style-type: none"> <li>• Seborrheic keratosis</li> <li>• Squamous cell papilloma</li> <li>• Warts</li> <li>• Skin tags (acrochordons)</li> <li>• Pyogenic granuloma</li> <li>• Keloids</li> </ul>	<ul style="list-style-type: none"> <li>• Bowen's disease</li> <li>• Keratoacanthoma</li> <li>• Marjolin's ulcer</li> <li>• Paget's disease of the nipple</li> <li>• Senile keratosis/actinic keratosis</li> <li>• Erythroplasia of Queyrat</li> </ul>

## Malignant Skin Tumors

**Q. Write short essay/answer on common malignant skin tumors.**

Malignant tumor of skin is the most common malignancy in fair-skinned populations.

### Categories (Table 22.6)

#### *Etiology and Pathogenesis of Skin Malignancy*

- **Sun exposure:** UVR (ultraviolet radiation) is the main environmental risk factor for skin cancer.
- **Genetic predispositions:**
  - Xeroderma pigmentosum.
  - Basal cell nevus (Gorlin's) syndrome.
- **Cutaneous immune surveillance:** Immunosuppressed organ transplant recipients have an increased risk of skin cancer, particularly SCC (squamous cell carcinoma). Patients who have received high numbers of PUVA treatments (more than 150), which are immunosuppressive, are also at increased risk of skin cancer, particularly SCC.
- **Chronic inflammation:** It is also a risk factor for SCC, which may arise in chronic skin ulcers/scars.

**Table 22.6:** List of malignant skin tumors.

<i>Common malignant tumors</i>	<i>Uncommon malignant tumors</i>
<ul style="list-style-type: none"> <li>• Basal cell carcinoma</li> <li>• Squamous cell carcinoma and its precursor Bowen's diseases</li> </ul>	<ul style="list-style-type: none"> <li>• Primary <ul style="list-style-type: none"> <li>– Malignant melanoma</li> <li>– Cutaneous T-cell lymphomas (e.g. mycosis fungoides)</li> </ul> </li> </ul>

- Kaposi sarcoma
- Apocrine carcinoma of the skin
- Metastasis

## Basal Cell Carcinoma (Rodent Ulcer)

Basal cell carcinomas (BCC) are the most common slow-growing **invasive** malignant skin tumor that rarely metastasizes.

### *Types of Basal Cell Carcinoma (Box 22.15)*

**Box 22.15:** Types of basal cell carcinoma (BCC).

- Superficial BCC
- Nodular BCC, Rodent type (most common type—75%)
- Pigmented BCC
- Sclerosing or morphea form BCC
- Metaphysical
- Recurrent BCC
- Cystic BCC

### *Clinical Presentation*

- Incidence of BCCs increases with age on exposed sites and males are more commonly affected.
- **Sites:** Occur at **sun-exposed sites** and in fair skinned people. Usual site is **above a line drawn from angle of mouth to the pinna of the ear.**
- Appear as a slow-growing **pearly papules** or nodule (or rarely be cystic), often containing prominent, dilated subepidermal blood vessels (telangiectasia).
- Advanced tumors **may ulcerate** to form a crater with a rolled, pearly edge. They **locally invade and erode the underlying bone or facial sinuses like a rodent** and are known as **rodent ulcers**. Crusting and bleeding in the center of the tumor is frequently seen.
- They are 10–20 times more common in the chronically immunosuppressed solid organ transplant recipients.

### **Management/Treatment**

Basal cell carcinoma rarely metastasizes. Hence, a metastatic work-up is usually not required.

- **Surgical therapy:**
  - **Surgical excision** with controlled borders is often the treatment of choice and recurrence rates

are lowest.

- **Mohs' micrographic surgery**
- **Non-surgical therapies:**
  - Topical photodynamic therapy and topical 5% imiquimod cream and 5-fluorouracil.
  - Cryotherapy: It is a destructive treatment that uses liquid nitrogen.
  - Radiotherapy
  - Hedgehog pathway inhibitors (vismodegib) for advanced inoperable BCC.
  - Curettage and cauterization: Occasionally can be used in older patients.

## Squamous Cell Carcinoma

- **Second most common skin cancer** arising on sun-exposed sites.
- More aggressive than basal cell carcinoma as it can metastasize if left untreated.
- **Sex:** More common in elderly men than in women.
- **Clinical presentation:** Appear as sharply defined, red, scaling plaques.

### *Risk Factors (Box 22.16)*

### *Clinical Features*

- **Sites:** Usually occurs on chronically sun-exposed portions of the skin, such as bald scalp, tops of ears, face, lower lip and back of hands.
- **Appearance:** Depends on histological grading. Well-differentiated tumors present as keratotic nodules, whereas poorly differentiated tumors tend to be ill-defined and infiltrative, often-warty nodule or plaque that may ulcerate.
- **Behavior:** They can grow very rapidly. SCC has metastatic potential.

### **Box 22.16:** Risk factors for squamous cell carcinoma of skin.

- Precursors of SCC: Solar/actinic keratoses or Bowen's disease
- Industrial carcinogens: Tars and oils
- Chronic non-healing skin ulcers, e.g. chronic osteomyelitis
- Old burn scars (e.g. Marjolin's ulcers)
- Ingestion of arsenicals
- Ionizing radiation or previous X-ray therapy
- Tobacco and betel nut chewing in the oral cavity
- Chronic venous ulcers, discoid lupus erythematosus

### **Management**

- **Early diagnosis** is important. **Regional lymph nodes** should be routinely examined particularly for high-risk tumors arising on lips, ears, perigenital regions, or tumor developing at sites of chronic ulceration, burn scars, or sites of previous radiotherapy.
- **Complete surgical excision** is the usual treatment of choice. Excision with a 3–4 mm margin has a cure rate of about 90–95% for most SCC.
- **Other options:**
  - Curettage and cautery: Curettage should be avoided and is reserved for small, low-risk lesions.
  - Radiotherapy: If surgery is not feasible.
  - **Medical management** is not usually considered for invasive SCC. These include photodynamic therapy, systemic retinoids, imiquimod and other immunomodulators, new formulations of 5-fluorouracil, diclofenac in hyaluronic acid gel and ingenol mebutate.

## Malignant Melanoma

Malignant melanoma is a **relatively common** and is the most serious malignant tumor of epidermal melanocytes. Melanoma has metastatic potential which can occur early and it causes deaths even in young individual.

### *Etiology and Pathogenesis*

#### *Predisposing factors*

#### 1. Sun exposure

- **Melanomas most commonly develop on sun-exposed surfaces**, particularly the upper back in men and the back and legs in women.
- **Lightly pigmented** (pale/fair skinned) **individuals** are at **greater risk** than darkly pigmented individuals.

Other environmental factors may also contribute to risk.

#### 3. Inherited genes

About 10–15% of melanomas are familial and the genetic abnormalities are:

**Mutations in tumor suppressor gene:** *CDKN2A* gene, RB gene, PTEN gene, mutations of NRAS and BRAF

2. **Other risk factors:** These include, multiple melanocytic nevi (>50), sun sensitivity, immunosuppression, giant congenital melanocytic nevi, lentigo maligna and a family history of malignant melanoma.

### *Clinical Features*

**Age and gender:** Can occur at any age and either sex, but typically affects the leg in females and back in males. It is rare before puberty.

## Sites

- **Skin:** It is the most common site and may develop in the trunk, leg, face, sole, palm and nail beds.
- **Other sites:** Oral and anogenital mucosal surfaces, esophagus, leptomeninges, eye, and the substantia nigra.

## Classification of Malignant Melanoma of Skin (Box 22.17)

Clinical signs that help distinguish malignant from benign moles are presented in Table 22.7.

### Box 22.17: Classification of malignant melanoma of skin.

- **Melanoma without metastatic potential (non-invasive)**
  - Melanoma in situ
  - Lentigo maligna
- **Melanoma with invasive potential**
  - Superficial spreading melanoma
  - Nodular melanoma
  - Acral lentiginous melanoma
  - Lentigo maligna melanoma
  - Subungual melanoma

**Table 22.7: Clinical criteria for the diagnosis of malignant melanoma.**

#### ABCDE features of malignant melanoma

Asymmetry of mole	Diameter greater than 6 mm
Border irregularity	Elevation irregular
Color variegation	(+ loss of skin markings)

#### The Glasgow 7-point checklist

<b>Major criteria</b> <ul style="list-style-type: none"><li>• Change in size</li><li>• Change in shape</li><li>• Change in color</li></ul>	<b>Minor criteria</b> <ul style="list-style-type: none"><li>• Diameter &gt;6 mm</li><li>• Inflammation</li><li>• Mild itch or altered sensation</li><li>• Oozing or bleeding</li></ul>
--	--

#### Management/Treatment

- **Surgical excision:** For local disease, surgical excision is the only curative treatment.
  - **Metastatic disease:** If there is sentinel node metastasis, surgical resection of lymph nodes, isolated limb perfusion, radiotherapy, immunotherapy (Peginterferon alfa-2b, Ipilimumab (anti-CTLA-4), Vemurafenib, Dabrafenib (BRAF inhibitor) Trametinib (MEK inhibitor) Pembrolizumab (PD-1 blocker) and chemotherapy may be required.

## Mycosis Fungoides (MF)

MF is a cutaneous lymphoma of mature CD4<sup>+</sup> T-cells. The commonest cutaneous T-cell lymphoma. Not all cutaneous T-cell lymphomas are MF. Incidence: 3 per million (0.29 per 100,000 population in USA) and 2% of all new cases of NHL. Age: Older adults (55–60 years). Male: Female: 2:1.

### *Clinical Features*

MF patches are usually distributed in sun-shielded areas such as those covered by a bathing suit or intertriginous regions. The cardinal features of MF are infiltration of epidermis and then dermis by atypical cerebriform lymphoid cells—**Pautrier micro abscess**. It is a chronic, slowly progressive disease that evolves from patch stage to plaque stage and subsequently to nodule/tumor stage. A diagnosis of **Sézary syndrome** is made when there is high number of these cells circulating in the peripheral blood in the presence of a lymphadenopathy and cutaneous erythroderma occupying more than 80% of the body surface area.

Chemotherapy, retinoids, electron beam therapy, photochemotherapy are used in the treatment.

## PHAKOMATOSES

### Neurocutaneous Syndromes

**Q.** Write short note on neurocutaneous syndromes.

- They are group of inherited syndromes characterized by involvement of the brain and skin (sometimes retina).
- Phakomatoses (or neuro-oculo-cutaneous syndromes) are multisystem disorders that have characteristic central nervous system, ocular and cutaneous lesions (embryologically all originate from ectoderm) of variable severity.

### *Common Neurocutaneous Syndromes (Box 22.18)*

**Box 22.18:** Common neurocutaneous syndromes.

- Neurofibromatosis I and II
- Tuberous sclerosis
- Von Hippel-Lindau disease

- Sturge-Weber syndrome
- Klippel-Trenaunay-Weber syndrome
- Osler-Weber-Rendu syndrome
- Wyburn-Mason syndrome
- Linear sebaceous nevus syndrome
- Neurocutaneous melanosis
- Waardenburg syndrome type 1 and 2
- Fabry's disease
- Lentiginosis, deafness, cardiopathy syndrome
- Hypomelanosis of Ito
- Ataxia-telangiectasia (Louis-Bar syndrome)
- Xeroderma pigmentosum (Fig. 22.18)
- Cockayne's syndrome
- Rothmund-Thomson syndrome
- Sjögren-Larsson syndrome
- Neuroichthyosis
- Werner syndrome and Progeria
- Incontinentia pigmenti
- Neurocutaneous melanosis
- Retinal-neuro-cutaneous cavernous hemangioma syndrome (Weskamp-Cotlier syndrome)

## Neurofibromatosis Type 1

### **Q.** Write short note on neurofibromatosis.

- Synonyms: von Recklinghausen disease, Watson disease
- An autosomal dominant neurogenetic disorder.

### **Box 22.19:** Diagnostic criteria for neurofibromatosis type 1.

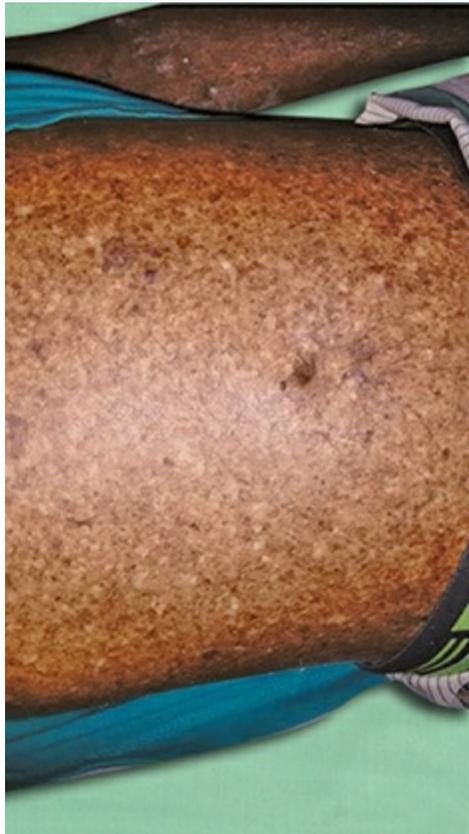

*Two or more of the following clinical features must be present:*

- Six or more café-au-lait macules of >5 mm in greatest diameter in prepubertal individuals, and more than 15 mm in greatest diameter in postpubertal individuals
- Two or more neurofibromas of any type (Fig. 22.19) or one plexiform neurofibroma
- Freckling in the axillary or inguinal regions
- Optic glioma
- Two or more iris hamartoma (Lisch nodules) (Fig. 22.20)
- Distinctive bony lesion, such as sphenoid dysplasia, or thinning of the long bone cortex with or without pseudoarthrosis
- A first-degree relative (parent, sibling, or offspring) with NF1 based on the above criteria.

### **Box 22.20:** Diagnostic criteria for neurofibromatosis type 2.

- Bilateral vestibular schwannomas

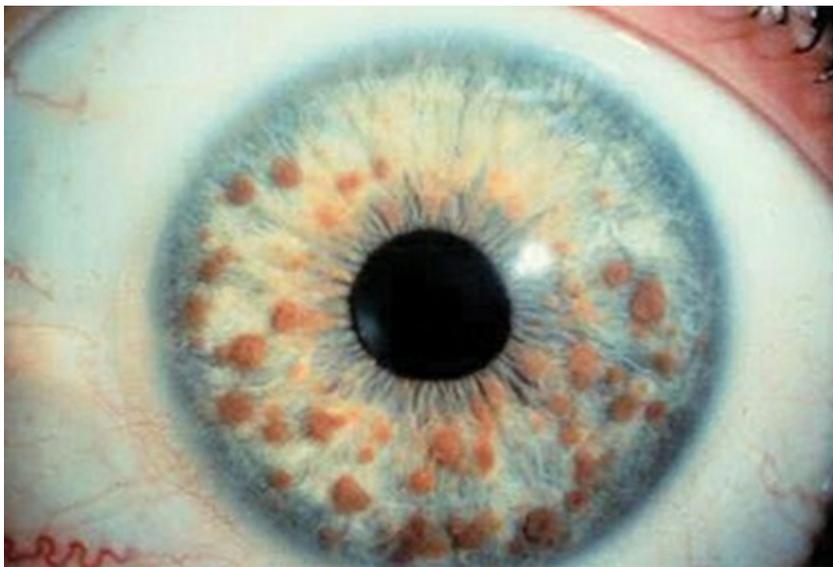

- A first-degree relative with NF2 and
    - Unilateral vestibular schwannoma or
    - Any two of: meningioma, schwannoma, glioma, neurofibroma, posterior subcapsular lenticular opacities\*
  - Unilateral vestibular schwannoma and
    - Any two of: Meningioma, schwannoma, glioma, neurofibroma, posterior subcapsular lenticular opacities\*
  - Multiple meningiomas and
    - Unilateral vestibular schwannoma or
    - Any two of: Schwannoma, glioma, neurofibroma, cataract
- \* 'Any two of' = Two individual tumors or cataract.

**Fig. 22.18:** Xeroderma pigmentosum.

**Fig. 22.19:** Neurofibromatosis.

**Fig. 22.20:** Iris nodules (Lisch nodules) in neurofibromatosis.

- NF1 affects about 1 in 3000 people. Neurofibromatosis type I (NF1) is caused by mutation in the neurofibromin gene located on chromosome 17, at the band q11.2.

## Diagnostic Criteria for Neurofibromatosis Type 1 (Box 22.19)

Three subtypes of neurofibroma exist: Cutaneous, subcutaneous, and plexiform. Freckles can be present since birth or sometimes appear later in life especially in the intertriginous region (**Crowe's Sign**).

## Neurofibromatosis Type 2

- Neurofibromatosis type 2 (NF2) is associated with abnormalities of the *NF2* gene, which is located on chromosome 22.
- The *NF2* gene produces merlin, also known as schwannomin, a cell membrane-related protein that acts as a tumor suppressor. NF2 has an estimated birth frequency of 1 in 33,000 to 40,000.

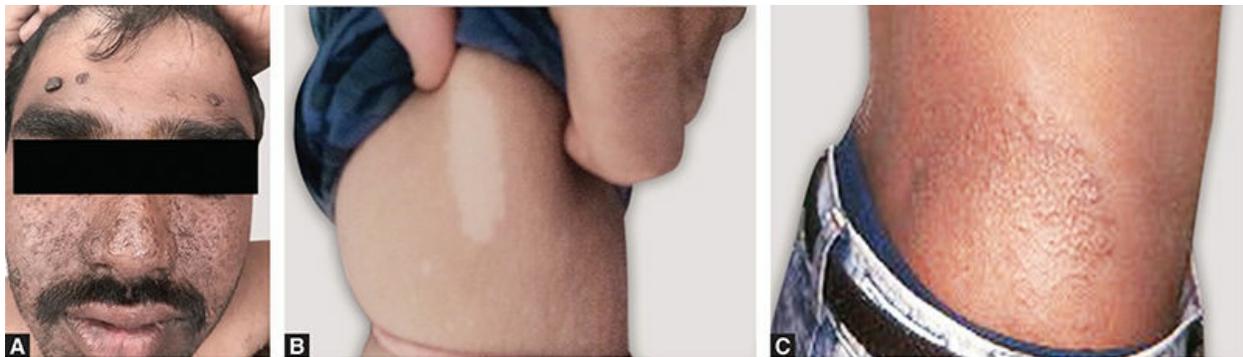

Diagnostic criteria for NF2 (Box 22.20).

## Tuberous Sclerosis

### Q. Write short note on tuberous sclerosis.

- Tuberous sclerosis complex is an inherited neurocutaneous disorder characterized by pleomorphic features involving many organ systems, including multiple benign hamartomas of the brain, eyes, heart, lung, liver, kidney, and skin.
- Called as **Bourneville disease** as it was first described by him in 1880.
- Clinical triad of Vogt—**EPI-LOI-A**: Epilepsy, low intelligence and adenoma sebaceum (Fig. 22.21A).
- Incidence 1 in 6000–9000
- Dominant inheritance but a high frequency of spontaneous mutation

Diagnostic criteria for tuberous sclerosis complex (Table 22.8)

**Figs. 22.21A to C:** (A) Adenoma sebaceum; (B) Ash leaf shaped macule is a hypopigmented macule oval at one end and pointed at the opposite end; (C) Shagreen patches.

**Table 22.8: Diagnostic criteria for tuberous sclerosis complex (TSC).**

<i>Major features</i>	<i>Minor features</i>
<ul style="list-style-type: none"> <li>• Facial angiofibromas or forehead plaque</li> <li>• Non-traumatic ungual or periungual fibroma</li> <li>• Hypomelanotic macules (more than three) (Fig. 22.21B)</li> <li>• Shagreen patch (connective tissue nevus) (Fig. 22.21C)</li> <li>• Multiple retinal nodular hamartomas</li> <li>• Cortical tuber</li> <li>• Subependymal nodule</li> <li>• Subependymal giant cell astrocytoma</li> <li>• Cardiac rhabdomyoma, single or multiple</li> <li>• Lymphangiomyomatosis</li> <li>• Renal angiomyolipoma</li> </ul>	<ul style="list-style-type: none"> <li>• Multiple randomly distributed pits in dental enamel</li> <li>• Hamartomatous rectal polyps</li> <li>• Bone cysts</li> <li>• Cerebral white matter migration lines</li> <li>• Gingival fibromas</li> <li>• Non-renal hamartoma</li> <li>• Retinal achromic patch</li> <li>• “Confetti” skin lesions</li> <li>• Multiple renal cysts</li> </ul>
Definite TSC: Either 2 major features or 1 major feature with 2 minor features Probable TSC: One major feature and one minor feature Possible TSC: Either 1 major feature or 2 or more minor features	

## Café-au-lait Macules (CALM)

### **Q. Write short note on café-au-lait macules (CALM).**

- Well-circumscribed, evenly pigmented macules (Fig. 22.22), size ranges from 1 to 2 mm to greater than 20 cm.
- Microscopically shows, increased melanin in both melanocytes and basal keratinocytes.
- In McCune-Albright syndrome, CALM may have a block-like distribution with midline demarcation and an irregular, jagged outline (‘coast of Maine’).
- In NF1, there is more numbers of CALM and has more widespread distribution (with the exception of segmental NF1) which is ‘typical’ based on their regular borders, smooth (‘coast of California’) and uniform pigmentation. In adults, the presence of six or more café-au-lait macules is highly suggestive of NF1.
- In fair-skinned infants, they may be difficult to detect on routine physical examination, but are accentuated with examination under a Wood’s lamp.
- CALMs may be observed in tuberous sclerosis, ataxia telangiectasia, Bloom’s syndrome, Watson’s syndrome.

Fig. 22.22: Café-au-lait macules (CALM).

## DISORDERS OF SKIN APPENDAGES

### Acne Vulgaris

**Q.** Write short note on etiology, clinical features and management of acne vulgaris.

- Acne is a multi-factorial disease characterized by abnormalities in sebum production, follicular desquamation, bacterial proliferation and inflammation.
- **Age and gender:** It starts after puberty and is seen primarily in teenagers (12–20 years of age) and young adults. 85% adolescents experience it. Prevalence of comedones in adolescents approaches 100%. But, it can persist into the thirties and forties, particularly in females. Affects both males and females, although males tend to have more severe disease.

Bacterial (*Propionibacterium acnes*) colonization within the upper and midportion of the hair follicle converts lipids within sebum to proinflammatory fatty acids.

### *Clinical Features (Table 22.9)*

**Table 22.9:** Factors that induce or exacerbate acne vulgaris (secondary acne).

- **Endocrine causes:** Polycystic ovary syndrome, Cushing's syndrome, congenital adrenal hyperplasia, androgen-secreting tumors of adrenals, ovary and testis, and acromegaly
- **Drugs**
  - **Glucocorticoids:** Systemic and local agents
  - **Hormones:** Adrenocorticotrophic hormone, testosterone, gonadotropins, oral contraceptives

- **Halides:** Iodides and bromides
- **Anabolic:** Danazole, stanazole
- **Anticonvulsants/antipileptics:** Phenytoin, carbamazepine, topiramate, gabapentin, lithium
- **Antidepressants:** Amitriptyline, lithium, setraline
- **Antituberculous:** Isoniazid, rifampicin
- **Chemotherapeutic agents:** Dactinomycin, pentostatin, gefitinib
- **Antineoplastic drugs:** Epidermal growth factor receptor (EGFR) inhibitor, cetuximab
- **Antiviral:** Ritonavir, ganciclovir
- **Vitamins:** B<sub>6</sub>, B<sub>12</sub>

- **Occupational exposures:** To cutting oils, chlorinated aromatic hydrocarbons, and coal tars

- **Conditions favoring occlusion of sebaceous glands:** e.g. heavy clothing, greasy cosmetics, and tropical climates.

- **Genetic factors**

- **Sites:** Most common location for acne is the face (Fig. 22.23), but it may involve the chest and back (trunk).
- Greasiness of the skin (seborrhea) is often observed.
- **Type of lesions:** The hallmark is the **comedone**.

**Fig. 22.23:** Acne vulgaris.

### *Microcomedone*

- *Hyperkeratotic plug made of sebum and keratin in follicular canal.*
- These comedones may be noninflammatory or inflammatory type (open or closed comedones).
- Open comedones (blackheads) appear as black papules due to the keratin debris and closed comedones (white heads) usually have no visible follicular opening. Inflammatory papules, nodules and cysts may arise from comedones.
  - Most cases remain mild and do not lead to scarring. Few may develop large inflammatory cysts and nodules and may heal by significant

scarring.

#### *Clinical variants*

- **Acne conglobata** is rare and commonly affects adult males. It is a severe form of acne characterized by numerous comedones, large abscesses with sinuses, grouped inflammatory nodules associated with suppuration. It may be associated with **hidradenitis suppurativa** (a chronic, inflammatory disorder of apocrine glands, mainly affecting axillae and groins), folliculitis and pilonidal sinus.
- **Acne fulminans** is a rare, severe variant of acne, usually affecting the trunk in adolescent males. It is present with fever, arthralgias and systemic inflammation, with leukocytosis and raised plasma viscosity.
- **Acne excoriée** (also known as “picker’s acne”) is self-inflicted excoriations produced by compulsive picking of pre-existing or imagined acne lesions. It is usually observed in teenage girls with psychological problems.
- **SAPHO Syndrome:** Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis syndrome.
- **Acne venenata:** Contact with acnegenic chemicals can produce comedones. For example, chlorinated hydrocarbons, cutting oils, petroleum oil, coal tar.
- **Acne aestivalis** (Mallorca acne): Rare, seen in females 25–40 years. Starts in spring, resolves by fall characterized by small papules on cheeks, neck, upper body. Comedones and pustules are sparse or absent.

#### **Management**

##### ***Mild to moderate disease***

###### *Local therapy:*

- Areas affected with acne should be kept clean by regular washing with soap and water. However, vigorous scrubbing may cause mechanical rupture of comedones.
- Topical agents such as benzoyl peroxide (most cost-effective therapy), retinoids {tretinoin (most potent keratolytic agent), adapalene (less irritating), or tazarotene}, or salicylic acid should be used.
- Topical antibacterial agents: Inflammatory acne responds to topical antibacterial agents such as azelaic acid, topical erythromycin, or clindamycin.

###### *Systemic therapy:*

- Antibiotics: Moderate inflammatory acne will benefit from the addition of systemic therapy such as oral tetracycline (oxytetracycline or lymecycline), doxycycline (200 mg/day), or minocycline (200 mg/day) for 3–6 months.
- Hormonal therapy: These include, estrogen-containing oral contraceptives or a combined estrogen/anti-androgen (such as cyproterone acetate) contraceptive.

##### ***Moderate to severe disease***

- **Isotretinoin:** Moderate to severe acne or if there is no adequate response to 6 months of therapy with the other therapies (combined systemic and topical approaches), patients should be considered for isotretinoin (13 *cis* -retinoic acid).
- **Mechanism of action:** It decreases sebaceous gland size and sebum excretion, decreases follicular hypercornification and reduces *P. acnes* colonization.
- **Side effects:** Oral isotretinoin is teratogenic (prevent pregnancy while taking isotretinoin), and possibly associated risk for severe depression, pseudotumor cerebri and other significant side effects.

Other treatments and physical measures:

- **For inflamed acne nodules or cysts:** They may require intralesional injections of **triamcinolone acetonide** or incision and drainage, or excision under local anesthesia.
- **Scarring:** Prevention of scarring by adequate treatment of active acne. Keloid scars respond to intralesional steroid injection and/or silicone dressings. Other measures for scarring include carbon dioxide laser, microdermabrasion, chemical peeling or localized excision.
- **UVB phototherapy:** They are rarely used in patients with inflammatory acne who are unable to use conventional therapy, such as isotretinoin.

## HAIR DISORDERS

**Q. Write short note on alopecia/causes of alopecia.**

**Alopecia:** Alopecia is loss of hair.

### Alopecia

#### *Classification and Causes of Alopecia (Table 22.10)*

**Table 22.10:** Classification and causes of alopecia.

<i>Localized</i>	<i>Diffuse</i>
<b>Non-scarring</b>	
<p><b>A. Abnormality of cycling</b></p> <ul style="list-style-type: none"> <li>• Alopecia areata</li> <li>• Syphilitic alopecia</li> </ul> <p><b>B. <b>Scarring</b>	
<b>A. Lymphocytic</b>	<ul style="list-style-type: none"> <li>• Discoid lupus erythematosus</li> </ul>

- Chronic cutaneous lupus erythematosus, discoid lupus erythematosus (DLE)
  - Lichen planopilaris
  - Classic pseudopelade of Brocq
  - Alopecia mucinosa
- B. Neutrophilic**
- Folliculitis decalvans
  - Dissecting folliculitis/cellulitis
- C. Mixed**
- Folliculitis (acne) keloidalis
  - Folliculitis (acne) necrotica
  - Erosive pustular dermatitis
- Radiotherapy
  - Folliculitis decalvans
  - Lichen planus

## ***Alopecia Areata***

**Definition:** Rapid and complete loss of hair in one or most often several round or oval patches, usually on the scalp (Fig. 22.24), bearded area, eyebrows, eye lashes and less commonly on other hairy areas of the body.

Approximately 1.7% of the population will experience an episode of alopecia areata during their life time.

### *Etiology*

It is an autoimmune disease

- Mediated by the cellular arm (T- cell, macrophages).
- Modified by genetic factors (HLA-R4,DR11,DQ7).

### ***Stages of Alopecia Areata (Box 22.21)***

#### *Clinical feature*

- Rapid and complete loss of hair in one or several patches (Fig. 22.24).

**Fig. 22.24:** Alopecia areata.

- **Site:** Scalp, bearded area, eyebrows, eye lashes and less commonly other areas of body.
- **Size:** Patches of 1–5 cm in diameter.

#### **Treatment**

- Spontaneous recovery is extremely common for patchy alopecia areata.
- Steroid: Both local (intralesional and topical) and systemic (in short course).
- Topical 1% anthralin cream: Applied for 15–20 minutes and then shampooed off the treated side.
- 5% topical minoxidil: As a single agent or as an adjuvant with topical anthralin.
- PUVA.
- Contact sensitizer: Squaric acid dibutyle ester, diphencyprone, dinitrochlorobenzene.
- Psychological support.
- In extensive scalp hair loss: Cosmetically expectable alternatives.

#### **Box 22.21:** Stages of alopecia areata.

- Acute hair loss
- Persistent (chronic) baldness
- Partial telogen to anagen conversion (incomplete recovery)
- Normal recovery

## **LEG ULCERS**

**Q.** Write short note on causes of non-healing leg ulcer.

# XEROSTOMIA

## **Q. Write short note on xerostomia.**

- Normal healthy adults daily produce about 1500 mL of saliva.
- Xerostomia is characterized by dry mouth and may be due to decrease in the production of saliva.

## Effects of Xerostomia

- Symptoms may be minor or may hamper activities of daily living.
- May produce burning sensation in mouth, difficulty in eating, chewing and swallowing.
- May produce tooth decay, bad breath, candida infection and viral infections (e.g. herpes simplex).

## Etiology

- **Anticholinergic drugs** (reduce volume of saliva): For example, anticholinergics, antidepressants, antipsychotics, antiemetics, antihistamines, antihypertensives, antiparkinsonian drugs, antispasmodics, diuretics.
- **Sympathomimetic drugs** (produce viscous saliva): For example, amphetamines, appetite suppressants, decongestants, bronchodilators.
- **Systemic diseases:** Addison's disease, Alzheimer's diseases, salivary gland infection, Sjögren's syndrome, alcoholic cirrhosis, diabetes mellitus, HIV/AIDS, radiation to head and neck region (e.g. for cancer therapy), severe dehydration.
- **Other causes:** Elderly individuals, sleep-related xerostomia (due to mouth-breathing during sleep).

## Management

- Stop the offending drug.
- Frequent sips of water and teeth brushing.
- **Oral hygiene:** Chlorhexidine rinses.
- **Artificial salivary substitutes:** They act as lubricant and protective and not as substitutes for digestive and enzymatic actions (e.g. sodium carboxymethyl cellulose, potassium dihydrogen orthophosphate and sorbitol).
- **Cholinergic agonists:**
  - Pilocarpine and cevimeline: Should be cautiously used in patients with cardiovascular disease and chronic respiratory conditions. They are contraindicated in patients with uncontrolled asthma, angle-closure (narrow angle) glaucoma and liver disease.

# PRURITUS

**Q. Write short essay/note on pruritus/generalized pruritus and its causes.**

The terms ‘itch’ and ‘pruritus’ are used synonymously; however, ‘pruritus’ is often used for generalized itch.

**Definition:** Itch is an unpleasant cutaneous sensation that leads to scratching or rubbing.

**Box 22.22:** Dermatological causes of pruritus.

Atopic dermatitis	Ichthyoses
Scabies	Dermatitis herpetiformis
Xerosis	Psoriasis
Lichen simplex chronicus	Lichen planus
Contact dermatitis	Fungal infections
Insect bites	Pediculosis
Sunburn	Plaster of Paris casts

## Causes (Box 22.22 and Table 22.12)

### Management/Treatment

General measures:

- Avoid soap
- Control of xerosis with moisturizers and humidification of indoor environment.

Specific measures:

- Establish the diagnosis and treat the underlying skin or systemic disease.
- If a clear-cut diagnosis is not possible, various non-specific measures can be used for symptom control. It is necessary to re-assess intermittently in order to avoid missing the diagnosis.
- UVB (ultraviolet B) phototherapy in chronic kidney disease.
- Ursodeoxycholic acid (UDCA) in cholestasis.
- Cholestyramine, rifampicin and opioid antagonists (e.g. naltrexone) in primary biliary cirrhosis.
- Corticosteroids in Hodgkin’s disease.
- Paroxetine (selective serotonin reuptake inhibitor) in itching as paraneoplastic manifestation of malignancies.

Symptomatic measures:

- These include sedation, often with H<sub>1</sub> antagonist antihistamines; emollients; and counter-irritants (such as topical menthol-containing preparations).
- Intractable cases: Phototherapy, low-dose tricyclic antidepressants (e.g. amitriptyline) or

gabapentin may help.

Complications of pruritus:

- Prurigo nodularis is a variant of lichen simplex chronicus in which nodules develop at the site of scratching.
- Local infection due to scratching.
- Lichen simplex chronicus is localized skin thickening produced due to intense scratching.

## PANNICULITIS

- Panniculitis is an inflammatory reaction in the subcutaneous fat tissue.
- Panniculitis may preferentially affect (1) the lobules of fat (lobular panniculitis with necrosis and purpura), or (2) the connective tissue that separates fat into lobules (septal panniculitis).

**Table 22.12: Systemic causes of pruritus.**

Autoimmune <ul style="list-style-type: none"><li>• Dermatitis herpetiformis</li><li>• Dermatomyositis</li></ul>	Hepatobiliary <ul style="list-style-type: none"><li>• Biliary cirrhosis</li><li>• Drug-induced cholestasis</li></ul>
Hematological <ul style="list-style-type: none"><li>• Hemochromatosis</li><li>• Mastocytosis</li><li>• Polycythemia vera</li></ul>	Metabolic and endocrine <ul style="list-style-type: none"><li>• Carcinoid syndrome</li><li>• Chronic renal disease</li><li>• Diabetes mellitus</li></ul>
Infectious diseases <ul style="list-style-type: none"><li>• AIDS</li><li>• Infectious hepatitis</li><li>• Parasitic diseases (e.g. giardiasis, ascariasis)</li></ul>	Malignancy <ul style="list-style-type: none"><li>• Leukemia, lymphoma</li><li>• Multiple myeloma</li><li>• Solid tumors with paraneoplastic syndrome</li></ul>

## Erythema Nodosum

**Q. Write short essay/note on the etiology, clinical features, diagnosis and treatment of erythema nodosum.**

- Erythema nodosum (septal panniculitis) is the most common form of panniculitis
- Most common type of panniculitis. It is also called subacute migratory panniculitis of Vilanova and Piñol.

## ***Etiology***

### *Factors provoking erythema nodosum*

Occurrence of erythema nodosum is often associated with provoking factors (Box 22.23)

Most often (0.50%) it is idiopathic without any identifiable underlying cause.

## ***Clinical Features***

Age and gender: Age 20 to 30 years but any age group may be affected, Female to male ratio is 3-6:1.

*Lesions (Table 22.13 and Fig. 22.26)*

**Fig. 22.26:** Erythema nodosum on both legs.

**Table 22.13:** Features of lesions erythema nodosum.

<ul style="list-style-type: none"><li>• Sudden onset</li><li>• Symmetrical</li><li>• Painful</li><li>• Erythematous</li><li>• Warm</li><li>• Nonulcerated nodules/plaques</li><li>• Knees, shins, feet, may be at thighs, arms, and face</li></ul>	<ul style="list-style-type: none"><li>• Undergo color changes as advance in the duration</li><li>• Resolve without scarring or atrophy</li><li>• Associated with pyrexia, malaise, headache, arthralgias</li><li>• Recurrent episodes are known</li></ul>
--	---

## ***Diagnosis***

- Most often based on clinical presentation.
- **Deep wedge biopsy** including the subcutis is usually required for histologic diagnosis. Histologically shows: Inflammation of the connective

tissue septa in the subcutaneous fat tissue (septal panniculitis). Vasculitis is not observed.

- **Identification of triggering factors causing erythema nodosum:**

- Complete blood count (CBC) with differential; ESR (erythrocyte sedimentation rate) and C-reactive protein level.
- Evaluation for  $\beta$ -hemolytic streptococcal infection: Throat culture for group A streptococci, rapid antigen test, antistreptolysin-O titer and polymerase chain reaction assay.
- Chest radiograph, e.g. to detect tuberculosis and sarcoidosis, Mantoux test.
- Stool examination for ova and parasite, e.g. in patients with GIT symptoms.
- Evaluation for inflammatory bowel disease in patient with symptoms of IBD.

#### **Treatment**

- Identify and remove/treat any underlying cause (treatment of tuberculosis/IBD/sarcoid).
- Bed rest, leg elevation and analgesics with NSAIDs may produce symptomatic relief. However, avoid NSAIDs if secondary to Crohn disease because they may trigger a flare-up the underlying Crohn disease.
- Systemic corticosteroids must be avoided in cases with infection and malignancy.
- Dapsone and potassium iodide orally (400–900 mg/day) have been effective for stubborn disease (if NSAIDs do not relieve pain or the lesions persist) for symptomatic relief. Recalcitrant, chronic, or recurring EN is treated with thalidomide, colchicine, and hydroxychloroquine.

### **Box 22.23:** Triggering factors associated with erythema nodosum.

#### Infections

- Bacteria, e.g.  **$\beta$ -hemolytic streptococci**, mycobacteria (usually primary **tuberculosis**, leprosy), *Brucella*, *Mycoplasma*, *Rickettsia*, *Chlamydia*, *Salmonella*, *Yersinia*.
- Viruses, e.g. hepatitis B and infectious mononucleosis
- Fungi, e.g. coccidioidomycosis, histoplasmosis, blastomycosis
- Parasitic, e.g. amebiasis, giardiasis.

Drug administration, e.g. **sulfonamides**, sulfonyleureas, oral contraceptives

Systemic disease, e.g. **sarcoidosis**, inflammatory bowel disease, Behcet's

Malignancies: Lymphoma, leukemia, renal cell carcinoma.

Idiopathic: >50% cases

# **Clinical Pharmacology**

# CHAPTER 23

## INTRODUCTION

- Drug metabolism that varies on genetic basis is often called polymorphic drug metabolism (Table 23.1).
- **Pharmacogenetics:** It is the study of individual gene-drug interactions, usually one or two genes that have dominant effect on a drug response.
- **Pharmacogenomics** is the study of genomic influence on drug response

**Table 23.1:** Genetic polymorphisms in drug metabolism.

<i>Defect</i>	<i>Enzyme involved</i>	<i>Drug</i>	<i>Consequences</i>
Oxidation	CYP2D6	Codeine	Reduced analgesia
Oxidation	Aldehyde dehydrogenase	Ethanol	Facial flushing, hypotension, tachycardia, nausea, vomiting
N-Acetylation	N-acetyl transferase	Isoniazid	Peripheral neuropathy
Ester hydrolysis	Plasma cholinesterase	Succinylcholine	Prolonged apnea
Oxidation	CYP2C9	Warfarin	Bleeding

## ADVERSE DRUG REACTION (ADR)

**Definition:** An unwanted or harmful reaction experienced following the administration of a drug or combination of drugs under normal conditions of use and suspected to be related to the drug.

It could be trivial or serious or fatal.

### Classification of ADR (Table 23.2)

**Table 23.2:** Classification of adverse drug reactions.

<p><b>Type A</b></p> <ul style="list-style-type: none"> <li>• Response qualitatively normal but quantitatively abnormal.</li> <li>• Common, less serious, dose-related.</li> <li>• Corrected by dose adjustment.</li> <li>• Include side effect, toxic effect, and withdrawal.</li> </ul>	<p><b>Type D</b></p> <ul style="list-style-type: none"> <li>• Refer to carcinogenic and teratogenic effects.</li> <li>• These reactions are delayed in onset.</li> </ul>
<p><b>Type B</b></p> <ul style="list-style-type: none"> <li>• Because of patient peculiarities such as allergy, idiosyncrasy, dose-related.</li> <li>• Uncommon.</li> <li>• Serious reactions need withdrawal of drug required.</li> <li>• Not always predictable OR preventable.</li> </ul>	<p><b>Type E</b></p> <ul style="list-style-type: none"> <li>• End of dose effect.</li> <li>• For example, abrupt cessation of corticosteroids produces acute adrenal insufficiency and stoppage of propranolol can produce rebound effect.</li> </ul>
<p><b>Type C</b></p> <ul style="list-style-type: none"> <li>• Associated with long-term drug therapy, e.g. benzodiazepine dependence and analgesic nephropathy.</li> <li>• They are well known and can be anticipated.</li> </ul>	<p><b>Type F</b></p> <ul style="list-style-type: none"> <li>• Failure of therapy.</li> <li>• Oral contraceptive pill (OCP) failure when on antitubercular therapy.</li> </ul>

## Severity of ADR

- **Minor:** No need of therapy, antidote, or hospitalization.
- **Moderate:** Requires drug change, specific treatment, hospitalization.
- **Severe:** Potentially life-threatening; permanent damage, and prolonged hospitalization.
- **Lethal:** Directly or indirectly leads to death.

## Types of ADR

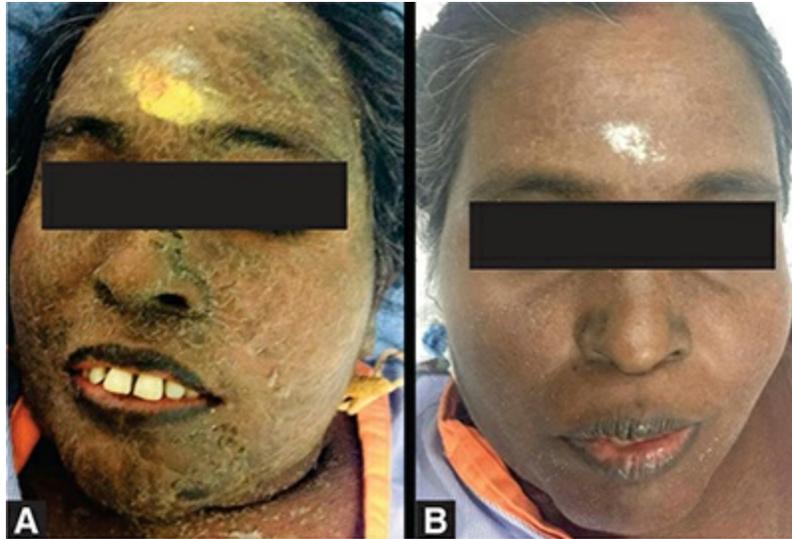

### 1. Side effects:

- Unavoidable, predictable, decreased dose results in amelioration.

**Figs. 23.1A to C:** (A) Mucositis induced by anticancer drug; (B) Phenytoin-induced gum hyperplasia; (C) Zidovudine- induced nail pigmentation.

- ***Occurs as extension of the same therapeutic effect, e.g.*** atropine as antisecretory in preanesthetic medication → dry mouth, mucositis induced by anticancer drug(Fig. 23.1A).
- ***Occurs as a distinctly different effect, e.g.*** promethazine as antiallergic → sedation, phenytoin-induced gum hyperplasia(Fig. 23.1B), Zidovudine-induced nail pigmentation(Fig. 23.1C).
- Estrogen as antiovolatory → nausea.
- ***Side effect exploited for a therapeutic use, e.g.*** codeine [antitussive] constipating action used in diarrhea.
  - Sulfonylureas [tested as antibacterial] were found to decrease blood glucose.

**Figs. 23.2A and B:** Drug rash with eosinophilia and systemic symptoms syndrome (DRESS)(A) presteroid therapy; (B) poststeroid therapy.

2. **Secondary effects:** Indirect effect of therapy. For example, intestinal microflora killed by tetracycline causing superinfection, corticosteroids decreases immunity causing oral candidiasis.
3. **Toxic effects:** Overdose or prolonged use. Examples of toxic effects, overdose or prolonged use includes atropine → delirium, paracetamol → hepatic necrosis, barbiturates → coma and morphine → respiratory failure.
4. **Intolerance:** It is opposite of tolerance and characterized by increased sensitivity to low doses. Examples, few doses of carbamazepine → ataxia, single dose of triflupromazine → muscular dystonia.
5. **Idiosyncrasy:** Genetically determined atypical or bizarre effect. Examples, barbiturate → excitement and mental confusion, streptomycin → deafness with single dose. **Drug reaction with eosinophilia and systemic symptoms (DRESS)** is a rare, potentially life-threatening, drug-induced hypersensitivity reaction that includes skin eruption, hematologic abnormalities (eosinophilia, atypical lymphocytosis), lymphadenopathy, and internal organ involvement (liver, kidney, lung). Common drugs associated are phenytoin, olanzepine, sulfonamides, febuxostat, dapsone and vancomycin (Figs. 23.2A and B).
5. **Drug allergy or hypersensitivity:** Immunologically mediated, independent of dose and occurs in a small proportion of patients. Prior sensitization is required and occurs after 1–2 weeks required after first

dose. Drug acts as an antigen or hapten. Chemically-related drugs may show cross sensitivity. Same drug can cause different allergic reactions in different individuals. Types of allergy include:

- **Type I:** Urticaria(Fig. 23.3), angioedema, asthma, anaphylactic shock.
- **Type II:** Thrombocytopenia, agranulocytosis, aplastic anemia, SLE.
- **Type III:** Arthralgia, lymphadenopathy, Stevens-Johnson syndrome.
- **Type IV:** Contact dermatitis, fever, photosensitization, e.g. penicillin, sulfonamides, carbamazepine, and methyldopa.

**Fig. 23.3:** Nevirapine-induced rash.

## 7. Photosensitivity

- **Phototoxic:** Drug accumulates in skin → absorbs light → photochemical reaction → photobiological reaction → tissue damage. Example, erythema, edema, blistering, etc. e.g. *tetracyclines*.
- **Photoallergic:** Drug → cell-mediated immune response → contact dermatitis on exposure to light, e.g. sulfonamides, griseofulvin.

3. **Drug dependence:** Can be psychological and/physical dependence.
9. **Teratogenicity:** Drug use in pregnancy affects offspring. Examples, thalidomide → phocomelia, phenytoin → cleft palate.
10. **Carcinogenicity and mutagenicity:** For example, anticancer drugs, estrogens.
11. **Drug-induced diseases, iatrogenic diseases:** Examples, salicylates → peptic ulcer, phenothiazine → Parkinsonism, INH → hepatitis.
12. **Drug withdrawal reaction:** Examples, propranolol → hypertension, acute adrenal insufficiency following withdrawal of corticosteroids.

### Management of ADR

#### *Evaluation*

- Airway
- Breathing
- Circulation
- Degree of consciousness
- History of exposure/ingestion
- Physical examination

#### *Supportive Care*

- Respiratory
- Cardiovascular
- CNS

#### *Enhancing Elimination*

- Activated charcoal
- Forced alkaline diuresis
- Hemodialysis/perfusion

#### *Decontamination*

- Gastric lavage
- Induction of emesis
- Activated charcoal
- Other decontamination

#### *Diagnostic Studies*

- Blood tests
- ECG
- X-rays
- Specific drug levels

#### *Antidotes*

- Organophosphates—atropine, oximes
- Morphine—naloxone
- Benzodiazepines—flumazenil
- Paracetamol—N-acetyl cysteine

The ways of preventing ADR are listed in Box 23.1.

### Box 23.1: Prevention of ADR.

- Avoid inappropriate drugs in the context of clinical condition
- Use right dose, route, frequency based on patient variables
- Elicit medication history; consider untoward incidents
- Elicit history of allergies (higher chances in patients with allergic diseases)
- Rule out drug interactions
- Adopt right technique, e.g. slow IV injection of aminophylline
- Carry out appropriate monitoring, e.g. prothrombin time (PT) with warfarin; drug levels

## DRUG INTERACTION

**Definition:** A measurable modification (in magnitude and/or duration) of the

action of one drug by prior or concomitant administration of another substance, including prescription, non-prescription (including complementary medicines) drugs, food, alcohol, cigarette smoking or diagnostic tests.

Outcomes of drug interaction are listed in Box 23.2.

### **Box 23.2:** Outcomes of drug interaction.

- Loss of therapeutic effect
- Toxicity
- Unexpected increase in pharmacological activity
- Beneficial effects, e.g. additive and potentiation (intended) or antagonism (unintended)
- Chemical or physical interaction, e.g. intravenous incompatibility in fluid or syringes mixture

## **Mechanism of Drug Interaction**

### ***Pharmacokinetic Interaction***

#### *Altered GIT absorption*

- **Altered pH:** The nonionized form of a drug is more lipid soluble and more readily absorbed from GIT than the ionized form does. For example, antacids and H<sub>2</sub> blockers change gastric pH → decrease the dissolution of ketoconazole which requires acidic pH. Therefore, these drugs must be separated by at least 2 hour in the time of administration of both.
- **Altered intestinal bacterial flora:** In patients receiving digoxin, 40% or more of the administered dose is metabolized by the intestinal flora. If patients simultaneous take antibiotics which destroy the intestinal flora, digoxin toxicity can occur.
- **Complexation or chelation:** Tetracycline interacts with iron preparations → unabsorbable complexes. Decrease absorption of ciprofloxacin by 85% due to chelation, if given along with antacids.
- **Drug-induced mucosal damage:** Antineoplastic agents, e.g. cyclophosphamide, vincristine, procarbazine → mucosal damage and inhibit absorption of several drugs, e.g. digoxin.
- **Altered motility:** Metoclopramide (antiemetic) → increase absorption of cyclosporine due to the increase of stomach emptying time.

#### *Displaced protein binding*

- It depends on the affinity of the drug to plasma protein.
- Phenytoin is a highly bound to plasma protein (90%), tolbutamide (96%),

and warfarin (99%). Drugs that displace these agents are aspirin, sulfonamides and phenylbutazone.

### *Altered metabolism*

- The effect of one drug on the metabolism of the other is well documented. The liver is the major site of drug metabolism but other organs can also be involved, e.g. WBC, skin, lung, and GIT.
- CYP450 family is the major metabolizing enzyme in phase I (oxidation process).
- Therefore, the effect of drugs on the rate of metabolism of others can involve the following examples:
  - **Enzyme induction:**
    - ◆ A drug may induce the enzyme that is responsible for the metabolism of another drug or even itself, e.g. carbamazepine (antiepileptic drug) increases its own metabolism.
    - ◆ Phenytoin increases hepatic metabolism of theophylline → leading to decrease its level, reduces its action and vice-versa.
  - **Enzyme inhibition:**
    - ◆ It is characterized by reduction of the rate of metabolism of a drug by another drug. This leads to increased concentration of the target drug and thereby increases its toxicity.
    - ◆ Inhibition of the enzyme may be caused by the competition on its binding sites. This shortens the onset of action (may be within 24 hours).
    - ◆ Example, erythromycin inhibit metabolism of astemizole and terfenadine → Raises the serum concentration of the antihistaminic and thereby increasing the cardiotoxicity which may be life-threatening.

### ***First-Pass Metabolism***

- Administration of drug by oral route increases its metabolism in the liver and GIT. This causes loss of a part of the drug dose and decreases its action.
- This is more evident when such drug is an enzyme inducer or inhibitor.
- By increase its first pass, rifampin reduces serum concentration of verapamil level. Also, rifampin induces the hepatic metabolism of

verapamil.

## **Renal Excretion**

### *Active tubular secretion*

- It occurs in the proximal tubules (a portion of renal tubules).
- The drug combines with a specific protein and reaches the proximal tubules.
- When a drug has a competitive reactivity to the protein that is responsible for active transport of another drug. This will increase its toxicity by reducing drug excretion and increasing its concentration.
- For example, probenecid → decreases tubular secretion of methotrexate.

### *Passive tubular reabsorption*

- In the tubules, excretion and reabsorption of drugs is by passive diffusion and is regulated by concentration and lipid solubility.
- For example, sodium bicarbonate → increases lithium clearance and decreases its action.

## **Pharmacodynamic Interaction**

- It indicates that there is alteration of the drug action without change in its serum concentration by pharmacokinetic factors.
- For example, **synergism** means  $1 + 1 = 3$ , **additive** means  $1 + 1 = 2$ , **potentiation** means  $1 + 0 = 2$ , and **antagonism** means  $1 + 1 = 0$  or  $0.5$ .

## **Prevention of Drug Interaction**

- Monitoring therapy and making adjustments.
- Monitoring blood level of some drugs with narrow therapeutic index, e.g. digoxin, anticancer agents, etc.
- Monitoring of some parameters may help to detect the early events of interaction or toxicity. For example, with warfarin treatment, it is necessary to monitor the prothrombin time to detect any change in the drug activity.
- Increase the interest in case report studies to report different possibilities of drug interaction.

## **DRUGS USED IN LIVER DISORDER**

Common drugs metabolized in liver are mentioned in Table 23.3.

**Table 23.3: Common drugs metabolized in the liver.**

Type of conjugation	Endogenous reactant	Examples
Glucuronidation	UDP glucuronic acid	Nitrophenol, morphine, acetaminophen, diazepam, N-hydroxy dapsone, sulfathiazole, digitoxin, digoxin
Acetylation	Acetyl-CoA	Sulfonamides, isoniazid, clonazepam, dapsone, mescaline
Glutathione conjugation	Glutathione (GSH)	Acetaminophen, ethacrynic acid, bromobenzene
Glycine conjugation	Glycine	Salicylic acid, benzoic acid, cholic acid, deoxycholic acid
Sulfation	Phosphoadenosyl phosphosulfate	Estrone, aniline, phenol, 3-hydroxy-coumarin, acetaminophen, methyl dopa
Methylation	S-adenosylmethionine	Dopamine, epinephrine, pyridine, histamine, thiouracil
Water conjugation	Water	Carbamazepine

### Cirrhotic Patients with Portosystemic Shunts

- Blood from intestines bypasses the liver, delivering much more of orally administered drugs to the systemic circulation. Thus, systemic bioavailability of orally administered high clearance drugs is much greater.
- *Hepatic impairment:*
  - Research has shown reduced drug-metabolizing enzyme (CYP and conjugation reactions) in cirrhotics which worsen disease severity (Child-Pugh score), but with large variability!
  - Preferentially recommend conjugatively metabolized agents in cirrhotics
  - In the absence of recommended doses:
    - ◆ *Child-Pugh A:* Reduce maintenance to 50%
    - ◆ *Child-Pugh B:* Reduce maintenance to 25%
    - ◆ *Child-Pugh C:* Use drugs proven safe, or drugs with level monitoring available.

# DRUGS USE IN KIDNEY DISORDERS

## Dosing of Drugs in Renal Failure

- Without careful dosing and therapeutic drug monitoring in patients with renal dysfunction, accumulation of drugs/toxic metabolites can occur. Drug dosing has to be adjusted to the calculated GFR.
- Renal disease affects the pharmacokinetic as well as pharmacodynamic effect of drugs.
- Uremia can alter drug disposition, protein binding, pharmacokinetics (PK), pharmacodynamics (PD) and can also increase sensitivity to drugs.

## Effect of Renal Failure on Bioavailability

- Absorption of drugs in patients with renal disorders could be inhibited by GI disturbances seen in uremia (nausea, vomiting, and diarrhea), uremic gastritis, and pancreatitis.
- Edema of GI tract can occur with nephrotic syndrome and impair absorption.
- Gastric motility can be impaired by uremia.
- Uremia can also increase gastric ammonia and lead to increased gastric pH > affecting drugs that require acidic pH (e.g. ferrous sulfate).
- First-pass effect is reduced in patients with renal disease (therefore, absorption of drugs with high first pass effect is increased, e.g. propranolol).

## Effect of Renal Failure on Protein Binding (PB) and Volume of Distribution (VD)

- The effect of a drug is related to the amount of free or unbound drug available to target tissues.
- Also, hypoalbuminemia is common to patients with renal failure. Therefore, highly PB drug has fewer albumins to cling to. This is especially important with phenytoin.

## Elimination

- As kidney disease progresses, the kidney's ability to excrete uremic toxins decreases as does its ability to eliminate certain drugs.
- Kidney eliminates primarily through filtration or active secretion.

- Drugs with low protein binding are filtered more readily.
- Large molecules (molecular weight >20000) daltons are not readily filtered due to size.

## Drug Removed by Dialysis

- Removal by dialysis is specific to each drug.
- *Factors affecting removal:* Type of machine, membrane surface area, pore size, flow rates.
- Dialysis is sometimes used to remove excess drug in an overdose situation.

**Table 23.4:** Current categories for drug use in pregnancy.

<i>Category</i>	<i>Description</i>
A	Adequate, well-controlled studies in humans show no risk to the fetus (e.g. magnesium sulfate)
B	No well-controlled studies have been conducted in humans. Animal studies show no risk to the fetus (e.g. amoxicillin, amoxicillin + clavulanic acid, cefotaxime, methyldopa, metronidazole, erythromycin).
C	No well-controlled studies have been conducted in humans. Animal studies have shown an adverse effect on the fetus (e.g. diclofenac, rifampicin, fluoroquinolones, aminoglycosides, glyburide).
D	Human studies have demonstrated a risk to the fetus. However, the benefits of therapy may outweigh the potential harm (e.g. tetracyclines, phenytoin, valproic acid, carbamazepine, ACE inhibitors).
X	Controlled studies in animals or humans have demonstrated fetal abnormalities. The use of the product is contraindicated in women who are or may become pregnant (e.g. thalidomide, oral contraceptive pills, misoprostol).

## DRUGS USE IN PREGNANCY

- The safety of approximately 50% of medications for the mother and fetus remains unknown.
- Pharmacokinetics are profoundly affected by pregnancy associated physiologic changes and dose adjustments are sometimes necessary for optimal clinical outcome.

### Current Categories for Drug Use in Pregnancy (FDA) (Table 23.4)

Few drugs contraindicated during pregnancy and those which have teratogenic effects are listed in Table 23.5. Common problems in pregnancy and drugs that can be safely used in these cases are mentioned in Table 23.6.

## CLINICAL TRIALS BASIC CONCEPTS

Clinical trial is an experimental epidemiological method. It is an interventional study on individuals, usually on patients.

### Objectives of Clinical Trials

Intervention trials determine whether experimental treatments or trials are safe and effective under controlled environments.

Observation trials address health issues in large groups of people in natural settings.

### Levels of Evidence (Table 23.7)

Levels of evidence (sometimes called hierarchy of evidence) are assigned to studies based on the methodological quality of their design, validity, and applicability to patient care. These decisions gives the “grade (or strength) of recommendation.”

Features of observational and experimental studies are mentioned in Table 23.8.

**Table 23.5:** List of few drugs contraindicated during pregnancy and those which have teratogenic effects.

<i>Drug</i>	<i>Side effects</i>
Tetracycline	Yellow staining of the primary or deciduous teeth and diminished growth of the long bones
Phenytoin	Fetal hydantoin syndrome consisting of intrauterine growth retardation, microcephaly, mental retardation, distal phalangeal hypoplasia
Retinoic acid	Craniofacial dysmorphisms, cleft palate, thymic aplasia, and neural tube defects
Thalidomide	Meromelia, absence of the limbs to rudimentary limbs to abnormally shortened limbs
Alcohol	IUGR, small head, small eyes or short eye openings, or a poorly developed philtrum and congenital heart disease
Nicotine	Intrauterine growth retardation (IUGR)

Warfarin	Nasal hypoplasia and a depressed nasal bridge, stippled epiphysis; termed fetal warfarin syndrome
Estrogen and androgens	Genital tract malformations
Chloramphenicol	Gray baby syndrome

## Types of Study (Table 23.9)

### Phases of Clinical Trials

Most trials that involve new drugs go through a series of steps:

1. Experiments in the laboratory

**Table 23.6: Common problems in pregnancy and drugs that can be safely used.**

<i>Common problems in pregnancy</i>	<i>Drugs that can be safely used</i>
Nausea and vomiting	Pyridoxine, meclizine diphenhydramine
Constipation	Mild purgative-like senna
Peptic ulcer	Sucralfate, H <sub>2</sub> blockers
Hematopoietic (iron and folic acid deficiency)	Iron and folic acid
Urinary tract infections	Ampicillin, amoxicillin, cefurixime axetil
Other infections	β-lactam antibiotics, cephalosporins
Malaria	Chloroquine, quinine, proguanil
Amoebiasis	Metronidazole and diloxanide furoate
Worm infestation	Piperazine citrate, pyrantel pamoate
Fungal infection	Miconazole, clotrimazole, nystatin
HIV infection	None of the anti-HIV drugs are safe, except zidovudine and nevirapine
Tuberculosis	INH and ethambutol are safe. If third drug is needed, then rifampicin
Diabetes mellitus	Insulin
Hypothyroidism	Thyroxine
Thyrotoxicosis	Propylthiouracil
Hypertension	α-methyldopa, in emergency—hydralazine, β blockers—labetolol, atenolol
Thromboembolic disease	Heparin
Headache and inflammatory condition	Paracetamol, avoid other NSAIDs
Epilepsy	Sodium valproate and phenytoin to be avoided,

	carbamazepine in lower dose can be used
Migraine	Paracetamol, propranolol, amitriptyline
Antidepressants	Amitriptyline and imipramine

**Table 23.7:** Levels of evidence.

<i>Level of evidence (LOE)</i>	<i>Description</i>
Level I	Evidence from a <b>systematic review or meta-analysis</b> of all relevant RCTs (randomized controlled trial) or evidence-based clinical practice guidelines based on systematic reviews of RCTs or three or more RCTs of good quality that have similar results
Level II	Evidence obtained from at least one well-designed <b>RCT</b> (e.g. large multisite RCT)
Level III	Evidence obtained from well-designed <b>controlled trials without randomization</b> (i.e. quasi-experimental)
Level IV	Evidence from well-designed <b>case-control or cohort studies</b>
Level V	Evidence from systematic reviews of descriptive and qualitative studies (metasynthesis)
Level VI	Evidence from a single descriptive or qualitative study
Level VII	Evidence from the opinion of authorities and/or reports of expert committees

**Table 23.8:** Features of observational and experimental studies.

<i>Observational studies</i>	<i>Experimental studies</i>
Cross-sectional, case series, case-control studies, Cohort studies <ul style="list-style-type: none"> <li>• Identify participants</li> <li>• Observe and record characteristics</li> <li>• Look for associations</li> </ul>	Before and after studies, comparative trials (controlled or head to head), randomized trials <ul style="list-style-type: none"> <li>• Identify participants</li> <li>• Place in common context</li> <li>• Intervene</li> <li>• Observe/evaluate effects of intervention</li> </ul>

2. Once deemed safe, go through 1–4 phases.
  - **Phase I:** Small group [20-80] for 1st time to evaluate safety, determine safe dosage range and identify side effects.

- **Phase II:** Treatment given to larger group (100-300) to confirm effectiveness, monitor SE, and further evaluate safety.
- **Phase III:** Treatment given to even larger group (1,000-3,000) to fulfill all of phase II objectives and compare it to other commonly used treatments and collect data that will allow it to be used safely.
- **Phase IV (Post-marketing surveillance):** Done after treatment has been marketed—studies continue to test treatment to collect data about effects in various populations and side effects from long term use.

**Table 23.9: Types of study with its pros and cons.**

<i>Type of Study</i>	<i>Description</i>	<i>Pros</i>	<i>Cons</i>
RCT (Randomized controlled trial)	An experimental comparison study where participants are allocated to treatment/intervention or control/placebo groups using a random mechanism. Best for studying the effect of an intervention	Unbiased distribution of confounders Blinding more likely Randomization facilitates statistical analysis	<b>Expensive:</b> Time and money Volunteer bias Ethically problematic at times
Crossover trial	A controlled trial where each participant has both therapies, i.e. randomized to treatment A first then starts treatment B	All participants serve as own controls and error variance is reduced, thus reducing sample size needed All participants receive treatment (at least some of the time) Statistical tests assuming randomization can be used Blinding can be maintained	All participants receive placebo or alternative treatment at some point Washout period lengthy or unknown Cannot be used for treatments with permanent effects
Cohort study	Data obtained from groups who have already been exposed, or not exposed, to the factor of interest. No allocation of exposure is made by the researcher. Best for studying effects of <i>risk</i>	Ethically safe. Participants can be matched Can establish timing and directionality of events Eligibility criteria and outcome assessments	Controls may be difficult to identify Exposure may be linked to a hidden Confounder Blinding is difficult For rare disease, large sample sizes or long follow-up necessary

	<i>factors on an outcome</i>	can be standardized	
Case-control study	Patients with a certain outcome or disease and an appropriate group of controls, without the outcome or disease, are selected (usually with some matching); then information is obtained on whether the subjects have been exposed to the factor under investigation	Quick and cheap as fewer people needed than cross-sectional studies Only feasible method for very rare disorders or those with long lag between exposure and outcome	Reliance on recall or records to determine exposure status Confounders Selection of control groups is difficult <i>Potential bias:</i> Recall, selection
Cross-sectional study	Examines the relationship between 1) diseases/other health-related characteristics, and 2) other variables of interest as they exist in defined population at one time. Exposure and outcomes both measured at the same time. Quantifies prevalence, risk, or diagnostic test accuracy	Cheap and simple Ethically safe	Establishes association at most, not causality Recall bias, social desirability bias Researcher's (Neyman) bias Group sizes may be unequal Confounders may be unequally distributed

## Informed Consent

Informed consent document will be obtained from the participants in the study population after explaining them fully about: (1) the purpose; (2) duration; (3) required procedures; (4) expectations; (5) risks and benefits; (6) adverse effects of the trial if any and (7) participants rights.

It is a continuous process throughout the study of learning of key facts by participants about a clinical trial. It also explains the rights of the participant. It is not a contract and the participant can withdraw from the trial at any time.

## Ethical Aspects

- Participants are human beings with a motive to help the researcher and society.
- Researcher should never be over-enthusiastic in his intervention to get his results while dealing with participants.
- Informed consent is not having a legal binding on the patients. It is a

communication document.

## Random Allocation

The participants in the study population are randomly allocated into two groups (Arms) using random number tables to avoid selection and confounding biases.

**Purpose of randomization:** This elimination of allocation bias will greatly enhance the validity of the trial.

## Blinding

The investigator, the participant and sometimes even the evaluator are all kept unaware (blinded) of the outcomes of the trial and secrecy is maintained to improve the validity.

**Purpose of blinding:** Blinding or masking is done to eliminate: (i) Investigator bias; (ii) evaluation bias; and (iii) Hawthorne effect.

## Types of Blinding

- Single blinding means the process wherein only the participant is unaware about what he is receiving.
- Double blinding means is where both the participant and the investigator are unaware about of the intervention. This eliminates observer bias to a large extent.
- Triple blinding is a trial where even the evaluator is also not aware of the process.

## Unblinding

In emergencies and life-threatening situations for participants, unblinding can be done.

## Assessment Criteria

- Whether the outcomes or end-points are single or multiple, subjective or objective, uniform and similar type of evaluation of end-points for both the groups is to be carried out.
- Subjectivity of the outcome, e.g. reduction of pain, may lead to observer error and poor assessment.
- Double blinding eliminates observer bias to a large extent.

## Intention-to-treat Principle

Whole of the experimental population including non-participants, once randomized, whether they are participating or not in the trial, have to be considered for evaluation as our intention is to treat all the people randomized.

### **Placebo Effect or Attention Bias**

Psychological relief of symptoms, not true biological relief, is often reported.

### **Hawthorne Effect**

- Sometimes the participants in comparison group may exaggerate the effects/outcomes to please the investigator or when they like the study or for some other reasons. Investigator does more frequent follow-up of exposed group in order to establish the cause.
- This will affect the assessment unless controlled.

# **Emergencies in Medical Practice**

# CHAPTER 24

## MANAGEMENT OF SEVERE HYPERKALEMIA

### Case Scenario

An 80-year-old male found collapsed at home, incontinent of urine and feces. He is a known case of HTN and CCF on enalapril for HTN, spironolactone and metoprolol for CCF

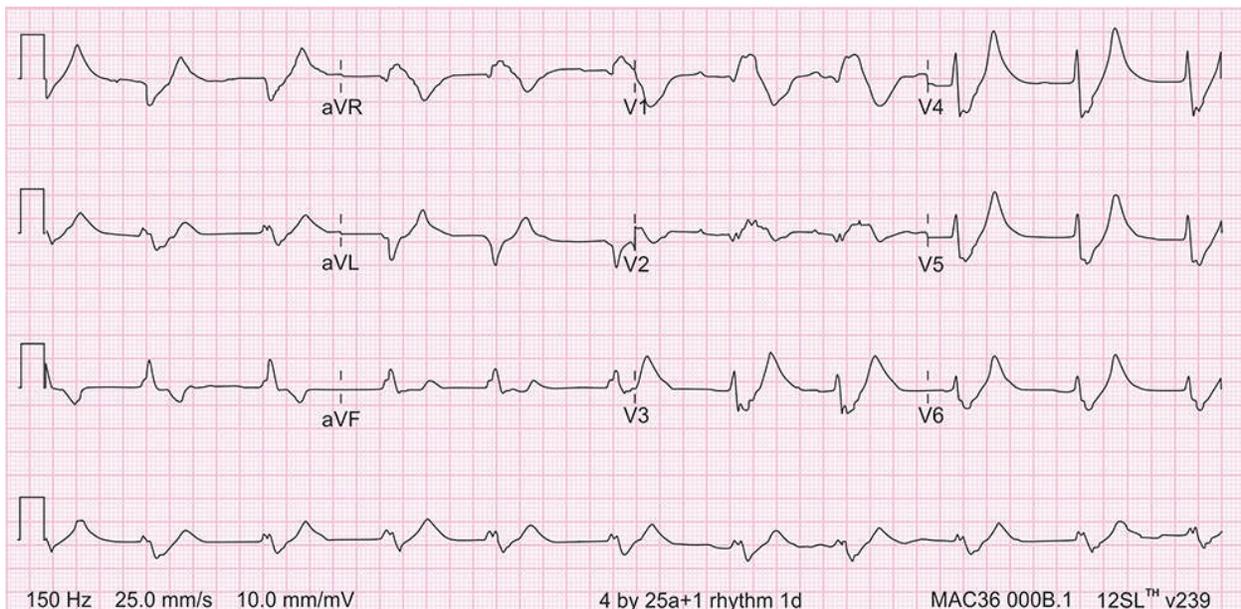

**On Examination:** Patient is confused and combative with GCS of 13.

BP: 78/60 mm      PR: 74 bpm      RR: 32/min      SpO<sub>2</sub>: 91%

Hg

Lab Data:              K<sup>+</sup> - 7.0              Blood glucose:

ABG:pH 7.23                              189 mg/dL

1. Immediate antagonism of cardiac effects of hyperkalemia: Membrane stabilization
  - Calcium gluconate 10 mL 10% slow IV over 10 min

- Calcium chloride 3–4 mL
2. Rapid reduction in plasma K<sup>+</sup> by redistribution into the cells
    - IV 50 mL of 50% dextrose + 10 units of regular insulin
    - 10–20 mg of nebulized albuterol in 4 mL NS inhaled over 10 minutes
  3. Removal of K<sup>+</sup> from the body
    - Ion exchange resin: Sodium polystyrene sulfonate 15–30 g powder
      - Given in a pre-made suspension with 33% sorbitol
    - IV furosemide and NS
    - Hemodialysis

## METABOLIC ACIDOSIS

### Case Scenario

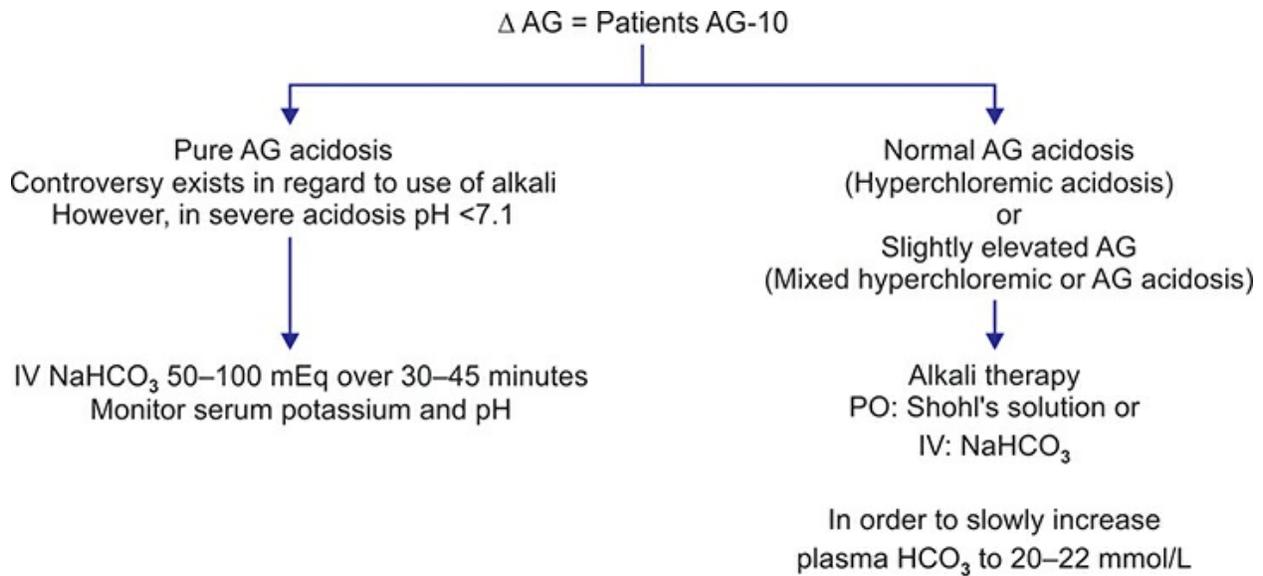

A 56-year-old man with a history of alcohol use presents with a 4 day history of severe abdominal pain, nausea and vomiting. On examination, his blood pressure is 80/50 mm Hg and has tenderness in his epigastrium. His initial laboratory studies reveal:

Na: 132	Cl: 92	HCO <sub>3</sub> : 16
Creatinine: 1.5	Amylase: 400	Lipase: 250

A room air arterial blood gas

pH: 7.28	PCO <sub>2</sub> : 34 mm Hg	PO <sub>2</sub> : 88 mm Hg	HCO <sub>3</sub> : 16.3 mEq/dL
----------	-----------------------------	----------------------------	--------------------------------

- Investigations: ABG, serum electrolytes
- Identify and treat the underlying cause
  - Controlling diarrhea, correcting shock
  - ↓
  - IV fluids — NS
- Determine  $\Delta$ AG

- Dialysis may be necessary in renal failure with metabolic acidosis

## HYPOGLYCEMIA

### Case Scenario

A 32-year-old patient with altered level of consciousness.

**On examination** PR: 72 bmp BP: 100/56 mm Hg SpO<sub>2</sub>: 98% GCS: 11 (3, 3, 5).

Blood sugar: 32 mg/dL

### Medical History

Diabetes mellitus on insulin

*Mild:*

If detected early and patient is able to take orally

Oral carbohydrates in an easily absorbable form

*Severe:*

1. Dextrose 75 mL of 20% dextrose IV  
Oral carbohydrate to be given as soon as the patient is able to eat
2. Glucagon 0.5–1 mg SC/IM
3. Octreotide

4. Identify and treat the cause
  - Adjusting the dose of OHA, insulin
  - Changing the timing of insulin injection

## MANAGEMENT OF ACUTE PULMONARY EDEMA

### Case Scenario

A 62-year-old elderly male patient came with complaint of sudden severe shortness of breath.

**P/H:** MI—6 months back.

**On Examination:** Patient is sitting leaning forward.

**Appearance:** Pale, distressed, sweaty. Productive pink tinged frothy sputum.

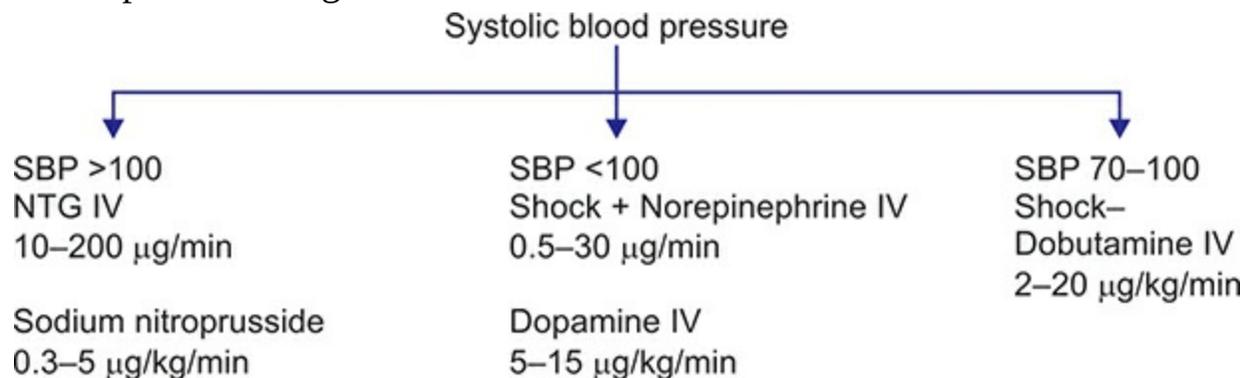

PR: 140 bpm      BP: 200/110 mm Hg      RR: 38/min      SpO<sub>2</sub>: 78% at room air

Ankle edema present bilaterally.

**S/E:** CVS: Gallop rhythm.

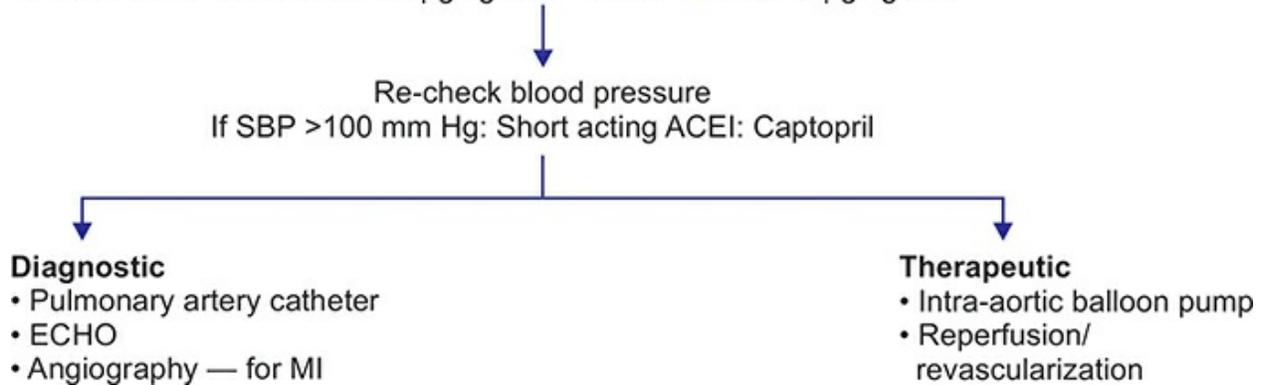

**RS:** Basal crepitations present bilaterally.

- Monitor vitals
- Oxygen: Noninvasive positive pressure ventilation or intubation and mechanical ventilation
- Furosemide 0.5 to 1 mg/kg IV bolus
- Morphine 2–4 mg IV

### Other inotropes

- Milrinone: Bolus 25–75 µg/kg over 10–20 min → 0.375–0.75 µg/kg/min
- Levosimendan: Bolus 12–24 µg/kg over 10 min → 0.05–2 µg/kg/min

## MANAGEMENT OF SEVERE HYPERCALCEMIA

### Case Scenario

A 80-year-old woman presented with vomiting, diarrhea, fatigue, malaise, generalized abdominal pain and weight loss.

**P/H:** K/C/O metastatic breast cancer

**On Examination:** BP: 90/70      RR: 14/min  
PR: 98 bpm                      mm Hg

**S/E:** PA: generalized abdominal tenderness present

**Lab Data:** Serum calcium > 11.0 mg/d

1. Intravenous normal saline
  - 4–6 L may be required over first 24 hours
2. Bisphosphonates: Inhibit bone resorption
  - Zoledronic acid 4 mg IV over 30 min
  - Pamidronate 60–90 mg IV over 2–4 hours
  - Ibandronate 2 mg IV over 2 hours
3. Calcitonin: Increases calcium excretion
  - 100 U; 3 times/day; IM/SC for first 24–48 hours
4. Gallium nitrate
  - 200 mg/m<sup>2</sup> IV daily for 5 days
  - Alternative to bisphosphonates

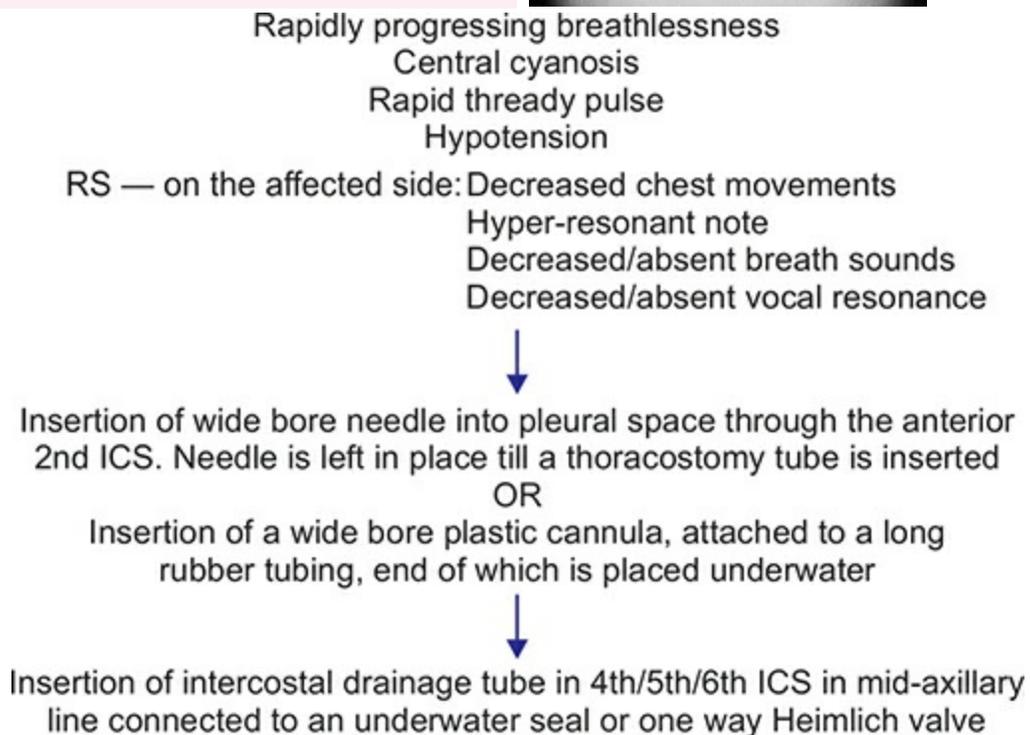

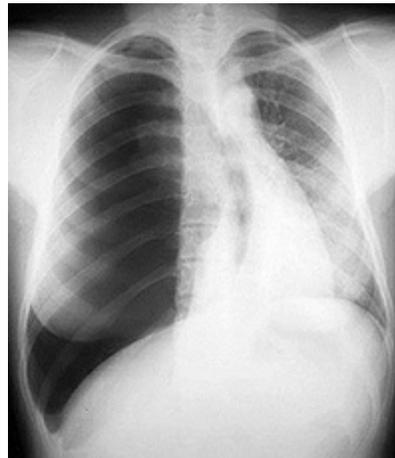

- Nephrotoxic
5. Dialysis.

## TENSION PNEUMOTHORAX

### Case Scenario

A 23-year-old man presents with a single gunshot wound to the right side of his chest.

**On Examination:** Conscious      Palpable pulse  
 BP: 100/60      RR: 30/min  
 Trachea deviated to the left  
 Jugular veins are distended  
 No breath sounds on right side of chest  
 Palpable crepitus  
 Percussion—hyper-resonance on right side

## MYXEDEMA COMA

### Case Scenario

A 47-year-old female patient known case of hypothyroidism presented to office with complaints of falls, leg edema and pain, drowsiness, headaches, shortness of breath.

**On Examination:** PR: 50      BP: 90/70 mmHg      RR: 20/min  
bpm

Periorbital edema is present. Non-pitting tibial edema is present.

S/E: CNS: Delayed tendon reflexes

Free T3—0.05 ng/dL (0.93–1.7)

TSH—30.12  $\mu$ IU/mL (0.27–5.0)

Na 121 mEq/L

K 4.2 mEq/L

Cl 87 mEq/L

Treatment must be initiated even before biochemical confirmation of diagnosis

- Monitor vitals – temperature
- Sepsis screen
- Investigations: T4, TSH, CPK, ABG, RBS, electrolytes.

1. Levothyroxine

- 500 mg IV bolus

OR

Triiodothyronine 10–25 mg every 8–12 hourly IV

↓ Followed by

Oral levothyroxine 50–100 mg daily

2. Hydrocortisone 100 mg IV TID
3. Slow rewarming
4. Cautious use of IV fluids: Hypotonic fluids to be avoided because they increase water retention
5. Broad spectrum antibiotics
5. High flow oxygen
7. Identify and treat the cause

## THYROTOXIC CRISIS/THYROID STORM

### Case Scenario

A 39-year-old woman presented with a 3 months history of increased sweating and palpitations with weight loss of 7 kg. She had family history of thyroid disease.

**On Examination:** PR: 122 bpm 130/80 mm Hg RR: 20/min

Warm and moist skin. Her thyroid gland is enlarged bilaterally. Bilateral exophthalmos present.

**S/E: CVS:** tachycardia present      **PA:** generalized abdominal tenderness

T4 - 12.00 ng/dL (0.73–1.84).      T3 - 1173.00 ng/dL (123-211 ng/dL).      TSH <0.018 uIU/m

**Investigations:** T3, T4, TSH, sepsis screen, LFT, ECG

1. Rehydrate
2. Propranolol
  - Per oral: 60–80 mg 4 times a day
  - IV: 1–5 mg 4 times a day
3. Propylthiouracil
  - 500–1000 mg loading dose → 250 mg 4th hourly oral or via NG tube
4. Carbimazole
  - 15–30 mg STAT → 15 mg TID
5. Lugol's Iodine
  - 10 drops TID – 1 hour after PTU/Carbimazole
5. Sodium ipodate
  - 500 mg/day orally
7. Hydrocortisone
  - 200 mg IV bolus → 100 mg every 8th hourly
3. Oxygen, IV fluids, external cooling
3. Identify and treat the cause
10. Antibiotics if infection is present.

## ACUTE ADRENAL INSUFFICIENCY

### Case Scenario

A 38-year-old female is admitted for complaints of progressive fatigue for two weeks. She also complains of nausea and vomiting. History of loss of 8 kilograms in the past two weeks. History of recent onset of breathlessness.

**On Examination:** PR: 134 bpm      BP: 80/40 mm Hg      Temp: 99° F  
RR: 18/min

Appears pale, dehydrated and malnourished.

S/E: Unremarkable

Na—120 mmol/L

K—5.9 mmol/L

Hb—12.4 g/dL

WBC—11600 and she had a mild eosinophili

**Investigations:** Electrolytes, RBS, CBC, plasma cortisol

1. Monitor vitals
2. Rehydration
  - Normal saline IV infusion: 1L/ hour with continuous cardiac monitoring
3. Hydrocortisone
  - 100 mg IV bolus

↓

100 mg 6th hourly for first 24 hours  
Continue parenteral hydrocortisone till patient can take orally
4. Treat hypoglycemia and hyperkalemia
5. Treat the precipitating cause.

## MANAGEMENT OF STATUS EPILEPTICUS

- Ensure airway patency – Give oxygen
- Monitor vitals, SpO<sub>2</sub>
- Secure IV access

**Investigations:** RBS, electrolytes, AED levels, LFT, RFT, CBC.

*Early: 5–30 minutes*

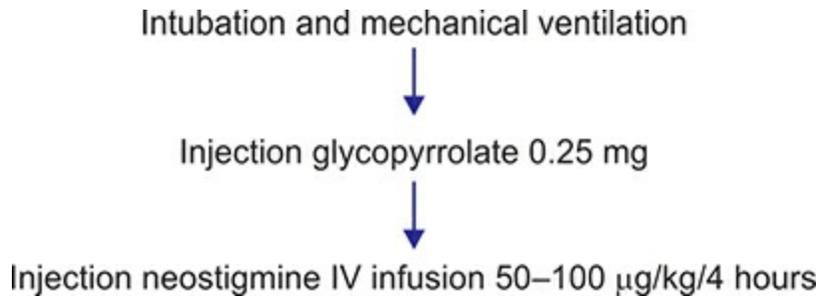

- Monitor vitals
- Protect the airway: Oropharyngeal airway/intubation if needed
- Avoid secondary insults to the brain like hypoxia, hypoglycemia, hypotension
- Secure IV access: Hypotonic IV fluids with close monitoring
- *Specific treatment*
  - Hypoglycemic coma: Thiamine followed by dextrose
  - Fever and meningismus indicate urgent need for CSF analysis followed by IV antibiotics
- *Long-term management*
  - Frequent change of position every 2–3 hourly to avoid bedsores
  - Lid taping
  - Catheterization
  - Prevent aspiration by positioning the patient left lateral.

## MANAGEMENT OF SNAKE BITE

- Reassure the patient
- Immobilize the bitten limb
- Investigations: CBC, coagulation screen, RFT, electrolytes, CPK, ECG, URE, FDP, fibrinogen level
- Monitor vitals
- I/O charting
- Secure IV access
- ASV if indicated
  - Mild cases: 5 vials
  - Moderate cases: 5–10 vials
  - Severe cases: 10–20 vials
- Given as IV infusion in 5–10 mL/kg of NS and given over 1 hour
- **Never give locally at the site of snakebite**
- Keep adrenaline ready in case of anaphylaxis
- For coagulopathy: FFP/cryoprecipitate/platelet concentrate
- In case of neurotoxic snake bite: If there is respiratory failure or bulbar

paralysis

- Antibiotic prophylaxis
- Antitetanus prophylaxis
- Renal failure managed with hemodialysis.

## MANAGEMENT OF HYPOVOLEMIA

**Investigations:** Hematocrit, BUN, creatinine, electrolytes, ABG, urinary sodium.

- Monitor vitals
- Secure IV line
- Strict input/output charting
- Mild hypovolemia can be treated with oral hydration
- Severe hypovolemia requires intravenous hydration

Isotonic normal saline – 0.9 % NaCl (154 mM Na<sup>+</sup>)

- Calculation of free water deficit

$$\text{Free water deficit} = \text{Total body water} \times \frac{[\text{plasma sodium} - 1]}{140}$$

50% of this calculated deficit is given over the first 24 hours and the remaining over the next 24 hours.

- Patients with bicarbonate loss and metabolic acidosis may need IV bicarbonate
- Patients with severe hemorrhage should receive red cell transfusion without increasing hematocrit > 35%
- Identify and treat the cause of hypovolemia.

# MANAGEMENT OF SHOCK

## Case Scenario

A 25-year-old male patient is admitted to ICU with 3 days old perforation. History of chills and fever present.

**On Examination:** Mental status is altered, restless

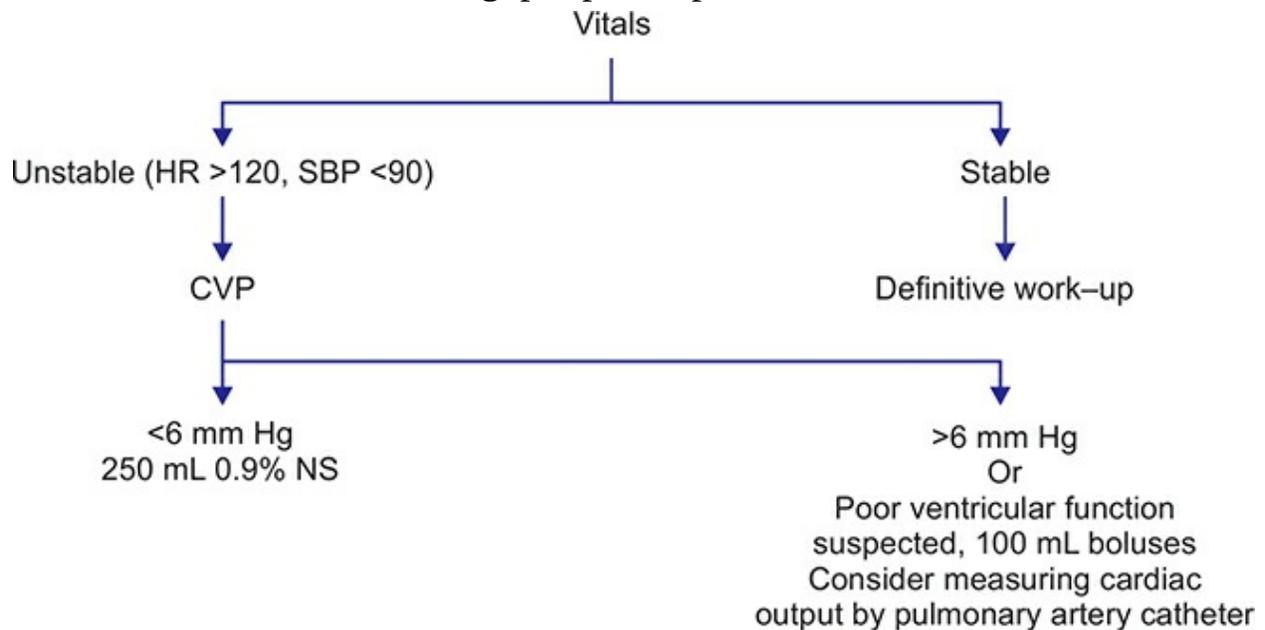

Skin – warmed and flushed

PR: 130 bpm BP: 80/60 mm Hg

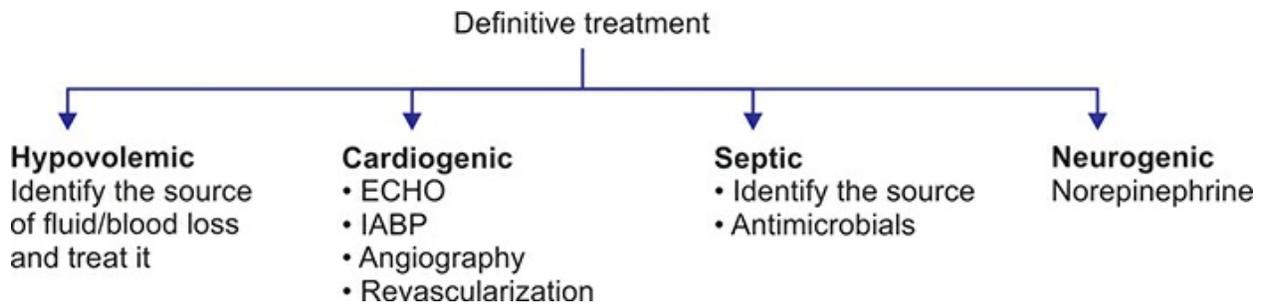

RR: 40/ min

**Investigations:** Hemoglobin, hematocrit, sepsis screen, LFT, RFT, electrolytes, ABG.

- Secure IV access
- Assess GCS
- Oxygen/intubation and mechanical ventilation if needed, e.g. GCS <8
- Monitor vitals, I/O charting, peripheral perfusion

- Optimize Hb: Transfuse red cells
- Achieve target BP: Inotropes once the hypovolemia is corrected
  - Dobutamine: 2–8  $\mu\text{g}/\text{kg}/\text{min}$
  - Adrenaline: 1–8  $\mu\text{g}/\text{kg}/\text{min}$

## ISCHEMIC STROKE

### Case Scenario

A 41-year-old male patient, alcoholic, k/c/o hypertension presents to casualty with chief complaint of right sided weakness, slurred speech and loss of balance. Symptoms began 90 minutes prior to arrival.

**On Examination:** PR: 88      BP: 177/90 mm Hg      RR: 18/ min  
bpm and irregular

S/E: CNS: GCS – 11/15

Right side facial weakness. Power is reduced on right side. No sensory deficit on right side. Plantar extensor on right side

**Investigations:** Plain CT brain, RBS, electrolytes, ECG, suspected AF → thyroid function tests, ECHO

#### 1. *General measures:*

- Airway – Ensure airway patency
- Breathing – O<sub>2</sub> if SpO<sub>2</sub> is < 95%
- Circulation
  - Check PR, BP. Secure IV access
  - Treat abnormalities with IV fluids/anti-arrhythmias/inotropes
- Look for hypoglycemia and treat accordingly

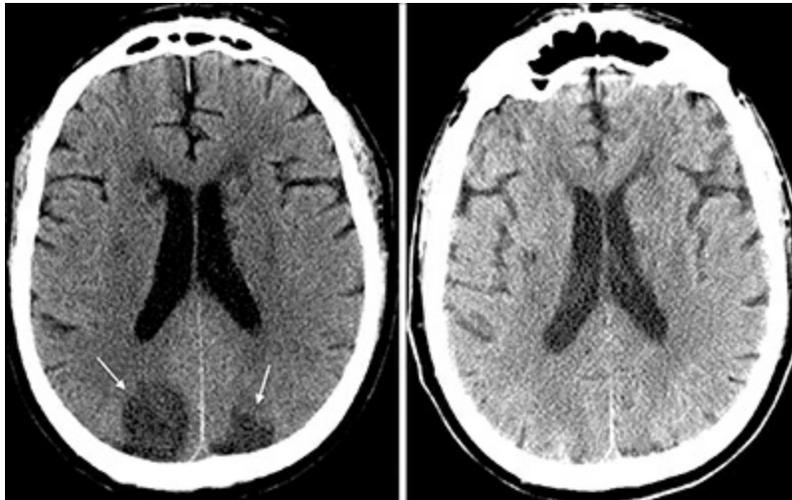

#### 2. *IV thrombolytics*

- Intravenous rtPA within 3 hours of onset of ischemic stroke
- Dose: 0.9 mg/kg → 10% of total dose as IV bolus, remaining as IV infusion over 60 minutes

#### 3. *Endovascular mechanical thrombectomy*

- If IV thrombolysis is contraindicated or has failed

4. *Anti-platelets*
  - Aspirin 75–150 mg OD
5. *Statins*
  - Atorvastatin, Rosuvastatin 10–20 mg OD
6. *Medical support*
  - Catheterization
  - RT feeding
  - Treat fever with antipyretics, surface cooling
  - Pneumatic compression stockings
  - Prevent bedsores and contractures
  - Initiates secondary preventive measures
7. *Rehabilitation*
  - Early physiotherapy, occupational/speech therapy.

## **HYPERVENTILATION**

**Investigation:** ABG

- Identify and treat the initiating factor
- Reassurance
- Rebreathing into a closed bag
- If there is associated palpitations/tremors: b-blockers.
- Identifying and eliminating habits that perpetuate hypocapnia such as sigh breathing

- Breathing exercises, diaphragmatic retaining may be helpful.

## ACUTE PULMONARY EMBOLISM

### Case Scenario

A 71-year-old woman bedridden for last 4 days following fall and trauma to right hip is brought to emergency with complaints of sudden onset of dyspnea and dizziness.

**On Examination:** PR: 124 bpm    BP: 118/89 mm Hg    SpO<sub>2</sub>: 84%    RR: 28/min

Diaphoresis present.

Right lower limb edema present extending from mid-thigh to foot. Calf muscle tenderness present.

**Investigations:** ECG, CXR, D-dimer, pulmonary angiography

- **Supportive measures:** Oxygen and IV fluids
- Anticoagulation:
  - Unfractionated heparin: 80 U/kg bolus → 18 U/kg/hr with aPTT monitoring
    - ◆ Note: Platelet count to be monitored at least every 3rd day
  - LMWH: Subcutaneously
    - ◆ LMWH should not be discontinued until INR is  $\geq 2$  for at least 24 hours
- Warfarin: 5 mg/day – Started on day 1 with INR monitoring
- Fondaparinux
- Others: Rivaroxaban, Apixaban, Argatroban, Ximelagatran
- *Note:* Anticoagulation to be continued for at least 6 months
- Thrombolysis:
  - Indication: Acute massive pulmonary embolism with cardiogenic shock. 100 mg rtPA IV infusion over 2 hours
- Surgical therapy:
  - Surgical embolectomy
  - Caval filter

## MANAGEMENT OF HEMOPTYSIS

## Case Scenario

A 40-year-old male chronic smoker, with past history of tuberculosis, presents with history of hemoptysis 3 episodes since 1 day. On examination he has clubbing, BP-100/60, PR-100 bpm, coarse crepitations in the right infraclavicular area.

**Investigations:** Blood grouping, cross matching, CBC, PT- INR CXR

- Measure vitals
- Patient should be positioned upright or bleeding side down
- Secure airway
  - Intubation with double lumen ET tube is preferable
- Secure IV access: large bore IV cannula
- Administer IV fluids or blood transfusion, if needed
- Vasopressin 0.2 to 0.4 U/min IV

### **Bronchoscopy**

- Rigid bronchoscopy is preferable
- Fiberoptic bronchoscopy may be used for cold saline lavage
- Topical thrombin
- Laser photocoagulation
- Balloon catheter can be inflated proximally in the bleeding bronchus

### **Endovascular embolization**

OR

### **Emergency surgery**

## HYPERTENSIVE EMERGENCY/CRISIS

### Case Scenario

A 69-year-old male patient presented with complaints of chest tightness and shortness of breath. K/c/o DM since 10 years and is a chronic smoker. History of hypertension, not on treatment.

**On Examination:** HR: 110 bpm BP: 230/120 mm Hg

**S/E:** CVS: S3 gallop, No murmur

**RS:** Bi-basal fine inspiratory crackles

**Investigations:** RFT, fundoscopy, ECG, echocardiography.

- Reduce the MAP by no more than 25% within minutes – 2 hours
  - Continuous monitoring of BP
1. Labetolol
    - 2 mg/min IV; maximum of 300 mg
    - In acute renal failure, SAH, IC bleed, acute aortic dissection
  2. Nitroglycerine
    - 0.6–1.2 mg/hr IV
    - In acute pulmonary edema, acute coronary syndrome, IC bleed
  3. Sodium nitroprusside
    - 0.3–1 ug/kg/min IV
    - Drug of choice for hypertensive encephalopathy
  4. Nicardipine
    - 5 mg/hr IV titrate by 2.5 mg/hr at 5–15 minute intervals → Maximum 15 mg/hr
  5. Esmolol
    - 80–500 mg/kg over 1 min → 50–300 mg/kg/min IV
  5. Hydralazine
    - 10–50 mg at 30 minute intervals.

## SEVERE DEHYDRATION

**Investigations:** Electrolytes, urea, creatinine, RBS.

**Signs:** Sunken eyes, dry tongue, skin pinch going back slowly—2 or more positive—severe dehydration.

- Secure IV access
- Monitor vitals
- I/O chartings
- IV fluids started immediately
  - RL + 5% dextrose

OR

Drugs: Adrenaline, Vasopressin, Amiodarone, MgSO<sub>4</sub>, Atropine

**Defibrillation**

Shockable rhythms are VF/pulseless VT

**Post-resuscitation care**

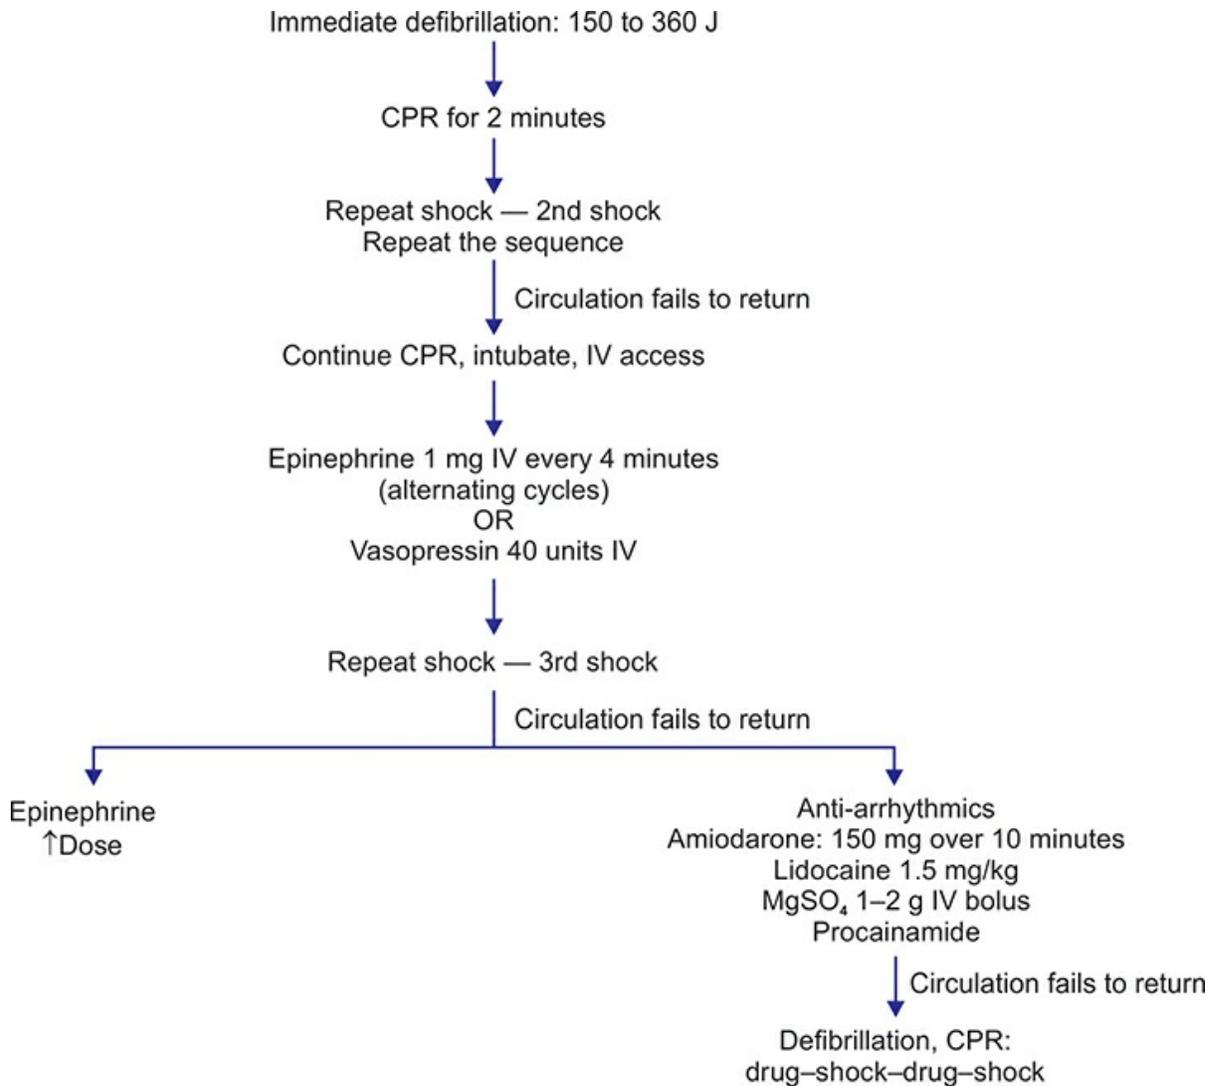

Mild therapeutic hypothermia for resuscitated cardiac arrest victims —  
who are hemodynamically stable but remain comatose

**Long-term management after survival of cardiac arrest**

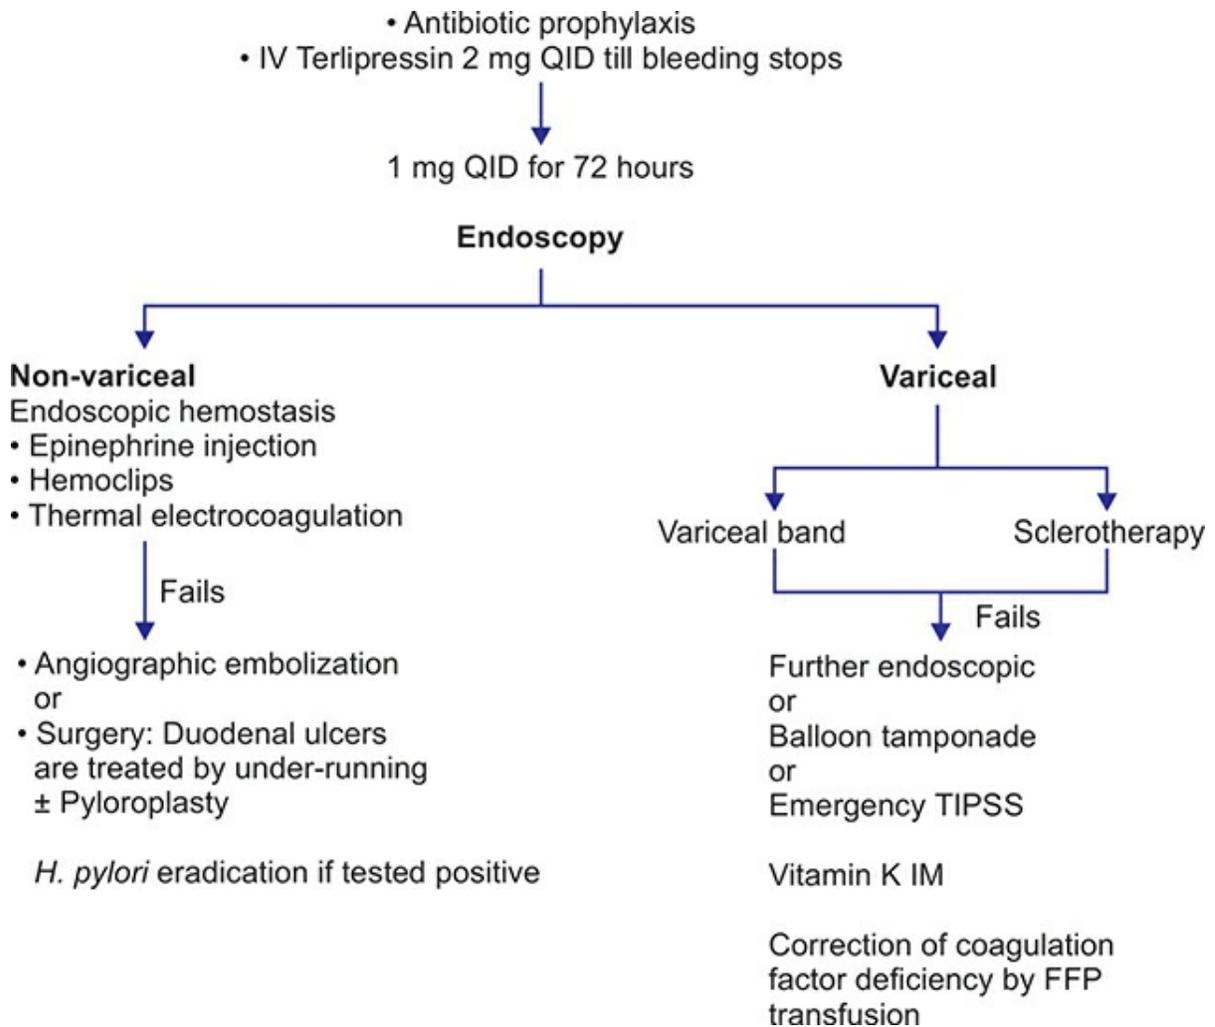

Identify and treat the cause, e.g.  
Consider ICD in Brugada syndrome  
Initiating anti-arrhythmics

## MANAGEMENT OF VENTRICULAR FIBRILLATION

## UPPER GASTROINTESTINAL BLEED

- NPO
- Secure IV access
- Monitor vitals, I/O charting
- Restore blood volume: IV fluids/blood transfusion if needed
- IV PPI 80 mg bolus → 8 mg/hr infusion
- Suspected variceal bleed

**Investigations:** CBC, electrolytes, LFT, urea, PT/INR, blood grouping and cross matching

## EMERGENCY MANAGEMENT OF ACUTE MYOCARDIAL INFARCTION

### Case Scenario

A 60-years-old male patient, k/c/o diabetes, was brought to casualty with complaints of single episode of sudden, rapid onset, severe chest pain, lasting more than 30 minutes, radiating to the medial aspect of his left arm associated with breathlessness, nausea, heavy perspiration, lightheadedness, fever and cold clammy skin.

**On Examination:** PR:112 bpm    BP:160/110 mm Hg    RR: 20/min    JVP: Normal

S/E: CVS: S1S2 + tachycardia

**Investigations:** 12 – Lead ECG, cardiac biomarkers: Troponin I, T, CKMB

- Monitor vitals
- Oxygen
- Nitrates

Glyceryl trinitrate 300–500 mg sublingually

↓ If pain persists after 3 doses given 5 min apart

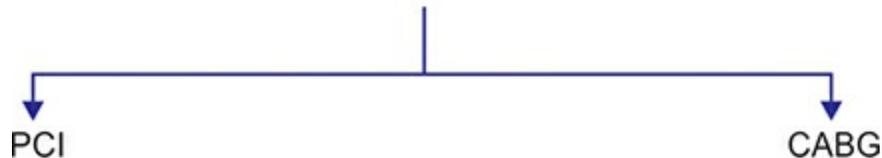

IV NTG 5–10 mg/min (Maintain SBP >40 mm Hg)

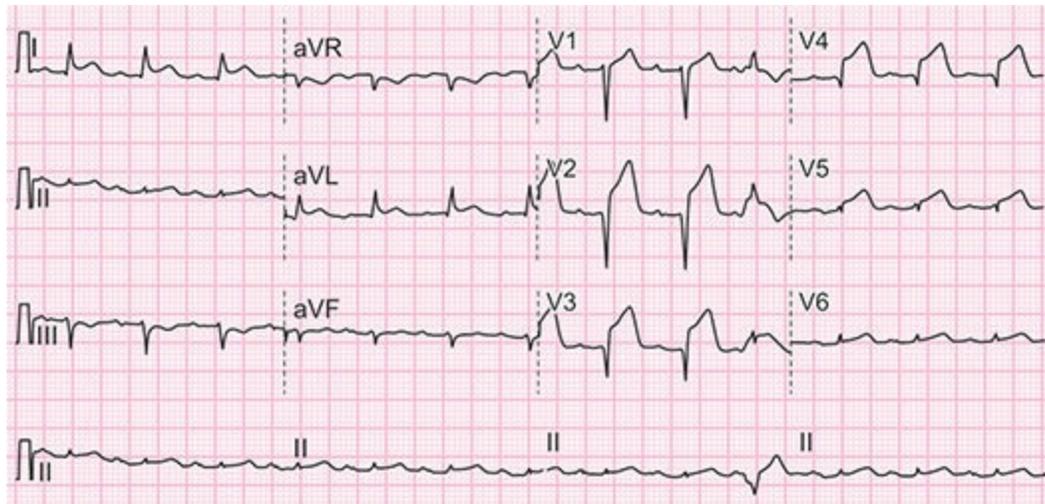

- Morphine: 2–5 mg IV–analgesia
- Antiplatelets
  - Aspirin: 325 mg non-enteric formulations → 75–100 mg/day
  - Clopidogrel: 300 mg orally → 75 mg/day
  - Others: Oral – Prasugrel, Ticagrelor
  - IV – Abciximab, Eptifibatide, Tirofiban
- Anticoagulants

- $\beta$ -blockers unless contraindicated; ACEI; high dose statins
- Specific treatment

- Thrombolytic therapy: Not recommended for patients with NSTEMI/Unstable angina
- Coronary intervention

## ORGANOPHOSPHATE POISONING

### Case Scenario

A 27-year-old male brought to casualty at 1:00 am with history of sudden loss of consciousness in his room after having a family quarrel. History of 4 episodes of vomiting and incontinence of urine and feces.

**On Examination:** PR: 100 bpm BP: 90/70 mm Hg RR: 28/min, shallow

Temperature: 102 °F

GCS – E1V2M4 = 7/15

**S/E:** CNS: Pupils – B/L pinpoint, non-reacting  
Tone: Increased  
Power: Grade I  
Plantar: Non-elicitable

PA: Bowel sounds are exaggerated.

- Prevent further exposure – remove contaminate clothing, wash the skin thoroughly with soap and water, irrigate eyes.
- Airway cleared of excessive secretions → high flow oxygen.
- IV access → 0.9% NS infusion
- Monitor vitals,  $S_pO_2$ , auscultate the lungs. Ventilatory support, if needed.

**Investigations:** LFT, ABG, ECG, electrolytes, glucose, amylase.

- Gastric lavage with activated charcoal if the patient presents within 1 hour of ingestion

<b>Atropine bolus</b>	<b>Atropine infusion</b>
1.8 to 3 mg IV bolus ↓	Start infusion at 20% of total dose of atropine required for atropinization  Bronchorrhea is the most important sign for titrating the dose
Aim for HR >80 bpm SBP >80 mm Hg Clear chest ↓ <b>If not</b>	
Double the dose every 5 minutes ↓ <b>Satisfactory improvement</b>	
Start atropine infusion	

### ***Pralidoxime***

Bolus: 30–45 mg/kg over 30 min → Infusion: 8–12 mg/kg/hr

Give PAM until atropine is no longer required

### ***BZP:***

Reduces agitation, seizures, fasciculations

Sedation during ventilation

**Intensive cardiorespiratory monitoring and support**

**Others:** MgSO<sub>4</sub>, NaHCO<sub>3</sub>, clonidine, hemodialysis.

## **MANAGEMENT OF ANAPHYLAXIS**

### **Case Scenario**

A 12-year-old boy is brought to the emergency department after being stung by a bee. Initially complained of localized pain and swelling, but 15 minutes later he began to complain of shortness of breath, weakness and dizziness.

**On Examination:** PR 120 bpm      BP: 69/45 mm Hg      RR: 39/min

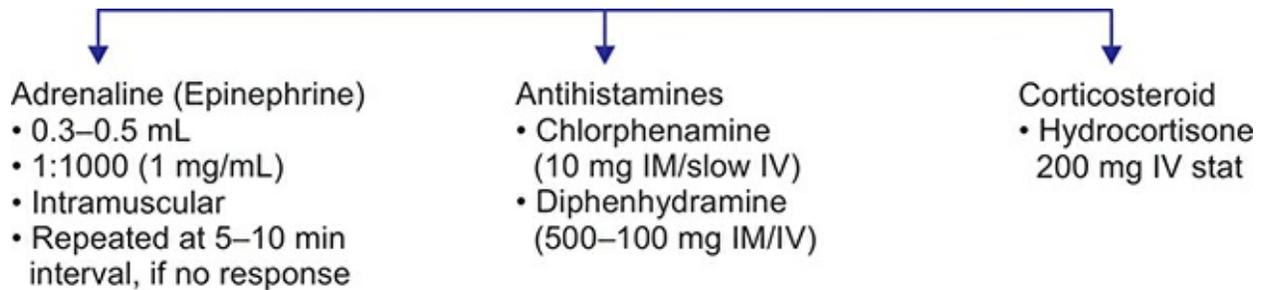

He has generalized urticaria

**S/E:** RS: mild wheeze bilaterally      CVS: tachycardia present      PA: NAD

- Prevent further contact with the antigen
- Ensure airway patency

- Supportive measures:

- Oxygen
- IV fluids
- B<sub>2</sub> agonist

## MANAGEMENT OF ANGINA

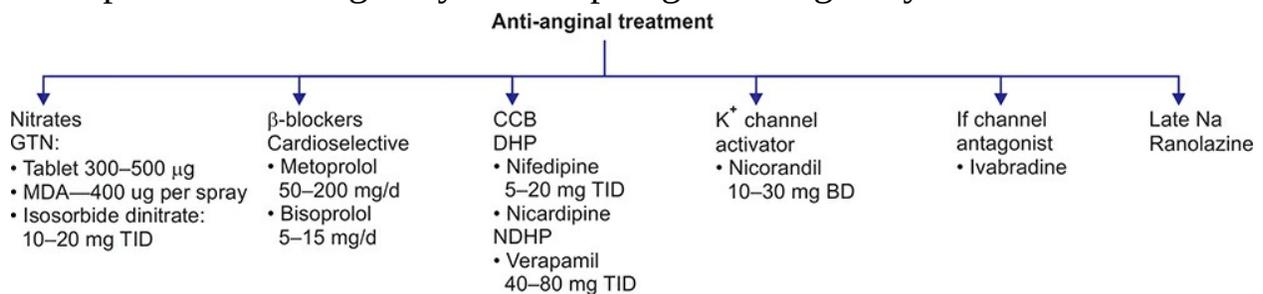

### Case Scenario

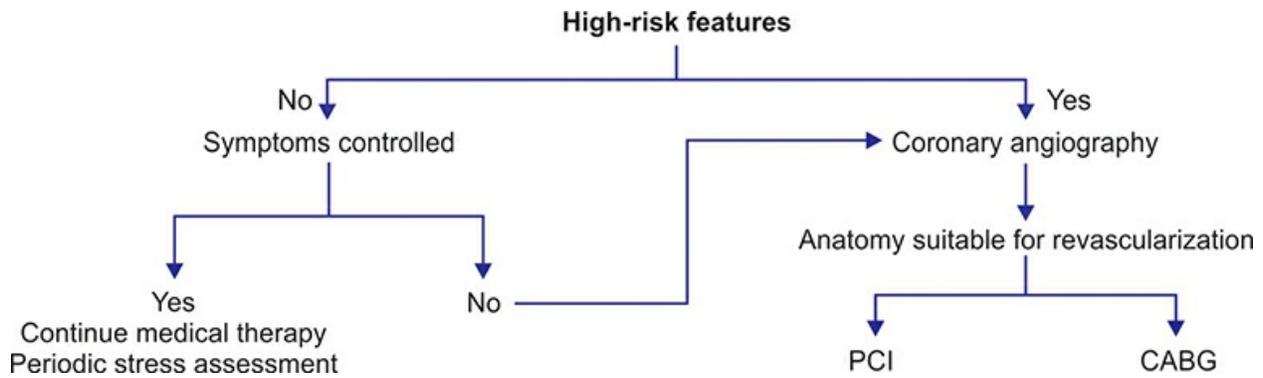

A 58-year-old male patient non-smoker, diabetic, hypertensive with dyslipidemia presented with severe shortness of breath and chest tightness since 1 month. Pain is localized to the breast bone and does not radiate. It is aggravated while playing golf and subsides on rest.

**On Examination:** PR: 88 bpm BP: 162/80 RR: 24/min Temp: mm Hg Afebrile

S/E: CVS, RS, PA: NAD

- Lifestyle modification:
  - Limit salt intake to <5 g/day
  - Increase PUFA consumption
  - Smoking cessation
  - Limit alcohol intake
  - Avoid simple carbohydrate
  - Saturated fatty acids should be <10% of the total intake
- Aspirin 75–150 mg daily OR Clopidogrel 75 mg daily.

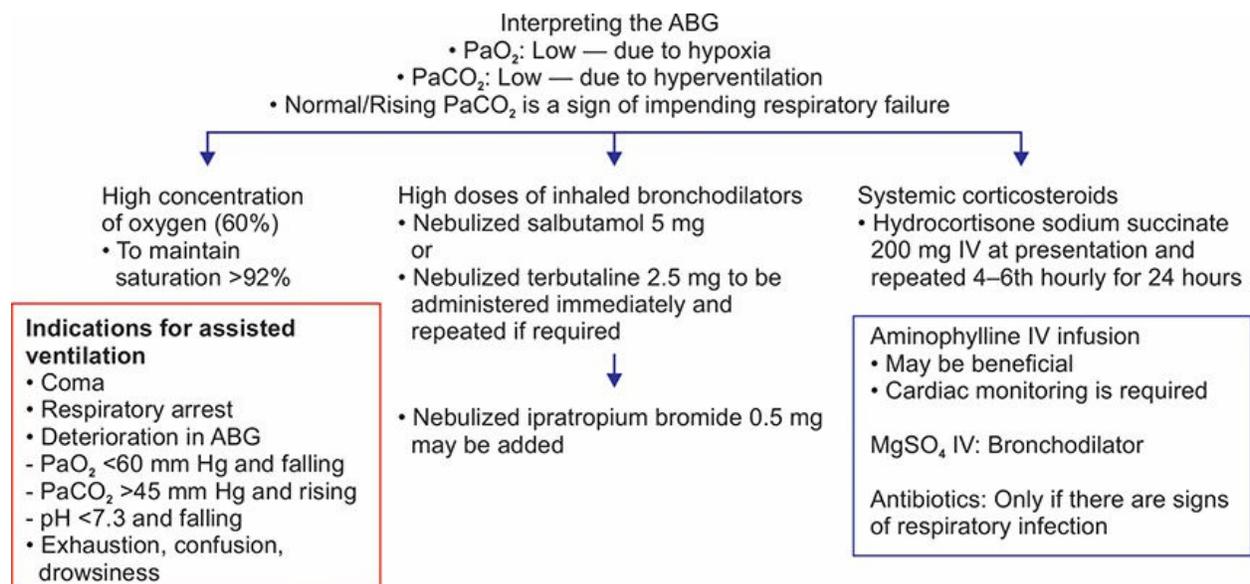

## MANAGEMENT OF ACUTE SEVERE ASTHMA

### Case Scenario

A 16-year-old female patient complains of difficulty in breathing. Symptoms increase on exposure to cold. Positive family history.

**On Examination:** PR: 126 bpm BP:148/86 mm Hg RR: 54/min SpO<sub>2</sub>: 88 at room air RS: Expiratory wheeze note

## MANAGEMENT OF DIABETIC KETOACIDOSIS

### Case Scenario

A 32-year-old male patient k/c/o type 1 diabetes mellitus was taken to casualty with complaints of drowsiness, fever, cough, diffuse abdominal pain and vomiting.

**On Examination:** Patient appears confused.

Temperature: 39° C      PR: 104 bpm      BP: 100/70 mm Hg      RR: 24/min

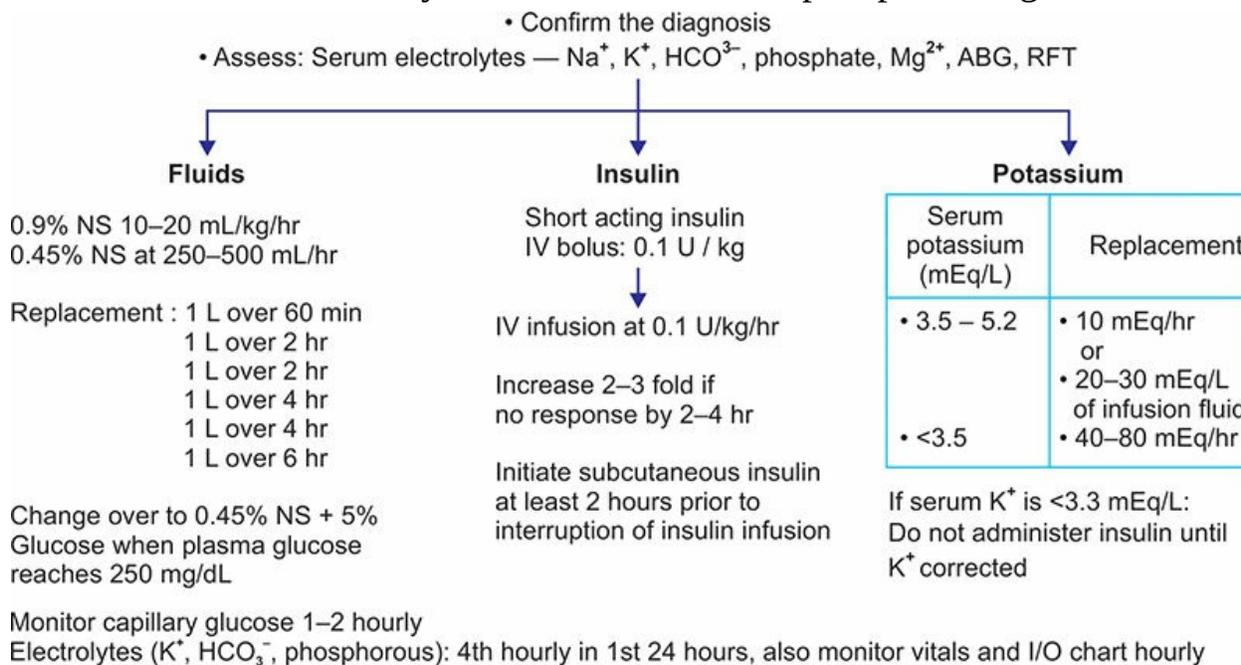

Dry mucous membranes, poor skin turgor and rales in right lower chest  
 pH: 7.12      pCO<sub>2</sub>: 17 mmHg  
 HCO<sub>3</sub>: 5.6 mEq/L.

Urinalysis revealed 4+ glucose and 3+ ketones.

Chemistry panel revealed a glucose of 420 mg/dL, BUN of 16 mg/dL, creatinine of 1.1 mg/dL

Na: 139 mEq/dL      Cl: 112 mEq/dL      HCO<sub>2</sub>: 11.2      K: 5.0 mEq/dL  
 mEq/L

- Confirm the diagnosis
- Assess: Serum electrolytes—Na<sup>+</sup>, K<sup>+</sup>, HCO<sub>3</sub><sup>-</sup>, phosphate, Mg<sup>2+</sup>

# Appendices

## APPENDIX 1: LABORATORY VALUES OF CLINICAL IMPORTANCE

In this appendix, tables of reference values of some important common laboratory investigations are provided which will help in interpreting the results during examinations as well as during clinician practice. The term 'reference values' has replaced older terminology 'normal values/ranges'. A variety of factors can influence reference values and it varies between laboratories depending on the laboratory methods, mode of standardization and other factors. This is especially the case with enzyme assays. The reference or 'normal' ranges given in this appendix may, therefore, not be appropriate for all laboratories and they should only be used as general guidelines. Hence, reference values provided by the laboratory performing the test should be used in the interpretation of laboratory results. Most clinical laboratories and all medical and scientific journals use SI system. Since, conventional units are still used in many laboratories of developing countries, in this section, laboratory values are given in both conventional and international units. Many analytes are measured in either serum (the supernatant of clotted blood) or plasma (the supernatant of anticoagulated blood).

The laboratory reference values in this appendix is divided into different section namely: (1) hematology and coagulation (Table A 1.1), (2) clinical chemistry of blood (Table A 1.2), (3) lipid profile (Table A 1.3), (4) urea and electrolytes (Table A 1.4), (5) thyroid function tests (Table A 1.5), (6) urine (Table A 1.6), and (7) cerebrospinal fluid (Table A 1.7), short list of routinely used formulas in medicine (Table A 1.8).

### Hematology and Coagulation (Table A 1.1)

**Table A 1.1:** Hematology and coagulation.

<b>Component (specimen)</b>	<b>Reference value</b>	
	<b>Conventional</b>	<b>SI units</b>
<b>RBCs and hemoglobin</b>		
RBC count <ul style="list-style-type: none"> <li>• Males</li> <li>• Females</li> </ul>	4.5–5.5 × 10 <sup>12</sup> /L (mean 5.0 × 10 <sup>12</sup> /L) 3.8–4.8 × 10 <sup>12</sup> /L (mean 4.3 × 10 <sup>12</sup> /L)	
RBC diameter	6.7–7.7 μm (mean 7.2 μm)	
RBC indices (absolute values) <ul style="list-style-type: none"> <li>• Mean corpuscular volume (MCV)</li> <li>• Mean corpuscular hemoglobin (MCH)</li> <li>• Mean corpuscular hemoglobin concentration (MCHC)</li> <li>• Red cell distribution width (RDW)</li> </ul>	82–100 fL 27–32 pg 31–35 g/dL 11.5–14.0%	
RBC lifespan	120 days	
Erythrocyte sedimentation rate (ESR) (Whole blood) <ul style="list-style-type: none"> <li>• Westergren, 1st hour <ul style="list-style-type: none"> <li>– Males</li> <li>– Females</li> <li>– Children</li> </ul> </li> <li>• Wintrobe, 1st hour <ul style="list-style-type: none"> <li>– Males</li> <li>– Females</li> </ul> </li> </ul>	0–15 mm 1st hour 0–20 mm 1st hour 0–10 mm 1st hour  0–9 mm 1st hour 0–20 mm 1st hour	
Ferritin (serum) <ul style="list-style-type: none"> <li>• Males</li> <li>• Females</li> </ul>	20–300 ng/mL 15–200 ng/mL	20–300 μg/L 15–200 μg/L
Folate (serum)	3–20 μg/L	3–20 ng/mL
Hematocrit (PCV) <ul style="list-style-type: none"> <li>• Males</li> <li>• Females</li> <li>• Infants (cord blood)</li> </ul>	38–47% 36–46% 45–70%	
Haptoglobin (serum)	40–240 mg/dL	0.4–2.4 g/L
Hemoglobin (Hb) <ul style="list-style-type: none"> <li>• Adult hemoglobin (HbA)</li> <li>• Males</li> <li>• Females</li> <li>• Hemoglobin A<sub>2</sub> (HbA<sub>2</sub>)</li> <li>• Hemoglobin, fetal (HbF) in adults</li> <li>• HbF, children under 6 months</li> </ul>	95–98% 13.0–17.0 g/dL 12.0–15.0 g/dL 1.5–3.5% <0–2% <5%	

Iron, total (serum)	50–150 µg/dL	7–25 µmol/L
• Total iron binding capacity (TIBC)	310–340 µg/dL	45–73 µmol/L
• Iron saturation	20–45%	0.20–0.45
Osmotic fragility	at 0.45 to 0.39 g/dL NaCl	
• Slight hemolysis	at 0.33 to 0.36 g/dL NaCl	
• Complete hemolysis	0.4–0.45 g/dL NaCl	
• Mean corpuscular fragility		
Reticulocytes	0.5–2.5%	
• Adults	2–6%	
• Infants	1–7%	
• Newborn (cord blood)		
Transferrin saturation	25–56%	
• Male	14–51%	
• Female		
Vitamin B <sub>12</sub> (serum)	10–12 mg	
• Body stores	2–3 µg	
• Daily requirement	280–1000 pg/mL	
• Serum level		
Autohemolysis test (whole blood)	0.4–4.50%	0.004–0.045
Autohemolysis test with glucose (whole blood)	0.3–0.7%	0.003–0.007
<b>Leukocytes</b>		
Differential leukocyte count (DLC)	40–70% (2,000–7,500/µL)	
• P (polymorphs or neutrophils)	20–40% (1,500–4,000/µL)	
• L (lymphocytes)	2–10% (200–800/µL)	
• M (monocytes)	1–6% (40–450/µL)	
• E (eosinophils)	<1% (10–100/µL)	
• B (basophils)		
Total leukocyte count (TLC)	4,000–11,000/µL	
• Adults	10,000–25,000/µL	
• Infants (full term, at birth)	6,000–16,000/µL	
• Infants (1 year)		
<b>Platelets and coagulation</b>		
Bleeding time (BT)	2–7 min	
• Ivy's method	2–9 min	
• Template method		
Clot retraction time (clotted blood)	Visible in 60 min (complete in <24 hours)	
• Qualitative	48–64% (55%)	
• Quantitative		
Clotting time (CT)	4–11 minutes	
• Lee and White method		

D-dimer (plasma)	220–740 ng/mL	
Fibrinogen (plasma)	200–400 mg/dL	
Fibrin split (or degradation) products (FSP or FDP)	<10 µg/mL	<10 mg/L
Partial thromboplastin time with kaolin (PTTK) or activated partial thromboplastin time (APTT/aAPTT)	30–40 sec	
Platelet count	150,000–450,000/µL	
Prothrombin time (PT) (Quick’s one stage method)	11–16 sec	
Thrombin time (TT)	15–19 sec (control ± 2 sec)	

## Clinical Chemistry of Blood (Table A 1.2)

**Table A 1.2:** Clinical chemistry of blood.

<b>Component</b>	<b>Specimen</b>	<b>Reference value</b>	
		<b>Conventional</b>	<b>SI units</b>
Alpha fetoprotein (AFP), adults	Serum	0–8.5 ng/mL	0–8.5 µg/L
Aminotransferases (transaminases)	Serum	12–38 U/L	0.20–0.65 µkat/L
<ul style="list-style-type: none"> <li>• Aspartate (AST, SGOT)</li> <li>• Alanine (ALT, SGPT)</li> </ul>	Serum	7–41 U/L	0.12–0.70 µkat/L
Amylase	Serum	20–96 U/L	0.34–1.6 µkat/L
Bilirubin	Serum	0.3–1.3 mg/dL	5.1–22 µmol/L
<ul style="list-style-type: none"> <li>• Total</li> <li>• Direct (conjugated)</li> <li>• Indirect (unconjugated)</li> </ul>		0.1–0.4 mg/dL	1.7–6.8 µmol/L
		0.2–0.9 mg/dL	3.4–15.2 µmol/L
CA 125	Serum	0–35 U/mL	0–35 Ku/L
Calcium—ionized	Whole blood	4.5–5.3 mg/dL	1.12–1.32 mmol/L
Calcium—total	Serum	8.7–10.2 mg/dL	2.2–2.6 mmol/L
Chloride	Serum	102–109 mEq/L	102–109 mmol/L
C-reactive proteins	Serum	0.2–3.0 mg/L	0.2–3.0 mg/L
Creatine kinase (CK), total	Serum	51–294 U/L	0.87–5.0 µkat/L
<ul style="list-style-type: none"> <li>• Males</li> <li>• Females</li> </ul>		39–238 IU/L	0.66–4.0 µkat/L
Creatine kinase MB	Serum	0–5.5 ng/mL	0–5.5 µg/L

(CKMB)			
Gamma glutamyl transpeptidase (transferase) ( $\gamma$ -GT)	Serum	9–58 IU/L	0.15–1.00 $\mu$ mol/L
Glucose (fasting) <ul style="list-style-type: none"> <li>• Normal</li> <li>• Impaired fasting glucose (IFG)</li> <li>• Diabetes mellitus</li> </ul>	Plasma	70–100 mg/dL 101–125 mg/dL >126 mg/dL	<5.6 mmol/L 5.6–6.9 mmol/L >7.0 mmol/L
Glucose (2-hour postprandial) <ul style="list-style-type: none"> <li>• Normal</li> <li>• Impaired glucose tolerance (IGT)</li> <li>• Diabetes mellitus</li> </ul>	Plasma	<140 mg/dL 140–200 mg/dL >200 mg/dL	<7.8 mmol/L 7.8–11.1 mmol/L >11.1 mmol/L
Glycated hemoglobin (HbA <sub>1c</sub> )	Whole blood	4.0–6.0%	20–42 mmol/mol Hb
Lactate dehydrogenase (LDH)	Serum	115–221 U/L	2.0–3.8 $\mu$ kat/L
Muramidase	Serum	5–20 $\mu$ g/mL	
5-nucleotidase	Serum	0–11 U/L	0.02–0.19 $\mu$ kat/L
Phosphatases <ul style="list-style-type: none"> <li>• Acid phosphatase</li> <li>• Alkaline phosphatase</li> </ul>	Serum	0–5.5 U/L 33–96 U/L	0.90 $\mu$ kat/L 0.56–1.63 $\mu$ kat/L
Prostate-specific antigen (PSA)	Serum	0–4.0 ng/mL	0–4.0 $\mu$ g/L
Proteins—total <ul style="list-style-type: none"> <li>• Albumin</li> <li>• Globulins</li> <li>• Albumin/globulin ratio</li> </ul>	Serum	6.7–8.6 g/dL 3.5–5.5 g/dL 2.0–3.5 g/dL 1.5–3 : 1	67–86 g/L 35–55 g/L 20–35 g/L
Rheumatoid factor	Serum	<15 IU/mL	< 15 kIU/L
Troponins, cardiac (cTn) <ul style="list-style-type: none"> <li>• Troponin I (cTnI)</li> <li>• Troponin T (cTnT)</li> </ul>	Serum Serum	0–0.08 ng/mL 0–0.01 ng/mL	0–0.8 $\mu$ g/L 0–0.1 $\mu$ g/L
Urea nitrogen (BUN)	Blood	7–20 mg/dL	2.5–7.1 mmol/L
Uric acid <ul style="list-style-type: none"> <li>• Males</li> <li>• Females</li> </ul>	Serum	3.1–7.0 mg/dL 2.5–5.6 mg/dL	0.18–0.41 $\mu$ mol/L 0.15–0.33 $\mu$ mol/L

## Lipid Profile (Table A 1.3)

**Table A 1.3:** Lipid profile.

<b>Component</b>	<b>Reference value</b>	
	<b>Conventional</b>	<b>SI units</b>
Total serum cholesterol <ul style="list-style-type: none"> <li>• Desirable for adults</li> <li>• Borderline high</li> <li>• High undesirable</li> </ul>	<200 mg/dL 200–239 mg/dL >240 mg/dL	<5.17 mmol/L 5.17–6.18 mmol/L >6.21 mmol/L
LDL cholesterol <ul style="list-style-type: none"> <li>• Desirable range</li> <li>• Borderline high</li> <li>• High</li> <li>• Very high</li> </ul>	100–130 mg/dL 130–159 mg/dL 160–189 mg/dL >190 mg/dL	<3.34 mmol/L 3.36–4.11 mmol/L 4.11–4.20 mmol/L >4.21 mmol/L
HDL cholesterol <ul style="list-style-type: none"> <li>• Low</li> <li>• High, protective range</li> </ul>	<40 mg/dL >60 mg/dL	<1.03 mmol/L >1.55 mmol/L
Triglycerides	<160 mg/dL	<2.26 mmol/L

## Urea and Electrolytes (Table A 1.4)

**Table A 1.4:** Urea and electrolytes.

<b>Analyte</b>	<b>Reference value</b>	
	<b>Conventional</b>	<b>SI units</b>
Sodium	136–146 mEq/L	136–146 mmol/L
Potassium	3.5–5.0 mEq/L	3.5–5.0 mmol/L
Chloride	95–107 mEq/L	95–107 mmol/L
Urea	20–40 mg/dL	3.3–6.6 mmol/L
Creatinine	0.6–1.2 mg/dL	53–106 µmol/L

## Thyroid Function Tests (Table A 1.5)

**Table A 1.5:** Thyroid function tests.

<b>Thyroid function tests</b>	<b>Specimen</b>	<b>Reference value</b>	
		<b>Conventional</b>	<b>SI units</b>
Radioactive iodine uptake (RAIU) 24 hours		5–30%	
Thyroxine (T4) total	Serum	5.4–11.7 µg/dL	70–151 nmol/L

Triiodothyronine (T3) total	Serum	77–135 ng/dL	1.2–2.1 nmol/L
Thyroid stimulating hormone (TSH)	Serum	0.4–4.25 $\mu$ U/mL	0.4–4.25 mU/L

## Urine (Table A 1.6)

**Table A 1.6:** Normal urine values.

<b>Component</b>	<b>Reference value</b>
Volume—24 hours	600–1800 mL (variable)
pH	5.0–9.0
Specific gravity, quantitative (random)	1.002–1.028 (average 1.018)
Protein—24 hours urine	<150 mg/day
Protein, qualitative (random)	Negative
Glucose, quantitative—24 hours urine	50–300 mg/day
Glucose, qualitative (random)	Negative
Urobilinogen—24 hours urine	1.0–3.5 mg/day
Microalbuminuria (24 hours)	0–30 mg/24 hours (0–0.03 g/day) (0–30 $\mu$ g/mg creatinine) (0–0.03 g/g creatinine)

## Cerebrospinal Fluid (Table A 1.7)

**Table A 1.7:** Normal values of cerebrospinal fluid.

<b>Component</b>	<b>Reference value</b>	
	<b>Conventional</b>	<b>SI units</b>
CSF volume	120–150 mL	
Appearance	Clear and colorless	
CSF pressure	60–150 mm water	
pH	7.31–7.34	
Total proteins	20–40 mg/dL	0.14–0.45 g/L
Glucose	40–80 mg/dL	2.3–4.5 mmol/L
Chlorides	720–750 mg/dL	
Cells	Usually absent	
<ul style="list-style-type: none"> <li>• Polymorphs</li> <li>• Lymphocytes</li> </ul>	0–5/ $\mu$ L	

## Short list of Routinely Used Formulas In Medicine (Table A 1.8)

**Table A 1.8: Short list of routinely used formulas in medicine.**

<b>Electrolyte disorders</b>	
Plasma osmolality	$2 \text{ Na}^+ \text{ (mEq/L)} + \text{Serum glucose (mg/dL)}/18 + \text{BUN (mg/dL)}/2.8$
Corrected sodium	Increase $\text{Na}^+$ by 1.6 mEq/L for each 100 mg% (when serum glucose >100 mg%)
Total body sodium deficit	(Desired sodium – measured sodium) x Body weight x [0.6 (men) or 0.5 (women)]
Potassium deficit	1 mmol/L decrease → approximately 200–400 mmol loss of total body $\text{K}^+$
Urine-plasma electrolyte ratio (in chronic hyponatremia)	Urinary (sodium + potassium)/plasma sodium <ul style="list-style-type: none"> <li>&gt;1 (fluid restriction up to less than 500 mL/day)</li> <li>=1 (500–700 mL/day)</li> <li>&lt;1 (fluid restriction up to 1 L)</li> </ul>
Water deficit (in hypernatremia)	Water deficit = (plasma sodium – 140) x TBW/140
TTKG (trans-tubular potassium gradient) in hypokalemia	Urinary potassium x plasma osmolality/serum potassium x urinary osmolality <ul style="list-style-type: none"> <li>&gt;4 indicates renal loss of potassium</li> </ul>
Corrected calcium	$0.8 \times (4 - \text{serum albumin}) + \text{serum calcium}$
<b>Acid base disorders</b>	
Anion gap (serum)	(Sodium + potassium) – (bicarbonate + chloride) <ul style="list-style-type: none"> <li>8–16 mEq/L (old methods)</li> <li>5–11 mEq/L (new techniques)</li> </ul>
Urine anion gap	Urine sodium + potassium – chloride <ul style="list-style-type: none"> <li>–25 to –50 (normal range)</li> </ul>
Delta ratio	(Serum anion gap – 12)/(24 – serum bicarbonate) <ul style="list-style-type: none"> <li>&lt;0.4 hyperchloremic normal anion gap acidosis</li> <li>&lt;1 high AG and normal AG acidosis</li> <li>&gt;2 high AG acidosis and a concurrent metabolic alkalosis</li> </ul>
Respiratory acidosis	Acute: 10 increase in $\text{pCO}_2$ → 1 increase in bicarbonate Chronic: 10 increase in $\text{pCO}_2$ → 4 increase in bicarbonate
Respiratory alkalosis	Acute: 10 decrease in $\text{pCO}_2$ → 2 decrease in bicarbonate Chronic: 10 decrease in $\text{pCO}_2$ → 5 decrease in

	bicarbonate
Metabolic acidosis	$p\text{CO}_2 = 1.5 (\text{bicarbonate}) + 8 \pm 2$
Metabolic alkalosis	10 increase in bicarbonate → $p\text{CO}_2$ increases by 6
<b><i>Nephrology</i></b>	
Renal failure index	Urine Na/(Urine Cr/PCr)
Cockcroft-Gault GFR	$> (140 - \text{Age}) \times (\text{Body wt. in kg}) \times (0.85 \text{ if female}) / (72 \times \text{Cr})$
Fractional excretion of sodium (FENa)	$(\text{Serum Cr} \times \text{Urine Na}) / (\text{Serum Na} \times \text{Urine Cr})\%$
<b><i>Hematology</i></b>	
Corrected reticulocyte count	Reticulocyte % $\times$ (Hb/15)
Reticulocyte production index	= Corrected reticulocyte count/maturation time <ul style="list-style-type: none"> <li>• At a hemoglobin of 15, the maturation time = 1 day</li> <li>• At a hemoglobin of 12, the maturation time = 1.5 days</li> <li>• At a hemoglobin of 8, the maturation time = 2 days</li> <li>• At a hemoglobin of 5, the maturation time = 2.5 days</li> </ul>
Mentzer index	(MCV, in fL) divided by (RBC, in millions per $\mu\text{L}$ ) <ul style="list-style-type: none"> <li>• Less than 13, thalassemia is said to be more likely</li> </ul>
Parenteral iron in iron deficiency anemia	$[2.3 \times \text{body weight (kg)} \times \text{Hb deficit (gm/dL)}] + 1000 \text{ mg (to replenish stores)}$
<b><i>Respiratory system</i></b>	
A-a gradient	$\text{PAO}_2 - \text{PaO}_2$ $(\text{PAO}_2 = (\text{FiO}_2 \times 713) - \text{PaCO}_2/0.8; \text{PaO}_2 \text{ is obtained from the ABG})$
<b><i>Cardiology</i></b>	
Corrected QT	$\text{QT}/\sqrt{\text{RR}}$ (Bazzett's formula)
MAP	$\text{Systolic BP} + (2 \times \text{diastolic BP})/3$
<b><i>Miscellaneous</i></b>	
BMI	$\text{W}/\text{H}^2$ (W = weight in kg and H = Height in meters)

## APPENDIX 2: NERVOUS SYSTEM EXAMINATION FORMAT

## General Examination

Patient is conscious, oriented

**Height:**                      **Weight:**

Pallor, icterus, clubbing, cyanosis, pedal edema

Carotid bruit, vertebral artery bruit

**Pulse:**

**BP:**

**JVP:**

Nerve thickening

Neurocutaneous markers

External markers of atherosclerosis

Signs of nutritional deficiency, alcoholism, etc.

Any other general examination finding

## Nervous System Examination

- Right/left handed person
- Education:

### *Higher Mental Functions*

- Consciousness—if impaired document using Glasgow coma scale
- Orientation to time/place/person
- Memory
  - Immediate (repetition—30 sec)
  - Recent (up to 5 min—recall)
  - Remote (>5 min)
- Intelligence
- Mood/emotion
- Concentration and calculation (subtract seven from 100)
- **Speech**
  - Spontaneous speech—comprehension
  - Fluency
  - Repetition
  - Reading

- Writing
- Naming objects
  - ◆ Phonation
  - ◆ Aphasia
  - ◆ Dysarthria
- Apraxias—present/absent
- Hemineglect—present/absent
- Hallucinations and delusions—present/absent

## Cranial Nerves

	<i>Right</i>	<i>Left</i>
<p><b>Olfactory—I nerve:</b> Sense of smell (peppermint, soap, coffee, lemon peel or vanilla) *Both eyes shut, one nostril checked at a time Appreciate smell +/- identify it</p>		
<p><b>Optic—II nerve:</b></p> <ul style="list-style-type: none"> <li>• Visual acuity (perception of light/hand movements and finger counting/Snellen’s chart at 6 mts/Jaeger’s chart at 14 inches)</li> <li>• Visual field (confrontation method/Menace reflex)—mention defects if any</li> <li>• Color vision (Ishihara’s test)</li> <li>• Fundus</li> </ul>		
<p><b>Oculomotor, trochlear, abducens—III, IV, VI nerves:</b> <i>Eyelids</i> (any ptosis) <i>Position of eyeballs at rest</i> (any deviation, exophthalmos, enophthalmos) <i>Extraocular movements:</i></p> <ul style="list-style-type: none"> <li>• Binocular movements           <ul style="list-style-type: none"> <li>– Saccadic</li> <li>– Pursuit</li> <li>– Reflex (Dolls eye, Caloric stimulation)</li> </ul> </li> <li>• Uniocular movements</li> </ul> <p>(#comment on ophthalmoplegia if present—supranuclear, internuclear, individual nerves, or muscles) <i>Pupil:</i></p> <ul style="list-style-type: none"> <li>• Size (in mm)</li> <li>• Shape</li> </ul>		

- Reaction
  - Direct light reflex
  - Consensual light reflex
  - Accommodation reflex

*Nystagmus*

(describe whether spontaneous or provoked/type—horizontal, vertical, rotatory, pendular,..)

**Trigeminal nerve—V nerve:**

- Sensory:
  - Touch
  - Pain
  - Temperature
 (to be checked on all 3 divisions around the jaw line, on the cheek and, on the forehead)
- Motor:
  - Jaw deviation
  - Hollowing above and below zygoma
  - Clenching teeth (feel temporalis and masseter)
  - Open mouth against resistance
  - Side to side movement of jaw (pterygoids)
- Reflexes:

Corneal—Present/absent (superficial reflex, 5th nerve afferent, 7th nerve efferent)

Jaw jerk—Present/absent/exaggerated (deep reflex, afferent and efferent both 5th nerve, center mid-pons)

**Facial nerve—VII nerve:**

Facial asymmetry (look for absence of wrinkling, drooping of corner of mouth, obliteration of nasolabial fold, widened palpebral fissures)

- Motor:
  - Frontalis (raise the eyebrows)
  - Orbicularis oculi (shut the eyes tight)
  - Buccinator (show teeth, smile, blow check, whistle)
  - Orbicularis oris (close lips, pronounce labials ‘p’, ‘b’, ‘m’)
  - Platysma (pull down the corners of mouth)

(## look for Bells phenomenon)

- Sensory:
  - Ant 2/3rd tongue taste (sugar, lime, salt, quinine)

<p>Lacrimation</p> <p>Hyperacusis—present/absent</p> <p>Emotional fibers checking—emotions preserved or not</p>		
<p><b>Vestibulocochlear nerve—VIII nerve:</b></p> <p>(The ability to hear the sound produced by rubbing the thumb and forefinger together is then tested for each ear at distances up to a few centimeters)</p> <ul style="list-style-type: none"> <li>• Rinnes test—AC/BC</li> <li>• Weber’s test—lateralized/centralized</li> <li>• Caloric test (irrigates one external auditory canal with cool (about 30°C) or warm (40°C) water. Normally, cool water in one ear produces nystagmus on the opposite side. Warm water produces it on the same side)</li> </ul>		
<p><b>Glossopharyngeal, Vagus—IX, X nerve:</b></p> <p>Note: The patient’s ability to drink water and eat solid food and the character and volume and sound of the patient’s voice</p> <ul style="list-style-type: none"> <li>• Position of uvula</li> </ul>		
<ul style="list-style-type: none"> <li>• Movement of uvula on saying ‘ah’—any deviation</li> <li>• Gag reflex—present/absent/exaggerated</li> </ul> <p>(Taste sensation over the posterior third of the tongue and can be tested)</p>		
<p><b>Spinal accessory—XI nerve:</b></p> <ul style="list-style-type: none"> <li>• Sternocleidomastoid (instruct the patient to rotate head against resistance applied to the side of the chin to tests the function of the opposite sternocleidomastoid muscle. To test both sternocleidomastoid muscles together, the patient flexes the head forward against resistance placed under the chin)</li> <li>• Trapezius (Shrugging a shoulder against resistance)</li> </ul>		
<p><b>Hypoglossal nerve—XII</b></p> <ul style="list-style-type: none"> <li>• Inspection (inside the mouth): <ul style="list-style-type: none"> <li>– Size of tongue</li> <li>– Symmetry/any wasting</li> <li>– Fasciculation (on protrusion)</li> <li>– Deviation—side</li> <li>– Tremors</li> </ul> </li> <li>• Palpation: <ul style="list-style-type: none"> <li>– Tone</li> </ul> </li> </ul>		

- Power
- Speech

## Motor System

### **Attitude**

- Upper limb
- Lower limb

### **Bulk**

*Inspection:* Symmetry, generalized wasting comment on small muscle wasting, deformities, claw hand, foot drop if any

<b>Measurement (cm)</b>	<b>Right</b>	<b>Left</b>
Arm		
Forearm		
Thigh		
Leg		

\*Bilateral similar distance from fixed bony points till the maximum bulk of muscle

### **Tone**

<b>Tone</b>	<b>Right</b>	<b>Left</b>
Upper limbs		
Lower limbs		

\*Comment whether normal, hypotonia or hypertonia (spasticity/rigidity)

### **Power**

Checked both isometric (resistance against movement) and isotonic (resistance at end of movement).

Grade the Power (MRC)

Grade 0	Complete paralysis
Grade 1	A flicker of contraction only
Grade 2	Power detectable only when gravity is excluded by postural adjustment
Grade 3	Limb can be held against gravity but not resistance
Grade 4	Limb can be held against gravity and some resistance

## Neck

- Flexors (SCM, platysma, scalene, suprahyoid, infrahyoid, longus collis and capitis, rectus capitis)
- Extensors (Trapezius and paravertebral muscles-splenii, erector spinae, transversospinalis, interspinal intertransverse)

\*avoid active movement checking if cervical cord injury suspected

<b>Upper limb</b>	<b>Right</b>	<b>Left</b>
<b>Shoulder</b> <ul style="list-style-type: none"> <li>• Abduction (0–15°—supraspinatus, 15–90° middle fibers of deltoid, above 90° trapezius and serratus anterior)</li> <li>• adduction (pectoralis major, latissimus dorsi and teres major)</li> <li>• Flexion (biceps brachii (both heads), pectoralis major, anterior deltoid and coracobrachialis)</li> <li>• Extension (posterior deltoid, latissimus dorsi and teres major)</li> </ul>		
<b>Elbow</b> <ul style="list-style-type: none"> <li>• Flexion (Biceps brachii)</li> <li>• Extension (Triceps brachii)</li> </ul>		
<b>Wrist</b> <ul style="list-style-type: none"> <li>• Flexion (Flexor carpi radialis, flexor carpi ulnaris)</li> <li>• Extension (Extensor carpi radialis longus, extensor carpi radialis brevis, extensor carpi ulnaris)</li> </ul>		
Hand grip (Long flexors)		
Small muscles (if needed)		

<b>Thenar muscles</b>	<b>Hypothenar muscles</b>	<b>Four lumbricals</b>
<ul style="list-style-type: none"> <li>• Opponens pollicis</li> <li>• Abductor pollicis brevis</li> <li>• Flexor pollicis brevis</li> </ul> All 3 supplied by median nerve	<ul style="list-style-type: none"> <li>• Opponens digiti minimi</li> <li>• Abductor digiti minimi</li> <li>• Flexor digiti minimi brevis</li> </ul> All 3 supplied by ulnar nerve	Medial two ulnar nerve, lateral two median nerve
<b>Interossei</b>	<b>Palmaris brevis</b>	<b>Adductor pollicis</b>
Abduction (dorsal interossei) and adduction (palmar interossei)	Supplied by ulnar nerve	Supplied by ulnar nerve
<b>Trunk</b>		

(rectus abdominis, transversus abdominis, obliqui, pyramidalis)		
<ul style="list-style-type: none"> <li>• Elevation of head or leg in supine position</li> <li>• Beevor's sign if present</li> <li>• Abdominal binding to check for intercostal muscle weakness</li> <li>• Intercostal binding to check for diaphragmatic weakness</li> </ul>		

<b>Lower limb</b>	<b>Right</b>	<b>Left</b>
<b>Hip</b> <ul style="list-style-type: none"> <li>• Flexion (Iliopsoas)</li> <li>• Extension (Gluteus maximus)</li> <li>• Abduction (Gluteus medius and minimus, tensor fascia lata)</li> <li>• Adduction (Adductor longus, brevis and magnus)</li> </ul>		
<b>Knee</b> <ul style="list-style-type: none"> <li>• Flexion (Hamstrings)</li> <li>• Extension (Quadriceps)</li> </ul>		
<b>Ankle</b> <ul style="list-style-type: none"> <li>• Plantar flexion (Gastrocnemius, Soleus)</li> <li>• Dorsiflexion (Tibialis anterior)</li> <li>• Small muscles of foot, EHL if needed</li> </ul>		

## **Reflexes**

<b>Superficial reflexes</b>	<b>Right</b>	<b>Left</b>
Corneal (Cranial nerve V and VII)		
<b>Abdominal</b> <ul style="list-style-type: none"> <li>• Epigastric (T6–T9)</li> <li>• Mid-abdominal (T9–T11)</li> <li>• Hypogastric (T11–L1)</li> </ul> (Stroke towards umbilicus)		
Cremasteric (L1, L2)		
Anal reflex (S2, S3)		
<b>Plantar</b> <ul style="list-style-type: none"> <li>• Reflexogenic zone—S1</li> <li>• Afferent nerve—tibial nerve</li> </ul>		

Chaddock's (lateral malleolus), Gordon's (Calf), Oppenheim's (anterior tibia), Schaffer's (Achilles tendon), Gonda's (press down 4th toe),

Stransky's (adduct little toe), Bing's (pinprick on dorsolateral foot)

<b>Deep tendon reflexes</b>	<b>Right</b>	<b>Left</b>
Jaw jerk (afferent and efferent both 5th nerve, center mid-pons)		
Biceps (C5, C6)		
Brachiradial/supinator/radial periosteal (C5, C6)		
Triceps (C6, C7, C8)		
Knee jerk/quadriceps/patellar reflex (L2, L3, L4)		
Ankle jerk (L5, S1, S2)		

<b>Deep tendon reflexes</b>	<b>Right</b>	<b>Left</b>
<b>Clonus</b> present/absent <ul style="list-style-type: none"> <li>• Patellar</li> <li>• Ankle</li> </ul>		
<b>Latent reflexes</b> (suggest pyramidal lesion if present unilaterally) <ul style="list-style-type: none"> <li>• Tromner's/Finger flexor reflex/Hoffman's sign</li> <li>• Wartenburg's sign</li> </ul>		

By convention the deep tendon reflexes are graded as follows:

- 0 = no response; always abnormal
- 1+ = a slight but definitely present response; may or may not be normal
- 2+ = a brisk response; normal
- 3+ = a very brisk response; may or may not be normal
- 4+ = a tap elicits a repeating reflex (clonus); always abnormal

*Please do reinforcement maneuvers before saying DTR's are absent*

## **Primitive Reflex**

- Glabellar tap
- Palmomenta (Both sides)
- Sucking
- Rooting
- Pout and snout
- Grasp

**Involuntary movements** (describe in detail)

**Coordination** (described later under cerebellum on page 1216)

## Sensory System

	<i>Right</i>	<i>Left</i>
<b>Primary sensations</b> <ul style="list-style-type: none"> <li>• Touch</li> <li>• Pain</li> <li>• Temperature</li> <li>• Vibration</li> <li>• Joint, position sense</li> </ul>		
Any sensory level Pattern of sensory loss (graded/dissociative/crossed/hemi)		
<b>Cortical sensations</b> (to be checked only if primary sensations intact) <ul style="list-style-type: none"> <li>• Tactile localization (Topognosis)</li> <li>• Two point discrimination</li> <li>• Stereognosis</li> <li>• Graphesthesia (figure identification)</li> <li>• Sensory extinction</li> </ul>		

## Cerebellum

<b>Upper extremity</b>	<i>Right</i>	<i>Left</i>
Limb ataxia <ul style="list-style-type: none"> <li>• Out streched arm test</li> <li>• Finger nose test</li> <li>• Nose-finger-nose test</li> <li>• Finger-finger test</li> </ul>		
Rapid alternating movements <ul style="list-style-type: none"> <li>• Rapid hand tapping</li> <li>• Pronation-supination</li> <li>• Thigh slapping</li> </ul>		
Pointing and past pointing		
Writing (Macrographia)		
Rebound phenomenon (Arm)		
Tremors (intention)		

<b>Lower limbs</b>	<b>Right</b>	<b>Left</b>
Heel knee test		
Pendular knee jerk		
Finger toe test		
Rapid alternating movements— foot tapping		

## General Signs of Cerebellar Disease

- Titubation
- Nystagmus
- Tremors
- Hypotonia
- Truncal ataxia
- Tandem walking
- Gait

## ROMBERG'S TEST

### Gait

- Base—wide or narrow
- Slow/rapid
- Falling to sides
- Look which part of foot touches ground first (toe/heel)
- How high foot lifted above ground
- Hand swing
- Turning around
- Position of hip, sound produced while foot touches ground

### Signs of Involvement of Autonomic Nervous System

- Dryness of skin/excessive sweating/spoon test
- Postural hypotension
- Heart rate—baseline, on respiration, on standing
- Palpable bladder
- Pupillary reactions
- Valsalva

## **Meningeal Signs of Irritation**

- Neck stiffness
- Kernigs sign
- Brudzinski's sign—neck, leg and pubis

## **Skull and Spine**

- Deformities
- Tenderness
- Short neck

## **Soft Neurological Signs**

### **Pronator Drift**

- *Pyramidal drift* describes a tendency for the hand to move upward and supinate if the hands are held outstretched in a pronated position (palms downward), or to pronate downward if the hands are held in supination.
- Cerebellar drift is generally upward, with excessive rebound movements if the hand is suddenly displaced downward by the examiner.
- Parietal drift is an outward movement on displacing the ulnar border of the supinated hand

### **Other Systems**

- Cardiovascular system
- Respiratory system
- Per abdomen/gastrointestinal system

## **Final Clinical Diagnosis**
